California Fish and Game Commission

Meeting Binder

October 9-10, 2019

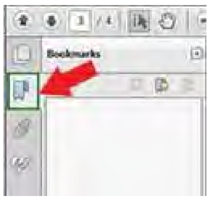
Valley Center

<u>**EASY GUIDE TO USING THE BINDER**</u>

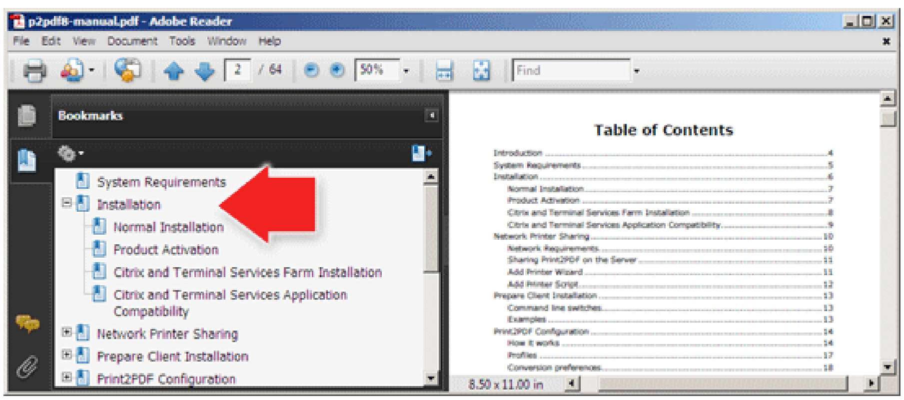
Note: We make every effort to ensure that documents we produce are compliant with Americans with Disabilities Act standards, pursuant to state and federal law; however, some materials included in our meeting binders that are produced by other organizations and members of the public may not be compliant.

1. Download and open the binder document using your Adobe Acrobat program/app.

2. If a bookmark panel does not automatically appear on either the top or left side of the screen, click/tap on the “bookmark symbol” located near the top left-hand corner.



3. To make adjustments to the view, use the Page Display option in the View tab. You should see something like:



4. We suggest leaving open the bookmark panel to help you move efficiently among the staff summaries and numerous supporting documents in the binder. It’s helpful to think of these bookmarks as a table of contents that allows you to go to specific points in the binder without having to scroll through hundreds of pages.

5. You can resize the two panels by placing your cursor in the dark, vertical line  located between the panels and using a long click /tap to move in either direction.

6. You may also adjust the sizing of the documents by adjusting the sizing preferences located on the Page Display icons found in the top toolbar or in the View tab.

7. Upon locating a staff summary for an agenda item, notice that you can obtain more information by clicking/tapping on any item underlined in blue.

8. Return to the staff summary by simply clicking/tapping on the item in the bookmark panel.

9. Do not hesitate to contact staff if you have any questions or would like assistance.

OVERVIEW OF FISH AND GAME COMMISSION BUSINESS MEETINGS

- This year marks the beginning of the 150th year of operation of the California Fish and Game Commission in partnership with the California Department of Fish and Wildlife. Our goal is the preservation of our heritage and conservation of our natural resources through informed decision making. These meetings are vital in achieving that goal. In that spirit, we provide the following information to be as effective and efficient toward that end. Welcome and please let us know if you have any questions.

- We are operating under the Bagley-Keene Open Meeting Act and these proceedings are being recorded and broadcast via https://videobookcase.com/.

- In the unlikely event of an emergency, please note the location of the nearest emergency exits. Additionally, the restrooms are located ______________.

- Items may be heard in any order pursuant to the determination of the Commission President.

- The amount of time for each agenda item may be adjusted based on time available and the number of speakers.

- Speaker cards need to be filled out **legibly** and turned in to the staff **before** we start the agenda item. Please make sure to list the agenda items you wish to speak to on the speaker card.

- We will be calling the names of several speakers at a time so please line up behind the speakers' podium when your name is called. If you are not in the room when your name is called you may forfeit your opportunity to speak on the item.

- When you speak, please state your name and any affiliation. Please be respectful. Disruptions from the audience will not be tolerated. Time is precious so please be concise.

- To receive meeting agendas and regulatory notices about those subjects of interest to you, please visit the Commission's website, www.fgc.ca.gov, and sign up for our electronic mailing lists.

- All petitions for regulation change must be submitted in writing on the authorized petition form, FGC 1, Petition to the California Fish and Game Commission for Regulation Change, available at https://fgc.ca.gov/Regulations/Petition-for-Regulation-Change.

- **Reminder!** Please silence your mobile devices and computers to avoid interruptions.

- **Warning**! The use of a laser pointer by someone other than a speaker doing a presentation may result in arrest.

INTRODUCTIONS FOR FISH AND GAME COMMISSION MEETINGS

Fish and Game Commission

Eric Sklar	President (Saint Helena)
Jacque Hostler-Carmesin	Vice President (McKinleyville)
Russell Burns	Member (Napa)
Peter Silva	Member (Jamul)
Samantha Murray	Member (Del Mar)

Commission Staff

Melissa Miller-Henson	Executive Director
Susan Ashcraft	Acting Deputy Executive Director
Mike Yaun	Legal Counsel
Elizabeth Pope	Acting Marine Advisor
Ari Cornman	Wildlife Advisor
Craig Castleton	Analyst
Sergey Kinchak	Analyst

California Department of Fish and Wildlife

Chuck Bonham	Director
Wendy Bogdan	General Counsel
David Bess	Deputy Director and Chief, Law Enforcement Division
Stafford Lehr	Deputy Director, Wildlife and Fisheries Division
Clark Blanchard	Assistant Deputy Director, Office of Communications, Education and Outreach
Kari Lewis	Chief, Wildlife Branch
Kevin Shaffer	Chief, Fisheries Branch
Craig Shuman	Manager, Marine Region

I would also like to acknowledge special guests who are present:
(i.e., elected officials, including tribal chairpersons, and other special guests)

MEETING AGENDA
October 9-10, 2019

Rincon Government Center
One Government Center Lane, Valley Center, CA 92082

The meeting will be live streamed; visit www.fgc.ca.gov the day of the meeting.

NOTE: See important meeting deadlines and procedures at the end of the agenda. Unless otherwise indicated, the California Department of Fish and Wildlife is identified as Department.

Invitation: The Commission invites members of the public to join commissioners and staff for one or more field trips that will take place following the meeting recess on Wednesday; details will be released before the Commission meeting. Members of the public are welcome but must provide their own transportation.

DAY 1 – OCTOBER 9, 2019; 9:00 AM

Call to order/roll call to establish quorum

1. **Consider approving agenda and order of items**

2. **General public comment for items not on agenda**
   Receive public comment regarding topics within the Commission's authority that are not included on the agenda.
   Note: The Commission **may not** discuss or take action on any matter raised during this item, except to decide whether to place the matter on the agenda of a future meeting (sections 11125 and 11125.7(a), Government Code).

CONSENT ITEMS

3. **Foothill yellow-legged frog**
   Receive the Department's one-year status review report on the petition to list foothill yellow-legged frog (*Rana boylii*) as an endangered or threatened species under the California Endangered Species Act.
   (Pursuant to Section 2074.6, Fish and Game Code)

4. **Executive director's report**
   Receive an update from the executive director on staffing and legislative information.

   (A) Staff report
   (B) Legislative report, federal regulatory notices, and possible action
      I. Discuss AB 1080 and SB 54 and consider authorizing a comment letter
      II. Discuss Pacific Fishery Management Council consideration of authorizing pelagic fishing using longline gear and consider submitting a comment letter

5. **Tribal Committee**
   Discuss updates and recommendations from the October 8, 2019 committee meeting. Consider approving new topics to address at a future committee meeting.

   (A) October 8, 2019 meeting summary
      I. Receive and consider adopting recommendations
   (B) Work plan development
      I. Update on work plan and draft timeline
      II. Discuss and consider approving new topics

6. **Wildlife Resources Committee**
   Discuss updates and recommendations from the September 10, 2019 committee meeting. Consider approving new topics to address at a future committee meeting.

   (A) September 10, 2019 meeting summary
      I. Receive and consider adopting recommendations
   (B) Work plan development
      I. Update on work plan and draft timeline
      II. Discuss and consider approving new topics

7. **Possession of nongame animals (nutria)**
   Discuss proposed changes to possession of nongame animals regulations, in order to exclude nutria (*Myocastor coypus*) from the list of nongame animals that can be possessed alive with a special permit.
   (Section 473, Title 14, CCR)

8. **Wildlife and inland fisheries items of interest from previous meetings**
   These items are generally updates on agenda topics recently heard before the Commission.

   (A) Update on stakeholder discussions related to the Commission's draft Delta Fisheries Management Policy and existing Striped Bass Policy

9. **Wildlife and inland fisheries petitions for regulation change**
Consider requests submitted by members of the public to adopt, amend, or repeal a regulation.
(Pursuant to Section 662, Title 14, CCR)

(A) Action on current petitions
  I. Petition #2019-013: Authorize falconers and raptor propagators to receive non-releasable raptors from rehabilitation facilities
  II. Petition #2019-016 AM 1: Authorize spring bear hunting
  III. Petition #2019-017 AM 1: Establish an open archery season for bear and deer hunting in Marble Mountain and Trinity Alps wilderness areas
  IV. Petition #2019-018: Exempt ferrets from the list of restricted species

(B) Action on pending regulation petitions referred to staff or the Department for review – None scheduled at this time

10. **Wildlife and inland fisheries non-regulatory requests from previous meetings**
Consider non-regulatory requests submitted by members of the public at previous meetings.

(A) Action on non-regulatory requests
(B) Action on pending non-regulatory requests referred to staff or the Department for review

11. **Strategic planning**
Receive an update on the strategic planning process, discuss initial input received through interviews and surveys, and initial discussion about goals and objectives.

12. **Departmental informational items (wildlife and inland fisheries)**
The Department will highlight wildlife and inland fisheries items of note since the last Commission meeting.

(A) Director's report
(B) Law Enforcement Division
(C) Wildlife and Fisheries Division, and Ecosystem Conservation Division

13. **Commission administrative items**

(A) Next meeting – December 11-12, 2019 in Sacramento
(B) Rulemaking timetable updates
(C) New business

Recess

DAY 2 – OCTOBER 10, 2019; 9:00 AM

Call to order/roll call to establish quorum

14. **General public comment for items not on agenda**
Receive public comment regarding topics within the Commission's authority that are not included on the agenda.
Note: The Commission **may not** discuss or take action on any matter raised during this item, except to decide whether to place the matter on the agenda of a future meeting (sections 11125 and 11125.7(a), Government Code).

15. **Marine Resources Committee**
Discuss and consider approving draft agenda topics for the next committee meeting. Consider approving new topics to address at a future committee meeting.

    (A) Work plan development
        I. Update on work plan and draft timeline
        II. Discuss and consider approving new topics
    (B) Update on abalone fishery management plan

16. **Experimental fishing permit program (Phase 1)**
Discuss and consider adopting proposed changes to experimental fishing permit (EFP) regulations, to allow for issuing EFPs to fishermen that were issued experimental gear permits in 2018 for the box crab experimental gear permit program, as approved by the Commission.
(Adopt Chapter 5.6, Section 90; and adopt Section 704, Title 14, CCR)

17. **Pacific Herring Fishery Management Plan (FMP)**
Discuss and consider adopting the draft Pacific Herring FMP.
(Pursuant to Fish and Game Code Section 7075, et seq.)

18. **Pacific herring regulations**
Consider adopting Pacific herring sport fishing and commercial take regulations that implement the Pacific Herring FMP.
(Add sections 55.00, 55.01, and 55.02, and amend sections 27.60, 28.60, 28.62, 163, 163.1, 163.5, 164, and 705, Title 14, CCR)

19. **Malibu Oyster Company application for state water bottom lease**
Determine whether considering a new shellfish aquaculture lease offshore Malibu as applied for by Malibu Oyster Company would be in the public interest.
(Pursuant to Section 15400, Fish and Game Code)

20. **Marine items of interest from previous meetings**
These items are generally updates on agenda topics recently heard before the Commission.

(A) Update on razor clams/domoic acid

21. **Marine petitions for regulation change**
Consider requests submitted by members of the public to adopt, amend, or repeal a regulation.
(Pursuant to Section 662, Title 14, CCR)

(A) Action on current petitions
    I. Petition #2019-014: Increase restrictions on recreational take of California grunion
(B) Action on pending regulation petitions referred to staff or the Department for review – None scheduled at this time

22. **Departmental informational items (marine)**
The Department will highlight marine items of note since the last Commission meeting.

(A) Director's report
(B) Law Enforcement Division
(C) Marine Region
    I. MLMA master plan prioritization

Adjourn

EXECUTIVE SESSION

(Not Open to Public)

At a convenient time during the regular agenda of the meeting listed above, the Commission will recess from the public portion of the agenda and conduct a closed session on the agenda items below. The Commission is authorized to discuss these matters in a closed session pursuant to Government Code Section 11126, subdivisions (a)(1), (c)(3), and (e)(1), and Fish and Game Code Section 309. After closed session, the Commission will reconvene in public session, which may include announcements about actions taken during closed session.

(A) Pending litigation to which the Commission is a Party

I. Dennis Sturgell v. California Department of Fish and Wildlife, and California Fish and Game Commission (revocation of Dungeness crab vessel permit No. CT0544-T1)

II. Public Interest Coalition v. California Fish and Game Commission (CEQA compliance during adoption of dog collar regulation)

III. Aaron Lance Newman v. California Fish and Game Commission (revocation of hunting and sport fishing privileges)

IV. Adam Aliotti and Alicia Dawn, Inc. v. California Fish and Game Commission, and California Department of Fish and Wildlife (suspension of commercial fishing license and tier-1 spot prawn trap vessel permit)

V. Almond Alliance of California et al. v. California Fish and Game Commission and California Department of Fish and Wildlife (bumble bees California Endangered Species Act determination)

(B) Possible litigation involving the Commission

(C) Staffing

(D) Deliberation and action on license and permit items

I. Consider Agency Case No. 19ALJ11-FGC, the appeal filed by Darren Johnson regarding the Department’s denial of a request to renew a salmon vessel permit.

OTHER 2019 AND 2020 MEETINGS OF INTEREST

Association of Fish and Wildlife Agencies

- No additional 2019 meetings are scheduled at this time
- March 8-13, 2020, Omaha, NE
- September 13-16, 2020, Sacramento, CA

Pacific Fishery Management Council

- November 13-20, 2019, Costa Mesa, CA
- March 3-9, 2020, Rohnert Park, CA
- April 3-10, 2020, Vancouver, WA
- June 11-18, 2020, San Diego, CA
- September 10-17, 2020, Spokane, WA

- November 13-20, 2020, Garden Grove, CA

Pacific Flyway Council

- No additional 2019 meetings are scheduled at this time
- March 2020 (date/location TBD)
- August/September 2020 (date/location TBD)

Western Association of Fish and Wildlife Agencies

- No additional 2019 meetings are scheduled at this time
- January 9-12, 2020, Monterey, CA
- July 9-14, 2020, Park City, UT

Wildlife Conservation Board

- November 21, 2019, Sacramento, CA
- No additional 2020 meetings are scheduled at this time

IMPORTANT COMMISSION MEETING PROCEDURES INFORMATION

WELCOME TO A MEETING OF THE CALIFORNIA FISH AND GAME COMMISSION

This year marks the beginning of the 150th year of operation of the Commission in partnership with the California Department of Fish and Wildlife. Our goal is the preservation of our heritage and conservation of our natural resources through informed decision making; Commission meetings are vital in achieving that goal. In that spirit, we provide the following information to be as effective and efficient toward that end. Welcome and please let us know if you have any questions.

PERSONS WITH DISABILITIES

Persons with disabilities needing reasonable accommodation to participate in public meetings or other Commission activities are invited to contact the Reasonable Accommodation Coordinator at (916) 651-1214. Requests for facility and/or meeting accessibility should be received at least 10 working days prior to the meeting to ensure the request can be accommodated.

STAY INFORMED

To receive meeting agendas and regulatory notices about those subjects of interest to you, please visit the Commission's website, www.fgc.ca.gov, to sign up on our electronic mailing lists.

SUBMITTING WRITTEN COMMENTS

The public is encouraged to comment on any agenda item. Submit written comments by one of the following methods: **E-mail** to fgc@fgc.ca.gov; **mail** to California Fish and Game Commission, P.O. Box 944209, Sacramento, CA 94244-2090; **delivery** to California Fish and Game Commission, 1416 Ninth Street, Room 1320, Sacramento, CA 95814; or **hand-deliver to a Commission meeting.** Materials provided to the Commission may be made available to the general public.

COMMENT DEADLINES

The **Written Comment Deadline** for this meeting is **5:00 p.m. on September 26, 2019.** Written comments received at the Commission office by this deadline will be made available to Commissioners prior to the meeting.

The **Late Comment Deadline** for this meeting is **noon on October 4, 2019.** Comments received by this deadline will be marked "late" and made available to Commissioners at the meeting.

After these deadlines, written comments may be delivered in person to the meeting – Please bring ten (10) copies of written comments to the meeting.

NON-REGULATORY REQUESTS

All non-regulatory requests will follow a two-meeting cycle to ensure proper review and thorough consideration of each item. All requests submitted by the **Late Comment Deadline** (or heard during public comment at the meeting) will be scheduled for receipt at this meeting, and scheduled for consideration at the next business meeting.

PETITIONS FOR REGULATION CHANGE
Any person requesting that the Commission adopt, amend, or repeal a regulation must complete and submit form FGC 1, titled, “Petition to the California Fish and Game Commission for Regulation Change” (as required by Section 662, Title 14, CCR). The form is available at https://fgc.ca.gov/Regulations/Petition-for-Regulation-Change. To be received by the Commission at this meeting, petition forms must have been delivered by the **Late Comment Deadline** (or delivered during public comment at the meeting). Petitions received at this meeting will be scheduled for consideration at the next business meeting, unless the petition is rejected under staff review pursuant to subsection 662(b), Title 14, CCR.

VISUAL PRESENTATIONS/MATERIALS
All electronic presentations must be submitted by the **Late Comment Deadline** and approved by the Commission executive director before the meeting.

1. Electronic presentations must be provided by email to fgc@fgc.ca.gov.
2. All electronic formats must be Windows PC compatible.
3. It is recommended that a print copy of any electronic presentation be submitted in case of technical difficulties.
4. A data projector, laptop and presentation mouse will be available for use at the meeting.

CONSENT CALENDAR
A summary of all items will be available for review at the meeting. Items on the consent calendar are generally non-controversial items for which no opposition has been received and will be voted upon under single action without discussion. Any item may be removed from the consent calendar by the Commission upon request of a Commissioner, the Department, or member of the public who wishes to speak to that item, to allow for discussion and separate action.

LASER POINTERS
Laser pointers may only be used by a speaker during a presentation; use at any other time may result in arrest.

SPEAKING AT THE MEETING
To speak on an agenda item, please complete a “Speaker Card" and give it to the designated staff member before the agenda item is announced. Cards will be available near the entrance of the meeting room. Only one speaker card is necessary for speaking to multiple items.

1. Speakers will be called in groups; please line up when your name is called.
2. When addressing the Commission, give your name and the name of any organization you represent, and provide your comments on the item under consideration.
3. If there are several speakers with the same concerns, please appoint a spokesperson and avoid repetitive testimony.
4. The presiding commissioner will allot between one and three minutes per speaker per agenda item, subject to the following exceptions:
    a. The presiding commissioner may allow up to five minutes to an individual speaker if a minimum of three individuals who are present when the agenda item is called have ceded their time to the designated spokesperson, and the individuals ceding time forfeit their right to speak to the agenda item.
    b. Individuals may receive advance approval for additional time to speak if requests for

additional time to speak are received by email or delivery to the Commission office by the **Late Comment Deadline**. The president or designee will approve or deny the request no later than 5:00 p.m. two days prior to the meeting.

c. An individual requiring an interpreter is entitled to at least twice the allotted time pursuant to Government Code Section 11125.7(c).

d. An individual may receive additional time to speak to an agenda item at the request of any commissioner.

5. If you are presenting handouts/written material to the Commission at the meeting, please provide ten (10) copies to the designated staff member just prior to speaking.

2. GENERAL PUBLIC COMMENT (DAY 1)

Today's Item **Information** ☒ **Action** ☐

Receive public comments, petitions for regulation change, and requests for non-regulatory actions for items not on the agenda.

Summary of Previous/Future Actions

- **Today's receipt of requests and comments** **Oct 9-10, 2019; Valley Center**
- Consider granting, denying or referring requests Dec 11-12, 2019; Sacramento

Background

This agenda item is primarily to provide the public an opportunity to address FGC on topics not on the agenda. Staff also includes written materials and comments received prior to the meeting as exhibits in the meeting binder (if received by written comment deadline), or as late comments at the meeting (if received by late comment deadline), for official FGC "receipt."

Public comments are generally categorized into three types under general public comment: (1) petitions for regulation change; (2) requests for non-regulatory action; and (3) informational-only comments. Under the Bagley-Keene Open Meeting Act, FGC cannot discuss any matter not included on the agenda, other than to schedule issues raised by the public for consideration at future meetings. Thus, petitions for regulation change and non-regulatory requests generally follow a two-meeting cycle (receipt and direction); FGC will determine the outcome of the petitions for regulation change and non-regulatory requests received at today's meeting at the next in-person FGC meeting following staff evaluation (currently Dec 11-12, 2019).

As required by the Administrative Procedure Act, petitions for regulation change will be either denied or granted and notice made of that determination. Action on petitions received at previous meetings is scheduled under a separate agenda item titled "Petitions for regulation change." Action on non-regulatory requests received at previous meetings is scheduled under a separate agenda item titled "Non-regulatory requests."

Significant Public Comments

1. New petitions for regulation change are summarized in Exhibit 1, and the original petitions are provided as exhibits 2-3.
2. No requests for non-regulatory action were received for this meeting.
3. Informational comments are provided as exhibits 4-11.

Recommendation

FGC staff: Consider whether any new future agenda items are needed to address issues that are raised during public comment.

Exhibits

1. Summary of new petitions for regulation change received by Sep 26, 2019 at 5:00 p.m.
2. Petition #2019-019 AM 1: Remove Gila monster from the list of restricted species

3. Petition #2019-020: Increase bag and possession limits for recreational brown trout within the Klamath-Trinity River Basin
4. Letter from Linda Adams, in support of the proposed approval of a permit for Trinity Alps Resort's continued use of a seasonal dam and swimming hole while the status of foothill yellow-legged frog under the California Endangered Species Act is being determined, received Jul 31, 2019; similar letter from C. Douglas Taylor supports the resort's continued use of the seasonal dam, received Aug 6, 2019
5. Email from Kathleen Roche, providing notice of intent to file a petition under the federal Endangered Species Act to list and designate critical habitat for the Shasta snow-wreath, received Aug 22, 2019
6. Email transmitting a news release from the National Park Service (NPS), providing notice that NPS has approved a Management Plan for Developed Water Sources in Mojave National Preserve, and highlighting the impact of this decision on desert bighorn sheep, received Aug 23, 2019
7. Letter from Chairman Ryan Coonerty, Santa Cruz County Board of Supervisors, in support of DFW's work to study and propose a finalized low flow target for temporary closures of recreational steelhead angling in Santa Cruz County waterways, received Sep 3, 2019
8. Email from Nancy Dunn, concerning treatment of animals and the environment by humans, received Sep 6, 2019
9. Email from Nick Buckley, expressing concern that wildlife management decisions are being made by FGC based on politics as opposed to science, received Sep 10, 2019
10. Letter from Steve Boero, owner of Triple B Ranch, providing notice of withdrawal from DFW's Private Lands Management Program, received Sep 11, 2019
11. Email from Brett Bunge, expressing concern over the statewide lead ammunition ban and difficulty in finding certain ammunition, received Sep 18, 2019

Motion/Direction (N/A)

3. FOOTHILL YELLOW-LEGGED FROG (CONSENT)

Today's Item **Information** ☒ **Action** ☐

Receive DFW's status review report on the petition from Center for Biological Diversity to list foothill yellow-legged frog (*Rana boylii*) as threatened under the California Endangered Species Act.

Summary of Previous/Future Actions

• Receive petition	Dec 14, 2016
• FGC transmits petition to DFW	Dec 22, 2016
• Publish notice of receipt of petition	Jan 20, 2017
• Received evaluation and recommendation	Apr 26-27, 2017; Van Nuys
• FGC determined listing may be warranted	Jun 21-22, 2017; Smith River
• Approved DFW's request for 6-month extension	Jun 20-21, 2018; Sacramento
• **Today receive DFW status review report**	**Oct 9-10, 2019; Valley Center**
• Determine if listing is warranted	Dec 11-12, 2019; Sacramento

Background

On Dec 14, 2016, FGC received a petition from the Center for Biological Diversity to list foothill yellow-legged frog as a threatened species under the California Endangered Species Act. On Jun 21, 2017, FGC designated foothill yellow-legged frog as a candidate species, commencing DFW's review of the status of the species as required by Fish and Game Code Section 2074.6. In Jun 2018, FGC approved DFW's request for a six-month extension of time to complete its review.

DFW has completed its review and submitted its status review report to FGC (exhibits 1 and 2). The report represents DFW's final written review of the status of foothill yellow-legged frog and is based upon the best scientific information available to DFW.

In addition to evaluating the petitioned action to list the species as threatened or endangered, DFW evaluated whether listing the species was warranted for six unique genetic clades (a clade being a group of organisms that consist of a common ancestor and all its lineal descendants). The status review contains DFW's recommendation that listing the foothill yellow-legged frog is warranted at this time for five of the six genetic clades, with three specific recommendations:

- List the Feather River and Northeast/Northern Sierra clades as threatened;
- List the East/Southern Sierra, West/Central Coast, and Southwest/South Coast clades as endangered;
- Do not list the Northernwest/North Coast clade; listing is not warranted at this time.

Fish and Game Code Section 2075 requires FGC to receive DFW's recommendation, and to schedule final consideration of the petition at its next available meeting. Based on this, FGC could consider the petition, DFW's written evaluation and status review report, written and oral comments received, and the remainder of the administrative record, to determine if listing is warranted at its Dec 11-12, 2019 meeting in Sacramento. Findings would be adopted at a future meeting.

Significant Public Comments (N/A)

Recommendation (N/A)

Exhibits

1. DFW memo transmitting status review report, received Oct 1, 2019
2. DFW status review report, dated Sep 20, 2019

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

4A. EXECUTIVE DIRECTOR'S REPORT – STAFF REPORT

Today's Item **Information ☒** **Action ☐**

Receive the executive director's staff report.

Summary of Previous/Future Actions (N/A)

Background

Staffing Update

At its Sep 3 teleconference meeting, FGC unanimously chose Melissa Miller-Henson as its new executive director. Melissa brings a wealth of experience having served in various capacities at FGC, most recently as acting executive director since Sep 2018. Recruitment efforts for a deputy executive director are underway, with a month-long recruitment period expected to close in early Nov. FGC's marine advisor Susan Ashcraft continues to serve as acting deputy executive director, with Elizabeth Pope on loan from DFW's Marine Region as acting marine advisor. And, for the new tribal advisor and tribal liaison, staff is working with DFW to determine the most appropriate classification and then can begin a recruitment process to fill the position.

After receiving over 150 applications for a seasonal clerk, staff extended an offer to Ian Williams; his first day was Oct 1. Ian received his associate's degree from Chabot College in 2017 and plans to continue his education. Following a brief orientation, Ian will assist with meeting preparation, general reception needs, and administrative tasks.

Exhibit 1 provides an overview of FGC staff time allocation across eight focal areas, and highlights key activities of interest since the Aug FGC meeting.

New Resources Building

Construction of the state's new California Natural Resources building in Sacramento reached a milestone recently with placement of the final construction beam on the 22-story building. Construction is expected to continue through 2020, with expected move-in to begin in mid-2021. Secretary for Resources Wade Crowfoot invited the directors of departments, boards, commissions and conservancies that are administratively linked to the agency, including FGC's executive director, for a tour of the construction site and model office space in late Sep. The 900,000 square-foot building is designed to provide natural light through an open floor plan with few private offices. The building will also have ample meeting space, including a state-of-the-art 300-seat auditorium.

Paper-to-Digital Conversion Project

In preparation for the move to the new building, the California Natural Resources Agency has launched an initiative to convert most paper records to a digital format for all the offices moving to the new building. Workshops are currently underway to develop and share the plan of action. FGC has an abundance of important historical documents (including many years of meeting minutes), so this project will take considerable planning and personnel time. Staff plans to take full advantage of any resources made available.

Recommendation (N/A)

Exhibits

1. *Staff Report on Staff Time Allocation and Activities,* dated Sep 30, 2019

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

4B. EXECUTIVE DIRECTOR'S REPORT – LEGISLATIVE REPORT

Today's Item **Information** ☐ **Action** ☒

Review and discuss legislation and federal regulatory notices of interest and provide staff direction on potential actions.

Summary of Previous/Future Actions (N/A)

Background

FGC staff has prepared a list of state and federal legislation that may affect FGC's resources and workload or be of interest (below). DFW has provided a report on state bills it has identified as being of interest, including the current status of each (Exhibit 1).

Today is an opportunity for FGC to provide direction to staff concerning proposed legislation and regulatory actions. At any meeting, FGC may direct staff to provide information to or share concerns with bill authors or regulatory agencies. FGC members may also take positions on bills at the same meeting an update is provided.

State Legislation

Legislative Calendar Highlights for 2019-2020

- Last day for any bill to pass. Interim recess began upon adjournment — Sep 13, 2019
- Last day for Governor to sign or veto bills passed by the legislature on or before Sep 13 and in the Governor's possession after Sep 13 — Oct 13, 2019
- Statutes take effect — Jan 1, 2020
- Legislature reconvenes — Jan 6, 2020

Bills Introduced during the 2019-2020 Session

A number of the state bills identified in DFW's report (Exhibit 1) may affect FGC's resources and workload or are potentially of interest; listed below are those assembly bills (AB) or sentate bills (SB) that have been vetoed or chaptered, or are enrolled and awaiting Governor Newsom's signature.

- AB 44 (Friedman) Fur products: prohibition (Enrolled)
- AB 273 (Gonzalez) Fur-bearing and nongame mammals: recreational and commercial fur trapping: prohibition (Chaptered)
- AB 454 (Kalra) Migratory birds: California Migratory Bird Protection Act (Chaptered)
- AB 834 (Quirk) Freshwater and Estuarine Harmful Algal Bloom Program (Chaptered)
- AB 1254 (Kamlager-Dove) Bobcats: take prohibition: hunting season: management plan (Enrolled)
- AB 1260 (Maienschein) Endangered wildlife (Enrolled)

- SB 1 (Atkins) California Environmental, Public Health, and Workers Defense Act of 2019 (Vetoed)
- SB 62 (Dodd) Endangered species: accidental take associated with routine and ongoing agricultural activities: state safe harbor agreements (Chaptered)
- SB 262 (McGuire) Commercial fishing: landing fees: sea cucumbers (Enrolled)
- SB 307 (Roth) Water conveyance: use of facility with unused capacity (Chaptered)
- SB 395 (Archuleta) Wild game mammals: accidental taking and possession of wildlife: collision with a vehicle: wildlife salvage permits (Enrolled)

Other state bills not in Exhibit 1 that commissioners requested be included for discussion purposes:

- SB 54 *(Allen) Solid waste: packaging and products.* Introduced 12/11/2018. Status: Asm Committee on Natural Resources: Read second time. Ordered to third reading.
- AB 1080 *(Gonzalez) Solid waste: packaging and products*. Introduced 02/21/2019. Status: 09/14/19: Sen Committee on Environmental Quality: Measure returned to Senate floor for consideration. Ordered to inactive file at the request of Senator Bradford.

  Summary: These two bills are identical. Would require the California Department of Resources Recycling and Recovery (CalRecycle) to administer a regulatory program concerning use of single-use packaging and single-use products by producers, retailers, and wholesalers, and to finalize an implementation plan by January 1, 2023 and adopt regulations to that effect before January 1, 2024. The bills would additionally require CalRecycle to ensure that all single-use packaging and priority single-use products that are manufactured on or after January 1, 2030 and offered for sale, sold, distributed or imported in or into California are recyclable or compostable, and to achieve and maintain a statewide 75% reduction of the waste generated from single-use packaging and priority single-use products by January 1, 2030 (see Exhibits 2 and 3).

Federal Legislation

- *H.R. 30 (SAVES Act):* Rep. Louie Gohmert (TX-1). Status: House – 02/05/2019. Committeee on Natural Resources. Referred to the Subcommittee on Water, Oceans, and Wildlife.

  Summary: Limits the protection of endangered and threatened species to species that are native to the United States, thus removing protection given to non-native species in the United States that are listed as threatened or endangered.
- *H.R. 548 (FISH Act):* Rep. Ken Calvert (CA-42). Status: House – 02/04/2019. Committee on Natural Resources. Referred to the Subcommittee on Water, Oceans, and Wildlife.

  Summary: Amends the Endangered Species Act of 1973 to vest in the Secretary of the Interior functions under that Act with respect to species of fish that spawn in fresh or estuarine waters and migrate to ocean waters, and species of fish that spawn in ocean waters and migrate to fresh waters.

- *H.R. 1240 (Young Fishermen's Development Act of 2019):* Rep. Don Young (AK-At Large). Status: House – 05/08/2019. House Natural Resources Subcommittee on Water, Oceans, and Wildlife. Subcommittee hearings held.

  Summary: Effort to preserve United States fishing heritage through a national program dedicated to training and assisting the next generation of commercial fishermen.

- *H.R. 3742 (Recovering America's Wildlife Act (RAWA)):* Rep. Debbie Dingell (MI-12). Status: House – 07/29/2019. Committee on Natural Resources. Referred to the Subcommittee on Water, Oceans, and Wildlife.

  Summary: Amends the Pittman-Robertson Wildlife Restoration Act to make supplemental funds available for management of fish and wildlife species of greatest conservation need as determined by State fish and wildlife agencies, and for other education and enforcement related purposes. The Secretary of the Treasury shall annually transfer $1.3 billion to a fund established for the management and implementation of wildlife and habitat conservation and restoration programs.

- *S. 2092 (Modernizing the Pittman-Robertson Fund for Tomorrow's Needs Act):* Senator Jim Risch (ID). Status: Senate – 07/11/2019. Read twice and referred to the Committee on Environment and Public Works.

  Summary: Provides flexibility to state agencies to use Pittman-Robertson funds for the recruitment, retention, and reactivation of hunters and recreational shooters. The bill does not increase taxes or existing user fees, but would allow state fish and wildlife agencies to use existing revenues in new ways. This legislation is identical to H.R. 877 that was introduced earlier this year by Representatives Austin Scott (GA), Mark Veasey (TX), Debbie Dingell (MI), and Richard Hudson (NC).

Federal Regulatory Notices and Other Actions

Federal scoping has been initiated for authorizing shallow-set longline gear for pelagic fishing outside of the U.S. West Coast exclusive economic zone (EEZ).

- The Pacific Fishery Management Council (PFMC) is currently revisiting authrorization of pelagic shallow-set longline fishing outside of the EEZ, commencing with a scoping session scheduled for its Nov 14-20, 2019 meeting in Costa Mesa.
- Under the federal Highly Migratory Species Fishery Management Plan (FMP), shallow-set longline gear, used to target swordfish, is prohibited based on the federal Endangered Species Act (ESA) Section 7 consultation for the original FMP implementation. An FMP amendment would be required to authorize this gear type while addressing concerns associated with the current prohibition.
- Authorization was originally considered by PFMC in 2009, but it selected the no-action alternative due to bycatch concerns.
- PFMC is reconsidering its 2009 position in light of current conditions, as discussed in Sep 2018 (exhibits 4-5); conditions include West Coast landings by Hawaii-permitted shallow-set longline vessels. Vessels permitted under the Western PFMC's Pelagics Fishery Ecosystem Plan are permitted to fish with shallow-set longline gear outside the west

coast EEZ—both east and west of 150 W longtitude—and land those fish in West Coast ports.

- At the Aug 2019 FGC meeting, stakeholders requested that FGC write a letter regarding potential authorization of this gear.
- In the past, FGC has expressed concern about fishery gear types that have a high bycatch level, notably of ESA species, while also expressing a desire to support more sustainable commercial fishing in California and the United States and reduce the amount of fish imported from other countries with less stringent resource protections.

Significant Public Comments

Two requests made in Aug during public comment were added to the agenda for consideration at this meeting:

1. A stakeholder highlighted SB 54 and AB 1080 related to single-use plastics and requested that FGC write a letter to Governor Newsom in support of signing SB 54 and AB 1080.
2. A stakeholder expressed concern over PFMC scoping for potential authorization of a pelagic longline fishery outside of the EEZ, and asked FGC to write letter to PFMC. The commenter suggested that the gear type is no longer appropriate to consider outside the EEZ because of continued bycatch impacts.

Recommendation

FGC staff: Authorize the executive director to work with President Sklar to draft and send comment letters to: (1) Governor Newsom and the bill authors of SB 54 and AB 1080 expressing conceptual support for the statutory language; and (2) PFMC regarding its consideration of authorizing pelagic fishing using longline gear. Provide direction on the content of the letters.

Exhibits

1. DFW legislative report, dated Sep 30, 2019
2. SB 54 as compared to today's law, amended Sep 10, 2019
3. AB 1080 as compared to today's law, amended Sep 9, 2019
4. PFMC's draft Swordfish Management and Monitoring Plan (SMMP), Sep 2018
5. National Marine Fisheries Service report on the SMMP, Sep 2018

Motion/Direction

Moved by ______________ and seconded by ______________ that the Commission approves delegating authority to its executive director to work with President Sklar to draft and send a comment letter to Governor Newsom based on themes discussed today regarding support for signing Senate Bill 54 and Assembly Bill 1080.

AND

Moved by _____________ and seconded by _____________ that the Commission approves delegating authority to its executive director to work with President Sklar to draft and send a comment letter based on themes discussed today to the Pacific Fishery Management Council regarding its consideration of authorizing pelagic fishing using longline gear.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

5. TRIBAL COMMITTEE (TC)

Today's Item **Information** ☐ **Action** ☒

Receive summary from the Oct 8, 2019 TC meeting and potentially adopt TC recommendations. Receive update on TC work plan and draft timeline. Discuss and consider approving new topics for TC review.

Summary of Previous/Future Actions

• Most recent TC meeting	Oct 8, 2019; TC, Valley Center
• **Today consider TC recommendations and potential new topics**	**Oct 9-10, 2019; Valley Center**
• Next TC meeting	Jan 17, 2020; TC, Los Angeles area

Background

TC Work Plan and Timeline

TC works under FGC direction to set and accomplish its work plan (Exhibit 1). The agenda for the Oct 8 TC meeting (Exhibit 2) included five substantive items:

1. Discuss a co-management definition
2. Discuss potential commercial kelp and algae harvest regulation changes
3. Recommendation for DFW-managed lands regulations
4. Recommendation for changes to FGC meeting procedures regulations related to TC
5. Discuss potential topics for the annual FGC tribal planning meeting

In addition, TC received updates from FGC staff, FGC Marine and Wildlife resource committees, and other state agencies, as well as updates on the effort to develop simplified statewide inland sport fishing regulations.

During today's agenda item, a verbal report will be provided about the Oct 8 TC meeting and any resulting recommendations for FGC consideration.

TC Workgroup

As requested by TC and approved by FGC in Jun 2019, staff hosted a webinar/teleconference with representatives of California tribes and tribal communities to further progress on discussions around a co-management definition and potential commercial kelp and algae harvest management regulation changes. A half-dozen representatives participated with staff.

New TC Topics

No new topics are proposed by staff at this time.

Significant Public Comments (N/A)

Recommendation

Consider recommendations developed on Oct 8, which will be presented verbally to FGC today.

Exhibits

1. TC work plan, updated Sep 2019
2. Agenda for Oct 8, 2019 TC meeting

Motion/Direction

Moved by ____________ and seconded by ____________ that the Commission approves the ____________ recommendations from the October 8, 2019 Tribal Committee meeting.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

6. WILDLIFE RESOURCES COMMITTEE (WRC)

Today's Item **Information ☐** **Action ☒**

Receive summary from the Sep 10, 2019 WRC meeting and potentially approve WRC recommendations. Receive update on WRC work plan and timeline. Discuss and potentially approve new topics for WRC review.

Summary of Previous/Future Actions

• Most recent WRC meeting	Sep 10, 2019; WRC, Santa Rosa
• **Today consider WRC recommendations and potential new topics**	**Oct 9-10, 2019; Valley Center**
• Next WRC meeting	Jan 16, 2020; WRC, Los Angeles area

Background

WRC works under FGC direction to set and accomplish its work plan (Exhibit 2).

Meeting Summary

WRC met on Sep 10, 2019 and covered the following topics:

- Initial vetting for upland game bird hunting
- Review and recommendations for:
  - mammal hunting,
  - waterfowl hunting,
  - Central Valley sport fishing, and
  - Klamath River Basin sport fishing
- Update on simplification of statewide inland fishing regulations
- Update on bullfrogs and non-native turtle stakeholder engagement process

A written summary of the meeting is provided in Exhibit 1.

WRC Recommendations

Based on the meeting discussions, WRC has two recommendations for FGC consideration:

1. WRC recommends that FGC support the proposed regulation changes for mammal hunting, waterfowl hunting, Central Valley sport fishing, and Klamath River Basin sport fishing for the 2020-21 seasons, as recommended by DFW, and asked DFW to consider a two-week extension to the Central Valley sport fishing season on the Sacramento River.
2. WRC recommends that FGC schedule a special WRC meeting in Mar 2020, with a date to be determined, focused on simplification of statewide inland fishing regulations proposals.

Significant Public Comments (N/A)

Recommendation

FGC staff: Approve committee recommendations as described.

Exhibits

1. Summary of Sep 10, 2019 WRC meeting
2. WRC work plan, updated Sep 30, 2019

Motion/Direction

Moved by __________ and seconded by __________ that the Commission approves the recommendations from the Sep 10, 2019 Wildlife Resources Committee meeting.

OR

Moved by __________ and seconded by __________ that the Commission approves the recommendations from the Sep 10, 2019 Wildlife Resources Committee meeting, except for ___________________.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

7. POSSESSION OF NONGAME ANIMALS (NUTRIA)

Today's Item **Information** ☒ **Action** ☐

Discuss proposed changes to possession of nongame animal regulations, in order to exclude nutria from the list of nongame animals that can be possessed alive with a special permit.

Summary of Previous/Future Actions

- Notice hearing Aug 7-8, 2019; Sacramento
- **Today's discussion hearing** Oct 9-10, 2019; Valley Center
- Adoption hearing Dec 11-12, 2019; Sacramento

Background

Nutria (*Myocastor coypus*) is a mammal of the order Rodentia; subsection 671(c)(2)(J) designates all rodents (with certain exceptions), including nutria, as "detrimental animals." Nutria are semi-aquatic rodents native to South America and are a highly destructive, invasive species. The detrimental impacts caused by nutria include harm to the State's wildlife, wetland habitats, waterways, water supplies, water conveyance and flood protection infrastructure, and agriculture. Since early 2017, DFW has been planning and implementing eradication efforts with multiple partners in response to the discovery of a pregnant nutria in a managed wetland in the San Joaquin Valley.

Under current law, possession of live nutria can be authorized by DFW under a restricted species permit. DFW has identified that, in addition to eradication efforts already underway, banning the possession of any live nutria is necessary to help prevent new introductions of nutria in the state. The proposed regulation (exhibits 1 and 2) would amend Section 473 to make possession of live nutria unlawful and authorize DFW to deny any application for the possession of live nutria (see Exhibit 5).

Significant Public Comments (N/A)

Recommendation (N/A)

Exhibits

1. DFW memo transmitting initial statement of reasons (ISOR), received Jul 11, 2019
2. ISOR
3. Notice of exemption
4. Economic and fiscal impact statement (Std. 399)
5. DFW presentation from Aug 7, 2019 notice hearing

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

8. ITEMS OF INTEREST FROM PREVIOUS MEETINGS (WILDLIFE AND INLAND FISHERIES)

Today's Item **Information** ☒ **Action** ☐

This is a standing agenda item to provide FGC with updates on items of interest from previous meetings. For this meeting: Update on stakeholder discussions related to FGC's draft Delta Fisheries Management Policy and existing Striped Bass Policy.

Summary of Previous/Future Actions

• Delta Fisheries Forum	May 24, 2017; Sacramento
• WRC vetting of draft policy	Sep 2018 – May 2019
• FGC accepted WRC recommendation to schedule	Jun 12-13, 2019; Redding
• Discussion of draft policy and potential adoption	Aug 7-8, 2019; Sacramento
• **Today's update**	**Oct 9-10, 2019; Valley Center**
• Discussion of revised draft policy and potential changes to existing policy	Dec 11-12, 2019; Sacramento

Background

This item is an opportunity for staff to provide follow-up information on wildlife and inland fisheries topics previously before FGC.

At its Aug 2019 meeting, FGC received a revised draft Delta Fisheries Management Policy for discussion and potential adoption; see Exhibit 1 for further background. Following extensive public comment at the meeting, FGC accepted a staff recommendation to postpone discussion of the draft policy until the Dec 2019 meeting, in order to continue stakeholder discussions with FGC staff and DFW regarding both the draft policy and existing FGC Striped Bass Policy, and to invite a broader array of participants. FGC requested that staff provide at the Oct 2019 FGC meeting an update on the progress of stakeholder discussions on revising the draft policies.

To facilitate broader stakeholder input, staff scheduled a meeting for Sep 30 in Sacramento and publicized it through the FGC listserv (Exhibit 2); nine representatives participated from various organizations representing fishing and water interests. At today's meeting, staff will report on outcomes of the Sep 30 meeting and progress in developing draft revised policies.

Significant Public Comments (N/A)

Recommendation (N/A)

Exhibits

1. Staff summary from Aug 7-8 2019 FGC meeting, for background purposes only
2. FGC staff email invitation to stakeholders for Sep 30 Delta Fisheries Management Policy meeting, sent Sep 26, 2019

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

9. WILDLIFE AND INLAND FISHERIES PETITIONS FOR REGULATION CHANGE

Today's Item **Information** ☐ **Action** ☒

This is a standing agenda item for FGC to act on regulation petitions from the public that are related to wildlife and inland fisheries issues. For this meeting:

(A) Action on petitions for regulation change received at the Aug 2019 meeting

(B) Pending regulation petitions referred to FGC staff and DFW for review – *none scheduled*

Summary of Previous/Future Actions

(A)

- Receive petitions — Aug 7-8, 2019; Sacramento
- **Today's actions on petitions — Oct 9-10, 2019; Valley Center**

(B)

N/A

Background

Pursuant to Section 662, any request for FGC to adopt, amend, or repeal a regulation must be submitted on form FGC 1, "Petition to the California Fish and Game Commission for Regulation Change" (Section 662, Title 14). Petitions received at an FGC meeting are scheduled for consideration at the next business meeting under (A), unless the petition is rejected under 10-day staff review as prescribed in subsection 662(b). A petition may be (1) denied, (2) granted, or (3) referred to committee, staff or DFW for further evaluation or information-gathering. Referred petitions are scheduled for action under (B) once the evaluation is completed and a recommendation made.

(A) ***Petitions for regulation change***

Four petitions received at the Aug meeting are scheduled for action:

I. *Petition #2019- 013: Authorize falconers and raptor propagators to receive non-releasable raptors from rehabilitation facilities (Exhibit A2)*

II. *Petition #2019-016 AM 1: Authorize spring bear hunting (Exhibit A3)*

III. *Petition #2019-017 AM 1: Establish an open archery season for bear and deer hunting in Marble Mountain and Trinity Alps wilderness areas (Exhibit A4)*

IV. *Petition #2019-018: Exempt ferrets from the list of restricted species (Exhibit A5)*

Staff recommendations and rationales are provided in Exhibit A1. See Exhibit A6 for background on the staff recommendation for Petition #2019-018.

(B) ***Pending regulation petitions.*** This is an opportunity for staff to provide a recommendation on petitions previously referred by FGC to staff, DFW, or a committee for review.

No pending regulation petitions are scheduled for action at this meeting.

Significant Public Comments

1. One comment on Petition #2019-016 (spring bear hunting) was received, in support of a spring bear hunt as proposed in the petition (Exhibit A7).
2. Several comments on Petition #2019-018 (ferrets) were received with the following perspectives:
   a. The executive director of United California Ferret Alliance states that Petition #2019-018 comes from a separate, independent organization. She recounts her organization's efforts to pursue legislation to legalize ferrets as pets (Exhibit A8).
   b. Several ferret organizations and individual commenters in support of the petition state that ferrets are domesticated and provide substantiating information, links to websites, and journal articles in support of that view (exhibits A9-A14); dispute that ferrets cause environmental damage (Exhibit A15); and urge FGC to base its decisions on sound science (Exhibit A16).
   c. Commenters sent 199 additional emails in support of the petition, stating that domestic ferrets are not wild animals (see Exhibit A17 for a sample email).

Recommendation

(A) ***FGC staff:*** Adopt staff recommendations as reflected in Exhibit A1.

Exhibits

A1. Table of petitions and staff recommendations received at Aug 2019 FGC meeting, revised Sep 27, 2019
A2. Petition #2019- 013, received Jun 10, 2019
A3. Petition #2019-016 AM 1, received Jul 31, 2019
A4. Petition #2019-017 AM 1, received Jul 31, 2019
A5. Petition #2019-018, received Jul 10, 2019
A6. FGC memo regarding considerations for ferret legalization, associated with Petition #2016-008, dated Oct 10, 2016 (provided for background purposes)
A7. Email from Gary Ward, received Sep 24, 2019
A8. Email from Megan Mitchell, United California Ferret Alliance, received Jul 11, 2019
A9. Email from the World Ferret Union and the World Ferret Information Centre, received Sep 16, 2019
A10. Email from Karl A. Swartz, received Sep 8, 2019
A11. Email from Kathleen Dodson, received Sep 9, 2019
A12. Email from Josh Hall, received Sep 6, 2019
A13. Email from Donna Ferreira, received Sep 23, 2019
A14. Email from Mishele Barker, received Sep 25, 2019
A15. Email from Monica Hail, received Sep 17, 2019
A16. Email from Rene Gandolfi, received Sep 23, 2019
A17. Sample email, from Juliana Lenny, received Sep 8, 2019

Motion/Direction

Moved by ____________ and seconded by ____________ that the Commission adopts the staff recommendations as reflected in Exhibit A1.

OR

Moved by ____________ and seconded by ____________ that the Commission adopts the staff recommendations as reflected in Exhibit A1, except for Petition #________ for which the action is ______________________.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

10. WILDLIFE AND INLAND FISHERIES NON-REGULATORY REQUESTS

Today's Item **Information** ☐ **Action** ☒

This is a standing agenda item for FGC to act on non-regulatory requests from the public that concern wildlife and inland fisheries. For this meeting:

(A) Action on non-regulatory requests received for the Aug 2019 meeting

(B) Update on pending non-regulatory requests referred to FGC staff or DFW for review – *none scheduled*

Summary of Previous/Future Actions

(A)

- FGC receipt of requests — Aug 7-8, 2019; Sacramento
- **Today's action on requests** — **Oct 9-10, 2019; Valley Center**

(B)

N/A

Background

FGC provides direction regarding requests from the public received by mail and email and during general public comment at the previous FGC meeting. Public requests for non-regulatory action follow a two-meeting cycle to ensure proper review and consideration.

(A) ***Non-regulatory requests.*** Non-regulatory requests scheduled for consideration today were received at the Aug 2019 meeting in one of three ways: (1) submitted by the comment deadline and published as tables in the meeting binder, (2) submitted by the late comment deadline and delivered at the meeting, or (3) received during public comment.

Today, five non-regulatory requests received at the Aug 2019 meeting are scheduled for action. Exhibit A1 summarizes and contains staff recommendations for each request, and one original written request is provided as Exhibit A2.

(B) ***Pending non-regulatory requests.*** This item is an opportunity for staff to provide a recommendation on non-regulatory requests that were scheduled for action at a previous meeting and referred by FGC to staff or DFW for further review.

There are no pending non-regulatory requests for today.

Significant Public Comments (N/A)

Recommendation

FGC staff: Adopt staff recommendations for Aug 2019 non-regulatory requests (Exhibit A1).

Exhibits

1. List of non-regulatory requests and staff recommendations for requests received through Aug 7, 2019, dated Sep 30, 2019

2. Email from Danny Offer, Platinum Advisors, on behalf of Chairman Curt Hagman, San Bernardino County Board of Supervisors, received Aug 7, 2019

Motion/Direction

(A) Moved by ____________ and seconded by ____________ that the Commission adopts the staff recommendations for actions on August 2019 non-regulatory requests.

OR

Moved by ____________ and seconded by ____________ that the Commission adopts the staff recommendations for actions on August 2019 non-regulatory requests, except for item(s) ____________ for which the action is ____________.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

11. STRATEGIC PLANNING

Today's Item **Information** ☒ **Action** ☐

This is a standing agenda item for 2018-19 FGC meetings as FGC develops a new strategic plan. Staff will provide an update on current progress.

Summary of Previous/Future Actions (N/A)

• Adopted mission, vision, and core values	Dec 12-13, 2018; Oceanside
• Received updates on second phase	Feb, Apr, Jun 2019; various
• Discussed seven key questions	Aug 7-8, 2019; Sacramento
• **Today's update**	**Oct 9-10, 2019; Valley Center**
• Discuss potential goals and objectives	Dec 11-12, 2019; Sacramento

Background

In anticipation of FGC's upcoming 150-year anniversary in 2020, a strategic planning process was initiated in early 2018 (Exhibit 1 provides additional background). In the first of a three-phase process, FGC reassessed its mission and vision, and developed a set of core values, in concert with staff and stakeholders. Adopted in Dec 2018, the revised mission, vision, and new core values (Exhibit 2) are serving to guide a forward-thinking update to the strategic plan.

In Jun 2019, staff reported that the second phase of the planning process was ramping up, to consist primarily of data gathering and synthesis with staff, stakeholders and commissioners. The Aug 2019 FGC discussion was held in a workshop format so that commissioners, staff, and stakeholders could have a direct dialogue about several key questions related to FGC's performance and priorities (Exhibit 3).

After the Aug discussion, staff finalized an online survey designed to solicit broader input on key questions, which will be sent to a randomly selected subset of FGC's mailing lists; the survey commences Oct 4 and will be available through Oct 20. Staff is currently scheduling in-depth interviews with individual commissioners, leadership from DFW and other sister agencies, and non-governmental organization representatives.

The information gathered during this phase will be analyzed and used to help guide development of draft goals and objectives for FGC consideration. In anticipation of this process, staff has prepared a document that provides samples of goals and objectives from strategic plans of other fish and game commissions in the United States as well as the U.S. Fish and Wildlife Service; in some cases, there is not a separate fish and game commission from the state's wildlife management agency (Exhibit 4). FGC is scheduled to review and discuss possible goals and objectives at its Dec 2019 meeting.

Recommendation (N/A)

Exhibits

1. Staff summary from Agenda Item 17, Strategic Planning, Aug 22-23, 2018 (for background only)
2. FGC mission, vision and core values, adopted Dec 13, 2018
3. Staff summary from Agenda Item 15, Strategic Planning, Aug 7-8, 2019 (for background only)
4. Samples of strategic plan goals and objectives from other states (to be presented during meeting)

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

12. DEPARTMENT INFORMATIONAL ITEMS (WILDLIFE AND INLAND FISHERIES)

Today's Item **Information** ☒ **Action** ☐

This is a standing agenda item to receive and discuss informational updates from DFW.

(A) Director's report

(B) Law Enforcement Division

(C) Wildlife and Fisheries Division and Ecosystem Conservation Division

Summary of Previous/Future Actions (N/A)

Background

Verbal reports on items of interest since the last FGC meeting are expected at the meeting for items (A) through (C). DFW news releases of particular interest are provided as exhibits B1 and C1-C3.

Significant Public Comments (N/A)

Recommendation (N/A)

Exhibits

B1. DFW news release: *CDFW and Partners Remove Illegal Cannabis Grows Near Sensitive Wildlife Habitat in Trinity and Shasta Counties,* Sep 19, 2019

C1. DFW news release: *CDFW Steps in to Protect Animals at Wildlife Waystation*, Aug 13, 2019

C2. DFW news release: *CDFW Expands Statewide Sampling for Chronic Wasting Disease [in deer and elk herds]*, Sep 19, 2019

C3. DFW news release: *Paiute Cutthroat Trout Reintroduced to Native Habitat in High Sierra Wilderness*, Sep 23, 2019

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

13A. ADMINISTRATIVE ITEMS – NEXT MEETING

Today's Item **Information** ☐ **Action** ☒

This is a standing agenda item to review logistics and approve draft agenda items for the next FGC meeting and consider any changes to meeting dates or locations.

Summary of Previous/Future Actions (N/A)

Background

The next FGC meeting is scheduled for Dec 11-12, 2019 in Sacramento. Staff does not anticipate any special logistics for this meeting.

Potential agenda items for the Dec meeting are provided in Exhibit 1 for consideration and potential approval.

FGC staff would also like to highlight the possibility of a field trip to view a grunion run in southern California in conjunction with the Jun 2020 FGC meeting.

Significant Public Comments (N/A)

Recommendation

FGC staff: Approve potential agenda items for the Dec 11-12, 2019 FGC meeting.

Exhibits

1. Potential agenda items for the Dec 11-12, 2019 FGC meeting

Motion/Direction

Moved by _____________ and seconded by _____________ that the Commission approves the agenda items for the December 11-12, 2019 Commission meeting, as amended at this meeting.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

13B. ADMINISTRATIVE ITEMS – RULEMAKING TIMETABLE

Today's Item **Information** ☐ **Action** ☒

Review and consider approving requested changes to the perpetual timetable for anticipated regulatory actions.

Summary of Previous/Future Actions

- FGC approved changes to rulemaking timetable — Aug 7-8, 2019; Sacramento
- **Today consider approving proposed changes to the rulemaking timetable** — **Oct 9-10, 2019; Valley Center**

Background

FGC maintains a perpetual timetable for anticipated regulatory actions. At each FGC meeting, staff provides the latest approved timetable with requests for changes from FGC staff and/or DFW (Exhibit 1) highlighted in bolded and underlined blue text (Exhibit 2).

FGC staff made two changes:

- To assist in tracking consideration of granted petitions for regulation changes, FGC staff made an administrative change to the rulemaking timetable to include granted petition numbers where the petitions are expected to be considered.
- The proposed special WRC meeting for Mar 2020, recommended by WRC under Agenda Item 6 for this meeting, is reflected with the exact date to be determined.

DFW makes three requests:

- Move *Simplification of Statewide Inland Fishing Regulations* from TBD to scheduled dates, with final WRC review and recommendation in Mar 2020 (if approved under Agenda Item 6) and rulemaking notice in Jun 2020, discussion in Aug 2020, and adoption in Oct 2020.
- Move up extensions of the current *Klamath River Basin 2084 Emergency* rulemaking*,* which is set to expire on Dec 24, 2019, with the first 90-day extension scheduled for Dec 2019 and a second 90-day extension scheduled for Feb 2020. At the same time, DFW is preparing to submit a full Klamath River Basin 2084 regular rulemaking to implement a certificate of compliance; DFW proposes to schedule this for notice in Dec 2019, discussion in Feb 2020, and adoption in Apr 2020. The proposed actions will ensure continuous coverage under emergency regulations until the regular rulemaking is completed and approved.
- Remove *Upland Game Bird* regulations from the calendar for 2020 since there are no proposed changes for that year.

Significant Public Comments (N/A)

Recommendation

FGC staff: Adopt proposed changes to the timetable for anticipated regulatory actions (Exhibit 2) and provide direction on scheduling any rulemaking changes identified during the meeting.

Exhibits

1. DFW memo, received Sep 26, 2019
2. Proposed timetable for anticipated regulatory actions, dated Sep 30, 2019

Motion/Direction

Moved by ___________ and seconded by ____________ that the Commission approves the proposed changes to the rulemaking timetable as discussed today.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

13C. ADMINISTRATIVE ITEMS – NEW BUSINESS

Today's Item **Information ☒** **Action ☐**

This is a standing agenda item to allow Commissioners to bring new items of business to FGC.

Summary of Previous/Future Actions (N/A)

Background (N/A)

Significant Public Comments (N/A)

Recommendation (N/A)

Exhibits (N/A)

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

14. GENERAL PUBLIC COMMENT (DAY 2)

Today's Item **Information** ☒ **Action** ☐

Receive public comments, petitions for regulation change, and requests for non-regulatory actions for items not on the agenda.

Summary of Previous/Future Actions

- **Today's receipt of requests and comments** **Oct 9-10, 2019; Valley Center**
- Consider granting, denying or referring Dec 11-12, 2019; Sacramento

Background

This agenda item is primarily to provide the public an opportunity to address FGC on topics not on the agenda. Staff also includes written materials and comments received prior to the meeting as exhibits in the meeting binder (if received by written comment deadline), or as late comments at the meeting (if received by late comment deadline), for official FGC "receipt."

Public comments are generally categorized into three types under general public comment: (1) petitions for regulation change; (2) requests for non-regulatory action; and (3) informational-only comments. Under the Bagley-Keene Open Meeting Act, FGC cannot discuss any matter not included on the agenda, other than to schedule issues raised by the public for consideration at future meetings. Thus, petitions for regulation change and non-regulatory requests generally follow a two-meeting cycle (receipt and direction); FGC will determine the outcome of the petitions for regulation change and non-regulatory requests received at today's meeting at the next in-person FGC meeting following staff evaluation (currently Dec 11-12, 2019).

As required by the Administrative Procedure Act, petitions for regulation change will be either denied or granted and notice made of that determination. Action on petitions received at previous meetings is scheduled under a separate agenda item titled "Petitions for regulation change." Action on non-regulatory requests received at previous meetings is scheduled under a separate agenda item titled "Non-regulatory requests."

Significant Public Comments

All written comments were summarized and provided as exhibits under Agenda Item 2, "General public comment for items not on agenda".

Recommendation

FGC staff: Consider whether any new future agenda items are needed to address issues that are raised during public comment.

Exhibits

See exhibits for Agenda Item 2.

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

15. MARINE RESOURCES COMMITTEE (MRC)

Today's Item **Information** ☐ **Action** ☒

(A) Discuss and consider approving draft agenda topics for the next MRC meeting. Consider approving new topics for MRC to address at a future meeting.

(B) Receive update on red abalone fishery management plan (FMP)

Summary of Previous/Future Actions

• Most recent MRC meeting	Jul 11, 2019; MRC, Ventura
• **Today consider approving draft MRC agenda topics**	**Oct 9-10, 2019; Valley Center**
• Next MRC meeting	Nov 5, 2019; MRC, Sacramento

Background

(A) *MRC Work Plan and Draft Timeline*

FGC directs committee work. The updated work plan in Exhibit 1 includes topics and timelines for items referred by FGC to MRC. Draft agenda topics proposed for the Nov 2019 MRC meeting are:

- Update on implementing the 2018 MLMA master plan for fisheries (standing item)
- Red abalone FMP development update (standing item)
- Update and discussion on kelp and algae commercial harvest rulemaking
- Update on FGC's Coastal Fishing Communities Project
- Discussion of whale and turtle protections in the management of Dungeness crab fisheries
- Stakeholder informational presentation on aspects of State commercial fisheries management not under FGC regulatory authority

New MRC Topics

No new topics have been identified at this time.

(B) *Update on red abalone FMP*

Although FMP development is a standing agenda item on the MRC work plan, the topic has been of broad interest to FGC. As such, an update on public engagement and FMP development will be provided at this meeting.

Significant Public Comments (N/A)

Recommendation

FGC staff: Approve the draft agenda topics for the Nov 2019 MRC meeting.

Exhibits

1. Updated MRC work plan, dated Sep 30, 2019

Motion/Direction

Moved by __________ and seconded by __________ that the Commission approves the draft agenda topics for the Nov 2019 Marine Resources Committee meeting as proposed.

16. EXPERIMENTAL FISHING PERMIT PROGRAM (PHASE 1)

Today's Item **Information** ☐ **Action** ☒

Discuss and consider adopting proposed changes to experimental fishing permit (EFP) regulations, to allow for issuing EFPs to fishermen who were issued experimental gear permits (EGPs) in 2018 for the box crab EGP program.

Summary of Previous/Future Actions

• FGC approves two-phase rulemaking approach	Jun 12-13, 2019; Redding
• DFW update and MRC discussion	Jul 11, 2019; MRC, Ventura
• Notice hearing	Aug 7-8, 2019; Sacramento
• **Today's discussion/adoption hearing**	**Oct 9-10, 2019; Valley Center**

Background

In Aug 2019, FGC authorized publishing notice of proposed adoption of sections 90 and 704, concerning the issuance of EFPs, as Phase 1 of a two-phase rulemaking process.

As described in greater detail within the staff summary for the Aug 2019 FGC meeting (Exhibit 1), DFW currently administers an EGP program for the box crab fishery, in order to research the potential for developing a new targeted fishery in California (hereinafter referred to as the box crab experimental program). In Dec 2018, pursuant to Fish and Game Code Section 8606 (2017), FGC approved eight EGPs associated with the box crab experimental program for issuance by DFW; these eight permits will expire on Mar 31, 2020.

Fish and Game Code Section 8606 was repealed effective Jan 1, 2019, thus eliminating FGC's ability to renew or authorize any new EGPs. A new Fish and Game Code Section 1022 was created, which provides for establishing an EFP program upon FGC adopting regulations. With the repeal of Section 8606, and absent regulations implementing the new Section 1022, the box crab experimental program cannot be continued beyond the Mar 31, 2020 expiration of the existing permits.

Per the two-phase rulemaking approach approved by FGC in Jun 2019 (see Exhibit 1), this Phase 1 rulemaking proposes a process for issuing EFPs pursuant to Fish and Game Code Section 1022 only to fishermen approved by FGC in Dec 2018 for box crab EGPs. Adopting the proposed regulations in this rulemaking (Phase 1) will ensure that the current box crab experimental program can continue while a larger programmatic rulemaking (Phase 2) can be developed with stakeholder engagement.

Proposed Regulations

The proposed regulations will add to Title 14 a new Chapter 5.6, Experimental Fishing Permit Program, containing new Section 90, Issuance of Experimental Fishing Permits. The proposed Section 90 will establish a process for FGC approval and DFW issuance of EFPs to those applicants previously approved to receive a box crab EGP, and includes the following concepts:

- No more than eight valid EFPs will be issued at any one time.

- An applicant shall submit a written request for an EFP at least 60 days prior to the expiration date of their current EGP.
- FGC may establish standard terms applicable to all fishery participants.
- FGC may approve the adoption, amendment, or repeal of special conditions unique to the experimental fishery set forth in Form DFW 1085 as it deems necessary for research and the conservation and management of marine resources and the environment.
- DFW shall notify a permittee at least 30 days before recommending a change to the special conditions of the EFP issued to that permittee.
- Access to future permits, if a fishery is developed, is not implied by participation in the EFP program.

The proposed regulations will also add new Section 704, Experimental Fishing Permits; Fees and Forms to Title 14, which will stipulate an annual box crab EFP fee of $4,487.75. Pursuant to Fish and Game Code, subdivision 1022(g), FGC is authorized to charge a fee as necessary to fully recover, but not exceed, all reasonable implementation and administrative costs of DFW and FGC related to the EFP. A detailed discussion of these costs can be found in the initial statement of reasons (ISOR; Exhibit 2) and economic and fiscal impact statement (Std 399; Exhibit 3).

Proposed Section 704 will also incorporate by reference the Experimental Fishing Permit Terms and Conditions Form DFW 1085 (New 08/01/2019) (Exhibit 4), which identifies the person(s) and vessel authorized to conduct activities under the EFP and specifies the standard terms and special conditions to which EFP permit holders will be subject. The proposed standard terms and special conditions are consistent with those used to issue the box crab EGPs (Exhibit 5).

California Environmental Quality Act (CEQA)

A notice of exemption (Exhibit 6) has been drafted consistent with FGC staff's recommendation to rely on two CEQA categorical exemptions (Class 6 and Class 7) for the proposed regulation changes. Staff has reviewed all of the available information possessed by FGC relevant to the issue, including the analysis and rationale presented in exhibits 6 and 7, and does not believe that reliance on these categorical exemptions is precluded by the exceptions set forth in CEQA Guidelines Section 15300.2.

Significant Public Comments

Two comments were received during the public comment period. DFW has provided a detailed summary of and response to the individual comments and, for the reasons set forth in its responses to public comments, does not believe that the comments received warrant changes to the proposed regulations (Exhibit 8).

Recommendation

FGC staff: Rely on two CEQA categorical exemptions (Class 6 and Class 7) for the proposed regulation changes and adopt the proposed regulation changes as recommended by DFW.

DFW: Adopt the proposed regulation changes as detailed in the ISOR.

Exhibits

1. Staff summary from Aug 7-8, 2019 FGC meeting (for background only)
2. ISOR
3. Economic and fiscal impact statement (Std. 399)
4. Proposed form DFW 1085, *Experimental Fishing Permit Terms and Conditions*
5. Box crab experimental gear permit terms and conditions, dated Dec 20, 2018 (for background only)
6. Draft notice of exemption
7. DFW memo transmitting ISOR and providing overview of CEQA categorical exemptions, received Jul 22, 2019
8. DFW memo responding to public comments, received Sep 25, 2019
9. DFW presentation

Motion/Direction

Moved by _____________ and seconded by _____________ that the Commission has determined, based on the record, that this approval is exempt from the California Environmental Quality Act pursuant to the guidelines in sections 15306 and 15307, Title 14, California Code of Regulations, and adopts the proposed regulations in Section 90 and Section 704, related to issuing experimental fishing permits.

17. PACIFIC HERRING FISHERY MANAGEMENT PLAN

Today's Item **Information** ☐ **Action** ☒

Discuss and potentially adopt a Pacific Herring Fishery Management Plan (FMP) and California Environmental Quality Act (CEQA) documentation.

Summary of Previous/Future Actions

• DFW updates on FMP progress	2016-2017; MRC meetings
• DFW updates and MRC recommendation	Jul 17, 2018; MRC, San Clemente
• FGC endorsed MRC recommendation	Aug 22-23, 2018; Fortuna
• Updated on FMP progress	Mar 20, 2019; MRC, Sacramento
• Received draft FMP	Jun 12-13, 2019; Redding
• Discussed draft FMP	Aug 7-8, 2019; Sacramento
• **Potentially adopt FMP/CEQA document**	**Oct 9-10, 2019; Valley Center**

Background

The Marine Life Management Act (MLMA) requires that FMPs form the primary basis for managing California's marine fisheries (Section 7072 et seq., Fish and Game Code). Pursuant to the mandates of MLMA, DFW has been developing the California Pacific Herring FMP (Herring FMP) since 2016 with a collaborative working group of herring fleet leaders, staff from conservation non-governmental organizations, and DFW. Exhibit 1 provides additional background information.

FGC received the draft Herring FMP in Jun 2019, which commenced both a 45-day CEQA public comment period that ran through Aug 1, 2019, and an FMP-specific comment period that is open through FMP adoption. A public comment letter received in Jul 2019 alerted staff that Appendix R was missing from the Jun draft Herring FMP; the missing appendix was transmitted at the Aug FGC meeting, a notice of its inclusion was sent to all draft Herring FMP commenters, and an updated draft Herring FMP was posted to FGC and DFW websites.

FGC directed staff to provide a copy of the draft Herring FMP to the California State Legislature's Joint Committee on Fisheries and Aquaculture for review prior to adoption, in fulfillment of Fish and Game Code 7078(d) (Exhibit 2). The accompanying memo identifies statutes proposed for repeal through adoption of the FMP, which establishes authority for FGC to promulgate regulations pursuant to the FMP. No comments have been received from the committee to date.

Today, DFW is requesting that FGC adopt the Oct 2019 Herring FMP as final and has provided a memo and presentation to support the request (exhibits 3-5). The draft Herring FMP has been updated to include *Appendix S: Public Comments Received, Responses, and Changes to the Draft California Pacific Herring Fishery Management Plan*, which summarizes public comments received by FGC during the public comment period, DFW responses, and changes to the Herring FMP incorporated since Jun 2019.

The Herring FMP serves as the functional equivalent of an environmental impact report under CEQA, consistent with FGC's Certified Regulatory Program, thus allowing FGC to comply with CEQA when considering and adopting the Herring FMP. If the Herring FMP is adopted, FGC will need to adopt implementing regulations, which will be considered under Agenda Item 18 – Pacific Herring Regulations (this meeting).

Significant Public Comments

1. Oceana submitted a letter with 3,091 signatures supporting adopting the Herring FMP and its implementing regulations (Exhibit 6).
2. The Environmental Action Committee of West Marin submitted a letter to reiterate its previous comments supporting the Herring FMP, the updated proposed recreational limit, and the management goals of the Herring FMP, and provided specific recommendations for implementing regulations (Exhibit 7).
3. Additional comments received during the public comment period are summarized, with responses from DFW, in Appendix S of the Oct 2019 Herring FMP (Exhibit 3).

Recommendation

FGC staff: Adopt the final draft Pacific Herring FMP as recommended by DFW.

DFW: Adopt the Oct 2019 Herring FMP with *Appendix S: Public Comments received, Responses, and Changes to the Draft California Pacific Herring Fishery Management Plan* as final.

Exhibits

1. Staff summary for Agenda Item 25, Jun 12-13, 2019 FGC meeting (for background only)
2. Memo to Joint Committee on Fisheries and Aquaculture, dated Sep 12, 2019
3. Final draft Herring FMP, including *Appendix S: Public Comments Received, Responses, and Changes to the Draft California Pacific Herring Fishery Management Plan*, dated Oct 2019
4. DFW memo transmitting the final draft Herring FMP, received Sept 25, 2019
5. DFW Presentation
6. Letter and signatures from Oceana, received Sep 24, 2019
7. Email from Ashley Eagle-Gibbs, Environmental Action Committee of West Marin, received Sep 26, 2019

Motion/Direction

Moved by________________ and seconded by________________ that the Commission finds the California Pacific Herring Fishery Management Plan as an environmental document reflects the independent judgment of the Commission; adopts the document for purposes of compliance with the California Environmental Quality Act; and adopts the final draft herring fishery management plan as presented as *Final California Pacific Herring Fishery Management Plan* consistent with the Marine Life Management Act.

OR

Moved by_______________ and seconded by_______________ that the Commission finds that the California Pacific Herring Fishery Management Plan as an environmental document reflects the independent judgment of the Commission; adopts the document for purposes of compliance with the California Environmental Quality Act; and adopts the final draft herring Fishery Management Plan as presented as the *Final California Pacific Herring Fishery Management Plan* consistent with the Marine Life Management Act with the following modifications: ___________________.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

18. PACIFIC HERRING REGULATIONS

Today's Item **Information** ☐ **Action** ☒

Discuss and consider proposed changes to adopt new and amend existing regulations to implement the *California Pacific Herring Fishery Management Plan* (Herring FMP).

Summary of Previous/Future Actions

• MRC vetting	Jul 2016–Mar 2019
• Notice hearing	Jun 12-13, 2019; Redding
• Discussion hearing	Aug 7-8, 2019; Sacramento
• **Today's adoption hearing**	**Oct 9-10, 2019; Valley Center**

Background

The draft Herring FMP (see Agenda Item 17, this meeting) initiates the process for concurrently considering and adopting regulations to implement the Herring FMP under authority established through the FMP; this includes revisions to current recreational and commercial Pacific herring regulations (sections 27.60, 28.60, 163, 163.1, 163.5, 164 and 705) and proposed new regulatory sections (Section 28.62; and Article 6, sections 55.00, 55.01 and 55.02). See the Jun 2019 FGC staff summary (Exhibit 3) for a more detailed background.

One of the significant proposed changes is new Section 28.62, related to recreational take of herring; currently there are no limits. However, DFW has proposed a daily bag limit for recreational take of herring in a range from 0-100 pounds; 100 pounds which is the equivalent of two 5-gallon buckets (approximately 260 each bucket). Today, DFW will ask FGC to adopt a recreational bag limit within the range (Exhibit 2).

At FGC's Aug 2019 meeting, DFW notified FGC that the draft Herring FMP received in Jun was missing one of its appendices, titled *Appendix R: Harvest Control Rule Framework Development and Guidance for Amending the Decision Tree*. Appendix R was added to the proposed rulemaking file in Aug, triggering a 15-day notice of availability pursuant to Government Code 11346.8. The notice was mailed to interested parties on Sep 5, 2019 and FGC staff has not received any comments to date.

For today's adoption hearing, DFW has identified two proposed changes that it considers to be errors that can be addressed if FGC selects the "no change" alternative (Exhibit 11). In a memo received Oct 1, 2019 (Exhibit 11), DFW requests that FGC select the "**no change**" alternative for two subsections, 163.1(d) and 164(d)(1):

1. ***Subsection 163.1(d)***, related to net tending distance. Members of the commercial industry members provided feedback to DFW and requested to retain the existing Title 14 language; the steering committee did not express opposition to the request.

<u>Noticed change</u>:

(d) Net Tending. Permitted vessels shall be in the immediate proximity, not exceeding one nautical mile, of any single gill net being fished.

<u>No change alternative</u> *[original text moved from Section 163(f)(2)(A)]:*

(d) Net tending. Permitted vessels shall be in the immediate proximity, not exceeding three nautical miles, of any single gill net being fished. (Exhibit 11)

2. ***Subsection 164(d)(1),*** related to herring eggs on kelp gear type, including gear allowances, proposed a rewording of the existing regulatory language with the intent of clarifying the meaning; however, the change inadvertently introduced an error and inconsistency related to the total number of allowable lines and rafts.

   <u>Noticed change</u>:

   (1) Not more than two (2) rafts; or two (2) lines; or one (1) raft and one (1) line may be used per permit.

   <u>No change alternative</u> *[original text moved from Section 164(j)(1)]:*

   (1) Not more than two (2) rafts and/or two (2) lines may be used per permit.

Finally, DFW has provided a detailed summary of and responses to individual comments received during the 45-day public comment period; for the reasons set forth in its responses to public comments, DFW does not believe the comments warrant changes to the regulations as proposed (Exhibit 11).

California Environmental Quality Act (CEQA)

A notice of exemption (Exhibit 13) has been drafted consistent with FGC staff's recommendation to rely on the statutory exemption in Fish and Game Code Section 7078(e), based on the assumption that the Herring FMP will be adopted as an environmental impact report-equivalent under Agenda Item 17 (this meeting), consistent with the Commission's Certified Regulatory Program. Pursuant to Fish and Game Code Section 7078(e), adopting regulations to implement an FMP or FMP amendment shall not trigger an additional review process under CEQA.

Significant Public Comments

1. Six commenters are opposed to the recreational daily bag limit as proposed and request a higher bag limit. Commenters state that take by recreational fishermen is minimal based on the amount of times spawning occurs; the majority of fishermen go once or twice a year, and a low number of between 30-50 fishermen participate (see exhibits 5 and 6). Commenter is not aware of recreational fishermen harvesting huge quantities of herring for illicit commercial trade as stated in the initial statement of reasons (Exhibit 10). Commenter has not seen scientific data indicating that recreational take has an impact on the fishery (Exhibit 8). Commenters recommend at least two 5-gallon buckets, or preferably four 5-gallon buckets (see Exhibit 9).

2. The Environmental Action Committee of West Marin recommends that the recreational take of roe should be prohibited in Tomales Bay, due to the sensitive nature of the eco-system and supports the Herring FMP's maximum daily bag limit of two 5-gallon buckets of Pacific herring (see Herring FMP Exhibit 17.7).

Recommendation

FGC staff: (1) Determine that a statutory exemption applies; and (2) Adopt the proposed regulations as recommended by DFW, unless FGC wishes to select a higher recreational take limit based on comments, in which case select within the 0-10 gallon range and adopt remaining regulations as recommended by DFW.

DFW: Adopt a recreational take limit of 5 gallons, adopt the regulations as proposed, except adopt the "No Change" Alternative for subsections 163.1(d) and 164(d).

Exhibits

1. DFW transmittal memo, received May 24, 2019
2. Initial statement of reasons
3. Staff summary for Agenda Item 26, Jun 12-13, 2019 FGC meeting (for background only)
4. Draft economic and fiscal impact statement (std. 399)
5. EML from Kirk Lombard, received Jul 24, 2019
6. EML from anonymous stakeholder, received Aug 7, 2019
7. EML from Ashley Eagle-Gibbs, Environmental Action Committee of West Marin, received Sep 26, 2019 (see Exhibit 17.7)
8. EML from Bradley Cain, received Jul 24, 2019
9. EML from Andrew Bland, received Jul 24, 2019
10. EML from John Vogel, received Jul 23, 2019
11. DFW memo and table with responses to public comments, received Oct 1, 2019
12. DFW presentation
13. Draft notice of exemption

Motion/Direction

Moved by _____________ and seconded by _____________ that the Commission determines, based on the record, that this approval is exempt from the California Environmental Quality Act as being subject to the statutory exemption in Fish and Game Code Section 7078(e) and adopts the proposed changes to Section 163 et al, related to the California Pacific Herring Fishery Management Plan implementing regulations with the "No Change" alternatives for subsections 163.1(d) and 164(d).

19. MALIBU OYSTER COMPANY STATE WATER BOTTOM LEASE – PUBLIC INTEREST

Today's Item **Information** ☐ **Action** ☒

Determine whether a new state water bottom lease applied for by Malibu Oyster Company offshore Malibu would be in the public interest.

Summary of Previous/Future Actions

- Receive new lease application — Jun 12-13, 2019; Redding
- **Today's potential public interest finding** — **Oct 9-10, 2019; Valley Center**
- Consider approving lease — TBD

Background

FGC has the authority to lease state water bottoms to any person for aquaculture (Section 15400, Fish and Game Code). Requirements for new lease applications and their consideration by FGC are specified in Section 15403 et seq. of the Fish and Game Code.

New Lease Application

At its Jun 2019 meeting, FGC received an application from J.P. Garofalo and Nick Mercer of Malibu Oyster Company (the applicant) to lease a new area covering 100 acres of state water bottom off the Malibu coast. As detailed in the lease application, the proposed lease area is located approximately one-half to one mile offshore from Malibu Pier in Malibu and its proposed siting was selected by the applicant to avoid commercial shipping lanes, marine protected areas, California halibut trawl grounds, areas of special biological significance, and leasable kelp beds, to avoid competing uses (Exhibit 1).

The potential lease site would be used to culture shellfish and certain seaweed species. The applicant proposes to culture seven species, of which the final four have not yet been commercially cultivated in California state waters: Pacific oyster, Olympia oyster, Kumamoto oyster, giant rock scallop, red sea urchin, giant kelp, and sugar kelp.

Public Interest Determination

Fish and Game Code sections 15400(a) and 15404 require that, prior to considering a new lease application, FGC must find that the lease area applied for is available (i.e., not otherwise leased or encumbered for other uses) and that the lease would be in the public interest.

To assist FGC in determining if the lease would be in the public interest, DFW has completed a review of the application, has consulted with the California State Lands Commission to determine that the area applied for is available, and has considered other potential uses for the area in its review. DFW's analysis and findings are provided in Exhibit 2.

Should FGC find that the lease would be in the public interest, staff will publish notice that FGC is considering the lease as prescribed in Fish and Game Code Section 15404, DFW will initiate tribal outreach and interagency coordination, and environmental review will be conducted by the applicant prior to final FGC consideration of the lease application and public input (Exhibit 2).

Significant Public Comments

1. A local restaurant seafood distributor submitted a letter in support of the applicant and its application for a state water bottom lease, citing that the applicant will increase opportunity for access to locally raised products for distribution (Exhibit 4).
2. A commenter expressed concern that the proposed lease area is sited within Malibu's swell corridor, which is listed in the National Register of Historic Places, and thus poses an incompatible use, is not in the public interest, and should not be considered in the proposed area. Commenter offers to work with the applicant to find an alternative location (Exhibit 4).

Recommendation

FGC staff: Approve DFW's recommendation and direct staff to ensure that concerns expressed over the siting of the lease area are explored through the CEQA and public review processes.

DFW: Based on the reasons identified within Exhibit 2, find that the area of the proposed new state water bottom lease for shellfish and seaweed aquaculture is available for leasing and that the lease would be in the public interest; and proceed with the next steps in public notice, tribal outreach, interagency coordination, and environmental review.

Exhibits

1. Malibu Oyster Company application for new lease, received Apr 22, 2019
2. DFW memo, received Sep 16, 2019
3. Email from Randy Lovell, transmitting comment letter dated Aug 2, 2019 from Michael King, King Seafood Company, as attachment, received Sep 10, 2019
4. Email from Michael Blum, Sea of Clouds, with attachment, received Sep 26, 2019

Motion/Direction

Moved by________________and seconded by ________________that the Commission finds the state water bottom lease area applied for by Malibu Oyster Company, for the purposes of shellfish and seaweed aquaculture, is available for lease, and that the lease would be in the public interest. Further, the Commission directs staff to initiate public notice pursuant to Section 15404 of the Fish and Game Code, and schedule for consideration the lease application following tribal outreach and interagency review, and environmental review conducted by the applicant.

OR

Moved by________________and seconded by ________________that the Commission finds the state water bottom lease area applied for by Malibu Oyster Company, for the purposes of shellfish and seaweed aquaculture, is available for lease but leasing the area is not in the public interest.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

20. ITEMS OF INTEREST FROM PREVIOUS MEETINGS (MARINE)

Today's Item **Information** ☒ **Action** ☐

This is a standing agenda item to provide FGC with updates on items of interest from previous meetings. For this meeting: Update on domoic acid levels in razor clams in Humboldt and Del Norte counties.

Summary of Previous/Future Actions

- Adopt emergency razor clam regulations — Apr 25, 2016; teleconference
- Update on domoic acid levels — Jun 22-23, 2016; Bakersfield
- Update on domoic acid levels — Aug 22-23, 2018; Fortuna
- **Today's update on domoic acid levels — Oct 9-10, 2019; Valley Center**

Background

This item is an opportunity for staff to provide any follow-up information on marine topics previously before FGC.

The recreational razor clam fishery has been closed since Apr 2016, when FGC adopted an emergency closure in Humboldt and Del Norte counties. The closure was in response to persistently high concentrations of domoic acid in clam meat and viscera, which led to a closure recommendation from the California Office of Environmental Health Hazard Assessment to protect human health.

Regular sampling has confirmed the continued persistence of high levels of domoic acid in razor clam meat in Del Norte and Humboldt counties. The most recent samples, taken from Clam Beach and Crescent Beach on Aug 3, 2019, indicate that concentrations have lowered overall; however, some samples remain above the alert level of 20 parts per million (Exhibit 1).

Significant Public Comments (N/A)

Recommendation (N/A)

Exhibits

1. Email and sample results from Joe Christen, California Department of Public Health, received Sep 4, 2019

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

21. MARINE PETITIONS FOR REGULATION CHANGE

Today's Item **Information** ☐ **Action** ☒

This is a standing agenda item for FGC to act on regulation petitions from the public that are marine in nature. For this meeting:

(A) Action on the petition for regulation change received at the Aug 2019 meeting

(B) Pending regulation petitions referred to FGC staff and DFW for review – *none scheduled*

Summary of Previous/Future Actions

(A)

- Receive petition — Aug 7-8, 2019; Sacramento
- **Today's action on petition — Oct 9-10, 2019; Valley Center**

(B)

N/A

Background

Pursuant to Section 662, any request for FGC to adopt, amend, or repeal a regulation must be submitted on form FGC 1, "Petition to the California Fish and Game Commission for Regulation Change." Petitions received at an FGC meeting are scheduled for consideration at the next business meeting under (A), unless the petition is rejected under 10-day staff review as prescribed in subsection 662(b). A petition may be (1) denied, (2) granted, or (3) referred to committee, staff or DFW for further evaluation or information-gathering. Referred petitions are scheduled for action under (B) once the evaluation is completed and a recommendation made.

(A) ***Petitions for regulation change:*** One petition scheduled for consideration today was received at the Aug meeting; it was submitted by the comment deadline and published in the meeting binder.

Petition #2019-014: Increase restrictions on recreational take of California grunion (Exhibit A1).

(B) ***Pending regulation petitions:*** This is an opportunity for staff to provide a recommendation on petitions previously referred by FGC to staff, DFW, or a committee for review.

No pending regulation petitions are scheduled for action at this meeting.

Significant Public Comments (N/A)

Recommendation

FGC staff: Refer Petition #2019-014 to DFW for review and recommendation.

Exhibits

A1. Petition #2019-014, received Jun 20, 2019

Motion/Direction

Moved by _______________ and seconded by _______________ that the Commission adopts the staff recommendation to refer petition #2019-014 to the California Department of Fish and Wildlife for review and recommendation.

OR

Moved by __________ and seconded by __________ that the Commission adopts the following action for petition #2019-014: ______________________.

STAFF SUMMARY FOR OCTOBER 9-10, 2019

22. DEPARTMENT INFORMATIONAL ITEMS (MARINE)

Today's Item **Information** ☒ **Action** ☐

This is a standing agenda item to receive and discuss informational updates from DFW.

(A) Director's report

(B) Law Enforcement Division

(C) Marine Region

Summary of Previous/Future Actions (N/A)

Background

Verbal reports are expected at the meeting for items (A) through (C).

(A) The director's report will include items of interest since the last FGC meeting.

(B) Law Enforcement Division (LED) report: DFW's cannabis enforcement unit has worked with state, federal, and local partner agencies to remove illegal cannabis grows near sensitive wildlife habitat in Trinity and Shasta counties (See Agenda Item 12, Exhibit B1).

(C) The Marine Region report will include a video, *California Sea Cucumber Fishery: A Collaborative Project*, which showcases a DFW-fishing industry joint venture to support research and sustainable management of the fishery.

Also, decisions from the Pacific Fishery Management Council's Sep 13-18, 2019 meeting are provided to assist FGC in its continued tracking of council activities relevant to California (Exhibit C1).

Significant Public Comments (N/A)

Recommendation (N/A)

Exhibits

C1. *Decision Summary Document – Pacific Fishery Management Council, Sep 13-18, 2019, dated Sep 23, 2019*

Motion/Direction (N/A)

STAFF SUMMARY FOR OCTOBER 9-10, 2019

EXECUTIVE SESSION

Today's Item **Information** ☐ **Action** ☒

Executive session will include four standing topics:

(A) Pending litigation to which FGC is a party
(B) Possible litigation involving FGC
(C) Staffing
(D) Deliberation and action on license and permit items

Summary of Previous/Future Actions (N/A)

Background

During the public portion of its meeting, FGC will call a recess and reconvene in a closed session pursuant to the authority of Government Code subsections 11126(a)(1), (c)(3), and (e)(1), and Section 309 of the Fish and Game Code. FGC will address four items in closed session:

(A) ***Pending litigation to which FGC is a party***

See agenda for a complete list of pending civil litigation to which FGC is a party.

(B) ***Possible litigation involving FGC***

None to report at the time the meeting binder was prepared.

(C) ***Staffing***

During a special FGC meeting on Sep 3, FGC selected Melissa Miller-Henson, its acting executive director, to fill the position of executive director. Ms. Miller-Henson formally assumed the position on Sep 10. For other details about staffing, see the executive director's report under Agenda Item 4(A) for today's meeting.

(D) ***Deliberation and action on license and permit items***

I. Consider Agency Case No. 19ALJ11-FGC, the appeal filed by Darren Johnson regarding DFW's denial of a request to renew a salmon vessel permit. DFW provided Mr. Johnson notice that his permit could not be reinstated in response to an untimely request to renew the permit (Exhibit D1). Mr. Johnson appealed that notice to FGC (Exhibit D2). DFW has responded stating that DFW does not object to the requested renewal (Exhibit D3). Note that if the appeal is granted, payment of pending fees is statutorily mandated.

Significant Public Comments (N/A)

Recommendation

(D) ***FGC staff:*** Grant the appeal filed by Mr. Johnson.

Exhibits

D1. Letter from DFW to Darren Johnson, dated May 31, 2019
D2. Letter from Darren Johnson to FGC, received Jul 23, 2019
D3. Letter from David Kiene of DFW's Office of General Counsel to FGC, received Sep 10, 2019

Motion/Direction

(D) Moved by ___________ and seconded by ___________ that the Commission grants the appeal by Darren Johnson regarding the Department's denial of a request to renew a salmon vessel permit.

CALIFORNIA FISH AND GAME COMMISSION PETITIONS
RECEIPT LIST FOR PETITIONS FOR REGULATION CHANGE: RECEIVED BY 5:00 PM ON SEPTEMBER 26, 2019

Tracking Number: (2019-019 AM 1)

To request a change to regulations under the authority of the California Fish and Game Commission (Commission), you are required to submit this completed form to: California Fish and Game Commission, 1416 Ninth Street, Suite 1320, Sacramento, CA 95814 or via email to FGC@fgc.ca.gov. Note: This form is not intended for listing petitions for threatened or endangered species (see Section 670.1 of Title 14).

Incomplete forms will not be accepted. A petition is incomplete if it is not submitted on this form or fails to contain necessary information in each of the required categories listed on this form (Section I). A petition will be rejected if it does not pertain to issues under the Commission's authority. A petition may be denied if any petition requesting a functionally equivalent regulation change was considered within the previous 12 months and no information or data is being submitted beyond what was previously submitted. If you need help with this form, please contact Commission staff at (916) 653-4899 or FGC@fgc.ca.gov.

SECTION I: Required Information.

Please be succinct. Responses for Section I should not exceed five pages

1. **Person or organization requesting the change (Required)**
   Name of primary contact person: Leif Landry Orrell
   Address: [redacted]
   Telephone number: [redacted]
   Email address: [redacted]

2. **Rulemaking Authority (Required) -** Reference to the statutory or constitutional authority of the Commission to take the action requested: Authority cited: Sections 2118 and 2120, Fish and Game Code. Reference: Sections 1002, 2116, 2118, 2118.2, 2118.4, 2119, 2120, 2122, 2123, 2124, 2125, 2126, 2127, 2150, 2190 and 2271, Fish and Game Code.

3. **Overview (Required) -** Summarize the proposed changes to regulations: 1. Remove Heloderma Suspectum Suspectum "Reticulated Gila Monster" from CCR 671 Title 14, restricted species list 2. Remove the phrase "This definition includes all specimens regardless of their origin even if they were produced in captivity" from the definition of Native Reptiles in Title 14 3. Remove the phrase "possess, purchase, propagate, sell, transport, import or export any native reptile or amphibian, or part thereof" from Title 14, Division 1, Subdivision 1, Chapter 5, CCR 40.

4. **Rationale (Required) -** Describe the problem and the reason for the proposed change: Heloderma Suspectum Suspectum is on the Restricted species list, CCR 671 Title 14. The rationale for this is "Those species listed because they pose a threat to native wildlife, the agriculture interests of the state or to public health or safety are termed "detrimental animals" and are designated by the letter "D". The department shall include the list of welfare and detrimental wild animals" Through my own research and the reading of research by others, the difference between the two Gila subspecies, H.S. Suspectum, and H.S. Cinctum, is negligible enough to be non-existent. These are essentially color morphs of the same species, which generally does not warrant enough for a definition of subspecies. The definition of this also limits the introduction of new genetic lines into *Cinctum's* range, as the interaction is interfered with by some geography. The two species' ranges do in fact overlap, but sparingly in some places due to human destruction of habitat and other factors. Further, the designation as a "Restricted

Species" implies danger either to the native *Cinctum* population from *Suspectum*, which is moot, or that *Suspectum* would somehow be more of a danger to humans than *Cinctum*, which is nonsense. The rationale for restricting one of these lizards is mooted by the fact that they interbreed regularly in overlapping ranges with no observable ill effects. Removing *Suspectum*, even if the subspecies are in fact separate, would allow responsible pet hobbyists to engage in meaningful study and education without impacting the native population of *Cinctum* because A. *Suspectum* and *Cinctum* are both widely cultivated in captivity, they would therefore avoid poaching risks or over collection of our native species. B. If they were to escape, there would be minimal impact on the native *Cinctum*, with *Suspectum* perhaps bolstering the genetic diversity of the species overall since their ranges currently overlap in many areas. C. Restricting BOTH subspecies so that they could not be kept as pets, even from captive bred populations as I propose, would not be of significant gain for the reasons listed above and they do not pose a significant threat to humans, or when interaction between the subspecies would occur. This would amount to restricting them from the pet trade "just to restrict something". Most descriptions and studies of the species do not even differentiate between the two subspecies when referring to range, color, temperament, diet, husbandry, or any other significant factors because the differences even on the genetic level seem to be nil. Restricting one or both of these species is disadvantageous to the honest pet and education trade because it is currently easier and less expensive to acquire a Gila outside the United States than it is to attempt to navigate the onerous permit process. Even in the unlikely event a permit were to be granted to an individual in the state of California, the process and regulations to obtain said permit is specifically prohibitive for hobbyists and those educators not part of an institution. Due to the species IUCN listing as "Least Concern" in conservation status, adopting the above suggestions will result in ethical study, education, enjoyment, preservation, and appreciation of a wonderful reptile that has been unavailable for the vast majority of Californians. SUBMITTED AS AMENDMENT 22AUG19 BY LEIF LANDRY ORRELL: I WAIVE MY RIGHT TO A RESPONSE WITHIN THE TEN DAY REQUIREMENT SPECIFIED BY THE COMISSION AND HAVE UPDATED THE RULEMAKING AUTHORITIES. I AM AVAILABLE FOR CONTACT BY PHONE DURING NORMAL WORKING HOURS.

To request a change to regulations under the authority of the California Fish and Game Commission (Commission), you are required to submit this completed form to: California Fish and Game Commission, 1416 Ninth Street, Suite 1320, Sacramento, CA 95814 or via email to FGC@fgc.ca.gov. Note: This form is not intended for listing petitions for threatened or endangered species (see Section 670.1 of Title 14).

Incomplete forms will not be accepted. A petition is incomplete if it is not submitted on this form or fails to contain necessary information in each of the required categories listed on this form (Section I). A petition will be rejected if it does not pertain to issues under the Commission's authority. A petition may be denied if any petition requesting a functionally equivalent regulation change was considered within the previous 12 months and no information or data is being submitted beyond what was previously submitted. If you need help with this form, please contact Commission staff at (916) 653-4899 or FGC@fgc.ca.gov.

SECTION I: Required Information.

Please be succinct. Responses for Section I should not exceed five pages

1. **Person or organization requesting the change (Required)**
Name of primary contact person: Justin Alvarez
Address: PO Box 417, Hoopa, CA 95546
Telephone number: (530)6254267
Email address: jalvarez@hoopa-nsn.gov

2. **Rulemaking Authority (Required) -** Reference to the statutory or constitutional authority of the Commission to take the action requested: FGC1.2.1.205(b) & Sections 200, 202, 205, 210, 219 and 220, Fish and Game Code.

3. **Overview (Required) -** Summarize the proposed changes to regulations: We request that, within the Klamath Trinity River Basin, the bag limit and possession limit for recreational Brown Trout be raised to 10 and 20 respectively.

4. **Rationale (Required) -** Describe the problem and the reason for the proposed change: Introduced Brown Trout pose an impediment to the recovery of the native fishes such as Chinook and Coho salmon, steelhead trout, and Pacific lamprey. These native species support both tribal and non-Indian fisheries. A recent predation study conducted by the Hoopa Valley Tribe and Humboldt State University found Brown Trout have the potential to consume large portions of the natural and hatchery production of anadromous salmonids. The NMFS specifically listed Trinity River Brown Trout as an impediment to recovery in its Southern Oregon Northern California Coastal Evolutionary Significant Unit (ESU) Coho recovery plan. The State of California increased the bag limit to 5 fish per day in 2007 because of predation concerns, and lists the following actions to deal with invasive species in their Coho Salmon recovery plan. Develop a rapid-response eradication plan for invasive, non-native fish species that negatively affect Coho Salmon. Develop management guidelines to mitigate the impacts of non-native fish species on Coho Salmon. Remove non-native fish species from stock ponds where these fish pose a threat to Coho salmon. In 2015, Brown Trout were estimated to have consumed 7% of the hatchery production and 20% of the natural production for that year. Given the large scale efforts on the

Trinity River to restore the native fishes we request the above actions be taken to ameliorate the negative impacts to the native fishes.

SECTION II: Optional Information

5. Date of Petition: August 21, 2019

6. Category of Proposed Change

☒ Sport Fishing
☐ Commercial Fishing
☐ Hunting
☐ Other, please specify:

7. The proposal is to: (*To determine section number(s), see current year regulation booklet or https://govt.westlaw.com/calregs*)

☒ Amend Title 14 Section(s):7.50(b)(91.1)(C)1a & 7.50(b)(91.1)(E)
☐ Add New Title 14 Section(s):
☐ Repeal Title 14 Section(s):

8. If the proposal is related to a previously submitted petition that was rejected, specify the tracking number of the previously submitted petition

Or ☒ Not applicable.

9. Effective date: If applicable, identify the desired effective date of the regulation. If the proposed change requires immediate implementation, explain the nature of the emergency: Effective with release of 2020 supplemental regulations.

10. Supporting documentation: Identify and attach to the petition any information supporting the proposal including data, reports and other documents: Letter from Hoopa, Yurok, National Marine Fisheries Service, US Bureau of Reclamation, and Shasta Trinity Forest Service requesting action. Letter of support from Six Rivers Forest. Publication of Brown Trout Predation Study from Ecology of Freshwater Fishes. Letter of Support from US Fish and Wildlife Service. Mailed separately: Letter of Support from Trinity County Supervisors based on recommendation of the Trinity County Fish and Game Commission.

11. Economic or Fiscal Impacts: Identify any known impacts of the proposed regulation change on revenues to the California Department of Fish and Wildlife, individuals, businesses, jobs, other state agencies, local agencies, schools, or housing: Benefits of Brown Trout Persisting: 1)provides an additional target species for recreational fishing 2)Potential increase in local revenue from fisherman targeting Brown Trout 3)Potential for increased fishing guide job opportunities Cost of Brown Trout Persisting; 1)Potential decrease in local revenue through negative impacts to the native fishery. 2)Loss of hatchery fish to Brown Trout Predation includes the cost of producing the hatchery fish and also lost fishing opportunities both recreational and commercial 3) Hampering recovery efforts for Chinook salmon and endangered Coho salmon

12. Forms: If applicable, list any forms to be created, amended or repealed:

Re: Trinity River Brown Trout Management Plan

Dear Commissioners:

On April 26th, 2018 a workshop was held to discuss the issue of Brown Trout management on the Trinity River. The workshop invited staff from all the resource management agencies: United States Fish and Wildlife Service (USFWS) California Department Fish & Wildlife (CDFW), Yurok Tribe, United States Forest Service (USFS), and National Marine Fisheries Service (NMFS), some invited stakeholder groups, and university staff. In the end, no stakeholder groups were able to attend, but all other parties were present. The outcome of this workshop was a list of management actions to recommend to the California State Fish and Game Commission

The purpose of this letter is to make recommendations on behalf of the Hoopa Valley Tribe (HVT), Yurok Tribe, USFWS, NMFS, USFS, and the USBR regarding management of Brown Trout within the Trinity River. Introduced Brown Trout pose an impediment to the recovery of the native fishes such as Chinook and Coho salmon, steelhead trout, and pacific lamprey. These native species support both tribal and non-Indian fisheries. A recent predation study conducted by the HVT and Humboldt State University found Brown Trout have the potential to consume large portions of the natural and hatchery production of anadromous salmonids. The NMFS specifically listed Trinity River Brown Trout as an impediment to recovery in its Southern Oregon Northern California Coastal Evolutionary Significant Unit (ESU) Coho recovery plan.
The state of California increased the bag limit to 5 fish per day in 2007 because of predation concerns, and lists the following actions to deal with invasive species in their Coho Salmon recovery plan.

- Develop a rapid-response eradication plan for invasive, non-native fish species that negatively affect Coho salmon.
- Develop management guidelines to mitigate the impacts of non-native fish species on Coho salmon.
- Remove non-native fish species from stock ponds where these fish pose a threat to Coho salmon.

In 2015, Brown Trout were estimated to have consumed 7% of the hatchery production and 20% of the natural production for that year. Given the large scale efforts on the Trinity River to restore the native fishes we request the following actions be taken to ameliorate the negative impacts to the native fishes.

We request that the bag limit and possession limit for recreational Brown Trout be raised to unlimited. This action would be unlikely to eliminate the population but would facilitate some suppression and would help raise awareness of the fact that Brown Trout are an invasive species.

We request that, as a condition of permitting studies on the Trinity River, all captured Brown Trout be removed from the water and euthanized. We are amenable to having these individuals donated to a food bank to eliminate wastage.

We request permission to conduct periodic electrofishing, targeting deep water areas in March to remove Brown Trout. The timing and location would minimize effects on other species and would be the most effective means of population suppression.

We request permission to pursue a bounty for Brown Trout to help suppression and as a way to garner buy in from fishing guides and the public.

In summary, we hope to work together to address this issue and develop a management plan for Brown Trout in the Trinity River. We believe that Brown Trout suppression is a positive step to improving the health of native fish populations as we continue to work toward delisting and preventing future listing of Klamath-Trinity River origin salmon, steelhead, and lamprey.

If you have questions or want to discuss further please feel free to contact Justin Alvarez of the Hoopa Tribal Fisheries Department at (530-625-4267 x 1020) or PO Box 417, Hoopa, CA 95546. He can answer or direct questions to any of the resource agencies as needed.

Sacramento, California, 95814

Director Bonham:

This letter is in response to an August 7, 2019 formal request from the Hoopa Valley Tribe seeking the Service's support for the development and implementation of a Brown Trout Management Plan for the Trinity River by the California Department of Fish and Wildlife (CDFW).

The Trinity River is the focus of a large-scale river restoration project targeting recovery of anadromous fish populations to support the dependent ocean commercial, ocean and in-river sport, and in-river tribal commercial and subsistence fisheries. The U.S Fish and Wildlife Service's Fish and Aquatic Conservation (FAC) Program works closely with state, federal and tribal managers under a broad array of authorities such as the Fish and Wildlife Coordination Act to recover and restore endangered, threatened and imperiled aquatic species, fulfill tribal and public trust and mitigation responsibilities, and to restore and conserve a wide range of fish populations and other aquatic resources. To this end, the U.S Fish and Wildlife Service has been a long-time partner in the restoration of the Trinity River and recovery of its native species.

Brown Trout were introduced to the Trinity River, with a growing body of evidence that suggests they have been suppressing native species recovery efforts. Brown Trout opportunistically feed on other fishes, and their impact to native species has been well documented in rivers across the United States, including the Trinity River. According to a recent study led by the Hoopa Valley Tribe, Brown Trout consumed over 20% of the native wild salmonid biomass in the 40-mile reach of the Trinity River downstream of Lewiston Dam.

A workshop was held in Arcata in 2018 to discuss Brown Trout in the Trinity River. The workshop was hosted by the Hoopa Valley Tribe, and included representatives from a wide array of partners, including California Department of Fish and Wildlife, Yurok Tribe, U.S. Forest Service, Humboldt State University and U.S. Fish and Wildlife Service. The workshop culminated in a recommendation supporting the development of a CDFW management plan for Brown Trout in the Trinity River, with an emphasis on conservation and recovery of native species.

The Fish and Aquatic Conservation Program in the Arcata Fish and Wildlife Service Office is in full support of the development and implementation of a Brown Trout management plan, and we are willing to provide technical support and assistance to develop the plan, as requested by the Tribe.

Sincerely,

Dan Everson
Field Supervisor, Arcata Fish and Wildlife Office

To Whom It May Concern,
The Six Rivers National Forest is a strong supporter of our local partners that contribute to our mission to restore and conserve our watersheds and local fisheries. We are concerned about invasive species (non-native species) whose introduction continues to cause economic and environmental harm. Brown trout (*Salmo trutta*) is one of those species that was introduced to the Trinity River in Northern California beginning in the 1890's. After in river planting stopped in 1932, Brown Trout have sustained their population without additional stocking. Today, there are numerous large scale efforts to restore the salmon and steelhead fisheries on the Trinity River and many of the Trinity River managers have been concerned that predation by piscivorous Brown Trout may impede efforts to restore native salmonids, in particular endangered Coho Salmon.

The National Marine Fisheries Service specifically listed Trinity River Brown Trout as an impediment to recovery in the Southern Oregon Northern California Coho recovery plan. The state of California increased the bag limit to 5 fish per day in 2007 because of predation concerns, and lists the following actions to deal with invasive species in their Coho Salmon recovery plan.

- Develop a rapid-response eradication plan for invasive, non-native fish species that negatively affect coho salmon,
- Develop management guidelines to mitigate the impacts of non-native fish species on coho salmon, and
- Remove non-native fish species from stock ponds where these fish pose a threat to coho salmon.

In 2015 and 2016, research studies were conducted by the Hoopa Tribe to quantify predation by Brown Trout on the native fishes of the Trinity River. They concluded a large portion of the hatchery and wild production was being consumed by Brown Trout. Armed with these findings, the Hoopa Tribe brought together managers and stakeholders to draft a Brown Trout Management Plan (2018). Some of the proposed recommendations outlined below are being considered at this time.

- Increase to no limit the Brown Trout Bag and Possession Limits,
- Cull Brown Trout at projects conducted on the Trinity when they are encountered,
- Engage in public outreach to encourage retention,
- Periodic electrofishing targeting Brown Trout, and
- Pursue a bounty for Brown Trout to help suppression and as a way to garner buy in from fishing guides and the public.

It is our responsibility as land stewards to stop the spread of this non-native fish species on public lands. These actions which have been identified prioritize recovery of the salmon and steelhead populations that support tribal, commercial, and recreational fisheries. We look forward to working with our partners on development of this plan and alternatives to remove Brown Trout throughout the Klamath Basin.

Sincerely,

MERV GEORGE JR.
Forest Supervisor

Abstract

Non-native predators may interfere with conservation efforts for native species. For example, fisheries managers have recently become concerned that non-native brown trout may impede efforts to restore native salmon and trout in California's Trinity River. However, the extent of brown trout predation on these species is unknown. We quantified brown trout predation on wild and hatchery-produced salmon and trout in the Trinity River in 2015. We first estimated the total biomass of prey consumed annually by brown trout using a bioenergetics model and measurements of brown trout growth and abundance over a 64-km study reach. Then, we used stable isotope analysis and gastric lavage to allocate total consumption to specific prey taxa. Although hatchery-produced fish are primarily released in the spring, hatchery fish accounted for most of the annual consumption by large, piscivorous brown trout (>40 cm long). In all, the 1579 (95% CI 1,279–1,878) brown trout >20 cm long in the study reach ate 5,930 kg (95% CI 3,800–8,805 kg) of hatchery fish in 2015. Brown trout predation on hatchery fish was ca. 7% of the total biomass released from the hatchery. Brown trout only ate 924 kg (95% CI 60–3,526 kg) of wild fish in 2015, but this was potentially a large proportion of wild salmon production because wild fish were relatively small. As large brown trout rely heavily on hatchery-produced fish, modifying hatchery practices to minimise predation may enhance survival of hatchery fish and potentially reduce the abundance of predatory brown trout.

1 | INTRODUCTION

Brown trout (*Salmo trutta*) have undergone massive range expansion from their native waters in Europe and North Africa to the waters of every continent except Antarctica (Dill & Cordone, 1997; MacCrimmon & Marshall, 1968). This expansion was intentional. European colonists transported and introduced brown trout around the world because they considered them desirable for sport fishing and food (Wilson, 1879). However, introduced brown trout may negatively affect populations of native fishes in areas where they have been introduced (Belk, Billman, Ellsworth, & McMillan, 2016; Hoxmeier & Dieterman, 2016; McHugh & Budy, 2006; Townsend, 1996). In this study, we evaluated predation by introduced brown trout on native salmon and trout species that are the focus of a large-scale, intensive conservation and habitat restoration effort in the Trinity River, a large tributary of the Klamath River in Northern California.

In Northern California, Scottish, German and hybrid brown trout eggs were brought to Fort Gaston (Hoopa, CA) and Sisson hatcheries near Mt. Shasta by train in the 1890s (Adkins, 2007; Thomas, 1981). There were two introductions from those hatcheries to the Trinity River, one near the mouth at Fort Gaston and a separate effort closer to the headwaters in Stewart's Fork and the main stem Trinity River near Lewiston, CA (Adkins, 2007; Thomas, 1981). According to a Trinity Journal newspaper article (1911), the motivation behind the upstream introduction was the California Fish and Game Commission's plan to replace native rainbow trout (*Oncorhynchus mykiss)* with the “more desirable brown trout” throughout the state.

The downstream introduction was implemented to supplement the dwindling salmon fishery that the local Hoopa Tribe relies on for sustenance (Adkins, 2007). In the early years of brown trout introduction to the Trinity River, fisheries managers raised concerns that the brown trout predation was impacting abundance of native salmon species through predation (Thomas, 1981). This lead to a moratorium on brown trout releases in the Trinity River during the 1920s, but the moratorium was short lived and brown trout stocking was gradually phased back in and continued until 1932 (Thomas, 1981).

Prior to and during the time period when brown trout were introduced, native fishes of the Trinity River experienced steep declines in abundance (Adkins, 2007). Native and tribally-important species such as Chinook salmon (*Oncorhynchus tshawytscha*), coho salmon (*Oncorhynchus kisutch*), steelhead trout (*O. mykiss*) and Pacific lamprey (*Entosphenus tridentatus*) were affected by large-scale habitat loss from intensive mining and logging throughout the watershed. A pair of dams completed in the early 1960s exacerbated these effects, cutting off access to the entire upper watershed for migratory fish and diverting a substantial fraction of the Trinity River's water to California's Central Valley for irrigation. The Trinity River hatchery was completed in 1958 to partially mitigate the effects of habitat loss on salmon production. The hatchery currently releases more than 2 million juvenile salmon and steelhead per year into the Trinity River and spawns returning adults to produce the next generation of hatchery fish (California Hatchery Scientific Review Group, 2012). Recent efforts to rehabilitate the native fish populations of the Trinity River also include a massive investment in habitat restoration, including large-scale channel reconfiguration, cover addition, minimum flows, and habitat-forming flow releases from the dams (Beechie et al., 2015). Currently, Trinity River Chinook salmon and steelhead remain well below historic abundance and Trinity River coho salmon are considered threatened under both state and federal laws (National Marine Fisheries Service, 2014).

The potential for brown trout to directly affect native salmon populations by predation depends on brown trout feeding behaviour and abundance. Piscivory by Trinity River brown trout has been documented during field projects focused on other species and by local fisherman, but no formal diet studies of this brown trout population have been conducted. The best historical index for brown trout abundance in the Trinity River is the adult salmon sampling weir in Junction City (river kilometre 136.2). Brown trout catch totals increased at the weir during sampling from 2000 to 2013 to levels 200%–300% higher than those in the 1980s and 1990s, despite reduced sampling effort since 2000 (Borok, Cannata, Hileman, Hill, & Kier, 2014; Borok, Cannata, Hill, Hileman, & Kier, 2014; National Marine Fisheries Service, 2014). Documentation of piscivory combined with the potential increase in brown trout populations inferred from weir catch data suggests that brown trout may be having a substantial impact on native fishes. This threat was identified by the California Department of Fish and Wildlife in 2005 and provided the impetus for changing fishing regulations, adding a bag limit of one brown trout in 2006 and increasing it to five brown trout in 2007 (California Fish & Game Commission, 2007). Trinity River brown trout were also identified as an impediment to species recovery in the recovery plan for Southern Oregon and Northern California coho salmon (National Marine Fisheries Service, 2014).

To assess predation by brown trout on native species, we undertook the first large-scale sampling effort for brown trout in the Trinity River. Sampling included multi-pass electrofishing over a 64-km study reach to estimate abundance, size, growth and age structure of brown trout. We used diet sampling and isotope analysis to characterise brown trout diet composition. Finally, we used the brown trout population and diet data to parameterise a bioenergetics model to estimate brown trout consumption of salmon and other prey in the Trinity River.

2 | METHODS

2.1 | Study area

The Trinity River in Northern California is the largest tributary to the Klamath River, with a main stem length of 274 km and a watershed area of about 7,679 km^2. The Trinity River's headwaters are in the Trinity Alps at an elevation of about 1,850 m, and the confluence with the Klamath River in Weitchpec is 69.5 km from the ocean at an elevation of 56 m. There are two large earthen dams on the Trinity River. Upstream at river kilometre 261.6 is Trinity Dam, which is used for water storage, and downstream at river kilometre 250.3 is Lewiston Dam, which is used to export water to the Sacramento River basin. The Trinity River Fish hatchery is located at Lewiston Dam, and all hatchery-produced fish are released immediately downstream of the dam.

This study is focused on the 64 km of the main stem Trinity River below Lewiston Dam and above the North Fork of the Trinity River (Figure 1). Existing observations indicate that brown trout are widespread through the 178 km of anadromous habitat in the main stem Trinity River as well as major tributaries. However, based on habitat use data collected for other studies (Goodman, Som, Alvarez, & Martin, 2015), brown trout are most abundant in the focal area and it is the area where they likely have the most access to native salmon prey from hatchery releases and natural spawning grounds.

Discharge from Lewiston Dam ranges annually from 8.6 to 311.5 m^3/s. With tributary inputs downstream of the dam, the Trinity River near the North Fork experiences flows between 12 and 850 m^3/s. There is a characteristic seasonal flow pattern: during winter and spring storms and an annual spring dam release, the upper range is approached; by mid-summer and through winter the flows stay closer to the lower range.

The 64 river kilometres in which the study took place were divided into six reaches based on tributary inputs, river access and prior information about brown trout density (Figure 1). The boundaries of each reach occurred at the following locations and creek mouths in downstream order: the concrete weir below Lewiston Dam, Rush Creek, Steel Bridge river access, Indian Creek, Evans Bar river access, Canyon Creek and the North Fork of the Trinity River.

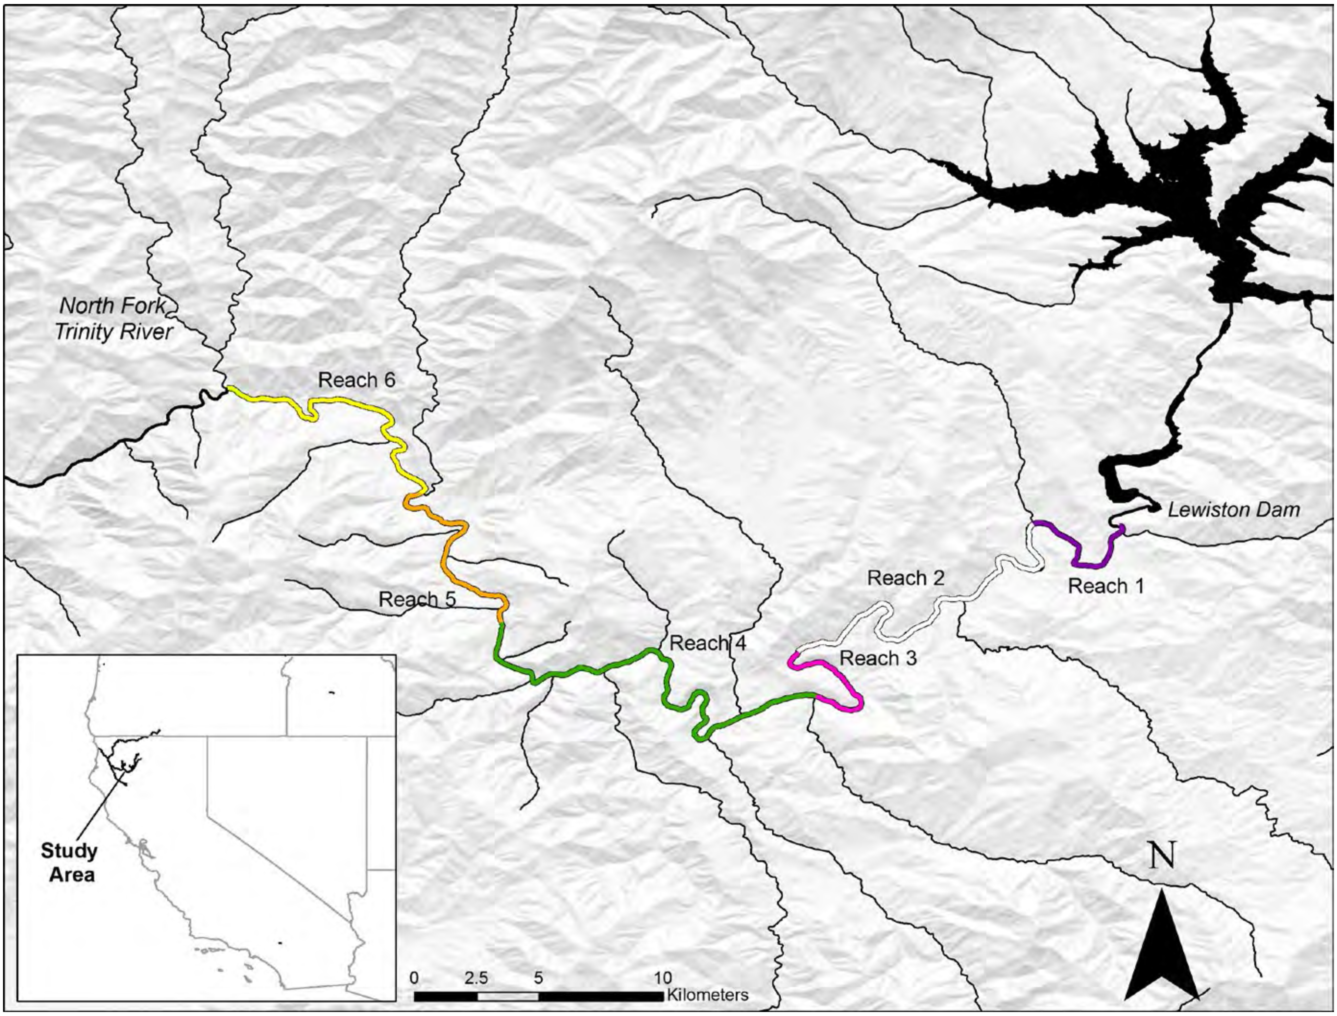

FIGURE 1 Map of the study area with an inset regional map of California. The Trinity River flows from right to left. The study area begins at Lewiston Dam and ends at the confluence of the main stem with the North Fork of the Trinity River. Within the study area, each reach is highlighted with the colour of the Floy T-bar tag that was used to mark fish, matching the temperature profile lines in Figure 2

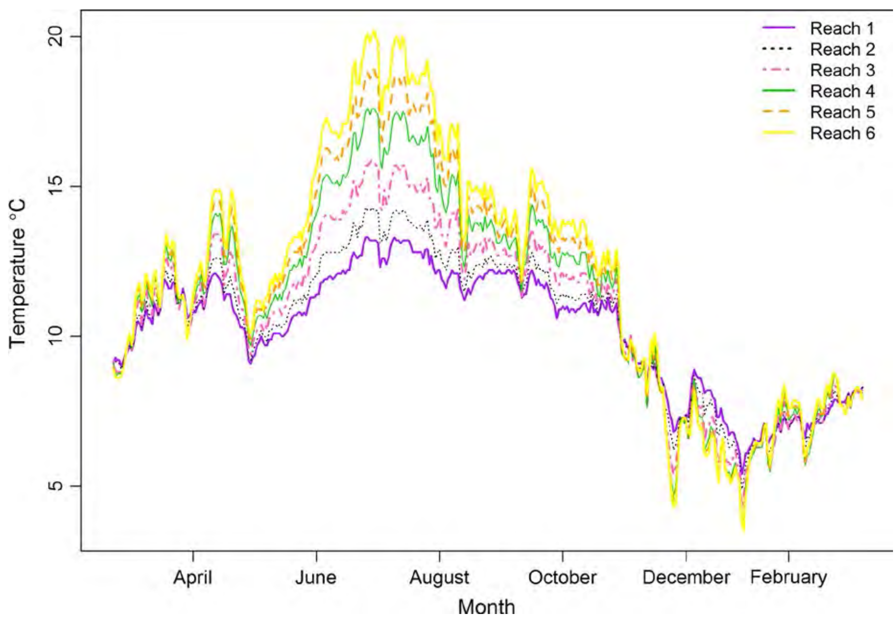

FIGURE 2 Temperature profiles of each reach where Reach 1 is the furthest upstream and Reach 6 is the furthest downstream. The colour of the line matches the colour of the reach in Figure 1

2.2 | Fish sampling

A 4.3-m raft with a Smith-Root 2.5 kW generator powered pulsator electrofisher system (Smith-Root Inc., Vancouver, WA) was used to sample the entire 64 km of river. The control box was set with a DC pulse rate of 30 Hz with voltage between 300 and 400. Sampling focused on the thalweg of the main stem while moving slowly downstream. In March of 2015, the study area was sampled with three passes. Each pass proceeded from upstream to down and took 4 days to complete. A single sampling pass started near Lewiston Dam on Monday and worked down to a river access. Tuesday sampling began where Monday's sampling left off and this pattern continued until the 64 km was completed on Thursday. The following Monday, a new pass would begin starting at Lewiston Dam again. The 7-day interval between samples at a given location allowed brown trout to recover from handling stress and resume normal feeding behaviour before being resampled (Pickering, Pottinger, & Christie, 1982). The three passes bounded the spring release of coho salmon smolts from the hatchery: the first pass was completed before the release, the second immediately following the release, and the third after many of the released smolts had migrated through the study area (Harris, Petros, & Pinnix, 2016). A similar brown trout sampling effort was conducted in the spring of 2016, providing additional diet samples and recaptures for final growth measurements of tagged individuals.

Most brown trout were sampled by electrofishing (859 total), but additional samples were collected opportunistically by other means to provide diet data from outside the spring electrofishing season and to provide additional samples for size and growth analyses. An Alaskan style weir, operated by the California Department of Fish and Wildlife and the Hoopa Tribe, was installed in Junction City California in late June and run through September in 2015 and 2016 to catch migrating adult salmon (Sinnen, Currier, Knechtle, & Borok, 2005). Brown trout captured in the weir in 2015 and 2016 (224 total) were processed as described below. We also processed some additional individuals captured using rod and reel (29 total). All methods produced a similar size range of fish, from 20 cm (minimum size used in the analysis) to at least 60 cm.

2.3 | Processing and handling

Once captured, all brown trout >20 cm long were anaesthetised in water saturated with CO_2 using Alka-Seltzer Gold tablets. Trinity River brown trout are the target of a recreational fishery, so alternative anaesthetics that require a withdrawal period before human consumption were not suitable for this work. Fish <20 cm long were too small for our tagging operation and were less likely to be piscivorous, so we did not include smaller fish in subsequent analysis. Once anaesthetised, the fish were measured (fork length) and the following samples were collected: scales were taken from the left side between the anal and dorsal fin just above the lateral line for age analysis, a 1 cm^2 fin clip was taken from the distal posterior tip of the dorsal fin for stable isotope analysis, and stomach contents were collected using gastric lavage for diet analysis. Fish were weighed following gastric lavage so that stomach contents would not contribute to the mass. Lavage was conducted using a hand-pumped garden sprayer. The spray pipe was placed through the fish's mouth into the stomach and water was sprayed in until the stomach was full. Through continued filling and massaging the belly from the outside, food items were washed and pushed out. A subsample of 30 fish was sacrificed after processing and the stomachs examined to gauge the effectiveness of the gastric lavage. Of these, 28 had completely empty guts, indicating that lavage was generally effective.

After the samples and measurements were taken, the fish were tagged with a uniquely numbered FD94 T-bar tag (Floy Tag & Manufacturing Inc., Seattle, WA) for future identification and then released. The tags were made of a 7.5-cm-long piece of monofilament with polyolefin coloured tubing around it. At the insertion, end was a 1.5-mm-thick, 2-cm-wide "T." The tag was injected using Floy Tag's Mark III pistol grip tagging gun. The needle was inserted below the dorsal fin to allow the T to articulate with the dorsal support skeleton. The colour of the T-bar tag corresponded with a reach (Figure 1) where the fish was collected. These colours allowed a quick visual indication of larger-scale movements while sampling fish in the field and were a check for the closure assumption of the population estimate. Fish captured at the weir received a Floy tag with a distinct tag colour to differentiate them from fish tagged during electrofishing.

2.4 | Analysis

2.4.1 | Population estimate

The electrofishing passes were used to generate the population estimate used in the energetics simulation (described below). The population estimate was calculated using Chapman's estimator (Seber, 1982). This estimator assumes a closed population, with no births, deaths, emigration or immigration. Movement assumptions were tested using the different coloured tags in each reach. During the three-pass sample bout, all but one of the recaptured fish were found in the reach where they were initially tagged. Based on the lack of individual movement and the short timeframe for births and deaths in the 1 week between passes, we considered the closure assumptions met. The first pass was used as the first sampling occasion while the second and third passes were combined into a second sampling occasion.

Not all of the reaches had enough recaptures of tagged fish to calculate a separate population estimate for each reach with reasonable precision, so the whole surveyed section of river was treated as one population for the main estimate. Subsequently, we calculated a population estimate for each reach by dividing the main population estimate among reaches proportionally to the catch in each reach. Using this approach, the overall population estimate used the maximum sample size available.

2.4.2 | Age and growth analysis

Brown trout scales were sorted, mounted and examined following the plastic impression method (Clutter & Whitesel, 1956; Van

Alen, 1982). After discarding unreadable or regenerated scales, each scale was assigned an age and a confidence level (high, medium or low); those scales with a low confidence level were not used in subsequent analyses. To ensure age readings were being performed consistently, scales taken from individual fish that were sampled in multiple years were checked to ensure the increase in age estimates from the scales matched the time that passed between sampling. These checks were conducted blind to the original data by the same reader. All repeat-sampled fish (n = 31) were aged consistently.

The length and age data were fit to a von Bertalanffy growth model assuming additive error with normally distributed residuals using the nonlinear least squares (nls) function in base R (R Development Core Team, 2009). The model is as follows: $L_t = L_\infty \left(1 - e^{-k(t-t_0)}\right) + \varepsilon$ where L_t is fork length at age t, L_∞ is the asymptotic maximum length, k defines the rate at which the asymptote is approached, t_0 is the hypothetical age of the fish at size zero, and ε is error.

We also fit individual length and mass measurements to an allometric curve with multiplicative error in base R (R Development Core Team, 2009) using the nls function. This relationship was used in the bioenergetics model to convert the predicted growth in length from the von Bertalanffy model to growth in mass for the bioenergetics model.

2.4.3 | Annual survival analysis

Age-frequency data can be analysed in multiple ways to estimate survival rates. In simulation studies, the Chapman–Robson survival estimate had less bias and less error than other techniques, especially at small sample sizes (Dunn, Francis, & Doonan, 2002), so that method was applied. The Chapman–Robson estimator is formulated as follows:

$$\hat{S} = \frac{T}{n + T - 1}$$

where $T = \sum (x \times N_x)$, where $\hat{S}$ is the annual survival estimate, n is the total number of aged fish from the fully recruited ages, x is the coded age where coded age 0 is the age with the highest number of individuals caught, and N_x is the number of individuals of each age. This approach assumes constant survival throughout the population and constant recruitment across years. We calculated separate survival estimates for the 2015 and 2016 catch and used the average of the two for the consumption model.

2.4.4 | Isotope analysis of diet composition

We measured carbon and nitrogen isotope ratios in 253 brown trout fin clip tissue samples as well as in samples of multiple potential prey items. We selected prey items to analyse for isotopes based on the prey that were most prevalent in the gut samples. Prey items included various mayflies (Ephemeroptera), golden stoneflies (Perlidae) and salmonflies (*Pteronarcys californica*), as well as lamprey ammocoetes, wild steelhead trout fry and hatchery coho salmon smolts. As juvenile salmonids of different species generally have similar diets, we assumed that wild steelhead fry represented the isotope composition of wild salmon and trout (including potential cannibalism on juvenile brown trout). All hatchery fish are fed the same food, based on marine-derived fish meal, so we assumed that the hatchery coho salmon smolts represented the isotope composition of all hatchery species. Nonsalmonid fish species besides lamprey were rare in the diet samples (present in <1% of samples), so they were not assessed as potential prey in the isotope analysis. The prey samples were collected from a rotary screw trap run by the Hoopa Tribal Fisheries programme that is located within the sample area in the downstream reach. Isotope samples were placed on ice immediately after collection and were transferred to a freezer upon return from the field at the end of the day. From the freezer, the samples were transferred to a drying oven set to 65°C and were dried for 36–60 hr. The dried samples were homogenised, and a subsample of 0.5–1.5 mg removed, weighed and placed into a tin capsule. The encapsulated tissue was placed in a plastic tray in one of 96 wells.

The filled trays were sent to UC Davis stable isotope laboratory for analysis of Carbon 13 (δ^{13}C) and Nitrogen 15 (δ^{15}N) using a PDZ Europa ANCA-GSL elemental analyzer interfaced to a PDZ Europa 20–20 isotope ratio mass spectrometer (Sercon Ltd., Cheshire, UK). The δ^{15}N and δ^{13}C values reported were the values of the sample relative to ratios of the international standard for each element, air for nitrogen and Vienna PeeDee Belemnite for carbon.

Isotopic data were used to determine the proportion of each prey type within the diets of the brown trout. Prey were grouped into four categories: ammocoetes, aquatic invertebrates, hatchery salmonids and wild salmonids. Limiting the ratio of prey groupings to isotopes improves model fit (Phillips & Gregg, 2003). As brown trout length was found to be positively correlated with δ^{15}N and δ^{13}C (r^2 of 0.55 and 0.58 respectively), the brown trout isotope data were grouped into five categories based on fork length: <30, 30–40, 40–50, 50–60 and >60 cm. These break points provided adequate samples within each bin to facilitate isotopic analysis and improved resolution within the bioenergetics model when converting food requirements to biomass consumed. The proportions of each prey type consumed by each brown trout group were estimated by fitting the isotope data using a Bayesian framework in the R package MixSIAR (Stock & Semmens, 2013). This package uses a Markov Chain Monte Carlo (MCMC) approach to fitting multi-linear models. Three chains were run with one million iterations each. The burn in length was 500,000, and the thinning rate was 500. The model was run with brown trout size category as a fixed effect and only residual error. Estimated fractionation rates were derived by averaging values from literature sources: 3.74 *SD* 0.477 for δ^{15}N and 1.38 *SD* 0.983 δ^{13}C (Flinders, 2012; McCutchan, Lewis, Kendall, & McGrath, 2003; Minagawa & Wada, 1984; Peterson & Howarth, 1987; Vander Zanden, Cabana, & Rasmussen, 1997; Vander Zanden & Rasmussen, 2001).

2.4.5 | Bioenergetics

A bioenergetics approach was used to estimate total prey consumption by brown trout, with a parametric bootstrap to characterise the variance of the estimate. The bioenergetics simulation represented

TABLE 1 Parameters of the Wisconsin bioenergetics model and the values used to implement it

Parameter	Value	Parameter definition
CTO	17.5	Water temp corresponding to 0.98 of the maximum consumption rate
CTM	17.5	The upper end of the temperature where still at 0.98 of the maximum consumption rate
CQ	3.8	Water temperature at which temperature dependence is a fraction (CK1) of the maximum rate
CA	0.2161	Intercept of mass dependence function for a 1-g fish at optimum water temperature
CB	−0.233	Coefficient of mass dependence for increasing portion of curve
CTL	20.8	Temperature at which consumption is reduced some fraction (CK4) of the maximum rate
CK1	0.23	Specific rate of respiration (g g^{-1} d^{-1})
CK4	0.1	See CTL
RA	0.0113	Intercept for the allometric mass function for respiration
RB	−0.269	Slope of allometric mass function for respiration
RQ	0.0938	Approximates the rate at which the function increases over relatively low water temperature
RK1	1	Intercept for swimming speed above the cut-off temperature
RK4	0.13	Mass dependent coefficient for swimming speed at all water temperatures
BACT	0.0405	Water temperature dependent coefficient of swimming speed at water temp below RTL
RTO	0.0234	Coefficient for swimming speed dependence on metabolism (s/cm)
RTL	25	Cut-off temperature at which activity relationship changes
ACT	9.7	Intercept of the relationship between swimming speed and mass at a given temperature
LOSS	0.35	Energy lost to faeces and specific dynamic action
EDA	6,582	Intercept for energy density–weight function
EDB	1.1246	Slope of the energy density–weight function

Note. The model equations and parameter meanings are described in Hansen et al. (1997). All parameter values are from Dieterman, Thorn, and Anderson (2004) except LOSS, which is from Burke and Rice (2002).

the growth and consumption of age 2–12 brown trout over 1 year. The model ran on a daily time step where 1 March 2015 was model day one. The base of the simulation was the Wisconsin Bioenergetics model (Hansen, Johnson, Kitchell, & Schindler, 1997) coded into R (code by Andre Buchheister, personal communication, August 2015). Published values for parameters relating to brown trout metabolism, egestion, activity, growth and consumption were used to set a baseline and facilitate comparison to other studies (Table 1). We did not have information about brown trout spawning frequency in the system, so we did not include gamete loss in our model, potentially producing an underestimate of total consumption.

To estimate the maximum amount a brown trout could consume, we used Hansen et al.'s (1997) third consumption equation, as it is designed for cold water fishes such as brown trout. In the model, consumption is dependent on size, water temperature and the amount of food consumed in laboratory experiments during ad libitum feeding at optimal temperatures. To estimate what brown trout actually consume, the modelled maximum consumption is scaled by the proportion of maximum consumption (p). The proportion of maximum consumption was allowed to vary between simulation iterations to achieve the targeted growth of the brown trout of each age. Parameters representing the mass at the start of the year, mass-specific growth rate, population size, survival rate and diet composition were randomly selected for each iteration of the model from a normal distribution, with a mean and standard deviation for each parameter derived from the field data (Table 2).

Additional input data required to estimate consumption included mean daily temperature and prey-specific energy density. The temperature fish experienced was determined using linear interpolation of the mean daily temperature between available U.S Geological Survey gage stations (ID numbers 11525500, 11525655, 11525854 and 11526400). The temperature profiles used in the energetics model were that of the midpoint of each reach from 1 March 2015 through 28 February 2016 (Figure 2). The prey energy densities were literature values: invertebrates 4.07 kJ/g (Groot, Margolis, & Clarke, 1995; Myrvold & Kennedy, 2015), lamprey ammocoetes 3.54 kJ/g (Alvarez, 2017), other fish 5.78 kJ/g (Hansen et al., 1997). Temperature and prey energy density were not randomised as part of the bootstrap.

Each simulation started with a random draw of average starting size for brown trout of each age from 2 to 12 (Table 2). Then, randomly drawn von Bertalanffy parameters were used to calculate average sizes at the end of the year. After converting length to mass, an optimisation function optim in R (R Development Core Team, 2009) was used to find the proportion of maximum consumption required to achieve the selected final mass within each reach for an individual of each age. During that growth interval, daily size and consumption were recorded for each fish. Next, a random draw of population size and survival rate was used to find the number of fish of each age on each day. Finally, the number of fish alive on each day within the appropriate reach and of the appropriate age was used to expand the individual brown trout daily consumption estimates to the reach level. To facilitate allocating total consumption to different prey types, the total biomass consumed each day was aggregated into the five length-based bins used in the stable isotope mixing model. This process was repeated 3,000 times to characterise the variation in consumption

TABLE 2 Brown trout population parameters for the bioenergetics simulation

Parameter	Mean	Standard error
Population size		
Reach 1	111	65.5
Reach 2	300	178.5
Reach 3	95	56.5
Reach 4	553	328.5
Reach 5	284	169
Reach 6	237	141
Annual survival	58.3%	2.4%
Initial size (cm)		
Age 2	20.0	2.4
Age 3	34.0	4.7
Age 4	40.6	4.0
Age 5	47.0	4.5
Age 6	53.2	4.7
Age 7	56.6	5.1
Age 8	62.8	5.2
Age 9	66.0	4.9
Age 10	69.0	4.9
Age 11	72.0	4.6
Age 12	75.0	4.6
Growth rate

Note. The estimates and variance are derived from field data collected during this study.

given different growth rates, and to account for the error associated with growth, abundance and survival estimates. The error estimate does not include variation associated with process error or bioenergetics parameters taken from the literature. These model runs produce estimates of the total biomass of food with the energy density of brown trout that is consumed for each size class.

Diet proportion, predator and prey energy densities, and the estimate of consumption from the simulation were combined to find the biomass of each prey category consumed by brown trout. For this portion of the analysis, the posterior distribution from the isotopic analysis was treated as a parametric bootstrap which we drew from with a multinomial random draw. A random multinomial draw of consumption by for each size bin was combined with a draw of prey proportion and energy densities in the equation = $\frac{E}{A\times E_A+H\times E_H+W\times E_W+I\times E_I}$, where B is the total biomass consumed and E is the total energy required. The symbols A, H, W and I are the proportion ammocoetes, hatchery fish, wild fish and invertebrates contribute to total biomass consumed respectively. E_x is the energy density of the prey category x. The resulting biomass combined with the random draw of proportions provides the biomass of each prey type consumed by the population for a single iteration. This process was repeated 100,000 times to generate a distribution of consumption estimates, ensuring multiple combinations of the consumption and diet composition estimates.

3 | RESULTS

In 2015, we captured 589 brown trout between 20 and 79 cm. Based on recaptures, we estimated the population to be 1580 (95% CI 1,279–1,878). The scale samples collected from these fish revealed

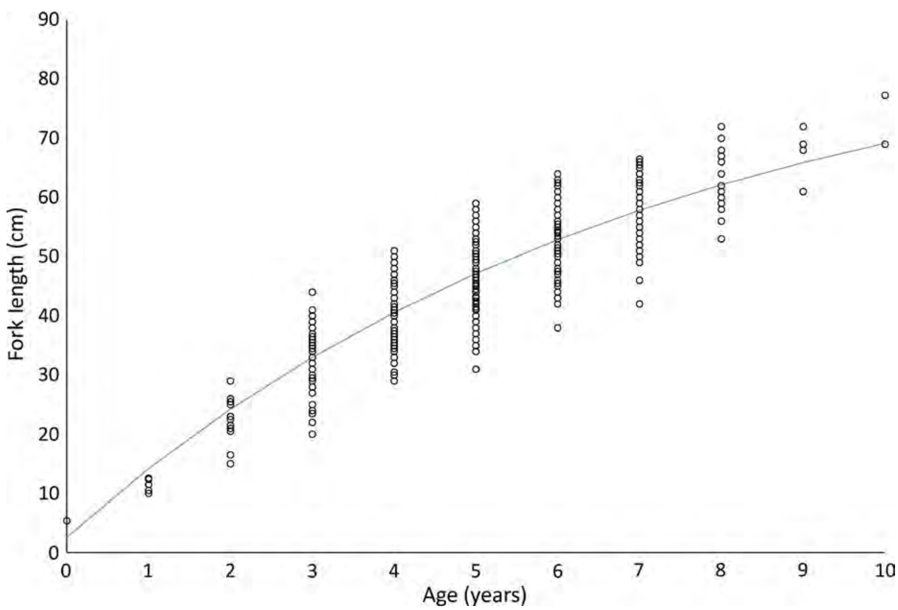

FIGURE 3 Age and size for all individual brown trout and the fitted Von Bertalanffy growth curve. Von Bertalanffy parameter estimates and standard errors are in Table 3

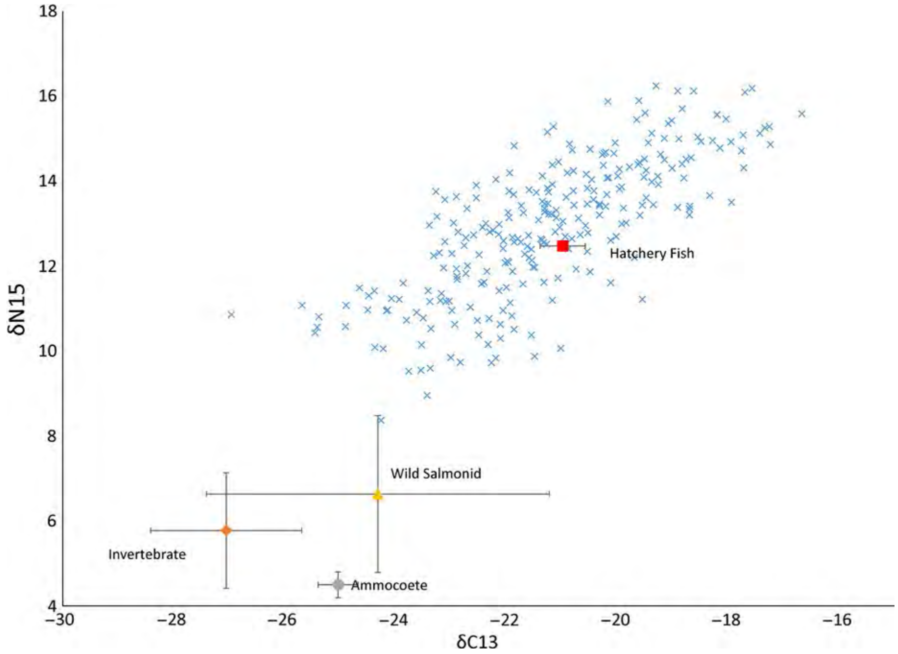

FIGURE 4 Isoplot of brown trout and prey items. Blue x's represent individual brown trout isotope ratios. Prey items are labelled and the location is the mean value for that prey category. The error bars are a single standard deviation

their ages ranged from 2 to 11 years (Figure 3). This sample provided sufficient representation of the population's age and size composition to estimate growth and survival parameters for the bioenergetics model (Table 2).

Wild fish and invertebrate prey had lower δ^{15}N and δ^{13}C than hatchery fish. Brown trout isotope values ranged from in between wild prey and hatchery fish values to higher than both (Figure 4). The MixSIAR model MCMC chains converged with all parameters having $\hat{R}$ values of >1.01 $\hat{R}$ < 1.05 is acceptable for inference (Stock & Semmens, 2013). The model results show that the large brown trout consume very a high proportion of fish, especially hatchery fish, and that reliance on fish declines in smaller brown trout (Figure 5). A relatively small proportion of the diet comes from wild fish.

The snapshot of diets from gastric lavage samples shows a similar level of piscivory as the isotope model for larger size classes, but lower than the isotope model for small size classes (Table 3). However, gastric lavage lacks the full temporal scale of the isotope analysis and is not as effective at parsing out wild and hatchery fish. While most fish retrieved during lavage were not identifiable to hatchery or wild origin (based on hatchery marking), the temporal pattern of fish consumption by brown trout was consistent with heavy reliance on hatchery-released fish. The number of fish found in stomachs of brown trout peaked in the sample pass conducted immediately following the release of coho salmon smolts from the hatchery (average: 2.2 fish per stomach; *SD* 2.6; range: 0–11) relative to the sample before the smolts were released (average: 0.3 fish per stomach; *SD* 0.8; range: 0–9) and after most hatchery coho salmon smolts had moved out of the study area (average: 0.3 fish per stomach; *SD* 0.7; range: 0–2). Across all samples, coho salmon were the most common identifiable fish in lavage samples (n = 36), followed by steelhead (n = 16), Chinook salmon (n = 5) and brown trout (n = 5, not counting one individual that apparently consumed four small brown trout in the live well during sampling). Additional fish recovered from lavage samples were not identifiable to a single species, but based on size and time of year we could narrow these fish to the two most likely prey species: larger fish were either yearling coho salmon or steelhead trout (n = 73) and the smaller fish were either Chinook or coho salmon (n = 14).

The energetics simulation predicted that the brown trout population needed to consume 58,382 megajoules (95% CI 39,334–77,432) of energy per year. Variation in growth rate accounted for most of the dispersion around the consumption estimates. The variation around the population size and survival rate estimates added additional variation around the consumption estimate, but this variation was almost inconsequential when compared to differences from growth. When energy was converted into prey biomass by category, the most-consumed prey item was hatchery fish, followed by invertebrates, wild fish and ammocoetes (Figure 6). In 2015, brown trout consumed 5,930 kg (95% CI 3,800–8,805 kg) of hatchery salmonids and 924 kg (95% CI 60–3,526 kg) wild salmonids.

4 | DISCUSSION

Non-native brown trout in the Trinity River are highly piscivorous. We found that large individual brown trout relied heavily on native salmonids as prey. This is a particular concern given the ongoing, intensive recovery efforts for native salmonids in the Trinity River. Here, we consider brown trout predation separately on hatchery and wild-spawned fish. We take this approach for three reasons: First, hatchery fish are isotopically distinct from other prey sources due to the marine fish component of hatchery fish feed, so we had to estimate consumption of hatchery fish separately from wild fish in our isotope analysis. Second, hatchery production and release practices

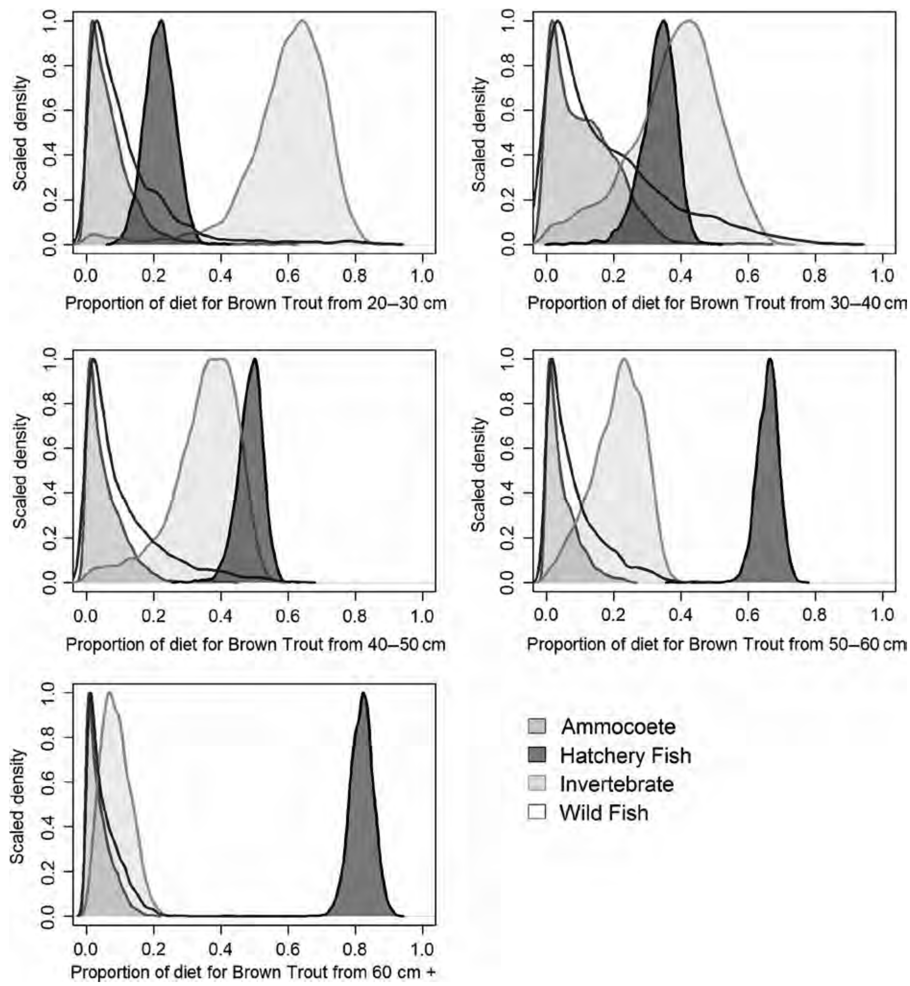

FIGURE 5 Diet proportions of brown trout grouped by fork length. Sample sizes for each size bin were *n* = 19 for 20–30 cm, *n* = 60 for 30–40 cm, *n* = 83 for 40–50 cm, *n* = 61 for 50–60 cm, and *n* = 30 for >60 cm

are factors that managers can control to potentially affect predation rate or brown trout abundance, but this is not true of wild-spawned fish. Third, although the Trinity River hatchery and wild runs of salmon and trout are genetically integrated, hatchery and wild-spawned individuals often have different survival and adult return rates (Araki, Berejikian, Ford, & Blouin, 2008) so predation on each type may have different effects on salmon and trout populations.

4.1 | Hatchery-produced fish

Piscivorous brown trout in the Trinity River relied heavily on hatchery-produced fish. Our isotope analysis indicates that most of the biomass of large brown trout in the Trinity River is derived from consumption of hatchery fish. Other studies have found that releases of large numbers of hatchery-produced fish can provide a substantial resource pulse that alters recipient ecosystems (Alexiades, Flecker, & Kraft, 2017; Warren & McClure, 2012). To put the results for predation on hatchery fish in context with regard to salmon production, the mean estimate of hatchery fish biomass consumed by brown trout was about 7% of the total biomass released from Trinity River Hatchery in 2015.

The artificial subsidy provided by juvenile salmon and trout from the hatchery likely allows Trinity River brown trout to maintain elevated population levels and reach larger size than would otherwise exist within the river. Historical records suggest that the Trinity River brown trout population increased substantially after hatchery releases began, (Moffett & Smith, 1950; Rodgers, 1973) giving some credence

TABLE 3 Comparison of diet composition results based on lavage and isotope analysis

Brown trout size interval (cm)	% Fish: Lavage (%)	% Fish: Isotope (%)
20–30	8	38
30–40	26	60
40–50	83	63
50–60	82	78
>60	98	92

Note. The lavage was calculated as the summed mass of content within a category divided by the total mass of stomach contents. All masses are wet masses and do not account for digestive state. Brown trout are grouped by fork length.

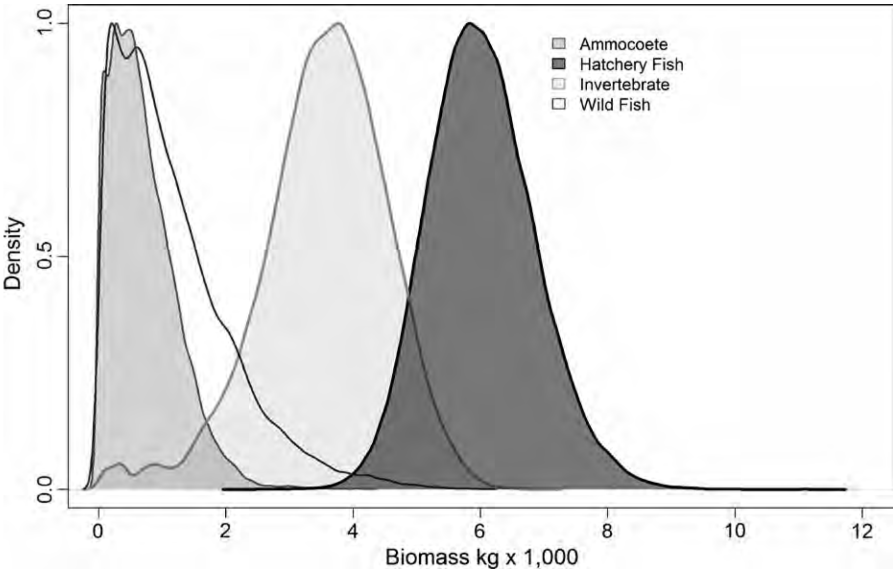

FIGURE 6 Estimated biomass of prey consumed by all brown trout >20 cm long in the Trinity River over the course of a year. Median consumption estimates were 5,930 kg of hatchery fish (95% CI 3,800–8,805 kg) 3,566 kg of invertebrates (95% CI 1,279–5,524 kg), 924 kg (95% CI 60–3,526 kg) of wild fish and 598 kg of lamprey ammocoetes (95% CI 18–2,058 kg)

to the notion that hatchery supplementation increased brown trout population growth, although habitat restoration and changes in flow management probably explain some of the variation in brown trout abundance. Brown trout are currently sustained by hatchery fish even though the availability of hatchery fish is seasonally limited to relatively brief periods after hatchery releases and before the hatchery fish migrate out of the Trinity River heading for the ocean (March for coho salmon, April for steelhead trout, June and October for Chinook salmon). Our bioenergetics model and observations of stomach contents suggest that the large brown trout feed voraciously immediately following hatchery releases and probably do not gain much biomass during the rest of the year. However, brown trout do still eat opportunistically when hatchery fish are not available, including during the vulnerable emergence and early rearing period for wild salmon and trout in the study area (January–February).

There was a clear ontogenetic diet shift for Trinity River brown trout, with increasing reliance on hatchery fish for larger, older individuals. An increase in piscivory with size is a well-documented phenomenon for brown trout (Jensen, Kiljunen, & Amundsen, 2012; L'Abée-Lund, Langeland, & Sægrov, 1992) and is often accompanied by a rapid increase in growth rate and a larger maximum size (Jonsson, Næsje, Jonsson, Saksgård, & Sandlund, 1999). However, recent work suggests that the shift to piscivory is contingent on the presence of a suitable prey species that is vulnerable to brown trout and abundant enough to support a population of predators (Sánchez-Hernández, Eloranta, Finstad, & Amundsen, 2017). Hatchery-released fish may fill this role for brown trout in the Trinity River, supporting a shift to piscivory and sustaining the biomass of large, predatory individuals.

4.2 | Wild-spawned fish

Our estimate of predation on wild-spawned salmon and trout is lower and less precise than the estimate for hatchery-produced fish. The lower precision of this estimate is caused in part by the isotopic similarity of wild salmon and trout to other naturally-occurring prey items in the Trinity River, including insects and lamprey ammocoetes. However, based on observations of fish in brown trout diets before the hatchery releases, we know that brown trout in the Trinity River do actively feed on wild-spawned salmon and trout. Although the total biomass of wild fish that brown trout consume is much lower than for hatchery fish, this predation is still a potential concern for conservation because it occurs over longer time spans, including the early rearing period when the total biomass of wild fish available is much lower than the biomass of hatchery fish available during hatchery releases. However, translating our consumption estimates into mortality rates and estimating the effects of brown trout on wild salmon populations in the Trinity River is not possible with the current data set.

Based on the average estimate of ca. 1,000 kg of wild salmonids consumed by brown trout and a total of ca. 4,000 kg of juvenile salmonids outmigrating from the upper Trinity River (Harris et al., 2016), we could naively say that 20% of wild salmonid production in 2015 was consumed by brown trout. However, this estimate could have a substantial positive or negative bias for a variety of reasons. First, some proportion of the wild salmonids consumed by piscivorous brown trout were juvenile brown trout, which are lumped with other wild-spawned salmon and trout in the isotope analysis (potential positive bias). The lavage data suggest that cannibalism was relatively rare, but our samples from outside of the spring electrofishing sample bouts are limited and cannibalism may have been more common in other seasons. Even if we assume cannibalism was truly rare, the naïve calculation of brown trout imposed mortality is premised on some very unlikely assumptions: that every fish consumed by brown trout was similar in size to outmigrants and that every fish consumed by brown trout would have survived their journey out of the 64 km below the dam if it was not consumed. In reality, brown trout can consume juvenile salmonids during their entire rearing period leading up to outmigration, including at sizes much smaller than outmigrants (potential negative bias). Further, not all of the wild fish consumed by brown trout would have otherwise survived (potential positive bias), some level of compensatory mortality is certain (Ward & Hvidsten, 2010). Finally, any attempt to estimate effects on populations would clearly require estimates of consumption at the species level, not lumped into hatchery and wild categories (unknown bias, possibly different for each prey species).

In addition to predation, brown trout may affect survival and growth of wild-spawned salmon and trout in the Trinity River through competition. Our sampling techniques and analysis focused on large brown trout with diets and microhabitat use that are distinct from native juvenile salmon and trout. However, other studies have found that juvenile brown trout can compete for food and territory space with juveniles of all three salmon and trout species native to the Trinity River (Fausch & White, 1986; Gatz, Sale, & Loar, 1987; Glova & Field-Dodgson, 1995). Competition could exacerbate any negative effects of brown trout on populations of native fish in the Trinity River, as has been suggested for non-native brook trout and native Chinook salmon in the Columbia River system (Levin, Achord, Feist, & Zabel, 2002). Evaluating effects of competition between brown trout and native salmon and trout in the Trinity River will require a new sampling effort.

4.3 | Management options

Historical records are incomplete, but existing information suggests that brown trout abundance in the Trinity River continues to fluctuate. Creel surveys prior to 1970 refer to catches of less than 10 brown trout per angler per year, with fish ranging from 30 to 50 cm (Moffett & Smith, 1950; Rodgers, 1973). Catches in recent years are generally 2–5 brown trout per angler per day with lengths reaching or exceeding 70 cm (J. Alvarez, personal observation). Our sampling in 2015 might represent part of a recent peak in brown trout abundance. As sampling continued into 2016 and 2017, the brown trout population estimates declined and younger year-classes were less common (Alvarez, 2017). Despite this potential recent decrease in brown trout abundance, our results suggest that Trinity River brown trout have the capacity to exist at abundance high enough to consume a substantial proportion of native salmonid production.

The consumption estimates that we produced are contingent on the validity of our bioenergetics model. Bioenergetics models provide a framework for accounting for metabolic costs and other energetic losses when inferring food consumption from observations of growth. The models are based on fundamental relationships between body size, temperature and physiological rates (Hansen et al., 1997). There is a large body of work on the energetics of brown trout growth that describes these relationships (Elliott, 1994), providing the basis for the parameters that we used. However, there are many uncertainties in bioenergetics models that can lead to biased estimates, including uncertainty in the parameter estimates, the functional form of the physiological relationships and how these vary across individuals and populations (Chipps & Wahl, 2008). In our model, we used simulations to incorporate the uncertainty in our field-derived parameter estimates into our estimate of consumption, but there are no estimates of the uncertainty available for most of the basic physiological parameters in the literature. One particular area of concern for our estimate is the highly seasonal pattern of prey availability and consumption, with most of the annual energy intake for large brown trout coming from the consumption of hatchery fish during the spring release. The standard bioenergetics model formulation often underestimates consumption when prey availability is high and overestimates consumption when prey availability is low (Chipps & Wahl, 2008). However, we do not know how these biases play out over time when food availability transitions from very high to low, or how this seasonal variation may affect our isotopic determination of diet composition.

If brown trout are suppressing survival of native salmon and trout, then direct control of brown trout abundance by altering sport harvest regulations, euthanising brown trout captured in the course of other sampling efforts and targeted removal sampling may aid in the recovery of native populations. However, direct control of invasive trout can be very expensive and such efforts have a mixed record of success (Meyer, Lamansky, & Schill, 2006; Syslo et al., 2011). If implemented, any such efforts should include assessment of survival of hatchery-released fish and recruitment success of wild fish to determine whether brown trout control efforts benefit native salmon and trout.

Efforts to manage the brown trout population to reduce impacts on native salmon and trout in the Trinity River are likely to generate some controversy. The authors of previous studies in other regions often comment on the importance of brown trout to the sport fishing community. For example, Belk et al. (2016) investigated the potential for maintaining the fishery for non-native brown trout in the Provo River in Utah while increasing native fish populations through physical habitat restoration. They found that rare species would persist only with low brown trout abundance; negative effects on native species could be ameliorated but not removed while brown trout persisted. Similarly, Townsend (1996) studied streams across New Zealand and found localised extirpations of galaxiid fishes and large-scale changes to entire aquatic communities associated with introduced brown trout. Despite these findings, in his conclusions he questioned the need for and feasibility of any brown trout removal programme. A community of recreational anglers is invested in brown trout in the Trinity River system because resident brown trout support a small recreational fishery, especially when native anadromous species are not available.

As an alternative to direct control efforts, it may be possible to reduce predation on hatchery fish by altering release practices at the hatchery. Reducing brown trout predation on hatchery-released fish has two potential benefits: increased survival of hatchery-released fish, supporting conservation efforts and harvest opportunities, and a reduced subsidy to the brown trout population. The latter could have cascading affects, including reducing the abundance of large, piscivorous brown trout that rely on hatchery-released fish and reducing predation on wild fish. This assumes that brown trout will not be able to sustain their high biomass by switching to an alternative prey, but we argue that this is a reasonable assumption given that large brown trout do not currently consume much biomass of other prey during the portion of the year when hatchery salmon are not available. Approaches that might reduce brown trout predation on hatchery fish include synchronising the releases of multiple species from the hatchery, so that large numbers of prey swamp the brown trout for a lower overall predation rate (Ward & Hvidsten, 2010), and minimising the time that hatchery fish remain in the system by delaying releases until fish are large and set to migrate rapidly to sea.

ACKNOWLEDGEMENTS

Funding for this project came from the Hoopa Valley Tribe Fisheries Department, the NOAA Cooperative Institute for Marine Ecosystems and Climate and the Bureau of Reclamation. Thank you to the many employees, students and volunteers who assisted with electrofising. Jason Adams of Amnis Opes Inc. provided the electrofishing raft. Thanks to Margaret Wilzbach, Nicholas Som and two anonymous reviewers for comments on an earlier draft.

RECEIVED
CALIFORNIA
FISH AND GAME
COMMISSION

2019 JUL 31 PM 12: 30

Linda Adams
[redacted]

July 22, 2019

Eric Sklar
President, California Fish and Game Commission
PO Box 94209
Sacramento, CA 94244-2090

Dear Mr. Sklar:

I am writing to you as an individual who holds a Bachelor's Degree in Environmental Studies from Sonoma State University with an emphasis in Parks and Natural Resources. My studies included Biodiversity (endangered species), fire ecology, geology, and field biology. I am also the daughter of Theodore E. Adams, Jr., formerly of the University of California, Cooperative Extension in the Agronomy Department at the University of California at Davis. He was a wildland specialist and dealt with range management and erosion control. I am sure you can appreciate my background at this point.

I am writing to you regarding the seasonal dam at Trinity Alps Resort, Trinity Center, CA. The resort was built in the 1920's and has been temporarily damming the stream from around July 4th to around September 30th every year (depending on the water level) to create a swimming hole for the guests. So I am sure that if there were truly any effects on the yellow legged frog this would have been a problem much earlier than now. Especially since the California Department of Fish and Game has recognized the main issue of the yellow legged frog being due to an introduction of a nonnative trout species into our lakes and streams, along with the use of pesticides, livestock grazing and of course, global warming (climate change) of which Trinity Alps Resort has no control over or participates in the above causes.

Last year, we became aware that the owner, Margo Gray, was having issues obtaining a permit for the dam. The dam is not what is affecting these frogs. It seems more likely caused by the predation from the nonnative trout introduced into an already balanced ecosystem. I am not sure how one small dam is going to affect the outcome when the causes are already clearly stated. I had no problem researching this information.

This year, Margo Gray has not been given permission for the dam yet. This affects the economy of the area tremendously as Trinity Alps Resort guests provide much needed economic support to an otherwise depressed area. We spend a lot of money in Trinity County when we come up here. The guests are people who come up every year and have done so for decades, including my family. We have been vacationing at Trinity Alps Resort since 1974. The local people and businesses depend on the money coming in. Trinity County will become an even more depressed area if Trinity Alps Resort guests decide to change their vacation venues to other areas that offer a similar venue. Trinity Alps Resort also provides jobs that would otherwise be nonexistent. The swimming hole is the focal point of the resort. No dam equals no jobs and no money.

Thank you for taking the time to ready my letter. I hope it will be part of the decision process.

Sincerely,

Linda Adams

Notification of Intent to file a petition to list Shasta Snow-Wreath (Neviusia cliftonii) under US ESA

To: California Fish and Game Commission and U.S. Fish and Wildlife Service:

Pursuant to US 50 C.F.R. §424.14(b), I, Kathleen S. Roche, hereby provide notice that I intend to file a petition under the federal Endangered Species Act to list and designate critical habitat for the Shasta snow-wreath,*Neviusia cliftonii*, no sooner than 30 days from the date that this notice is provided. This petition has been prepared with the participation of the California Native Plant Society and uses all available scientific information from the State of California.

The Shasta snow-wreath is a dicot, shrub in the rose family (Rosaceae) that is native to California and is endemic (limited) to northern California. The species was first described in 1992 and is now known from a total of 24 occurrences, restricted almost entirely to National Forest System lands, with six occurrences wholly or partly on private lands, including industrial forest lands. It is found exclusively in western Shasta County around the perimeter of Shasta Lake in northern California. It is one of only two species in the genus *Neviusia*. There are no other species of *Neviusia* in California nor adjacent states. There is agreement on the classification and the scientific name of this species (California Natural Diversity Database (California Department of Fish and Wildlife), Calflora, NatureServe, USDA Plants Database, the Jepson eFlora, and the Flora of North America). The species currently holds a NatureServe global rank of G2 and a California Rare Plant Rank of 1B.2. **The Shasta snow-wreath is endangered by the proposed destruction of habitat primarily by water inundation from raising Shasta Dam and accessory activities to relocate facilities as well as by other actions.**

The USFWS has not previously reviewed this species for listing, nor has the California Fish and Game Commission reviewed it for listing under the California Endangered Species Act (CESA).

Please feel free to contact me for more information.

Kathleen S. Roche

I am also sending you a paper copy of this notification via surface mail.

FONSI for a Management Plan for Developed Water Sources, Mojave National Preserve

Mojave National Preserve News Release

Release Date: August 22, 2019

Contact: Todd Suess, Mojave National Preserve, (760) 252-6103

Finding of No Significant Impact for a Management Plan for Developed Water Sources, Mojave National Preserve

BARSTOW—The National Park Service has approved a Management Plan for Developed Water Sources in Mojave National Preserve (Plan). The decision was recorded through the approval of a Finding of No Significant Impact.

The NPS selected the preferred alternative of the Plan, which will maintain essential wildlife water developments in wilderness and install new water developments outside of wilderness to improve regional habitat connectivity. The number of water developments for desert bighorn sheep will increase from six to eleven during a multi-year transition period. Based on the results of water use analysis, some of these water developments could be consolidated.

Key points include:

- The NPS will work collaboratively with the California Department of Fish & Wildlife (CDFW) and stakeholders to ensure all decisions regarding water developments are consistent, to the extent possible, with the CDFW Bighorn Sheep Management Plan.
- Selected water developments for birds and small game outside of wilderness will be evaluated and maintained according to their ecological importance.
- Developed springs will be evaluated and maintained based on feasibility and importance.

The selected alternative utilizes water developments for supporting native wildlife and habitat connectivity while protecting wilderness values. Relocating water developments for bighorn sheep to areas with easier access will facilitate their maintenance.

-NPS-

RE: SUPPORT FOR CALIFORNIA DEPARTMENT OF FISH AND WILDLIFE (DFW) LOW FLOW ANGLING CLOSURE

Dear California Fish and Game Commission,

I am writing to you on behalf of the Santa Cruz County Board of Supervisors to convey our strong support for current efforts to study and propose a finalized low flow target for temporary closures of recreational steelhead angling in Santa Cruz County waterways. While most steelhead and salmon streams throughout California have finalized closure thresholds in the accepted Sport Fishing Regulations, Santa Cruz County does not. Low flow fishing thresholds will provide and maintain angling opportunities, enhance protection of listed salmonids during stressful low flow conditions, simplify regulations and align Santa Cruz County with existing thresholds statewide.

Recent years of exceptional drought and low winter flow conditions have raised concerns about the potential adverse impacts of steelhead angling during critically dry conditions. During periods of low flow, adult steelhead are unable to migrate and are more vulnerable to getting caught multiple times or getting caught while spawning. Short winter storms sometimes allow adult salmonids (steelhead and salmon) to enter local creeks and streams but they may be unable to migrate further when stream flows recede. Young steelhead, including smolts ready to migrate to the ocean, are also more vulnerable to getting caught during winter low flow angling. The low-flow fishing closure criteria would draw from United States Geological Survey (USGS) gage data, which is easily available online. Implementation of low flow angling closures will protect salmonids by working to offset these possible negative effects.

Over the past year, the local CDFW fishery biologist has conducted outreach to fishing groups and anglers, successfully gathering support for the low-flow fishing regulations among both salmonid conservation and angling interest groups. For anglers, the establishment of low-flow fishing closure criteria avoids the risk of a possible closure blanketing more of the fishing season by the State Fish and Game Commission. The Santa Cruz County's Fish and Wildlife Advisory Commission discussed this issue at a meeting in Fall 2018. Enacting low-flow fishing closure criteria can maintain and build support for fishing - an important local recreational activity - while protecting our sensitive steelhead fishery.

The Santa Cruz County Board of Supervisors looks forward to analysis by the DFW regarding modifying existing Supplemental Regulation 8.00 (c) of the 2018 California Freshwater Sports Fishing Regulations regarding closure thresholds for stream flows.

Thank you for your consideration of this letter of support.

Sincerely,

RYAN COONERTY, Chair
Board of Supervisors

cc: Clerk of the Board
County Fish and Wildlife Advisory Commission

I wanted to let you know that under our Creators law all of His creatures are assigned by him to life.We dont actually have a right to take their lives .We respect God wants them to live His length of time. He also didnt assign them for food. They need space and food replenishment on their land. That includes Marine life who have also suffered terrtbly from our ignoring their starvation in the name of a hunt or licence. Hunting also leaves blood scent a safety hazard since those forced to injest it are very sensitive to to it and it really does not help conserve. The ither creatures cope withe verything we cope with plus selfish humans contamination not enough space r oads and birds are also plighted and they cope with aviators who ignore flyways. I have not seen a duck in years alive and am getting used to missing species appearing on cat and dog food cans. Marine life dropped an entire species in one summer of whales. In addition we have more than we can handle of the drug people who think they reserve a right to grab what they find and butcher it without mercy because their money is gone or theyve been permitted to behave barbaric . For that alone we dont need any of it permission ed That includes the USDA who think nothing of being inhumane and are not a good example.

Wildlife conservation

Nick Buckley

Tue 09/10, 07:22 AM

Commissioners,

I have grown very tired of wildlife conservation being dictated by politicians (yourselves) rather than biologists who would use a SCIENCE based approach to wildlife management. The nepotism is so thick within the fish and game commission that responsible wildlife management is being suffocated under the weight of your political agendas. Every decision you have made within the past 8-10 years at a minimum has put wildlife in a more compromised position than before.

Sincerely,
Nick Buckley

Attn: Victoria Barr

Dear Fish and Game Commission and Department of Fish and Wildlife:

In accordance with the Department of Fish and Wildlife's (Department) Private Lands Management (PLM) Program Policies and Procedures Handbook (March 2008), this letter serves as my notice to the Fish and Game Commission and the Department that I am withdrawing from the PLM Program, effective immediately. I understand that in doing so, my current PLM license and license agreement associated with Triple B Ranch, and therefore my PLM tags and seals, which I returned to the Department on August 12, 2019, will no longer be valid. I did not use any of the tags and seals and the fees for the tags and seals had already been paid in full. As a result, I did not receive any exchange tags and I do not owe any fees.

This letter also serves as notice that I am no longer acting as manager, operator, or in any other capacity of any other PLM, in particular, for JS Ranch, Dixie Valley Ranch, and Clover Creek Ranch. To that end, I have given the landowners of those ranches any of their PLM tags and seals that were in my possession.

Sincerely,

Steve Boero
Owner, Triple B Ranch

Attention Commissioner

Kristen Annis [redacted]

Wed 09/18, 09:00 AM

Attention Commissioner,

I have been a hunter for 40 years in California. This year you went to steel shot for Upland game birds. This season on Sept 1st for Dove. We were using #6 steel shot and the majority of every bird that we shot they were still alive after shooting them. Steel shot is ruining our barrel's and there also is a shortage of steel shot #7 in this State. The manufacturer's are not going to be supplying sufficient #7 steel shot to California, because California is the only state requiring Steel shot #7 for Upland Game. Also in California you cannot use slugs for hunting because they do not make a non lead slug. Also in California you can no longer use a .22 to hunt with because manufacturers do not make a non lead .22 caliber. These laws are affecting many hunters as myself. I completely disagree with these requirements all because of the Condor and other animals that ingest lead supposedly. Please consider my concerns and frustration by these outlandish requirements by the State of California.

Brett Bunge

Subject: **Status Review of the Foothill Yellow-legged Frog**

The Department of Fish and Wildlife (Department) prepared the attached Status Review for the Fish and Game Commission (Commission) regarding a petition by the Center for Biological Diversity (Petition) to list the Foothill Yellow-legged Frog (*Rana boylii*) as threatened pursuant to the California Endangered Species Act (CESA; Fish and Game Code section 2074.6). The Commission received the Petition on December 14, 2016. The attached report represents the Department's final written review of the status of the Foothill Yellow-legged Frog and is based upon the best scientific information available to the Department. In addition to evaluating the petitioned action to list the species as threatened, the Department evaluated whether listing the species was warranted for six unique genetic clades. The status review contains the Department's recommendation that listing the Foothill Yellow-legged Frog is warranted at this time for five of six genetic clades. The Department recommends listing the Feather River and Northeast/Northern Sierra clades as threatened and listing the East/Southern Sierra, West/Central Coast, and Southwest/South Coast clades as endangered. Listing the Northwest/North Coast clade is not warranted at this time.

Regarding the scientific determinations of the threats to the Foothill Yellow-legged Frog, the Department finds that without protections afforded by CESA, the continued existence of the Foothill Yellow-legged Frog throughout much of its range in California is in serious danger or is threatened as described in the report.

If you have any questions or need additional information, please contact Kari Lewis, Chief, Wildlife Branch at (916) 445-3789 or at Kari.Lewis@wildlife.ca.gov.

EXECUTIVE SUMMARY

This status review report contains the most current information available on the Foothill Yellow-legged Frog (*Rana boylii*) and serves as the basis for the California Department of Fish and Wildlife's (Department) recommendation to the California Fish and Game Commission (Commission) on whether to list the species as threatened or endangered under the California Endangered Species Act. The Center for Biological Diversity submitted a "Petition to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened Under the California Endangered Species Act" (Petition) to the Commission on December 14, 2016. At its scheduled public meeting on June 21, 2017, the Commission considered the Petition, and based in part on the Department's petition evaluation and recommendation, found sufficient information exists to indicate the petitioned action may be warranted and accepted the Petition for consideration. The Foothill Yellow-legged Frog was designated a candidate species on July 7, 2017 upon publication of the Commission's notice of its findings.

Foothill Yellow-legged Frogs are currently recognized as a California Species of Special Concern, a non-regulatory designation intended to focus attention on animals at conservation risk, stimulate research on poorly known species, and achieve conservation and recovery of these animals before they meet criteria for listing as threatened or endangered under the California Endangered Species Act (CESA; Fish & G. Code, § 2050 et seq.). Additionally, the Foothill Yellow-legged Frog throughout its range in California and Oregon is currently under review by the U.S. Fish and Wildlife Service for listing as threatened or endangered under the federal Endangered Species Act.

Foothill Yellow-legged Frogs are small- to medium-sized frogs that are typically gray, brown, olive, or reddish with brown-black flecking and mottling, which often matches the local substrate. Foothill Yellow-legged Frogs have a relatively squat body and granular skin, giving them a rough appearance like toads, and their dorsolateral folds are indistinct compared to other western North American ranids. Their abdomen is white with variable amounts of dark mottling on the chest and throat, and as their name suggests, the undersides of their hind limbs are often yellow. Foothill Yellow-legged Frogs reach sexual maturity around two to three years old and can live over a decade. Adult females likely lay one clutch of eggs per year. Egg masses resemble a cluster of grapes with several hundred embryos, and tadpoles metamorphose in the same season the eggs were laid.

Foothill Yellow-legged Frogs historically ranged from the Willamette River drainage in Oregon west of the Sierra-Cascade crest to at least the San Gabriel River drainage in Los Angeles County in California, and a disjunct population was discovered in the mid-1960s in the Sierra San Pedro Mártir, Baja California Norte, México. In California, the species has been reported from foothill and mountain streams in the Klamath, Cascade, Sutter Buttes, Coast, Sierra Nevada, and Transverse ranges from sea level to 6,400 ft, although rarely above 5,000 ft. Foothill Yellow-legged Frog populations exhibit strong genetic variation across their range. Two recent landscape genomics studies recovered five and six deeply divergent clades, respectively, and genetic diversity within clades is generally lower in the southern part of the species' range, making them less capable of adapting to changing conditions.

Foothill Yellow-legged Frogs inhabit rivers and streams ranging from primarily rain-fed (coastal populations) to primarily snow-influenced (most Sierra Nevada and Klamath-Cascade populations) from headwater streams to large rivers. Occupied rivers and streams flow through a variety of vegetation types including hardwood, conifer, and valley-foothill riparian forests; mixed chaparral; and wet meadows. The species is an obligate stream-breeder, which sets it apart from other western North American ranid frogs. Foothill Yellow-legged Frog habitat is generally characterized as partly-shaded, shallow, perennial rivers and streams with a low gradient and rocky substrate that is at least cobble-sized; however, the species also uses intermittent and ephemeral streams. Appropriate flow velocity, temperature, and timing are critically important to the success of Foothill Yellow-legged Frog populations. The habitats in which Foothill Yellow-legged Frogs are found can generally be categorized as breeding and rearing habitat, nonbreeding season habitat, and overwintering habitat. Foothill Yellow-legged Frog densities are often higher in areas with greater habitat heterogeneity likely because the diversity of habitats can support all life stages within a relatively short distance.

Foothill Yellow-legged Frog diet varies by life stage and likely by body size. Tadpoles graze on algae scraped from rocks and vegetation. Post-metamorphic Foothill Yellow-legged Frogs primarily feed on a wide variety of terrestrial arthropods but also some aquatic invertebrates, mostly insects and arachnids. In the fall when they are abundant, young-of-year Foothill Yellow-legged Frogs may provide an important source of nutrition for adults prior to overwintering. Foothill Yellow-legged Frogs are preyed upon by several native and introduced species, including aquatic insects, crayfish, salamanders, frogs, birds, and several species of fish and gartersnakes.

Few historical data on Foothill Yellow-legged Frog distribution and abundance exist, but widespread disappearances were documented as early as the 1970s and 80s in southern California, the southern Coast Range, and the central and southern Sierra Nevada foothills. In 1994, the authors of the first edition of *Amphibians and Reptile Species of Special Concern in California* concluded that Foothill Yellow-legged Frogs could be considered endangered in central and southern California south of the Salinas River in Monterey County, threatened in the west slope drainages of the Cascade Mountains and Sierra Nevada east of the Central Valley, and a species of special concern in the remainder of California.
In 2005, a range-wide assessment determined the species was likely extirpated from over 50% of historically occupied sites, and in another wide-ranging survey effort at least one Foothill Yellow-legged Frog was detected at 26.5% of sites with suitable habitat in California. In the latter study, fewer than 20 adults were observed at approximately 86% of the occupied sites, but the North Coast possessed the greatest proportion of occupied sites and most robust populations. The coarse-scale trend of Foothill Yellow-legged Frog populations in California is one of greater declines and extirpations in lower elevations and latitudes.

Several past and ongoing activities have changed the watersheds upon which Foothill Yellow-legged Frogs depend, and many interact with each other in ways that exacerbate their adverse impacts. In addition, because many Foothill Yellow-legged Frog populations are small, isolated from other populations, and possess low genetic diversity, they are at greater risk of extirpation than robust populations.

Most of the factors threatening the Foothill Yellow-legged Frog's ability to persist and thrive involve habitat destruction or degradation. The most widespread, and potentially most significant, impacts are associated with dams and their flow regimes, particularly in areas where dams are concentrated and occur in a series along a river or use hydropeaking to generate power. Dams can result in up- and downstream effects, including aseasonal or asynchronous breeding cues, scouring and stranding of egg masses and tadpoles, reducing quality and quantity of breeding and rearing habitat, lessening tadpole growth rate, impeding gene flow among populations, and creating conditions that support the establishment and spread of non-native species. The average abundance of Foothill Yellow-legged Frog populations below dams is one-fifth of those in unregulated rivers (undammed), and populations in regulated rivers face a 4- to 13-fold greater extinction risk in 30 years than populations in unregulated rivers due to smaller population sizes.

Another widespread threat to Foothill Yellow-legged Frog habitat is climate change. While drought, wildland fires, floods, and landslides are natural and often necessary disturbance events for preservation of native biodiversity, climate change is expected to result in increased frequency and severity of these events in ways that may exceed species' abilities to adapt. These disturbance events, which can lead to local extirpations, will occur across a landscape of fragmented and small populations, so the likelihood of natural recolonization may be highly impaired. Some climate models predict unprecedented dryness in the latter half of the century, and altered flow regimes may lead to increased competition, predation, and disease transmission as species become concentrated in remnant pools. Impacts from extended droughts will likely be greatest in areas that are naturally more arid, the lower elevations and latitudes of southern California and the foothills surrounding the Central Valley, where remaining populations are already small and isolated. In addition, loss of riparian vegetation from wildland fires can result in increased stream temperatures or concentrations of nutrients and trace heavy metals that inhibit growth and survival. Sedimentation from landslides following fire or excessive precipitation can also destroy or degrade breeding and rearing habitat.

Like many other amphibians across the globe, Foothill Yellow-legged Frogs are susceptible to the lethal and sublethal effects of disease and pollution. The fungal pathogen *Batrachochytrium dendrobatidis* (Bd) is linked to the greatest recorded loss of biodiversity attributable to a disease and is responsible for dramatic declines and extinctions in hundreds of species of amphibians around the world. Bd is widespread in the environment and likely contributed to the Foothill Yellow-legged Frog's disappearance from southern California and other parts of its range is implicated as the causative factor in two recent mass-mortality events in the Bay Area. As the nation's largest agricultural producer and exporter, tons of agricultural chemicals are applied to California farms annually and can travel substantial distances through the atmosphere. Disappearance and declines in Foothill Yellow-legged Frog populations correlate with proximity and proportion of nearby agriculture. The species is particularly sensitive to some of the commonly used organophosphates, which disrupt nerve impulse transmission. Pesticide exposure can result in direct mortality, immunosuppression, reduced resistance to the parasites that cause limb malformations, decreased growth and activity, and increased vulnerability to predation.

Predation likely contributed, and continues to contribute, to Foothill Yellow-legged Frog population declines, particularly where the habitat is degraded by one or many other risk factors. Predation by and competition with introduced species like American Bullfrogs can have substantial adverse effects; abundance of Foothill Yellow-legged Frogs was nearly an order of magnitude (i.e., 10 times) lower in stream reaches where bullfrogs were well established. Bullfrogs are also asymptomatic carriers of Bd.

Additional threats that can contribute to Foothill Yellow-legged Frog habitat degradation and population declines include mining, livestock grazing, recreational activities, urban and agricultural land use and expansion, cannabis cultivation, timber harvest, and some biological surveys and habitat restoration activities.

Several environmental laws and regulations reduce adverse impacts on Foothill Yellow-legged Frogs. Efforts to avoid, minimize, or mitigate these threats have been incorporated into many environmental impact assessments, regional conservation plans, and permits and licenses. Nevertheless, remaining populations throughout a large portion of the species' California range continue to be small and are losing genetic diversity. Additional actions are needed to conserve and improve existing populations in many areas and to re-establish populations in areas where they have been extirpated.

The scientific information available to the Department indicates that Foothill Yellow-legged Frog faces varying degrees of imperilment throughout its range. The Department recommends that the Commission find that the petitioned action to list Foothill Yellow-legged Frog as threatened is warranted for the Feather River and Northeast/Northern Sierra clades; that the East/Southern Sierra, West/Central Coast, and Southwest/South Coast clades be listed as endangered; and that listing of the Northwest/North Coast clade is not warranted at this time.

1.0 REGULATORY SETTING

1.1 Petition Evaluation Process

A petition to list the Foothill Yellow-legged Frog (*Rana boylii*) as threatened under the California Endangered Species Act (CESA) was submitted to the Fish and Game Commission (Commission) on December 14, 2016 by the Center for Biological Diversity. Commission staff transmitted the petition to the Department of Fish and Wildlife (Department) pursuant to Fish and Game Code section 2073 on December 22, 2016 and published a formal notice of receipt of the petition on January 20, 2017 (Cal. Reg. Notice Register 2017, No. 3-Z, p. 46). A petition to list or delist a species under CESA must include "information regarding the population trend, range, distribution, abundance, and life history of a species, the factors affecting the ability of the population to survive and reproduce, the degree and immediacy of the threat, the impact of existing management efforts, suggestions for future management, and the availability and sources of information. The petition shall also include information regarding the kind of habitat necessary for species survival, a detailed distribution map, and any other factors that the petitioner deems relevant" (Fish & G. Code, § 2072.3).

On April 17, 2017, the Department provided the Commission with its evaluation of the petition, "Evaluation of the Petition from the Center For Biological Diversity to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened under the California Endangered Species Act," to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5 & 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & (e)). Focusing on the information available to the Department relating to each of the relevant categories, the Department recommended to the Commission that the petition be accepted.

At its scheduled public meeting on June 21, 2017 in Smith River, the Commission considered the petition, the Department's petition evaluation and recommendation, and comments received. The Commission found that sufficient information existed to indicate the petitioned action may be warranted and accepted the petition for consideration. Upon publication of the Commission's notice of its findings, the Foothill Yellow-legged Frog was designated a candidate species on July 7, 2017 (Cal. Reg. Notice Register 2017, No. 27-Z, p. 986).

1.2 Status Review Overview

The Commission's action designating the Foothill Yellow-legged Frog as a candidate species triggered the Department's process for conducting a status review to inform the Commission's decision on whether listing the species is warranted. At its scheduled public meeting on June 21, 2018 in Sacramento, the Commission granted the Department a six-month extension to complete the status review and facilitate external peer review.

This status review report is not intended to be an exhaustive review of all published scientific literature relevant to the Foothill Yellow-legged Frog; rather, it is intended to summarize the key points from the best scientific information available relevant to the status of the species. This final report, based upon the best scientific information available to the Department, is informed by independent peer review of a draft report by scientists with expertise relevant to the Foothill Yellow-legged Frog. This review is intended to provide the Commission with the most current information on the Foothill Yellow-legged Frog and to serve as the basis for the Department's recommendation to the Commission on whether the petitioned action is warranted. The status review report also identifies habitat that may be essential to continued existence of the species and provides management recommendations for recovery of the species (Fish & G. Code, § 2074.6). Receipt of this report is to be placed on the agenda for the next available meeting of the Commission after delivery. At that time, the report will be made available to the public for a 30-day public comment period prior to the Commission taking any action on the petition.

1.3 Federal Endangered Species Act Review

The Foothill Yellow-legged Frog is currently under review for possible listing as threatened or endangered under the federal Endangered Species Act (ESA) in response to a July 11, 2012 petition submitted by the Center for Biological Diversity. On July 1, 2015, the U.S. Fish and Wildlife Service (USFWS) published its 90-day finding that the petition presented substantial scientific or commercial information indicating that the petitioned action may be warranted and initiated a status review of the species (USFWS 2015). On March 16, 2016, the Center for Biological Diversity sued the USFWS to compel issuance of a 12-month finding on whether listing under the ESA is warranted. On August 30, 2016, the parties reached a stipulated settlement agreement that the USFWS shall publish its 12-month finding in the Federal Register on or before September 30, 2020 (Center for Biological Diversity v. S.M.R. Jewell (D.D.C. Aug. 30, 2016, No. 16-CV-00503)).

2.0 BIOLOGY AND ECOLOGY

2.1 Species Description and Life History

> *"In its life-history* boylii *exhibits several striking specializations which are in all probability related to the requirements of life of a stream-dwelling species"* – Tracy I. Storer, 1925

The Foothill Yellow-legged Frog is a small- to medium-sized frog; adults range from 1.5 to 3.2 inches snout-to-urostyle length (SUL) with females attaining a larger size than males and males possessing paired internal vocal sacs (Zweifel 1955, Nussbaum et al. 1983, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs are typically gray, brown, olive, or reddish with brown-black flecking and mottling, which generally matches the substrate of the stream in which they reside (Nussbaum et al. 1983, Stebbins and McGinnis 2012). They often have a pale triangle between the eyes and snout and broad dark bars on the hind legs (Zweifel 1955, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs have a relatively squat body and granular skin, giving them a rough appearance similar to a toad, and fully webbed feet with slightly expanded toe tips (Nussbaum et al. 1983). The tympanum is also rough and relatively small compared to other ranids (frogs in the family Ranidae) at around one-half the diameter of the eye (Zweifel 1955). The Foothill Yellow-legged Frog's dorsolateral folds (glandular ridges extending from the eye area to the rump) are indistinct compared to other western North American ranids (Stebbins and McGinnis 2012). Ventrally, the abdomen is white with variable amounts of dark mottling on the chest and throat, which are unique enough to be used to identify individuals (Marlow et al. 2016). As their name suggests, the undersides of their hind limbs and lower abdomen are often yellow; however, individuals with orange and red have been observed within the range of the California Red-legged Frog (*Rana draytonii*), making hindlimb coloration a poor diagnostic characteristic for this species (Jennings and Hayes 2005).

Adult females likely lay one clutch of eggs per year and may breed every year (Storer 1925, Wheeler et al. 2006). Foothill Yellow-legged Frog egg masses resemble a compact cluster of grapes approximately 1.8 to 3.5 inches in diameter lengthwise and contain anywhere from around 100 to over 3,000 eggs (Kupferberg et al. 2009c, Hayes et al. 2016). The individual embryos are dark brown to black with a lighter area at the vegetative pole and surrounded by three jelly envelopes that range in diameter from approximately 0.15 to 0.25 inches (Storer 1925, Zweifel 1955, Hayes et al. 2016).

Foothill Yellow-legged Frog tadpoles hatch out around 0.3 inch long and are a dark brown or black (Storer 1925, Zweifel 1955). They grow rapidly to 1.5 to 2.2 inches and turn olive with a coarse brown mottling above and an opaque silvery color below (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012). Their eyes are positioned dorsally when viewed from above (i.e., within the outline of the head), and their mouths are large, downward-oriented, and suction-like with several tooth rows (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012, Hayes et al. 2016). Foothill Yellow-legged Frogs metamorphose at around 0.55 to 0.67 of an inch SUL (Fellers 2005). Sexual maturity is attained at around 1.2 to 1.6 inches SUL and 1 to 2 years for males and around 1.6 to 2.0 inches SUL and 3 years for females, although in some populations this has been accelerated by a year (Zweifel 1955, Kupferberg et al. 2009c, Breedveld and Ellis 2018). During the breeding season, males can be distinguished from females by the presence of nuptial pads (swollen darkened thumb bases that aid in holding females during amplexus) and calling, which frequently occurs underwater but sometimes from the surface (MacTague and Northen 1993, Stebbins 2003, Silver 2017).

The reported lifespan of Foothill Yellow-legged Frogs varies widely by study. Storer (1925) estimated a maximum age of 2 years for both sexes, and Van Wagner (1996) stated that Foothill Yellow-legged Frogs rarely exceeded 2 years old at his study site. Breedveld and Ellis (2018) calculated the typical lifespan of males at 3-4 years and 5-6 years for females. Bourque (2008), using skeletochronology, found an individual over 7 years old and a mean age of 4.7 and 3.6 years for males and females, respectively. Drennan et al. (2015) estimated maximum age at 13 years for both sexes in a Sierra Nevada population and 12 for males and 11 for females in a Coast Range population.

2.2 Range and Distribution

Based on the current understanding of the Foothill Yellow-legged Frog's historical distribution, which is sparse in many areas, the species likely ranged from the Willamette River drainage in Oregon west of the Sierra-Cascade crest to at least the San Gabriel River drainage in Los Angeles County, California (Zweifel 1955, Nussbaum et al. 1983, Stebbins 2003). In addition, a disjunct population was reported from 6,700 ft in the Sierra San Pedro Mártir, Baja California Norte, México (Loomis 1965). In California, the species has been reported from foothill and mountain streams in the Klamath, Cascade, Sutter

Buttes, Coast, Sierra Nevada, and Transverse ranges from sea level to around 6,000 ft, although Hemphill (1952) describes observing them as high as 6,400 ft at one North Coast location (Stebbins 2003, Olson et al. 2016). Zweifel (1955) considered Foothill Yellow-legged Frogs to be present and abundant throughout their range where streams possessed suitable habitat.

Figure 1 depicts the Department's approximation of the Foothill Yellow-legged Frog's historical range. The majority of the range boundaries in California were taken directly from Thomson et al. (2016) and are used for the Department's California Wildlife Habitat Relationships (CWHR) range. Their methodology included plotting observations in a geographic information system (GIS), intersecting those points with watershed boundaries, developing an approximate range boundary using interpolation between the observations and watershed boundaries, and expert opinion (Ibid.). The Sutter Buttes were added for this report based on Olson et al. (2016). The range in Oregon was based on the species' range map in Nussbaum et al. (1983), and the range in México was estimated from the locality description in Loomis (1965).

As described in more detail below, Foothill Yellow-legged Frog taxonomy has changed many times since originally described, and consequently, some museum specimens collected before the 1960s are erroneous. As stated in the Petition, to date, all recently reevaluated Foothill Yellow-legged Frog-labeled museum specimens south of the San Gabriel mountains in California were determined to be Southern Mountain Yellow-legged Frogs (*Rana muscosa*). No evidence suggests that those not re-evaluated would be reconciled another way. This likely happened in some places in the Sierra Nevada as well, as Foothill Yellow-legged Frogs are rarely found above 5,000 ft (R. Peek pers. comm. 2019a). Based on recent genetics work in the northern Sierra Nevada, all yellow-legged frogs located above 5,000 ft were Sierra Nevada Yellow-legged Frogs (*R. sierrae*) (Bedwell 2018, Peek 2018).

2.3 Taxonomy and Phylogeny

Foothill Yellow-legged Frogs belong to the family Ranidae (true frogs), which inhabits every continent except Antarctica and contains over 400 species (AmphibiaWeb 2019b). The species was first described by Baird (1854) as *Rana boylii*. After substantial taxonomic uncertainty with respect to its relationship to other ranids, several name changes (including the specific epithet spelling of *boylei*), and recognition of three subspecies over the next century, the Foothill Yellow-legged Frog (*R. boylii*) was again recognized as a monotypic species (i.e., without subspecies) by Zweifel (1955, 1968). The phylogenetic relationships among the western North American *Rana* spp. have been revised several times and are still not entirely resolved (Thomson et al. 2016). The Foothill Yellow-legged Frog was previously thought to be most closely related to the higher-elevation Sierra Nevada Yellow-legged Frog and Southern Mountain Yellow-legged Frog (Zweifel 1955; Green 1986a,b; Vredenburg et al. 2007). However, more recent genetic analyses suggest they are most closely related to Columbia Spotted Frogs (*R. luteiventris*) (Macey et al. 2001, Hillis and Wilcox 2005, Yuan et al. 2016).

Figure 1. Estimated historical range of the Foothill Yellow-legged Frog (adapted from Loomis [1965], Nussbaum et al. [1983], Olson et al. 2016, CWHR 2014). See Section 2.2 Range and Distribution for map construction methods and stipulations.

2.4 Population Structure and Genetic Diversity

Genetic divergence among populations and genetic diversity within those populations are critical to species protection. Genetic divergence is a measure of the number of mutations accumulated between population lineages since they last shared a common ancestor. It represents the amount of time that lineages have been separated; the longer the time, the greater the genetic divergence. Given that evolutionary processes, including local adaptation and speciation, tend to accumulate over time, a general principle in conservation genetics is that deeply diverged lineages need to be individually managed and protected to preserve the full evolutionary potential of a species. Molecular genetic/genomic analyses allow one to quantify genetic divergence and clearly delimit the geographic boundaries of populations and the amount of gene flow or isolation among them (McCartney-Melstad and Shaffer 2015). Genetic divergence is often depicted as a phylogenetic tree (see Figure 2), which visually summarizes the evolutionary relationships among populations and taxa (AmphibiaWeb 2019a). A branch on a phylogenetic tree that contains a group of lineages comprised of an ancestor and all its descendants is referred to as a monophyletic group, or a clade (Ibid.). Clades are nested hierarchically in a phylogenetic tree, and effective conservation strategies often identify the "major" clades, which represent populations from the most divergent lineages in that tree, as key management units. These major clades may be sufficiently differentiated into diagnosable species or subspecies, or they may diverge to that point if the evolutionary process continues.

Because the processes that drive genetic divergence among populations and among species are the same (i.e., mutation, natural selection, genetic drift), it can be difficult to determine when populations within species have differentiated enough to suggest they are evolving independently and may be considered separate species or subspecies (Hey and Pinho 2012). Hey and Pinho (2012) examined use of gene flow and separation time measures to distinguish between intraspecific and interspecific differences. The most widely used summary measure of population divergence is the fixation index F_{ST}, a quantitative measure of the proportion of the total genetic variance in a study among populations or lineages. Hey and Pinho's analyses indicated that F_{ST} values greater than 0.35 among lineages correlated best with species designations, while values below 0.35 were more consistent with within-species variation (Ibid.). This population-genetics based approach to estimating genetic divergence can help reveal cryptic diversity within a putative species, and in some cases may lead to the recognition of previously unrecognized species (AmphibiaWeb 2019a).

In contrast to divergence among populations, genetic diversity summarizes variation within a population or lineage, which provides information on population health and indicates the extent to which populations have the capacity to adapt (i.e., evolve) to changing conditions (Hughes et al. 2008). Loss of genetic diversity often signals extreme reductions in population size (genetic bottlenecks) and greatly increases the potential for inbreeding depression that can reduce survival and reproductive success (Lande and Shannon 1996, Frankham 2005, Hoffmann and Sgrò 2011, McCartney-Melstad et al. 2018). Amphibians as a group may be particularly vulnerable to the effects of low genetic diversity; there are several documented instances of reduced fitness as a result of eroded genetic diversity in amphibians that may be contributing to global declines in this taxon (Allentoft and O'Brien 2010).

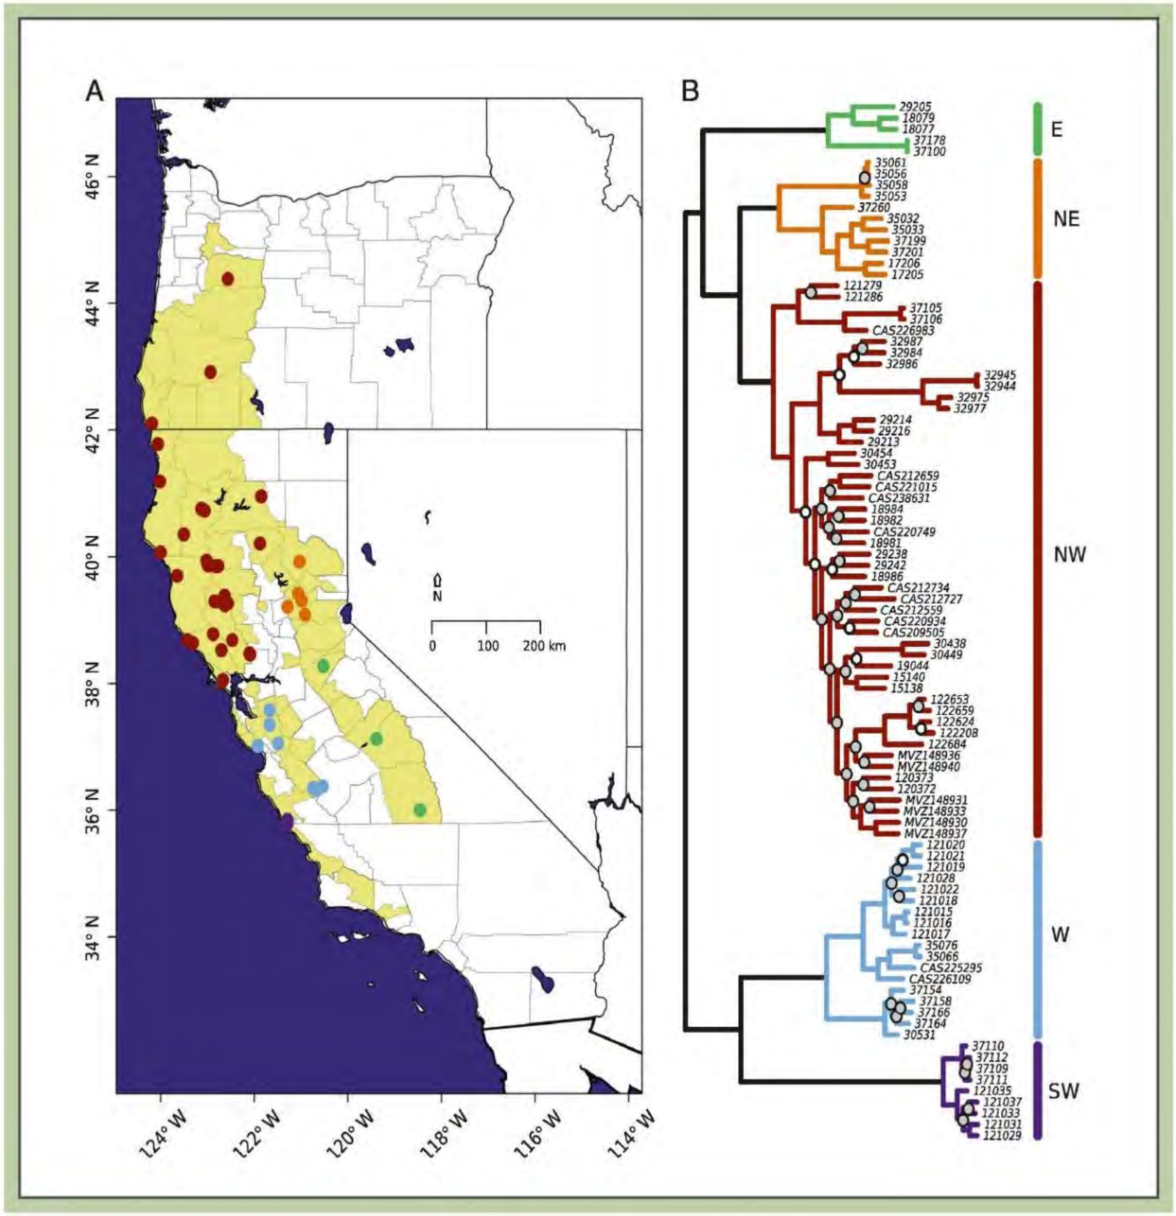

Figure 2. Foothill Yellow-legged Frog clades identified by McCartney-Melstad et al. (2018) Yellow polygons = International Union for Conservation of Nature's range map; colored circles = sampling sites.

Foothill Yellow-legged Frog populations exhibit varying levels of genetic divergence and diversity depending on the spatial scale of comparison. At the coarse scale, comprised of variation across the species' extant range, McCartney-Melstad et al. (2018) recovered five deeply divergent, geographically cohesive, genetic clades from their analyses (Figure 2), while Peek (2018) utilized expanded geographic sampling and recovered six (Figure 3). Both analyzed thousands of genomic loci generated using RADseq approaches. The lowest F_{ST} value McCartney-Melstad et al. (2018) calculated among their five recognized lineages was 0.312 between the Northwest and Northeast clades (see Figure 2 and below for details on estimated clade boundaries), and the highest was 0.794 between the Southwest and East clades. Peek (2018) calculated F_{ST} between pairs of populations across the Foothill Yellow-legged Frog's

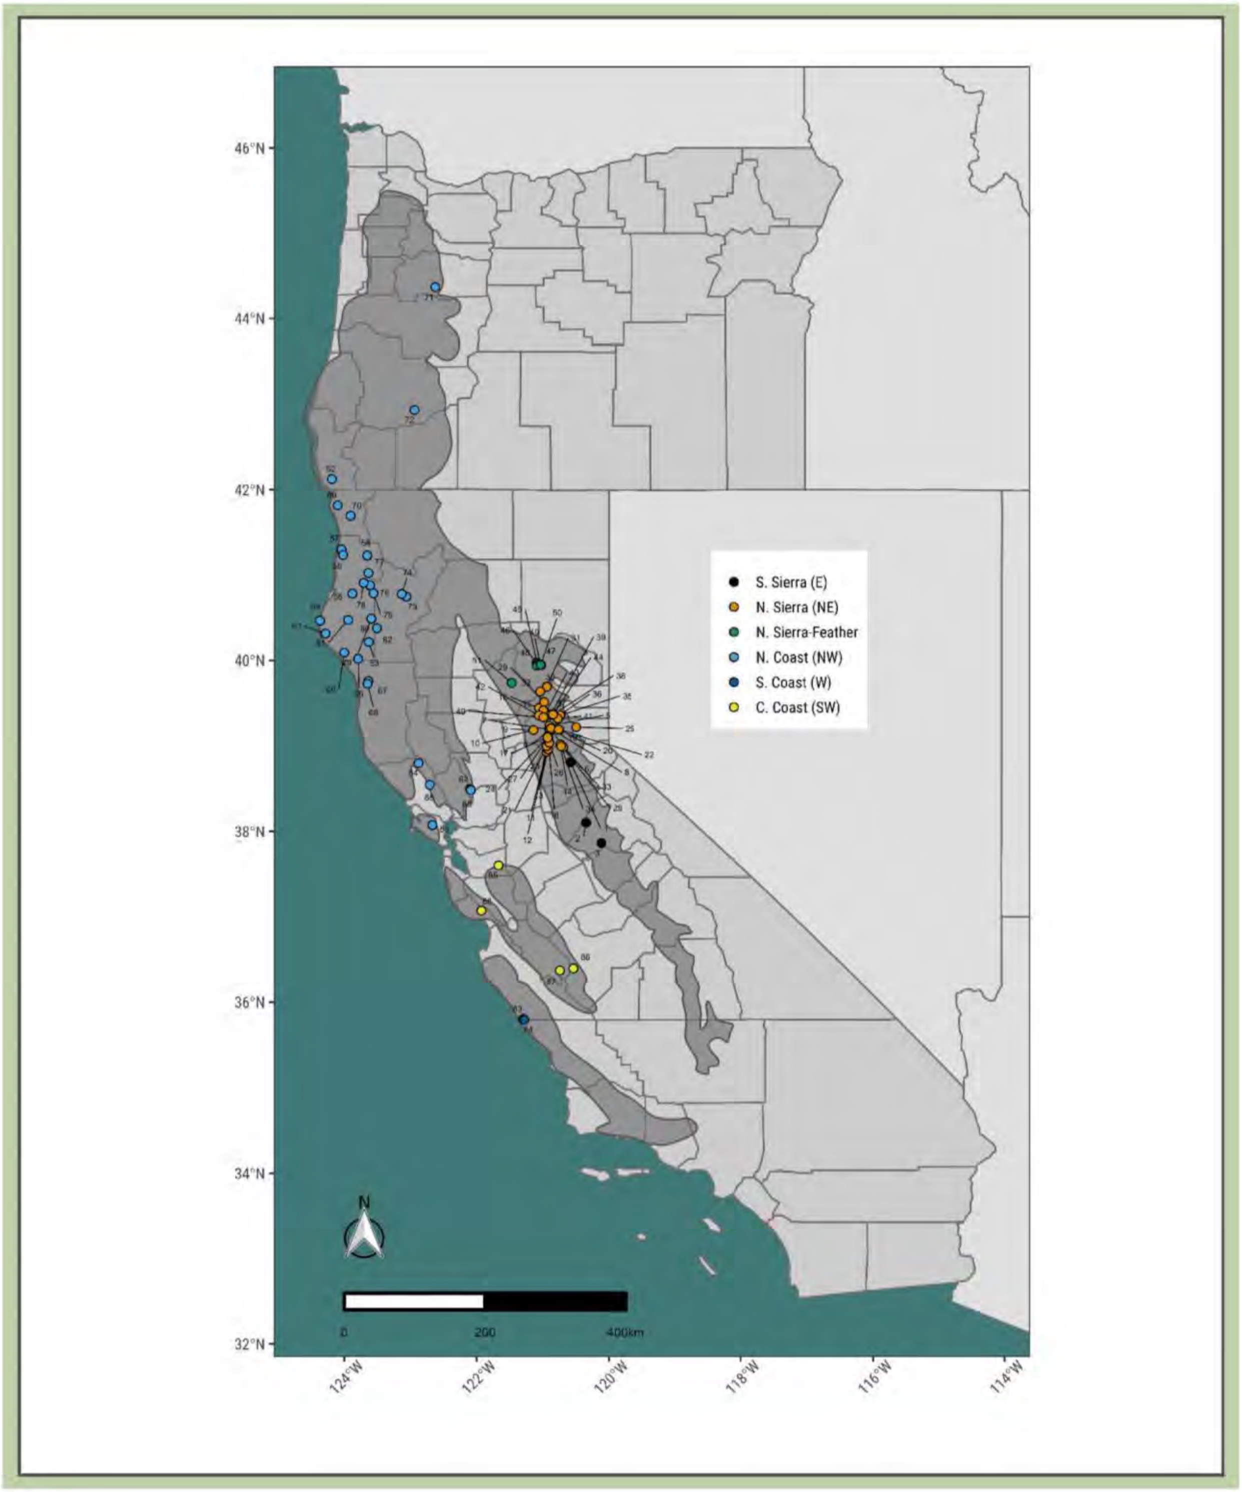

Figure 3. Foothill Yellow-legged Frog clades identified by Peek (2018) Dark gray polygon = presumed range and colored circles and numbers represent specific sampling sites and their clade assignments.

range (1,953 total combinations) and obtained values between 0 and 0.646, with the greatest divergence occurring between the South Coast and Southern Sierra clades (see Figure 3). The results of these two studies, which utilized independent sets of genes and tissues, are virtually identical in recognizing clades and their very high level of divergence (McCartney-Melstad et al. 2018, Peek 2018). These high genetic divergence values indicate that few to no genes have been exchanged between these clades for extended periods of evolutionary time, suggesting a long history of reproductive isolation from each other. These clades represent unique, largely non-overlapping, genetic lineages within the species that are important for the preservation of genetic variation within this wide-ranging species. Additional study may better delineate clade boundaries and suggest that they represent distinct species.

The geographic breaks among the five Foothill Yellow-legged Frog clades were similar between the studies; however, Peek (2018) identified a unique deeply divergent genetic clade in the Feather River watershed that is distinct from the rest of the northern Sierra Nevada clade. The five clades common to both studies include the following [Note: naming conventions follow McCartney-Melstad et al. (2018) and Peek (2018)]:

(1) Northwest/North Coast: north of San Francisco Bay in the Coast Ranges and east into Tehama County;

(2) Northeast/Northern Sierra: northern El Dorado County (North Fork American River watershed, includes Middle Fork American River) and north in the Sierra Nevada to southern Plumas County (Upper Yuba River watershed);

(3) East/Southern Sierra: El Dorado County (South Fork American River watershed) and south in the Sierra Nevada [no samples from Amador County were tested, but they would most likely fall within this clade because it is located between two other populations that occur within this clade];

(4) West/Central Coast: south of San Francisco Bay in the Coast Ranges to San Benito and Monterey counties, presumably east of the San Andreas Fault/Salinas Valley; and

(5) Southwest/South Coast presumably west of the San Andreas Fault/Salinas Valley in Monterey County and south in the Coast Ranges.

The Feather River clade is found primarily in Plumas and Butte counties (Peek 2018). Peek's analysis found that this clade is as distinct from the other Sierra Nevada clades as the Sierra Nevada populations are from all coastal clades, meaning it was found to be deeply divergent from the rest of the clades. McCartney-Melstad et al. (2018) also recognized the Feather River watershed as distinct from the rest of the northern Sierra but not as deeply divergent from the other clades as Peek. The Feather River watershed is also the only known location where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs co-occur and where three F1 hybrids (the offspring from a cross between parents of the two species) were found (Peek 2018, R. Peek pers. comm. 2019b). In addition, Peek's (2018) genetic data provided weak support for dividing the West/Central Coast and Southwest/South Coast groups into separate clades; however, his data set consisted of fewer samples from these localities than McCartney-Melstad et al. (2018).

Previous work conducted by Lind et al. (2011), using one nuclear and two mitochondrial genes, found a somewhat similar pattern, and their results suggested that hydrologic regions and river basins were important landscape features that influenced the genetic structure of Foothill Yellow-legged Frog populations. McCartney-Melstad et al. (2018), using a much larger genomic data set with thousands of genes rather than just three, also found evidence for divergence among river basins. However, they also found nearly twice the variation among the five phylogenetic clades than among drainage basins, indicating that other geological factors in addition to current riverine basins contributed to current population structure (Ibid.). They also report that the depth of genetic divergence among Foothill Yellow-legged Frog clades exceeds that of any frog or toad species for which similar data are available on earth and recommend treating them as key management units instead of the previously suggested watershed boundaries (Ibid.). Peek (2018) concurred and stated that the Foothill Yellow-legged Frog clades represented important units that should be carefully considered during planning and implementation of conservation actions.

Levels of genetic diversity within the clades differed significantly. Genetic diversity provides populations with the evolutionary capacity to adapt to changing conditions (i.e., evolve), and its loss often signals extreme population size reductions, which can result in genetic bottlenecks and inbreeding depression that can reduce survival and reproductive success (Lande and Shannon 1996, Hoffmann and Sgrò 2011, McCartney-Melstad et al. 2018). Loss of genetic diversity in Foothill Yellow-legged Frogs largely follows a north-to-south pattern, with the southern clades (Southwest/South Coast and East/Southern Sierra) particularly exhibiting the greatest loss of nucleotide diversity (McCartney-Melstad et al. 2018, Peek 2018). In addition, these study results demonstrate that Foothill Yellow-legged Frogs have lost genetic diversity over time across their entire range except for the large Northwest/North Coast clade, which appears to have undergone a relatively recent population expansion (McCartney-Melstad et al. 2018, Peek 2018).

At a watershed scale, Dever (2007) found that tributaries to rivers and streams are important for preserving genetic diversity, and populations separated by more than 6.2 mi show signs of genetic isolation. In other words, even in the absence of anthropogenic barriers to dispersal (e.g., dams and reservoirs), individuals located more than 6.2 mi are not typically considered part of a single interbreeding population (Olson and Davis 2009). Peek (2010, 2018) reported that at this finer-scale, population structure and genetic diversity appear to be more strongly influenced by river regulation type (i.e., dammed or undammed) than to geographic distance or watershed boundaries. In general, regulated (dammed) rivers had limited gene flow and higher genetic divergence among subpopulations compared with unregulated (undammed) rivers (Peek 2010, 2018). In addition, differences in hydrologic regimes within regulated rivers affected genetic connectivity and diversity (Peek 2010, 2018). Subpopulations in hydropeaking reaches, in which pulsed flows are used for electricity generation or whitewater boating, exhibited significantly lower gene flow and genetic diversity than those in bypass reaches where water is diverted from upstream in the basin down to power generating facilities (Figure 4; Peek 2018, R. Peek pers. comm. 2019b). River regulation had a greater influence on genetic

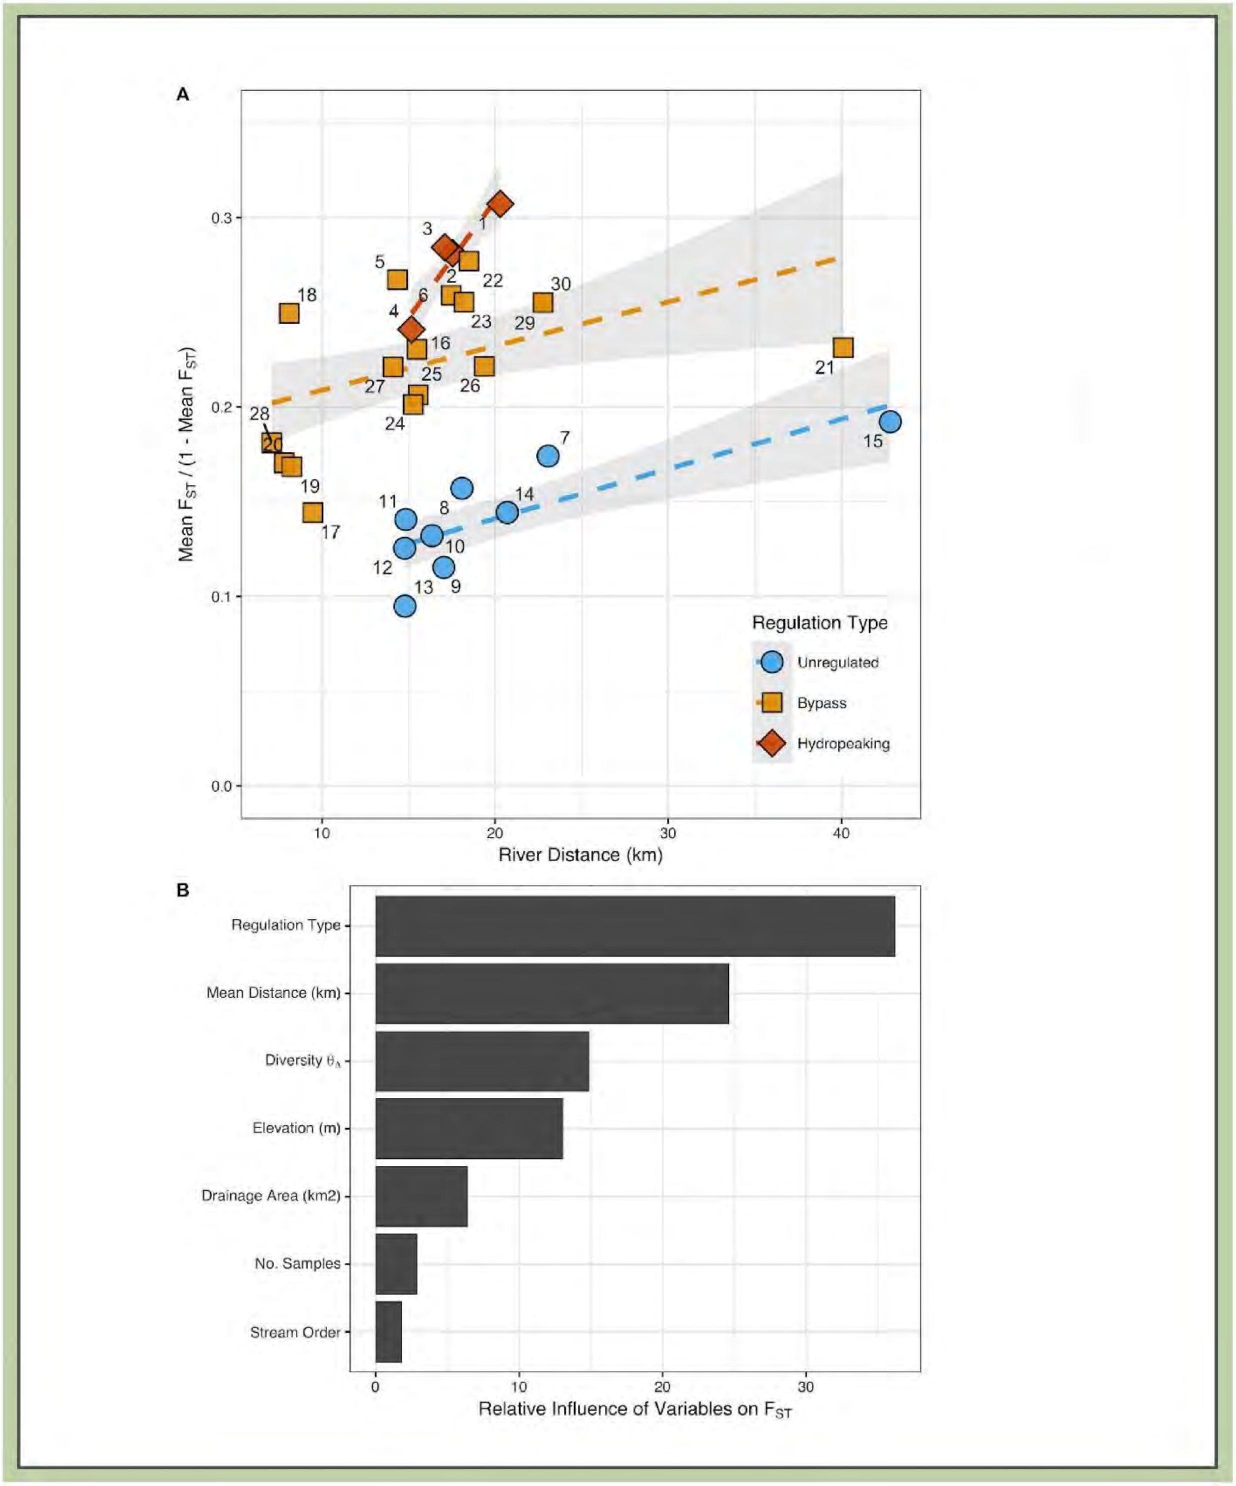

Figure 4. River regulation's relative influence on genetic differentiation from Peek (2018). A) Mean pairwise F_{ST} vs. mean river distance for each location (denoted by unique numbers); B) Relative influence of variables on F_{ST} from boosted regression tree models.

differentiation among sites than geographic distance in the Alameda Creek watershed as well (Stillwater Sciences 2012). Reduced connectivity among sites leads to lower gene flow and a loss of genetic diversity through genetic drift, which can diminish adaptability to changing environmental conditions (Palstra and Ruzzante 2008). Peek (2010) posits that given the *R. boylii* species group is estimated to be 8 million years old (Macey et al. 2001), the significant reductions in connectivity and genetic diversity over short evolutionary time periods in regulated rivers (often less than 50 years from the time of dam construction) is cause for concern with respect to population viability and persistence, particularly when combined with small population sizes.

2.5 Habitat Associations and Use

> *"These frogs are so closely restricted to streams that it is unusual to find one at a greater distance from the water than it could cover in one or two leaps."* – Richard G. Zweifel, 1955

Foothill Yellow-legged Frogs inhabit rivers and streams ranging from primarily rain-fed (coastal populations) to primarily snow-influenced (most Sierra Nevada and Klamath-Cascade populations) from headwater streams to large rivers (Bury and Sisk 1997, Wheeler et al. 2014). Occupied rivers and streams flow through a variety of vegetation types including hardwood, conifer, and valley-foothill riparian forests; mixed chaparral; and wet meadows (Hayes et al. 2016). Because the species is so widespread and can be found in so many types of habitats, the vegetation community is likely less important in determining Foothill Yellow-legged Frog occupancy and abundance than the aquatic biotic and abiotic conditions in the specific river, stream, or reach (Zweifel 1955). The species is an obligate stream-breeder, which sets it apart from other western North American ranids (Wheeler et al. 2014). Foothill Yellow-legged Frog habitat is generally characterized as partly-shaded, shallow, perennial rivers and streams with a low gradient and rocky substrate that is at least cobble-sized (Zweifel 1955, Hayes and Jennings 1988). However, the use of intermittent and ephemeral streams by post-metamorphic Foothill Yellow-legged Frogs may not be all that uncommon in some parts of the species' range in California (R. Bourque pers. comm. 2019). The species has been reported from some atypical habitats as well, including small impoundments, isolated pools in intermittent streams, and meadows along the edge of streams that lack a rocky substrate (Fitch 1938, Zweifel 1955, CDFW 2018a, Wilcox and Alvarez 2019). In addition, Wilcox and Alvarez (2019) described observations of Foothill Yellow-legged Frogs climbing a vertical, but undulating, dam wall covered in algae, suggesting that landscape features like steep, slick rock slopes may not preclude movement.

As stream-breeding poikilotherms (animals whose internal temperature varies with ambient temperature), appropriate flow velocity, temperature, and water availability are critically important to Foothill Yellow-legged Frogs (Kupferberg 1996a, Van Wagner 1996, Wheeler et al. 2006, Lind et al. 2016, Bedwell 2018). Habitat quality is also influenced by hydrologic regime (regulated vs. unregulated), substrate, presence of non-native predators and competitors, water depth, and availability of high-quality food and basking sites (Lind et al. 1996, Yarnell 2005, Wheeler et al. 2006, Catenazzi and Kupferberg 2017). Habitat suitability and use vary by life stage, sex, geographic location, watershed size, and season and can generally be categorized as breeding and rearing habitat, nonbreeding season habitat, and overwintering habitat (Van Wagner 1996, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011, Hayes et al. 2016, Catenazzi and Kupferberg 2017). Yarnell (2005) located higher densities of Foothill Yellow-legged Frogs in areas with greater habitat heterogeneity and suggested that they were selecting sites that possessed the diversity of habitats necessary to support each life stage within a relatively short distance.

2.5.1 Breeding and Rearing Habitat

Suitable breeding habitat must be connected to suitable rearing habitat for metamorphosis to be successful. When this connectivity exists, as flows decline through the season, tadpoles can follow the receding shoreline into areas of high productivity and lower predation risk as opposed to becoming trapped in isolated pools with a high risk of overheating, desiccation, and predation (Kupferberg et al. 2009c).

Several studies on Foothill Yellow-legged Frog breeding habitat, carried out across the species' range in California, reported similar findings. Foothill Yellow-legged Frogs select oviposition (egg-laying) sites within a narrow range of depths, velocities, and substrates and exhibit fidelity to breeding sites that consistently possess suitable microhabitat characteristics over time (Kupferberg 1996a, Bondi et al. 2013, Lind et al. 2016). At a coarse-spatial scale, breeding sites in rivers and large streams are often located near the confluence of tributary streams in sunny, wide, shallow reaches (Kupferberg 1996a, Yarnell 2005, GANDA 2008, Peek 2010). These areas are highly productive compared to cooler, deeper, closed-canopy sites (Catenazzi and Kupferberg 2013). At a fine spatial scale, females prefer to lay eggs in low velocity areas dominated by cobble- and boulder-sized substrates, often associated with sparsely-vegetated point bars (Kupferberg 1996a, Lind et al. 1996, Van Wagner 1996, Bondi et al. 2013, Lind et al. 2016). They tend to select areas with less variable, more stable flows, and in areas with higher flows at the time of oviposition, they place their eggs on the downstream side of large cobblestones and boulders, which protects them from being washed away (Kupferberg 1996a, Wheeler et al. 2006).

Appropriate rearing temperatures are vital for successful metamorphosis. Tadpoles grow faster and larger in warmer water to a point (Zweifel 1955; Catenazzi and Kupferberg 2017,2018). Zweifel (1955) conducted experiments on embryonic thermal tolerance and determined that the critical low was approximately 43°F, and the critical high was around 79°F. Welsh and Hodgson (2011) determined that best the single variable for predicting Foothill Yellow-legged Frog presence was temperature since none were observed below 55°F, but numbers increased significantly with increasing temperature. Catenazzi and Kupferberg (2013) measured tadpole thermal preference at 61.7-72.0°F, and the distribution of Foothill Yellow-legged Frog populations across a watershed was consistent within this temperature range. When the daily average temperatures during the warmest month of the year were below 61°F, tadpoles were absent under closed canopy and scarce even with an open canopy (Ibid.). Catenazzi and Kupferberg (2017) found regional differences in apparently suitable breeding temperatures. Inland populations from primarily snowmelt-fed systems with relatively cold water were relegated to reaches that are warmer on average during the warmest 30 days of the year than coastal populations in the chiefly rainfall-fed, and thus warmer, systems (63.7-75.6°F vs. 60.3-71.6°F, respectively). However, experiments on tadpole thermal preference demonstrated that individuals from different source populations selected similar rearing temperatures, which presumably optimized development (Ibid.). In regulated systems, where water released from dams is often colder than normal, suitable rearing temperatures downstream may be limited (Wheeler et al. 2014, Catenazzi and Kupferberg 2017).

Appropriate flow velocities are also critical for survival to metamorphosis. The velocity at which Foothill Yellow-legged Frog egg masses shear away from the substrate they are adhered to varies according to factors such as depth and degree to which the eggs are sheltered (Spring Rivers Ecological Sciences 2003). This critical velocity is expected to decrease as the egg mass ages due to the reduced structural integrity of the protective jelly envelopes (Hayes et al. 2016). Short duration increases in flow velocity may be tolerated if the egg masses are somewhat protected, but sustained high velocities increase the likelihood of detachment (Kupferberg 1996a, Spring Rivers Ecological Sciences 2003). Hatchlings and tadpoles about to undergo metamorphosis are relatively poor swimmers and require especially slow, stable flows during these stages of development (Kupferberg et al. 2011b). Tadpoles respond to increasing flows by swimming against the current to maintain position for a short period of time and eventually swimming to the bottom and seeking refuge in the rocky substrate's interstitial spaces (Ibid.). When tadpoles are exposed to repeated increases in velocities, their growth and development are delayed (Ibid.). Under experimental conditions, the critical velocity at which tadpoles were swept downstream ranged between 0.66-1.31 ft/s; however, as they reach metamorphosis it decreases to as low as 0.33 ft/s (Ibid.).

2.5.2 Nonbreeding Season Habitat

Post-metamorphic Foothill Yellow-legged Frogs utilize a more diverse range of habitats and are much more dispersed during the nonbreeding season than the breeding season. Microhabitat preferences appear to vary by location and season, but some patterns are common across the species' range. Foothill Yellow-legged Frogs tend to remain close to the water's edge (average <10 ft); select sunny areas with limited canopy cover; and are often associated with riffles and pools (Zweifel 1955, Hayes and Jennings 1988, Van Wagner 1996, Welsh et al. 2005, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011). Adequate water, food resources, cover from predators, ability to thermoregulate (e.g., presence of basking sites and cool refugia), and absence of non-native predators are important components of nonbreeding season habitat (Hayes and Jennings 1988, Van Wagner 1996, Catenazzi and Kupferberg 2013).

2.5.3 Overwintering Habitat

Overwintering habitat varies depending on local conditions, but as with the rest of the year, Foothill Yellow-legged Frogs are most often found in or near water where they can forage and take cover from predators and high discharge events (Storer 1925, Zweifel 1955). In larger streams and rivers, Foothill Yellow-legged Frogs are often found along tributaries during the winter where the risk of being displaced by heavy flows is reduced (Kupferberg 1996a, Gonsolin 2010). Bourque (2008) found 36.4% of adult females used intermittent and ephemeral tributaries during the overwintering season. Van Wagner (1996) located most overwintering Foothill Yellow-legged Frogs using pools with cover such as boulders, root wads, and woody debris. During high flow events, they moved to the stream's edge and took cover under vegetation like sedges (*Carex* sp.) or leaf litter (Ibid.). Rombough (2006) found most

Foothill Yellow-legged Frogs under woody debris along the high waterline and often using seeps along the stream-edge, which provided them with moisture, a thermally stable environment, and prey.

Exceptions to the pattern of remaining near the stream's edge during winter have been reported. Cook et al. (2012) observed dozens of juvenile Foothill Yellow-legged Frogs traveling over land, as opposed to using riparian corridors. They were found using upland habitats with an average distance of 234 ft from water (range: 52-1,086 ft) (Ibid.). In another example, a single subadult that was found adjacent to a large wetland complex 2,723 ft straight-line distance from the wetted edge of the Van Duzen River, although it is possible the wetland was connected to the river via a spillway or drainage that may have served as the movement corridor (CDFW 2018a, R. Bourque pers. comm. 2019).

2.5.4 Seasonal Activity and Movements

Because Foothill Yellow-legged Frogs occupy areas with relatively mild winter temperatures, they can be active year-round, although at low temperatures (<44°F), they become lethargic (Storer 1925, Zweifel 1955, Van Wagner 1996, Bourque 2008). They are active both day and night, and during the day adults are often observed basking on warm objects such as sun-heated rocks, although this is also when their detectability is highest (Fellers 2005, Wheeler et al. 2005). For example, Gonsolin (2010) located radio-telemetered Foothill Yellow-legged Frogs under substrate a third of the time and underwater a quarter of the time, but nearly all his detections of frogs without transmitters were basking.

Adult Foothill Yellow-legged Frogs migrate from their overwintering sites to breeding habitat in the spring, often from a tributary to its confluence with a larger stream or river. In areas where tributaries dry down, juveniles also make this downstream movement (Haggarty 2006). When the tributary itself is perennial and provides suitable breeding habitat, the frogs may not undertake these long-distance movements (Gonsolin 2010). Cues for adults to initiate this migration to breeding sites are somewhat enigmatic and vary by location, elevation, and amount of precipitation (S. Kupferberg and A. Lind pers. comm. 2017). They can include day length, water temperature, and sex (GANDA 2008, Gonsolin 2010, Yarnell et al. 2010, Wheeler et al. 2018). Males initiate movements to breeding sites where they congregate in leks (areas of aggregation for courtship displays), and females arrive later and over a longer period (Wheeler and Welsh 2008, Gonsolin 2010). Most males utilize breeding sites associated with their overwintering tributaries, but some move substantial distances to other sites and may use more than one breeding site in the same season (Wheeler et al. 2006, GANDA 2008).

While the predictable hydrograph in California consists of wet winters with high spring flows and dry summers with low flows, the timing and quantity of seasonal discharge can vary significantly from year to year. The timing of oviposition can influence offspring growth and survival. Early breeders risk scouring of egg masses from their substrate by late spring storms in wet years or desiccation if waters recede rapidly, but when they successfully hatch, tadpoles benefit from a longer growing season, which can enable them to metamorphose at a larger size and increase their likelihood of survival (Railsback et al. 2016). Later breeders are less likely to have their eggs scoured away or desiccated because flows are generally more stable, but they have fewer mate choices, and their tadpoles have a shorter growing period before metamorphosis, reducing their chance of survival (Ibid.). Some evidence indicates larger females, who coincidentally lay larger clutches, breed earlier (Kupferberg et al. 2009c, Gonsolin 2010). Consequently, early season scouring or stranding of egg masses or tadpoles can disproportionately impact the population's reproductive output because later breeders produce fewer and smaller eggs per clutch (Kupferberg et al. 2009c, Gonsolin 2010).

Timing of oviposition is often a function of water temperature and flow, but it consistently occurs on the descending limb of the hydrograph, which is the period of time when high spring discharge gradually recedes toward low summer base flow (Kupferberg 1996a, GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010, Yarnell et al. 2010, Yarnell et al. 2013). Under natural conditions, the timing coincides with intermittent tributaries drying down and increases in algal blooms that provide forage for tadpoles (Haggarty 2006, Power et al. 2008). Even in regulated systems, hydrodynamic modeling indicated that managing for flow recessions with down-ramping rates similar to those observed in unregulated systems (less than 10% per day) provided the most diverse hydraulic habitat for an appropriate duration in spring to support native species and maximize aquatic biodiversity (Yarnell et al. 2013). At lower elevations, breeding can start in late March or early April, and at mid-elevations, breeding typically occurs in mid-May to mid-June (Gonsolin 2010, S. Kupferberg and A. Lind pers. comm. 2017). The time of year a population initiates breeding can vary by as much as two months among water years, occurring later at deeper sites when colder water becomes warmer (Wheeler et al. 2018, R. Peek pers. comm. 2019a). In wetter years, delayed breeding into early July can occur in some colder snowmelt systems (Yarnell et al. 2013, GANDA 2018).

A population's period of oviposition can also vary from two weeks to three months, meaning they could be considered explosive breeders at some sites and prolonged breeders at others (Storer 1925, Zweifel 1955, Van Wagner 1996, Ashton et al. 1997, Wheeler and Welsh 2008). Water temperature typically warms to over 50°F before breeding commences (GANDA 2008, Gonsolin 2010, Wheeler et al. 2018). Wheeler and Welsh (2008) observed Foothill Yellow-legged Frogs breeding when flows were below 02 ft/s, pausing during increased flows until they receded, and GANDA (2008) reported breeding initiated when flow decreased to less than 55% above base flow.

Male Foothill Yellow-legged Frogs spend more time at breeding sites during the season than females, many of whom leave immediately after laying their eggs (GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010). Daily movements are usually short (<1 ft), but some individuals travel substantial distances: median 232 ft/day in spring and 104 ft/day in fall/winter, nearly always using streams as movement corridors (Van Wagner 1996, Bourque 2008, Gonsolin 2010). The maximum reported movement rate is 0.86 mi/day, and the longest seasonal (post-breeding) daily distance reported is 4.37 mi by a female that traveled up a dry tributary and over a ridge before returning to and moving up the mainstem creek (Bourque 2008). Movements during the non-breeding season are typically in response to drying channels or during rain events (Bourque 2008, Gonsolin 2010, Cook et al. 2012).

Hatchling Foothill Yellow-legged Frogs tend to remain with what is left of the egg mass for several days before dispersing into the interstitial spaces in the substrate (Ashton et al. 1997). They often move downstream in areas of moderate flow and will follow the location of warm water in the channel throughout the day (Brattstrom 1962, Ashton et al. 1997, Kupferberg et al. 2011a). Tadpoles usually

metamorphose in late August or early September (S. Kupferberg and A. Lind pers. comm. 2017). Twitty et al. (1967) reported that newly metamorphosed Foothill Yellow-legged Frogs mostly migrated upstream, which may be an evolutionary mechanism to return to their natal site after being washed downstream (Ashton et al. 1997).

2.5.5 Home Range and Territoriality

Foothill Yellow-legged Frogs exhibit a lek-type mating system in which males aggregate at the breeding site and establish calling territories (Wheeler and Welsh 2008, Bondi et al. 2013). The species has a relatively large calling repertoire for western North American ranids with seven unique vocalizations recorded (Silver 2017). Some of these can be reasonably attributed to territory defense and mate attraction communications (MacTeague and Northen 1993, Silver 2017). Physical aggression among males during the breeding season has been reported (Rombough and Hayes 2007, Wheeler and Welsh 2008, Wilcox and Alvarez 2019). In addition, Wheeler and Welsh (2008) observed a non-random mating pattern in which males engaged in amplexus with females were larger than males never seen in amplexus, suggesting either physical competition or female preference for larger individuals. Very little information has been published on Foothill Yellow-legged Frog home range size. Wheeler and Welsh (2008) studied males during a 17-day period during breeding season and classified some of them as "site faithful" based on their movements and calculated their home ranges. Two-thirds of males tracked were site faithful, and their mean home range size was 6.24 ft^2 (SE = 1.08 ft^2) (Ibid.). In contrast, perhaps because the study took place over a longer time period, Bourque (2008) reported approximately half of the males he tracked during the spring were mobile, and the other half were sedentary. The median distances traveled along the creek (a proxy for home range size since they rarely leave the riparian corridor) for mobile and sedentary males were 489 ft and 18 ft, respectively.

2.6 Diet and Predators

Foothill Yellow-legged Frog diet varies by life stage and likely body size. Tadpoles graze on periphyton (algae growing on submerged surfaces) scraped from rocks and vegetation and grow faster, and to a larger size, when it contains a greater proportion of epiphytic diatoms with nitrogen-fixing endosymbionts (*Epithemia* spp.), which are high in protein and fat (Kupferberg 1997b, Fellers 2005, Hayes et al. 2016, Catenazzi and Kupferberg 2017). Tadpoles may also forage on necrotic tissue from dead bivalves and other tadpoles, or more likely the algae growing on them (Ashton et al. 1997, Hayes et al. 2016). Post-metamorphic Foothill Yellow-legged Frogs primarily feed on a wide variety of terrestrial arthropods but also some aquatic invertebrates (Fitch 1936, Van Wagner 1996, Haggarty 2006). Most of their diet consists of insects and arachnids (Van Wagner 1996, Haggarty 2006, Hothem et al. 2009). Haggarty (2006) did not identify any preferred taxonomic groups, but she noted larger Foothill Yellow-legged Frogs consumed a greater proportion of large prey items compared to smaller individuals, suggesting the species may be gape-limited generalist predators. Hothem et al. (2009) found mammal hair and bones in a Foothill Yellow-legged Frog stomach. Adult Foothill Yellow-legged Frogs, like many other ranids, also cannibalize conspecifics (Wiseman and Bettaso 2007). In the fall when young-of-year are abundant, they may provide an important source of nutrition for adults prior to overwintering (Ibid.).

Foothill Yellow-legged Frogs are preyed upon by several native and introduced species, including each other as described above. Some predators target specific life stages, while others may consume multiple stages. Several species of gartersnakes (genus *Thamnophis*) are the primary and most widespread group of native predators on Foothill Yellow-legged Frog tadpoles through adults (Fitch 1941, Fox 1952, Zweifel 1955, Lind and Welsh 1994, Ashton et al. 1997, Wiseman and Bettaso 2007, Gonsolin 2010). Table 1 lists other known and suspected predators of Foothill Yellow-legged Frogs.

3.0 STATUS AND TRENDS IN CALIFORNIA

3.1 Administrative Status

3.1.1 Sensitive Species

The Foothill Yellow-legged Frog is listed as a Sensitive Species by the U.S. Bureau of Land Management (BLM) and USDA Forest Service (Forest Service). These agencies define Sensitive Species as those species that require special management consideration to promote their conservation and reduce the likelihood and need for future listing under the ESA.

3.1.2 California Species of Special Concern

The Department's Species of Special Concern (SSC) designation is similar to the federal Sensitive Species designation. It is administrative, rather than regulatory in nature, and intended to focus attention on animals at conservation risk. The designation is used to stimulate needed research on poorly known species and to target the conservation and recovery of these animals before they meet the CESA criteria for listing as threatened or endangered (Thomson et al. 2016). The Foothill Yellow-legged Frog is listed as a Priority 1 (highest risk) SSC (Ibid.).

3.2 Trends in Distribution and Abundance

3.2.1 Range-wide in California

Range is the general geographical area in which an organism occurs. For purposes of CESA and this Status Review, the range is the species' California range (*Cal. Forestry Assn. v. Cal. Fish and Game Com.* (2007) 156 Cal.App.4th 1535, 1551). Historical documentation of Foothill Yellow-legged Frog distribution and abundance is somewhat haphazard. However, systematic range-wide assessments of Foothill Yellow-legged Frog distribution were conducted relatively recently. Estimates of relative abundance or population trends are less common at both local and range-wide scales. This makes assessing trends in distribution and abundance difficult despite a relatively large number of observations compared to many other species tracked by the California Natural Diversity Database (CNDDB). A detailed account of what has been documented within the National Parks and National Forests in California can be found in Appendix 3 of the *Foothill Yellow-legged Frogs Conservation Assessment in California* (Hayes et al. 2016). The CNDDB contained 2,411 Foothill Yellow-legged Frog occurrences in its August 2019 edition, at least 529 (22%) of which were observed in 2014 or more recently.

Table 1. Confirmed and potential Foothill Yellow-legged Frog predators in California in addition to gartersnakes (*Thamnophis* spp.)

Common Name	Scientific Name	Classification	Native	Prey Life Stage(s)	Sources
Caddisfly (larva)	*Dicosmoecus gilvipes*	Insect	Yes	Embryos (eggs)	Rombough and Hayes 2005
Dragonfly (nymph)	*Aeshna walker*	Insect	Yes	Larvae	Catenazzi and Kupferberg 2018
Waterscorpion	*Ranatra brevicollis*	Insect	Yes	Larvae	Catenaazi and Kupferberg 2018
Signal Crayfish	*Pacifastacus leniusculus*	Crustacean	No	Embryos (eggs) and Larvae	Rombough and Hayes 2005; Wiseman et al. 2005
Speckled Dace	*Rhinichthys osculus*	Fish	Yes	Larvae	Rombough and Hayes 2005
Reticulate Sculpin	*Cottus perplexus*	Fish	Yes	Larvae	Rombough and Hayes 2005
Sacramento Pikeminnow	*Ptychocheilus grandis*	Fish	Yes*	Embryos (eggs) to Adults	Corum 2003; Ashton and Nakamoto 2007
Sunfishes	Family Centrachidae	Fish	No	Larvae	Moyle 1973; Hayes and Jennings 1986
Catfishes	Family Ictaluridae	Fish	No	Larvae	Moyle 1973; Hayes and Jennings 1986
Rough-skinned Newt	*Taricha granulosa*	Amphibian	Yes	Embryos (eggs)	Evenden 1948
California Giant Salamander	*Dicamptodon ensatus*	Amphibian	Yes	Larvae	Fidenci 2006
American Bullfrog	*Rana catesbeiana*	Amphibian	No	Larvae to Adults	Crayon 1998; Hothem et al. 2009
California Red-legged Frog	*Rana draytonii*	Amphibian	Yes	Larvae to Adults	Gonsolin 2010
American Robin	*Turdus migratorius*	Bird	Yes	Larvae	Gonsolin 2010
Common Merganser	*Mergus merganser*	Bird	Yes	Larvae	Gonsolin 2010
American Dipper	*Cinclus mexicanus*	Bird	Yes	Larvae	Ashton et al. 1997
Mallard	*Anas platyrhynchos*	Bird	Yes	Adults	Rombough et al. 2005
Raccoon	*Procyon lotor*	Mammal	Yes	Larvae to Adults	Zweifel 1955; Ashton et al. 1997
River Otter	*Lontra canadensis*	Mammal	Yes	Larvae to Adults	S. Kupferberg pers. comm. 2019; T. Rose pers. comm. 2014

* Introduced to the Eel River, location of documented predation; Foothill Yellow-legged Frogs are extirpated from most areas of historical range overlap

A few wide-ranging historical survey efforts that included Foothill Yellow-legged Frogs exist. Reports from early naturalists suggest Foothill Yellow-legged Frogs were relatively common in the Coast Ranges as far south as central Monterey County, in eastern Tehama County, and in the foothills in and near Yosemite National Park (Grinnell and Storer 1924, Storer 1925, Grinnell et al. 1930, Martin 1940). In addition to these areas, relatively large numbers of Foothill Yellow-legged Frogs (17-35 individuals) were collected at sites in the central and southern Sierra Nevada and the San Gabriel Mountains between 1911 and 1950 (Hayes et al. 2016). Widespread disappearances of Foothill Yellow-legged Frog populations were documented as early as the 1970s and 80s in southern California, the southern Coast Range, and the central and southern Sierra Nevada foothills (Moyle 1973, Sweet 1983).

Twenty-five years ago, the Department published the first edition of *Amphibians and Reptile Species of Special Concern in California* (Jennings and Hayes 1994). The authors revisited hundreds of localities between 1988 and 1991 that had historically been occupied by Foothill Yellow-legged Frogs and consulted local experts to determine presumed extant or extirpated status. Based on these survey results and stressors observed on the landscape, they considered Foothill Yellow-legged Frogs endangered in central and southern California south of the Salinas River in Monterey County. They considered the species threatened in the west slope drainages of the Cascade Mountains and Sierra Nevada east of the Central Valley, and they considered the remainder of the range to be of special concern (Ibid.).

Fellers (2005) and his field crews conducted surveys for Foothill Yellow-legged Frogs throughout California. They visited 804 sites across 40 counties with suitable habitat within the species' historical range. They detected at least one individual at 213 sites (26.5% of those surveyed) over 28 counties. They located Foothill Yellow-legged Frogs in approximately 40% of streams in the North Coast, 30% in the Cascade Mountains and south of San Francisco in the Coast Range, and 12% in the Sierra Nevada. Fellers estimated population abundance was 20 or more adults at only 14% of the sites where the species was found and noted the largest and most robust populations occurred along the North Coast. In addition, to determine status of Foothill Yellow-legged Frogs across the species' range and potential causes for declines between 2000 and 2002, Lind (2005) used previously published status accounts, species expert and local biologist professional opinions, and field visits to historically occupied sites. She determined that Foothill Yellow-legged Frogs had disappeared from 201 of 394 of the sites, representing just over 50%. The coarse-scale trend of Foothill Yellow-legged Frog populations in California is one of greater declines and extirpations in lower elevations and latitudes (Davidson et al. 2002).

Few site-specific population trend data are available from which to evaluate status. However, some long-term monitoring efforts have used egg mass counts as a proxy to estimate adult breeding female abundance. The results of these studies revealed extreme interannual variability in number of egg masses laid (Ashton et al. 2010, S. Kupferberg and M. Power pers. comm. 2015, Peek and Kupferberg 2016). In a meta-analysis of egg mass count data collected across the species' range in California over the past 25 years, Peek and Kupferberg (2016) reported declines in two unregulated rivers and an increase in another. Their models did not detect any significant trends in abundance across different locations or regulation type (dammed or undammed); however, high interannual variability can render trend detection difficult. Interannual variability was substantially greater in regulated rivers vs.

unregulated; the median coefficients of variation were 66.9% and 41.6%, respectively (Ibid.). The greater variability in regulated rivers decreases the probability of identifying significant declines, and coupled with low abundance, it can lead to populations dropping below a density necessary for persistence undetected, resulting in extirpation.

Regional differences in Foothill Yellow-legged Frog persistence across its range have been recognized for nearly 50 years (i.e., more extirpations documented in the south than other parts of the range). Because of these differences and the recent availability of new landscape genomic data, more detailed descriptions of trends in Foothill Yellow-legged Frog population distribution and abundance in California are evaluated by clade below. Figure 5 depicts Foothill Yellow-legged Frog localities across all clades in California by the most recent confirmed sighting in the datasets available to the Department within a Public Land Survey System (PLSS) section. "Transition Zones" are those areas where the exact clade boundaries are unknown due to a lack of samples. In addition, while not depicted as an area of uncertainty, no genetic samples have been evaluated from south of the extant population in northern San Luis Obispo County, in the Sutter Buttes in Sutter County, or northeastern Plumas County. It is possible there were historically more clades than is currently understood. For management purposes and the Department's listing recommendation using the best available science, clade boundaries were delineated along commonly recognized geographic features like county lines, watershed subbasin (HU8) boundaries, and anthropogenic linear features that coincide as closely as possible with what is known about Foothill Yellow-legged Frog genetic population structure (Figure 6).

Caution should be exercised in comparing the following observation data across the species' range and across time since survey effort and reporting are not standardized. These data can be useful for making some general inferences about distribution, abundance, and trends. For instance, the species was present at a location at least as recently as the date of the record, assuming the species was correctly identified. However, this only works in the affirmative. For example, at a site where the last time the species was seen was 75 years ago, the species may continue to persist there if no one surveyed it adequately since the original observation. CNDDB staff use information on land use conversion, subsequent survey results, and biological reports to categorize an occurrence location as "extirpated" or "possibly extirpated".

3.2.2 Northwest/North Coast Clade

The current known range of Northwest/North Coast clade extends from north of San Francisco Bay through the Coast Range and Klamath Mountains to the northern limit of the Foothill Yellow-legged Frog's range and east through the Cascade Range. For management purposes and the Department's listing recommendation, and based on the best available science, the boundaries of the Northwest/North Coast clade include the following whole counties: Colusa, Del Norte, Glenn, Humboldt, Lake, Marin, Mendocino, Napa, Shasta, Solano, Sonoma, Tehama, Trinity, and Yolo. Portions of Butte, Lassen, Modoc, and Siskiyou counties are also included in this clade and are delineated by the following watershed subbasins: Applegate, Big-Chico Creek-Sacramento, Lower Klamath, Lower Pit, McCloud, Sacramento Headwaters, Salmon, Scott, Shasta, and Upper Klamath (Figure 6). This clade covers the largest geographic area and contains the greatest amount of genetic diversity

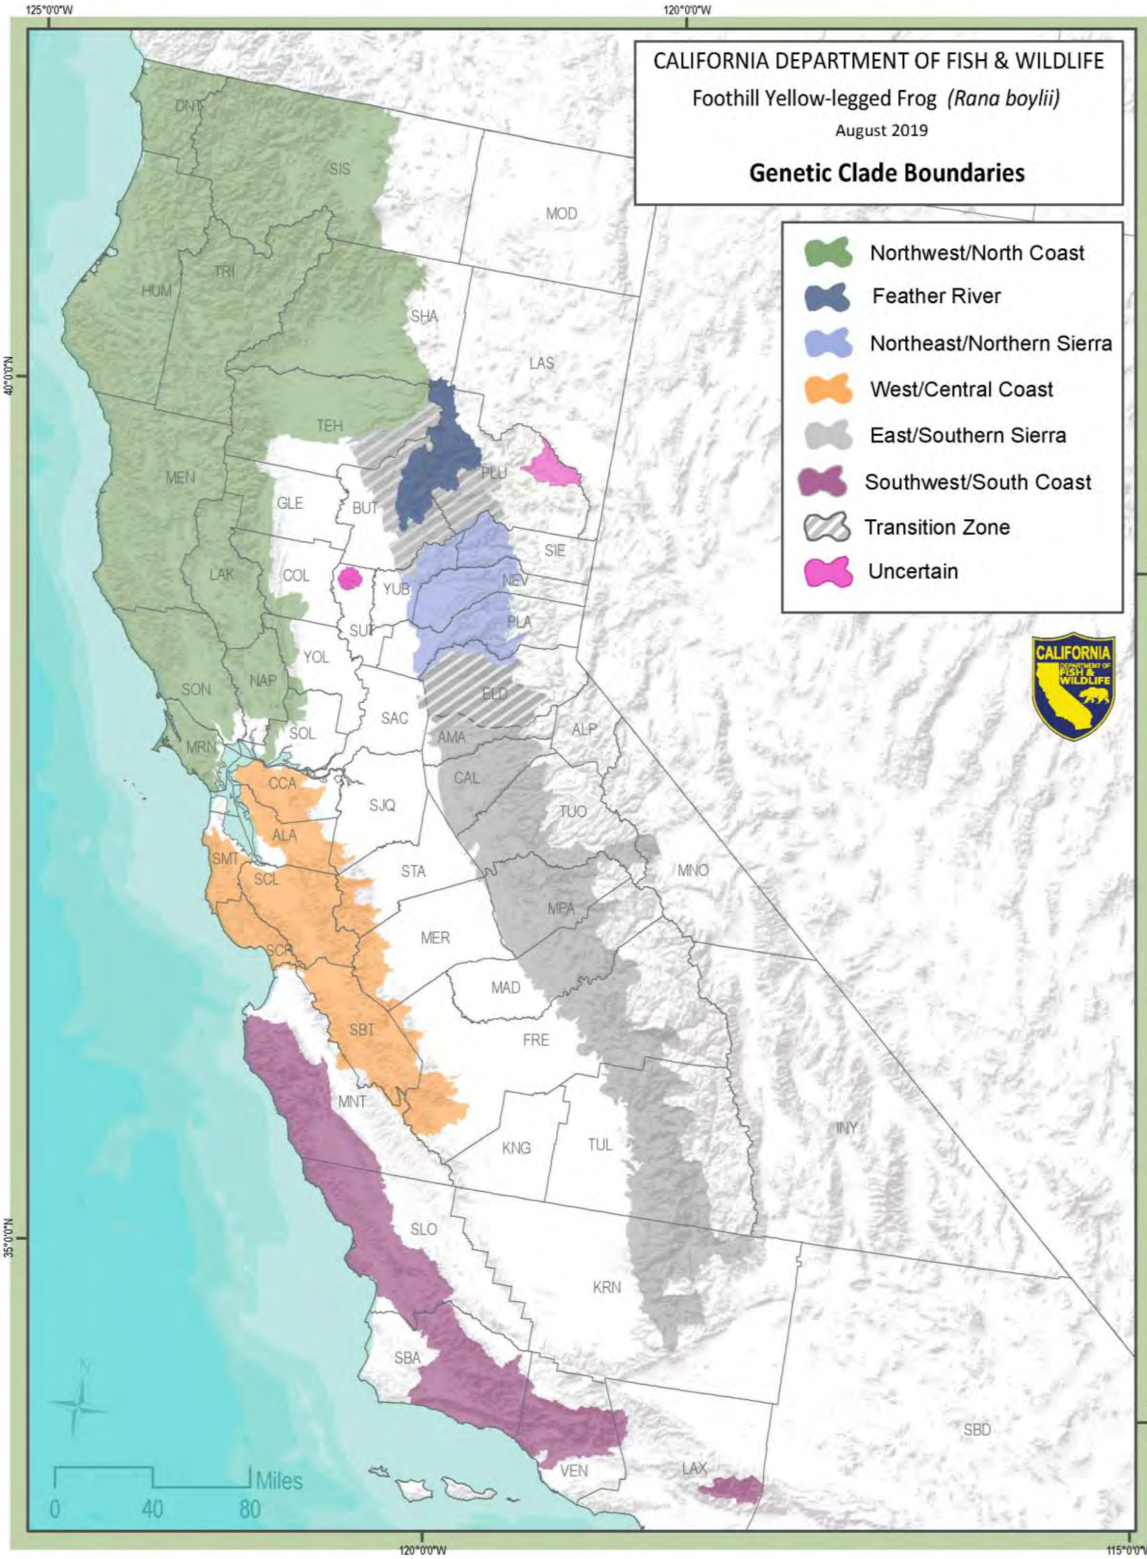

Figure 5. California Foothill Yellow-legged Frog occurrences from 1889-2019 overlaying the species' range and clade boundaries by most recent sighting in a Public Land Survey System section (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

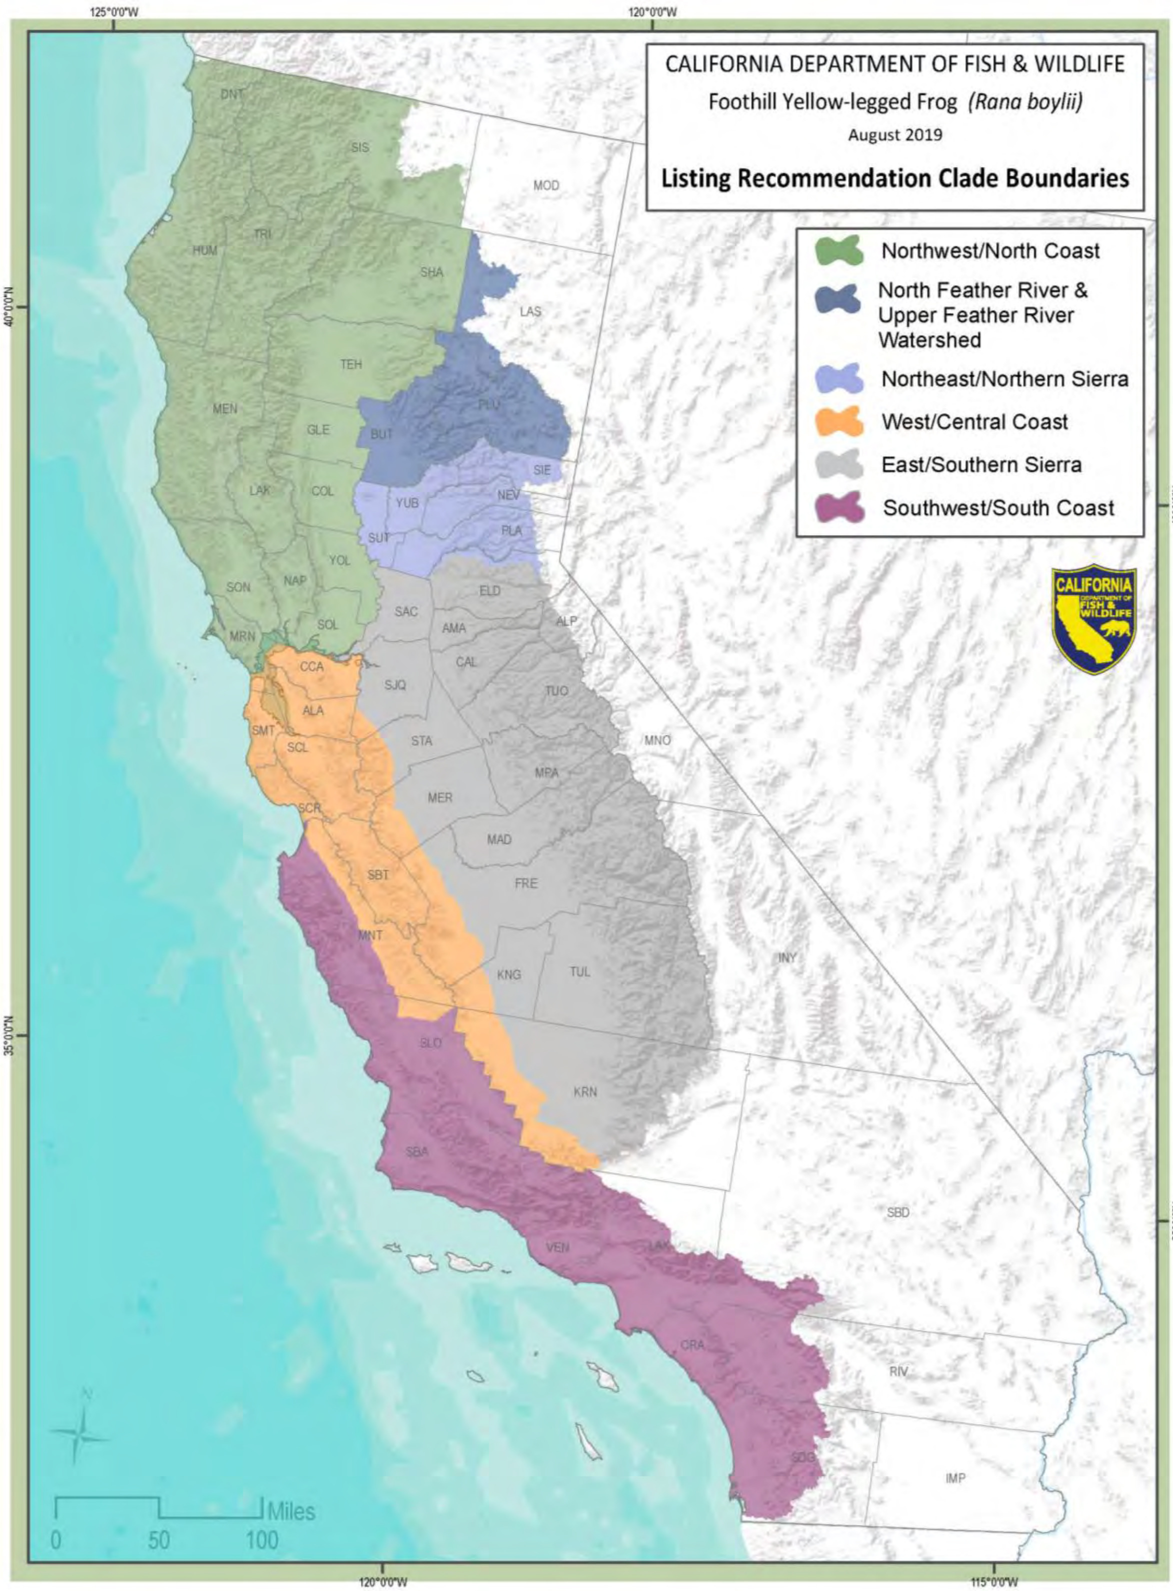

s

Figure 6. Foothill Yellow-legged Frog clade boundaries for management purposes and the Department's listing recommendation

(McCartney-Melstad et al. 2018, Peek 2018). In addition, it is the only clade with an increasing trend in genetic diversity (Peek 2018).

Early records note the comparatively high abundance of Foothill Yellow-legged Frogs in this area. Storer (1925) described Foothill Yellow-legged Frogs as very common in many of Coast Range streams north of San Francisco Bay, and Cope (1879,1883 as cited in Hayes et al. 2016) noted they were “rather abundant in the mountainous regions of northern California.” In addition, relatively large collections occurred over short periods of time in this region in the late 1800s and the first half of the 20th century (Hayes et al. 2016). Nineteen were taken over two weeks in 1893 along Orrs Creek, a tributary to the Russian River, and 40 from near Willits (both in Mendocino County) in 1911; 112 were collected over three days at Skaggs Spring (Sonoma County) in 1911; 57 were taken in one day along Lagunitas Creek (Marin County) in 1928; and 50 were collected in one day near Denny (Trinity County) in 1955 (Ibid.).

A few long-term Foothill Yellow-legged Frog egg mass monitoring efforts undertaken within this clade’s boundaries found densities vary significantly, often based on river regulation type, and documented several robust populations. The Green Diamond Resources Company has monitored a stretch of the Mad River near Blue Lake (Humboldt County) since 2008 (GDRC 2018). The greatest published density of Foothill Yellow-legged Frog egg masses was documented here in 2009 at 520.7 egg masses/mi (Bourque and Bettaso 2011). However, in 2017, surveyors counted 1,006 egg masses/mi along the same reach (GDRC 2018). At its lowest during this period, egg mass density was calculated at 115.1/mi in 2010, although this count occurred after a flooding even that likely scoured over half of the egg masses laid that season (GDRC 2018, R. Bourque pers. comm. 2019). During a single day survey in 2017 along approximately 1.3 mi of Redwood Creek in Redwood National Park (Humboldt County), 2,009 young and 126 adult Foothill Yellow-legged Frogs were found (D. Anderson pers. comm. 2017). Some reaches of the South Fork Eel River (Mendocino County) also support high densities of Foothill Yellow-legged Frogs. Kupferberg (pers. comm. 2018) recorded 333 and 171 egg masses/mi along two stretches in 2016, and 324 and 189 egg masses/mi in 2017. However, other reaches yielded counts as low as 9.8 and 13.5 egg masses/mi (Ibid.). In the Angelo Reserve (an unregulated reach), the 24-year mean density was 175.4/mi (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015). In contrast, a 10-year mean density of egg masses below Lewiston Dam on the Trinity River (Trinity County) was 1.43/mi (Ibid.).

Figure 7 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, Biological Information Observation System (BIOS) datasets, and personal communications that are color coded by the most recent date of detection. Nearly 65% of Foothill Yellow-legged Frog CNDDB records (1,558) occur within this clade, and recent observations (2014 and later) were made in at least 366 areas (CNDDB 2019). The species remains widespread within many watersheds, although most observations only verify presence, or fewer than ten individuals or egg masses are recorded (Ibid.). Documented extirpations are comparatively rare (Figure 8), and nearly all occurred just north of the high-populated San Francisco Bay area (Ibid.).

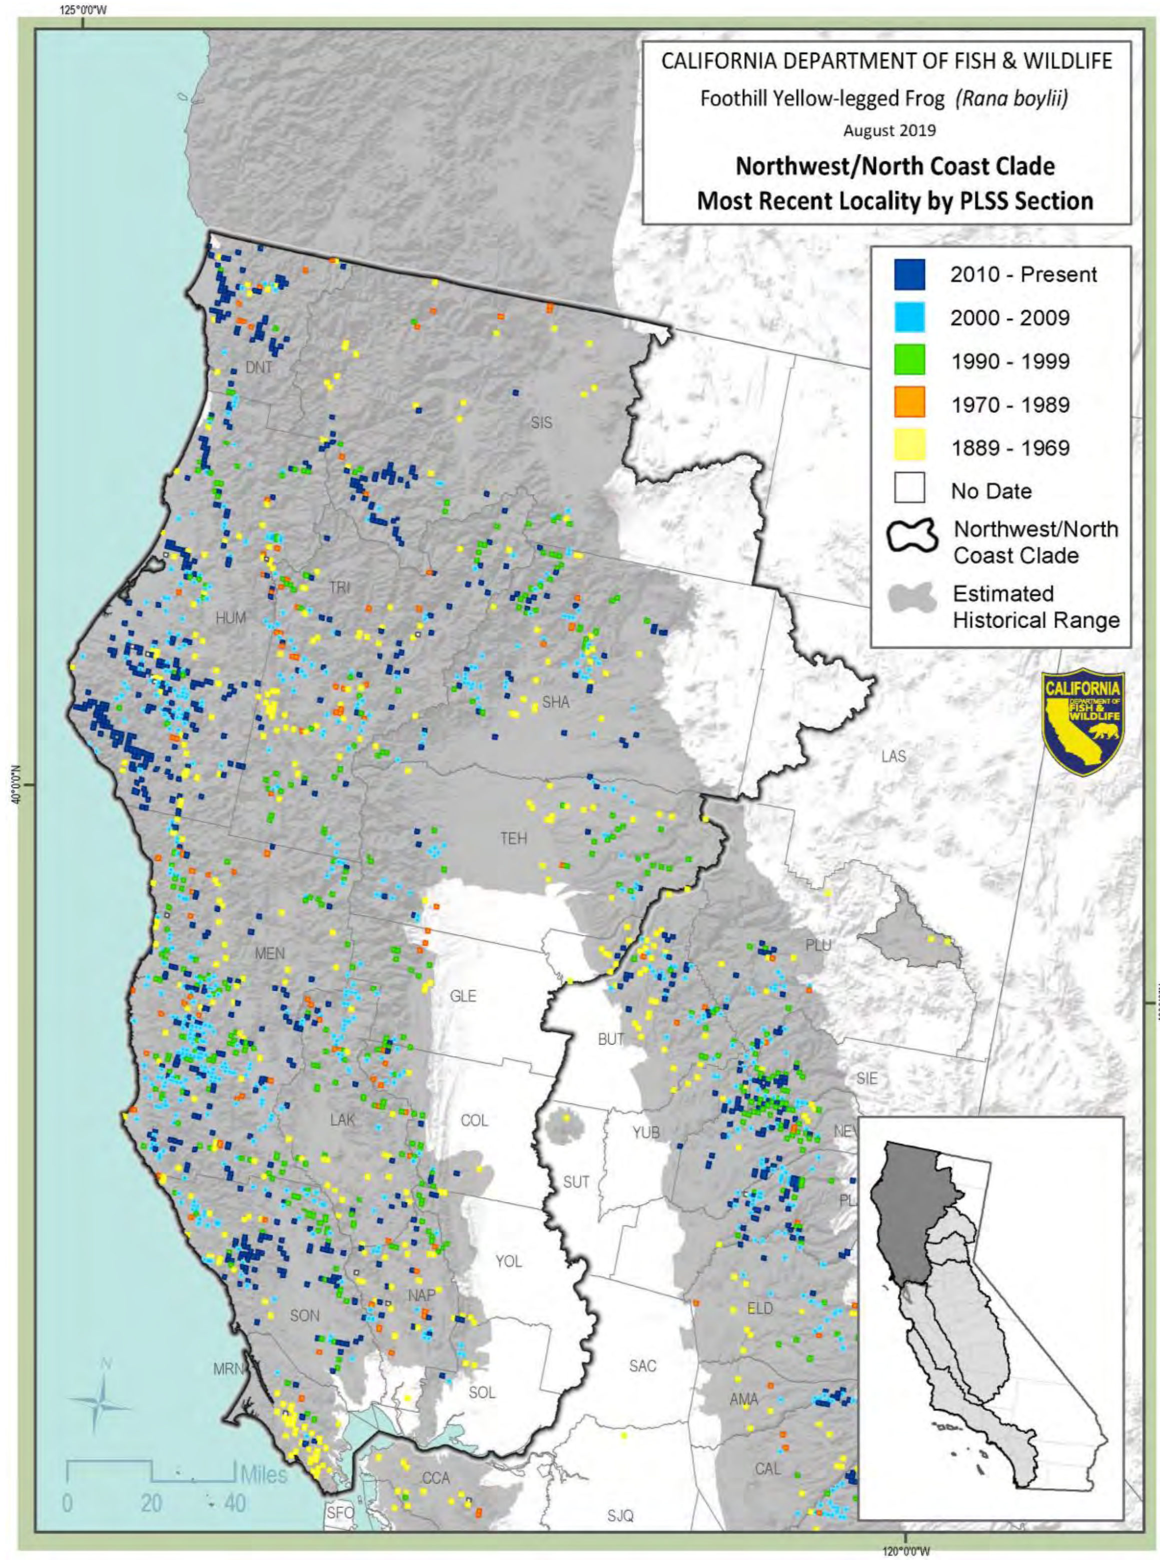

Figure 7. Northwest/North Coast Foothill Yellow-legged Frog clade observations from 1889-2019 by most recent sighting in a Public Land Survey System section (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

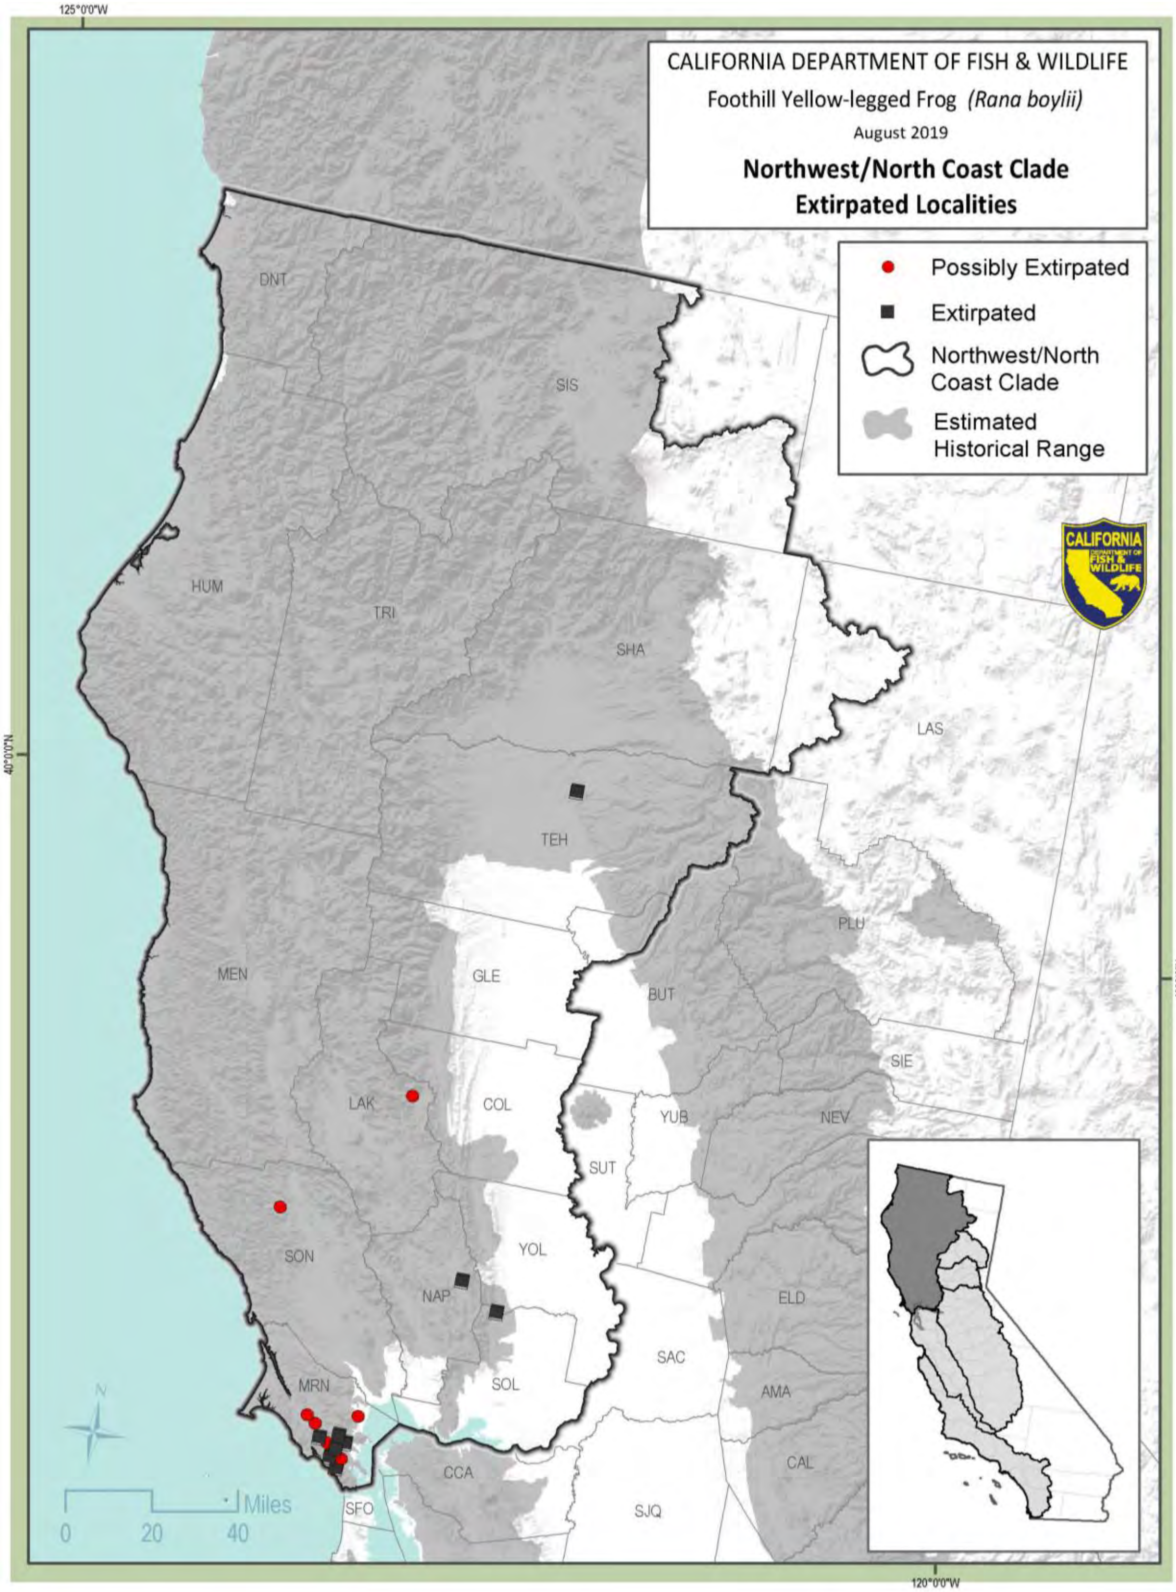

Figure 8. Possibly extirpated and extirpated Northwest/North Coast Foothill Yellow-legged Frog clade occurrences (CNDDB)

3.2.3 Feather River Clade

The Feather River clade was included in the Northeast clade as defined by McCartney-Melstad et al. (2018), but according to Peek (2018), it is very distinct and located primarily in Plumas and Butte counties. No genetic samples were available for testing from the disjunct population in northeastern Plumas County before it was extirpated. If these were correctly identified Foothill Yellow-legged Frogs, as opposed to Sierra Nevada Yellow-legged Frogs, they may have belonged to a separate clade. However, for management purposes and the Department's listing recommendation, and based on the best available science, the boundaries of the Feather River clade include the following subbasins in Butte, Lassen, Plumas, and Sierra counties: Butte Creek, East Branch of North Fork Feather, Honcut Headwaters-Lower Feather, Middle Fork Feather, and North Fork Feather (Figure 6).

In general, there is a paucity of historical Foothill Yellow-legged Frog data for west-slope Sierra Nevada streams, particularly in the lower elevations of the Sacramento Valley, and no quantitative abundance data exist prior to major changes in the landscape (i.e., mining, dams, and diversions) or the introduction of non-native species (Hayes et al. 2016). Foothill Yellow-legged Frogs were collected frequently from the Plumas National Forest area in small numbers from the turn of the 20th century through the 1970s (Ibid.). Estimates of relative abundance are not clear from the records, but they suggest the species was somewhat widespread in this area.

More recently, Foothill Yellow-legged Frog populations in the Sierra Nevada have been the subject of a focused surveys and research associated with relicensing of hydropower generating dams by the Federal Energy Regulatory Commission (FERC). Foothill Yellow-legged Frogs have been observed in at least 110 locations within this clade, 24 (22%) of which were in 2014 or later (CNDDB 2019). As with the rest of the range, most records are observations of only a few individuals; however, many observations occurred over multiple years, and in some cases all life stages were observed over multiple years (Ibid). The populations appear to persist even with the small numbers reported. Figure 9 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, BIOS, and personal communications that are color coded by the most recent date of detection. Documented extirpations are shown in Figure 10 and occur in lower elevation sites closer to the Sacramento Valley (Ibid.).

The only long-term consistent survey effort in this area has been occurring on the North Fork Feather River along the Cresta and Poe reaches (GANDA 2018). The Cresta reach's subpopulation declined significantly in 2006 and never recovered despite modification of the flow regime to reduce egg mass and tadpole scouring and some habitat restoration (Ibid.). A pilot project to augment the Cresta reach's subpopulation through in situ captive rearing was initiated in 2017 (Dillingham et al. 2018). It resulted in the highest number of young-of-year Foothill Yellow-legged Frogs recorded during fall surveys since researchers started keeping count (Ibid.). The number of egg masses laid in the Poe reach varies substantially year-to-year, from a low of 26 in 2001 to a high of 154 in 2015 and back down to 36 in 2017 (GANDA 2018).

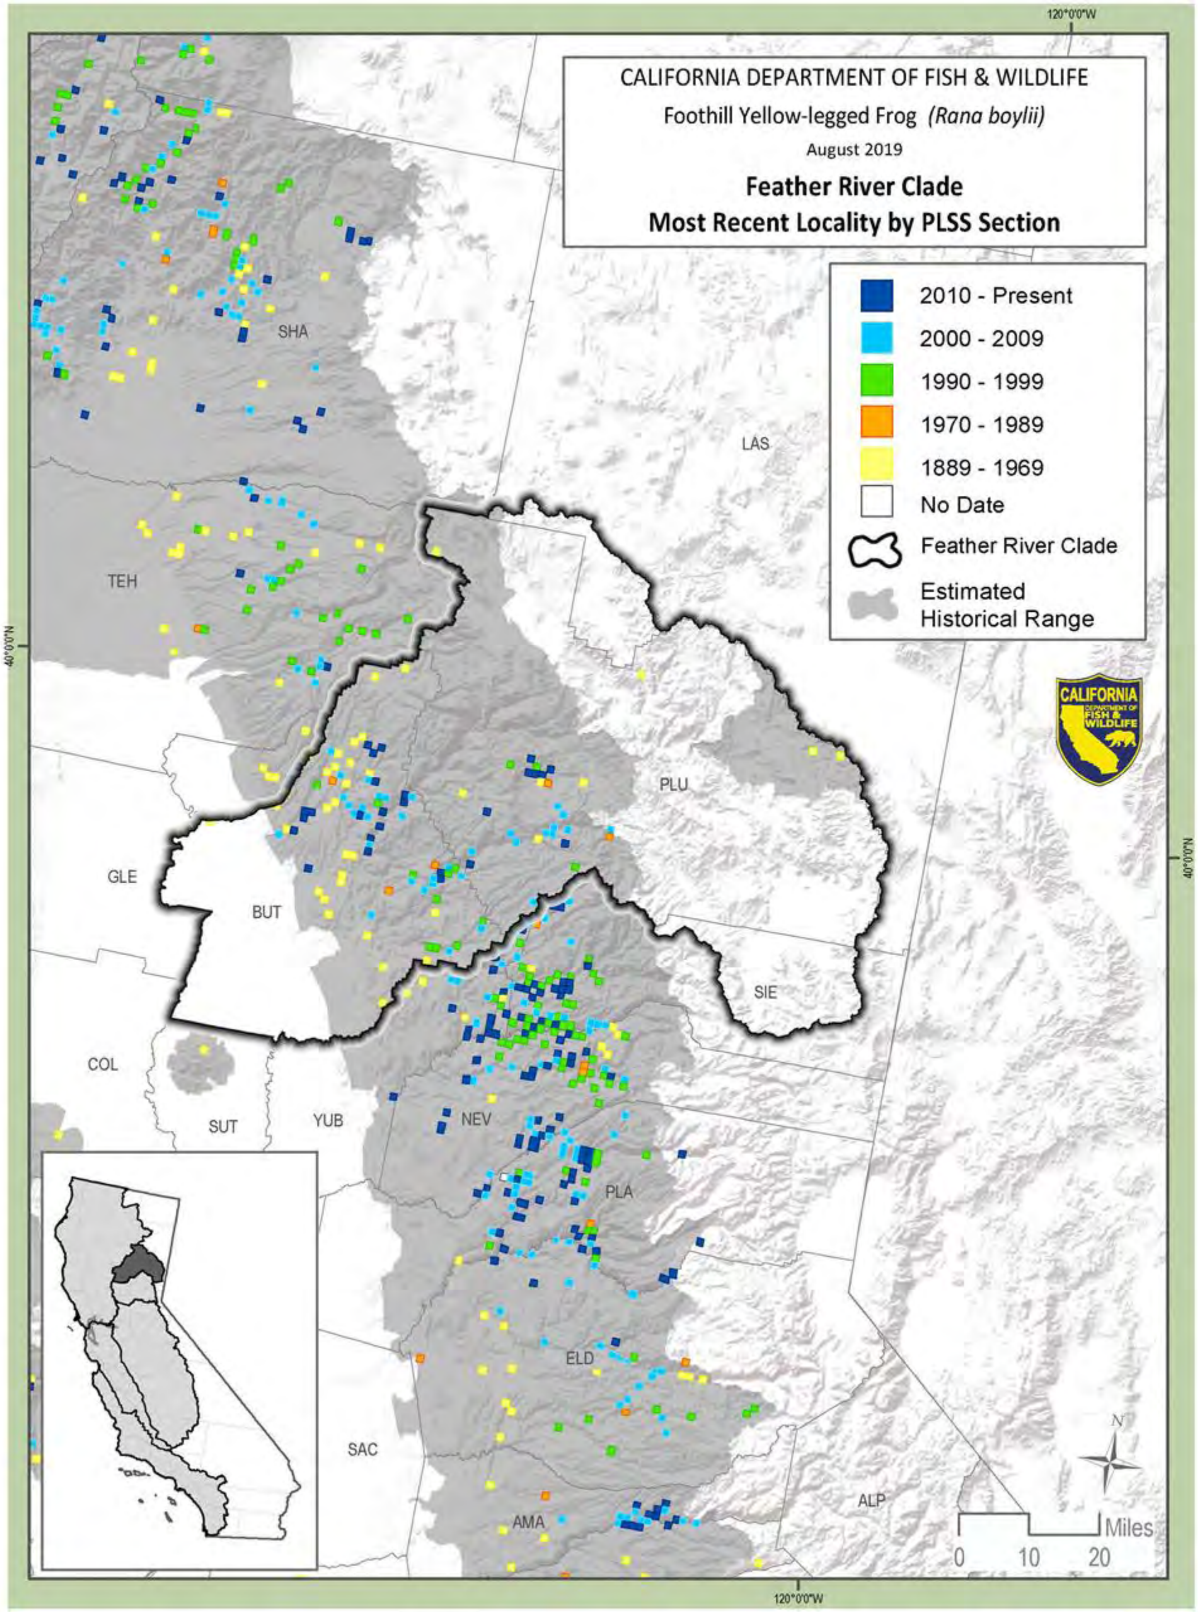

Figure 9. Feather River Foothill Yellow-legged Frog clade observations from 1889-2019 by most recent sighting in a Public Land Survey System section (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

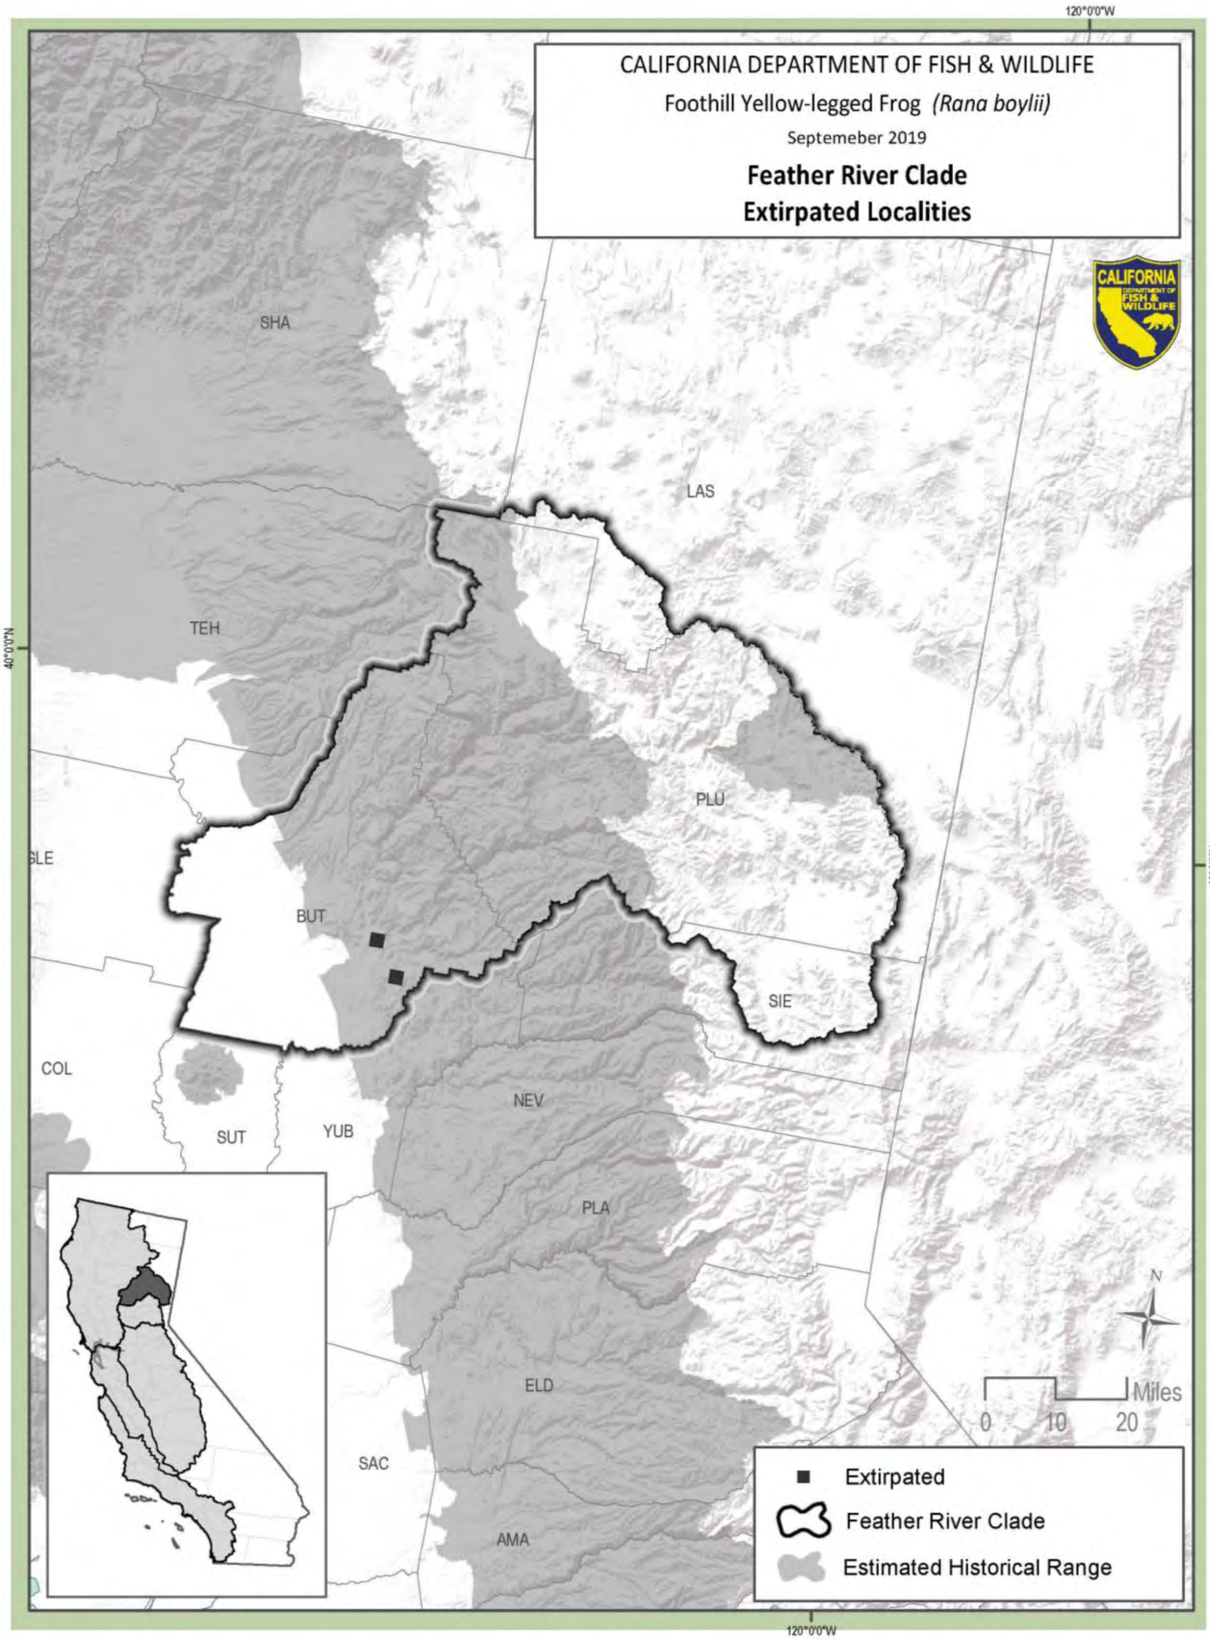

Figure 10. Extirpated Feather River Foothill Yellow-legged Frog clade occurrences (CNDDB)

3.2.4 Northeast/Northern Sierra Clade

The current known range of the Northeast/Northern Sierra clade roughly extends from the Upper Yuba Subbasin south through the North Fork American River Subbasin. No genetic samples were available to test in the Sutter Buttes to determine which clade it belonged to before it was extirpated (Figure 5; Olson et al. 2016). However, for management purposes and the Department's listing recommendation, and based on the best available science, the boundaries of the Northeast/Northern Sierra clade include Sutter County and the following watershed subbasins in Nevada, Placer, Sierra, and Yuba counties: Lower American, North Fork American, Upper Bear, Upper Coon-Upper Auburn, and Upper Yuba (Figure 6).

As described above, little historical data exist for the Foothill Yellow-legged Frog's distribution along west-slope Sierra Nevada streams, and no abundance data exist prior to major changes in the landscape. Foothill Yellow-legged Frogs have been observed in at least 231 locations within this clade, 76 (33%) of which were in 2014 or later (CNDDB 2019). The general pattern in this clade, and across the range, is that unregulated rivers or reaches have more areas that are occupied more consistently over time and in larger numbers than regulated rivers or reaches (CNDDB 2019, S. Kupferberg pers. comm. 2019).

Foothill Yellow-legged Frogs were rarely observed in the hydropeaking reach of the Middle Fork American River and were observed in low numbers in the bypass reach, but they were present and breeding in small tributary populations (PCWA 2008). Relatively robust populations appear to inhabit the North Fork American River and Lower Rubicon River, both in Placer County (Gaos and Bogan 2001, PCWA 2008, Hogan and Zuber 2012, K. Kundargi pers. comm. 2014, S. Kupferberg pers. comm. 2019). Additional apparently sufficiently large and relatively stable populations occur on Clear Creek, South Fork Greenhorn Creek, and Shady Creek (Nevada County) and the North and Middle Yuba River (Sierra County), but the remaining observations are of small numbers in tributaries with minimal connectivity among them (CNDDB 2019, S. Kupferberg pers. comm. 2019).

Figure 11 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, BIOS, and personal communications that are color coded by the most recent date of detection. Only one extirpation has been documented within this clade (Figure 12), but due to the lack of distribution data on the species prior to the Gold Rush in this area, there were undoubtedly others (CNDDB 2019).

3.2.5 East/Southern Sierra Clade

The current known range of the East/Southern Sierra clade extends from the South Fork American River Subbasin (the northernmost area where individuals from this clade were sampled) south to where the Sierra Nevada meets the Tehachapi Mountains. The Central Valley is not considered suitable habitat, and specimens collected from the Mokelumne River in northern San Joaquin County were likely waifs that washed down in a flood (CNDDB 2019). Because some of the San Joaquin Valley counties span both this clade and the West/Central Coast clade, the California Aqueduct was selected as geographic boundary between the two (Figure 6). This is an imperfect boundary because some east-draining creeks from the Coast Range flow into the San Joaquin Valley under the aqueduct. Therefore, for management

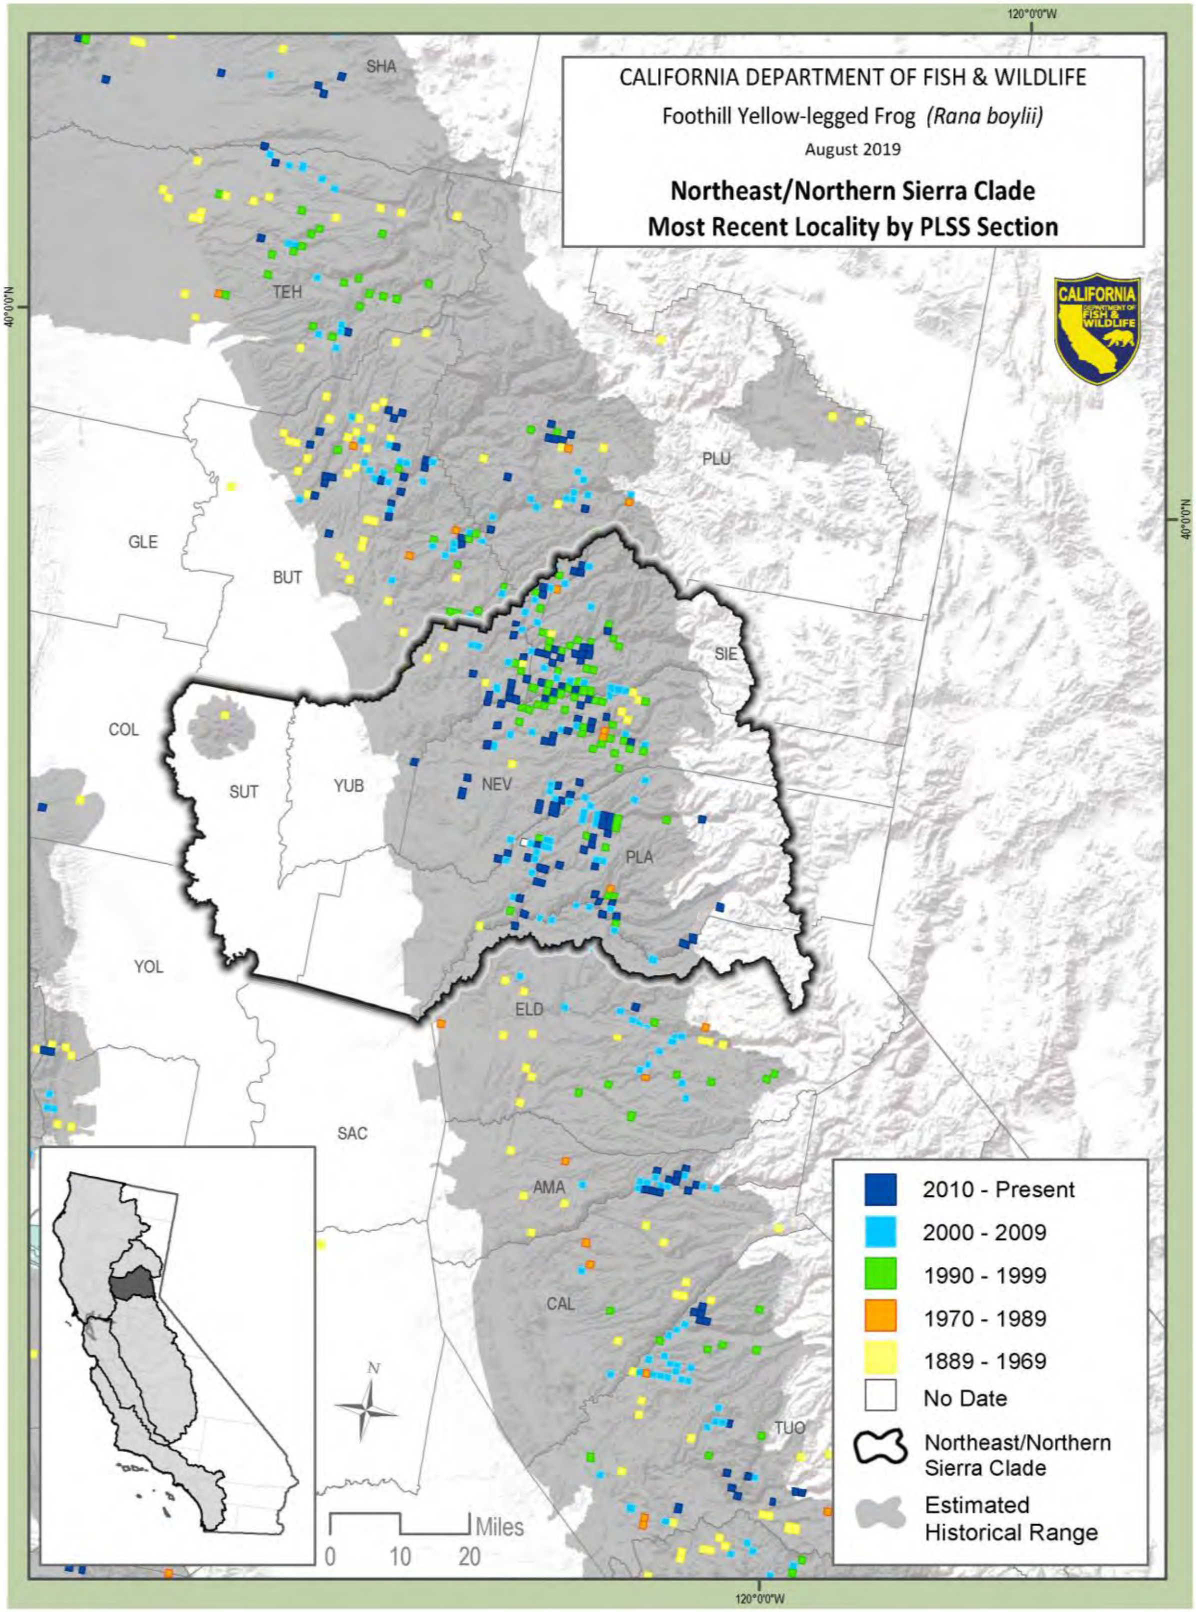

Figure 11. Northeast/Northern Sierra clades observations from 1889-2019 by most recent sighting in a Public Land Survey System section (ARSSC, BIOS, CNDDB)

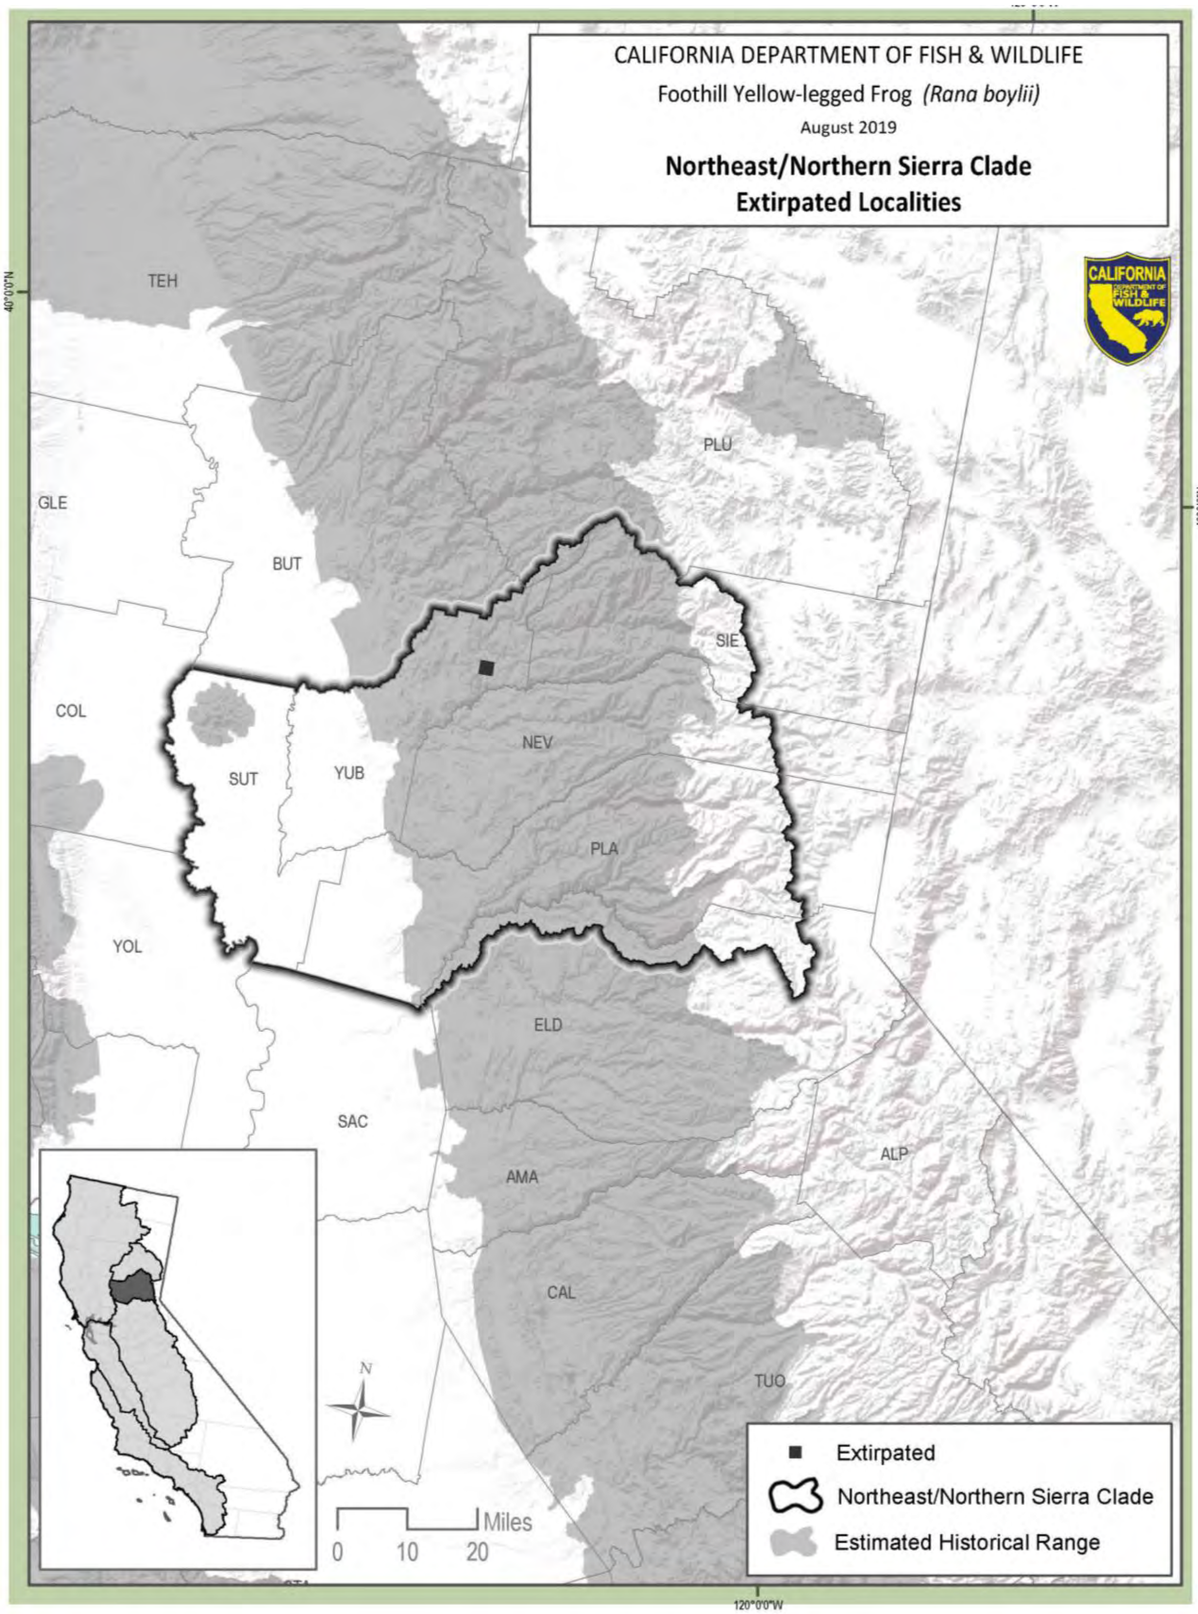

Figure 12. Extirpated Northeast/Northern Sierra Foothill Yellow-legged Frog clades occurrences (CNDDB)

purposes and the Department's listing recommendation, and based on the best available science, the boundaries of the East/Southern Sierra clade include the following whole counties: Amador, Calaveras, Madera, Mariposa, Sacramento, Tulare, and Tuolumne. The portion of Kern County within this clade is bounded on the west by the California Aqueduct and by the following subbasins in the east: Middle Kern-Upper Tehachapi-Grapevine, South Fork Kern, and Upper Kern. The following subbasins in El Dorado and Alpine counties are included in this clade: South Fork American, Upper Cosumnes, and Upper Mokelumne. A small area where the estimated historical range spans into Mono County is also included in this clade. The following counties east of the California Aqueduct are included in this clade: Fresno, Kings, Merced, San Joaquin, and Stanislaus.

Historical collections of small numbers of Foothill Yellow-legged Frogs occurred in every major river system within this clade beginning as early as the turn of the 20th century, indicating widespread distribution, but little information on abundance exists (Hayes et al. 2016). By the early 1970s, declines in Foothill Yellow-legged Frog populations from this area were already apparent; Moyle (1973) found them at 30 of 95 sites surveyed in 1970. Notably bullfrogs inhabited the other 65 sites formerly occupied by Foothill Yellow-legged Frogs, and they co-occurred at only three sites (Ibid.). In 1992, Drost and Fellers (1996) revisited the sites around Yosemite National Park (Tuolumne and Mariposa counties) that Grinnell and Storer (1924) surveyed in 1915 and 1919. Foothill Yellow-legged Frogs had disappeared from all seven historically occupied sites and were not found at any new sites surveyed surrounding the park (Ibid.). Resurveys of previously occupied (pre-1990) sites on the Stanislaus (Tuolumne County), Sierra (Fresno County), and Sequoia (Tulare County) National Forests, six sites per forest, were also undertaken (Lind et al. 2003b). Two of the previously occupied sites on the Stanislaus were still occupied, and 19 new populations were found with evidence of breeding at seven of them (Ibid.). Foothill Yellow-legged Frogs were absent from all of the previously occupied sites in Sierra National Forest, but one new population discovered (Ibid.) Similarly, Foothill Yellow-legged Frogs were absent from all of the previously occupied sites in the Sequoia National Forest, but two new populations were discovered (Ibid.). These populations remain extant but are small and isolated (CNDDB 2019). Twenty of the 24 populations extant at the time inhabited unregulated waterways (Ibid.). Most of the CNDDB (2019) records of Foothill Yellow-legged Frogs on the Stanislaus are at least a decade old and are represented by low numbers.

More recently, surveys for Foothill Yellow-legged Frogs were conducted along the South Fork American River as part of the El Dorado Hydroelectric Project's FERC license amphibian monitoring requirements (GANDA 2017). Between 2002 and 2016, counts of different life stages varied significantly by year, but the trend for every life stage was a decline over that period (Ibid.). Foothill Yellow-legged Frogs have been observed in at least 260 locations within this clade, 34 (13%) of which were in 2014 or later (CNDDB 2019). There appears to be a small population persisting along the North Fork Mokelumne River (Amador and Calaveras counties), but it was only productive during the 2012-2014 drought years (Ibid.). Small numbers have also been observed recently in several locations on private timberlands in Tuolumne County (CNDDB 2019).

Figure 13 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, BIOS, and personal communications that are color coded by the most recent date of detection. The proportion of extirpated sites in this clade is second only to the Southwest/South Coast and follows the pattern of greater losses in the south (Figure 14). Like the southern coastal clade, the southern Sierra clade has low genetic variability and a trajectory of continued loss of diversity (Peek 2018).

3.2.6 West/Central Coast Clade

The current known range of the West/Central Coast clade extends south from the San Francisco Bay through the Diablo Range and down the peninsula through the Santa Cruz and Gabilan Mountains in the Coast Range east of the Salinas Valley. No Foothill Yellow-legged Frogs belonging to this clade are expected south of Monterey and Fresno counties (Figure 5), and whether the species ever occurred in San Francisco County is unknown. For management purposes and the Department's listing recommendation, and based on the best available science, the West/Central Coast clade includes the following whole counties: Alameda, Contra Costa, San Benito, San Francisco, San Mateo, Santa Clara, and Santa Cruz. It includes the following counties west of the California Aqueduct: Fresno, Kern, Kings, Merced, San Joaquin, and Stanislaus, as well as portions of the east-draining creeks from the Coast Range that flow under the California Aqueduct. Monterey County east of Highway 101 is also included in this clade as well as the northeastern portion of San Luis Obispo County bounded by Highways 101 and 46 (Figure 6). Like the California Aqueduct, the highways represent imperfect boundaries, but they are intended to approximate the Salinas Valley separating the Sierra de Salinas and Santa Lucia Range to the west (in the Southwest/South Coast clade) from the Gabilan and Diablo ranges in this clade.

Records of Foothill Yellow-legged Frogs occurring south of San Francisco Bay did not exist until specimens were collected in 1918 around what is now Pinnacles National Park in San Benito County, and little information exists on historical distribution and abundance within this clade (Storer 1923, Hayes et al. 2016). Figure 15 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, BIOS, and personal communications that are color coded by the most recent date of detection. Foothill Yellow-legged Frogs have been observed in at least 174 locations within this clade, 27 (15.5%) of which were in 2014 or later (CNDDB 2019).

The San Francisco Bay Area is heavily urbanized. Documented and possible extirpations are concentrated around the San Francisco Bay and sites at the southern portion of the clade's range (Figure 16); however, the latter may not have been resurveyed since their original observations in the 1940s through 1960s, with the exception of a 1994 survey conducted in Pinnacles National Park (Ibid.). Foothill Yellow-legged Frogs may be gone from Contra Costa County; eight of the nine CNDDB records from the county are museum specimens collected between 1891 and 1953. The most recent observation was two adults in a plunge pool in an intermittent tributary to Moraga Creek in 1997, but its veracity is dubious (CNDDB 2019, S. Kupferberg pers. comm. 2019). No recent (2010 or later) observations exist from San Mateo County (Ibid.). In addition, although not depicted, two populations south of Livermore (Alameda County) are also likely extirpated (M. Grefsrud pers. comm. 2019).

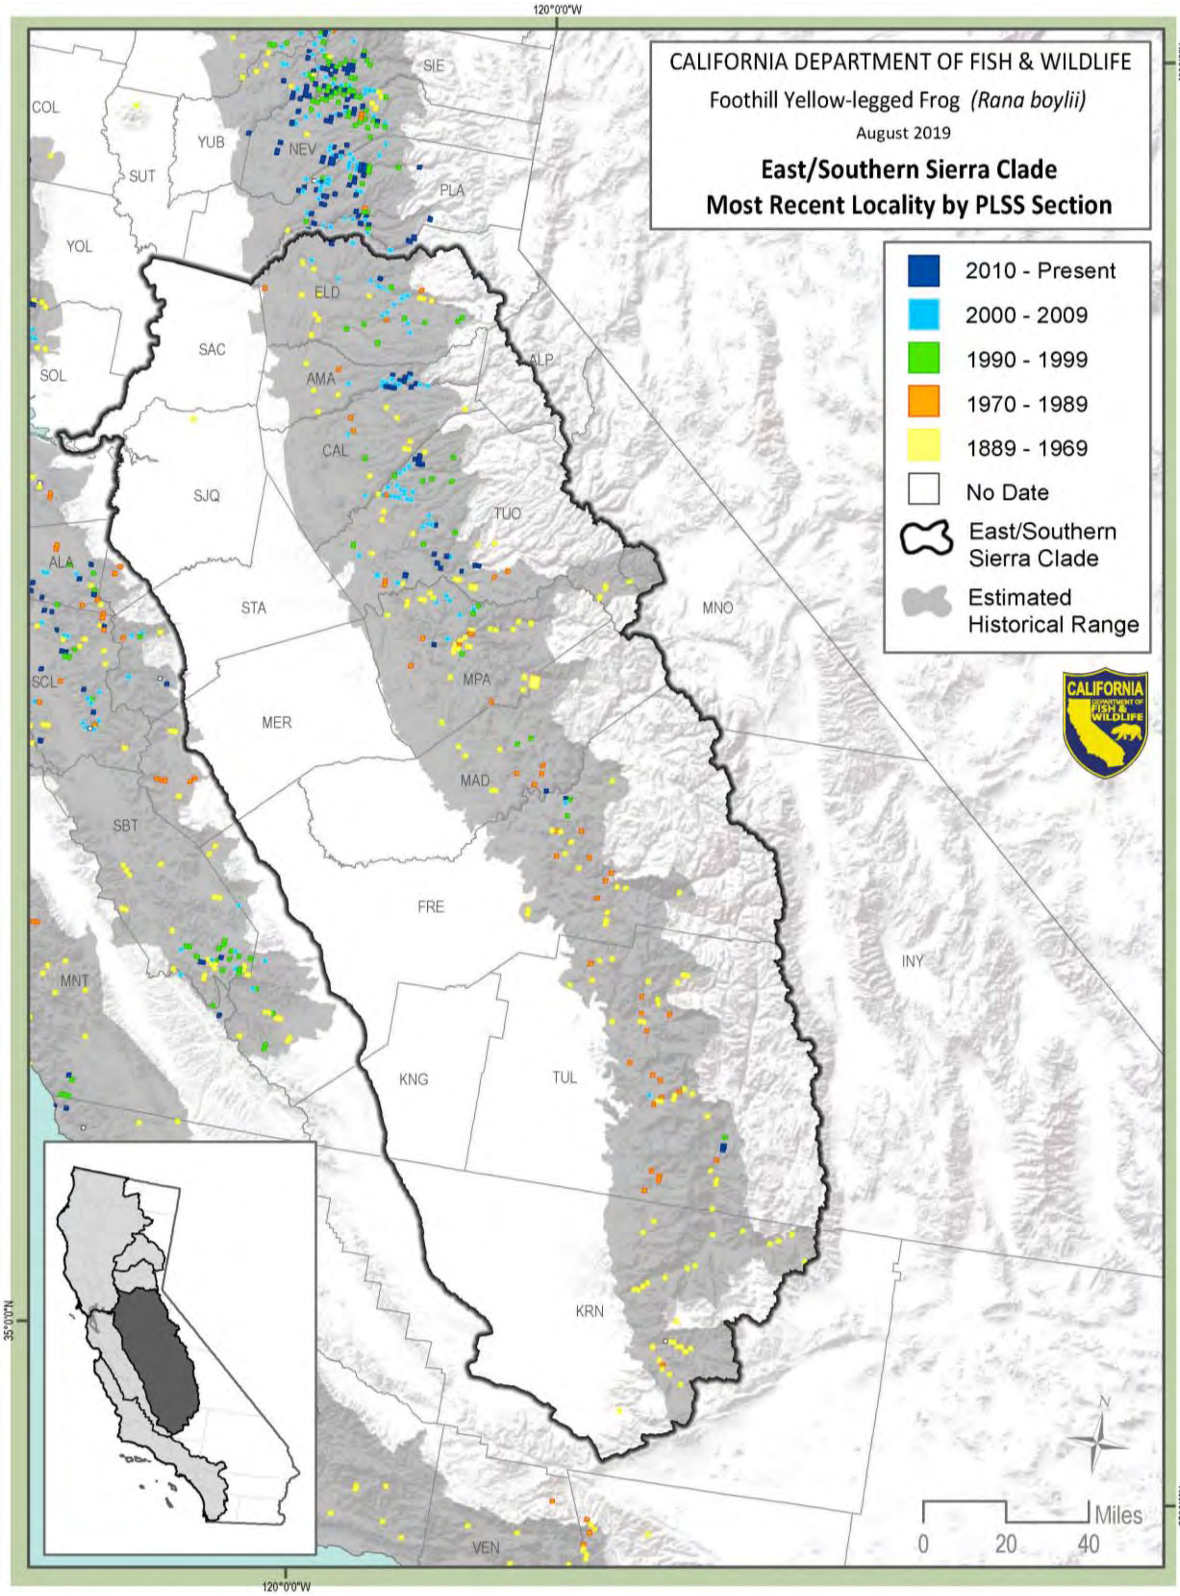

Figure 13. East/Southern Sierra clade observations from 1889-2019 by most recent sighting in a Public Land Survey System section (ARSSC, BIOS, CNDDB)

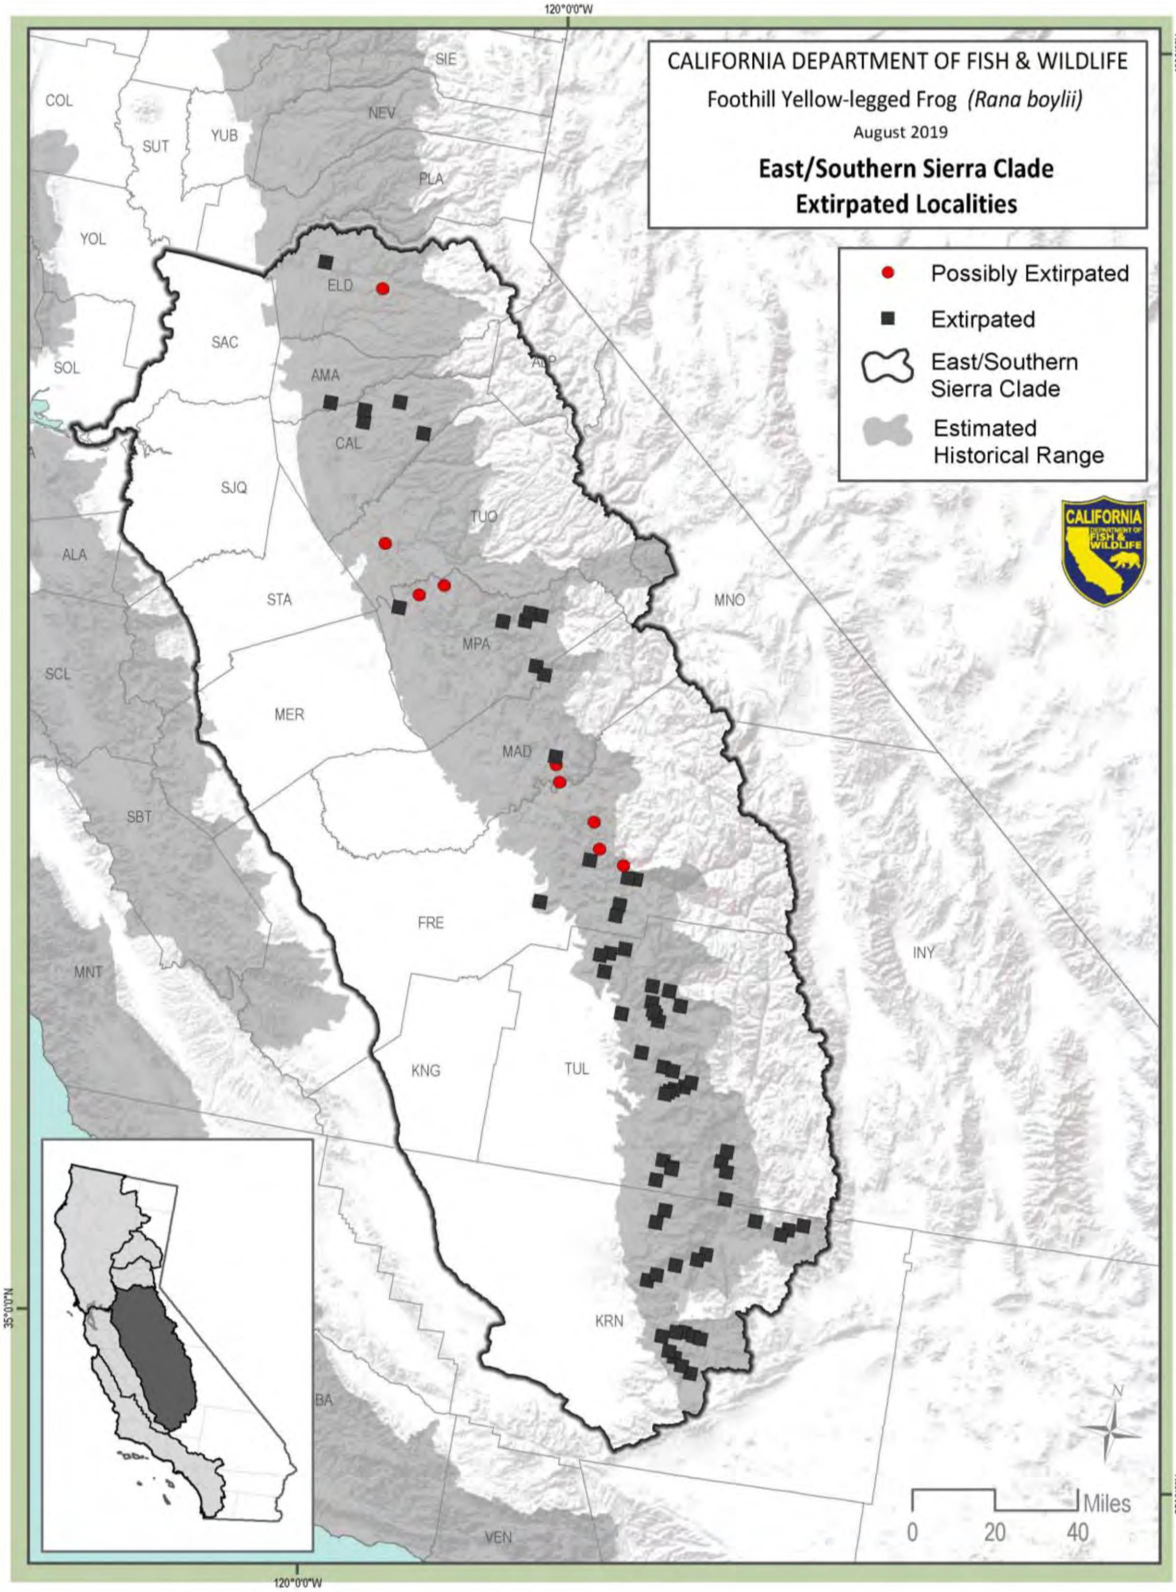

Figure 14. Possibly extirpated and extirpated East/Southern Sierra Foothill Yellow-legged Frog clade occurrences (CNDDB)

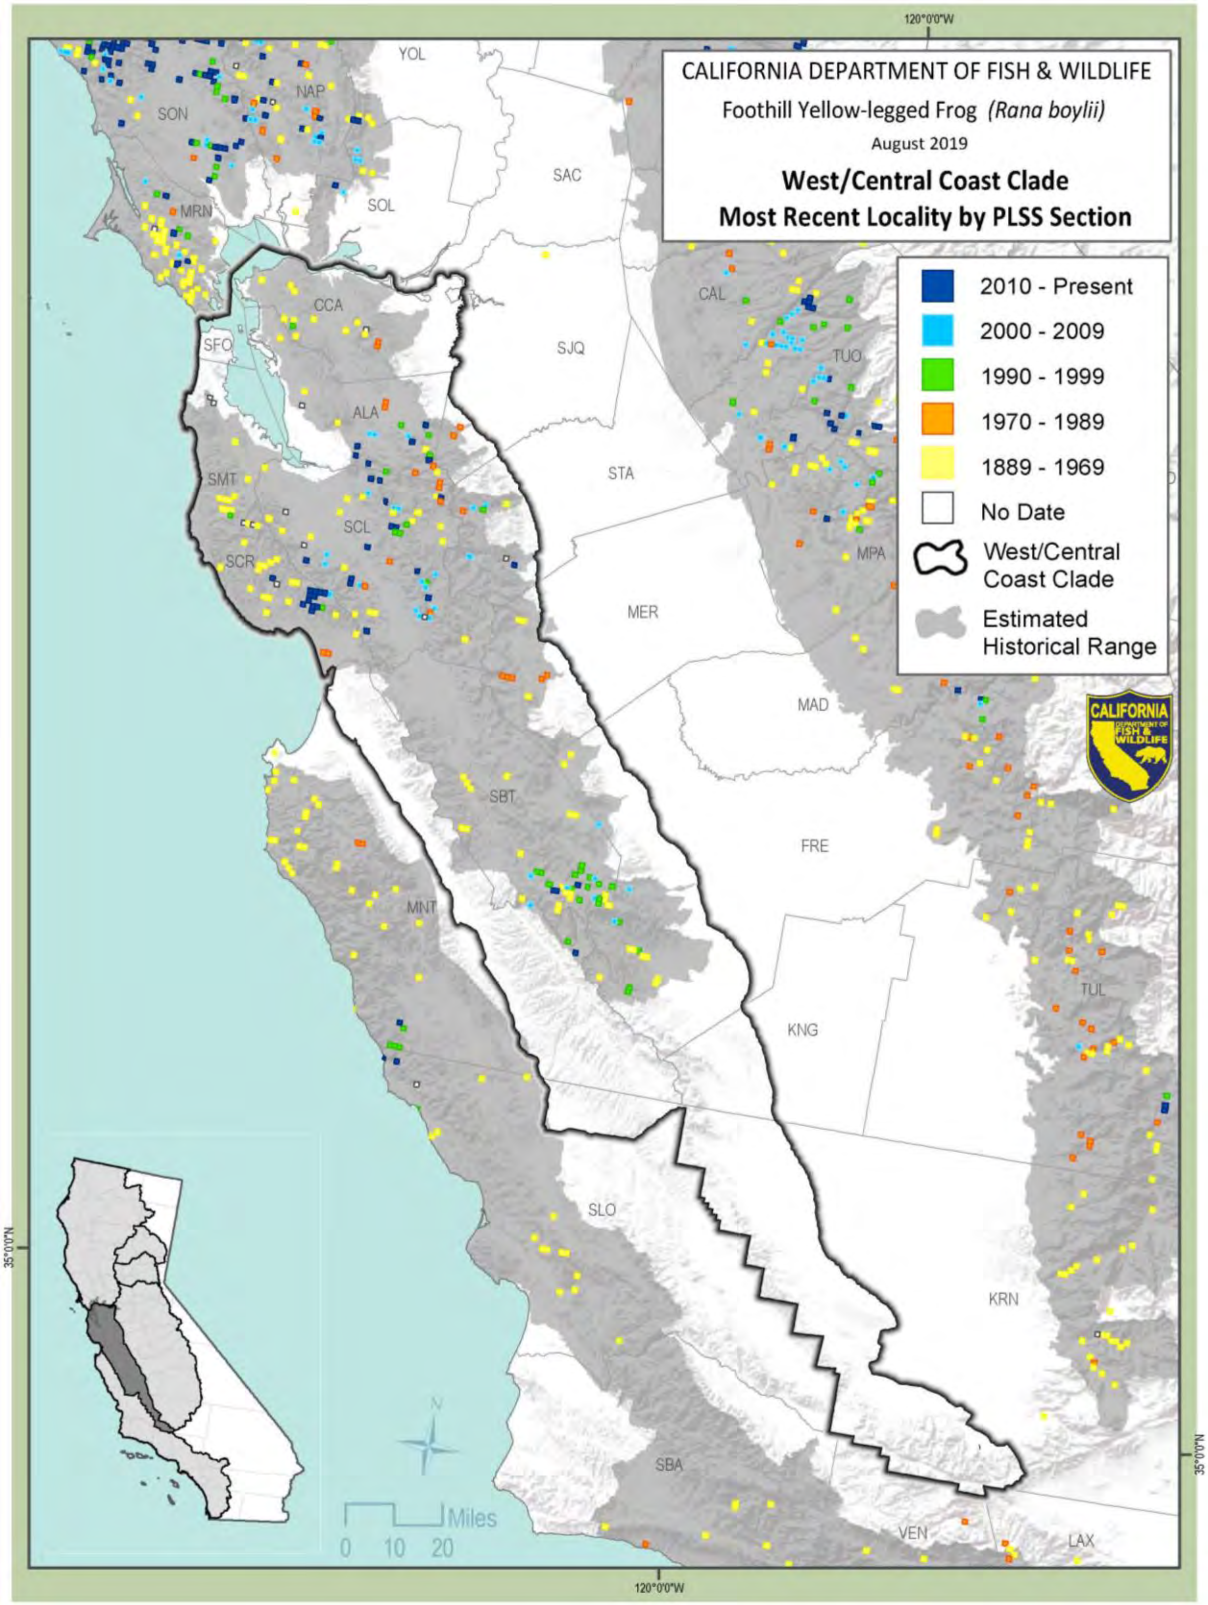

Figure 15. West/Central Coast clade observations from 1889-2019 by most recent sighting in a Public Land Survey System section (ARSSC, BIOS, CNDDB)

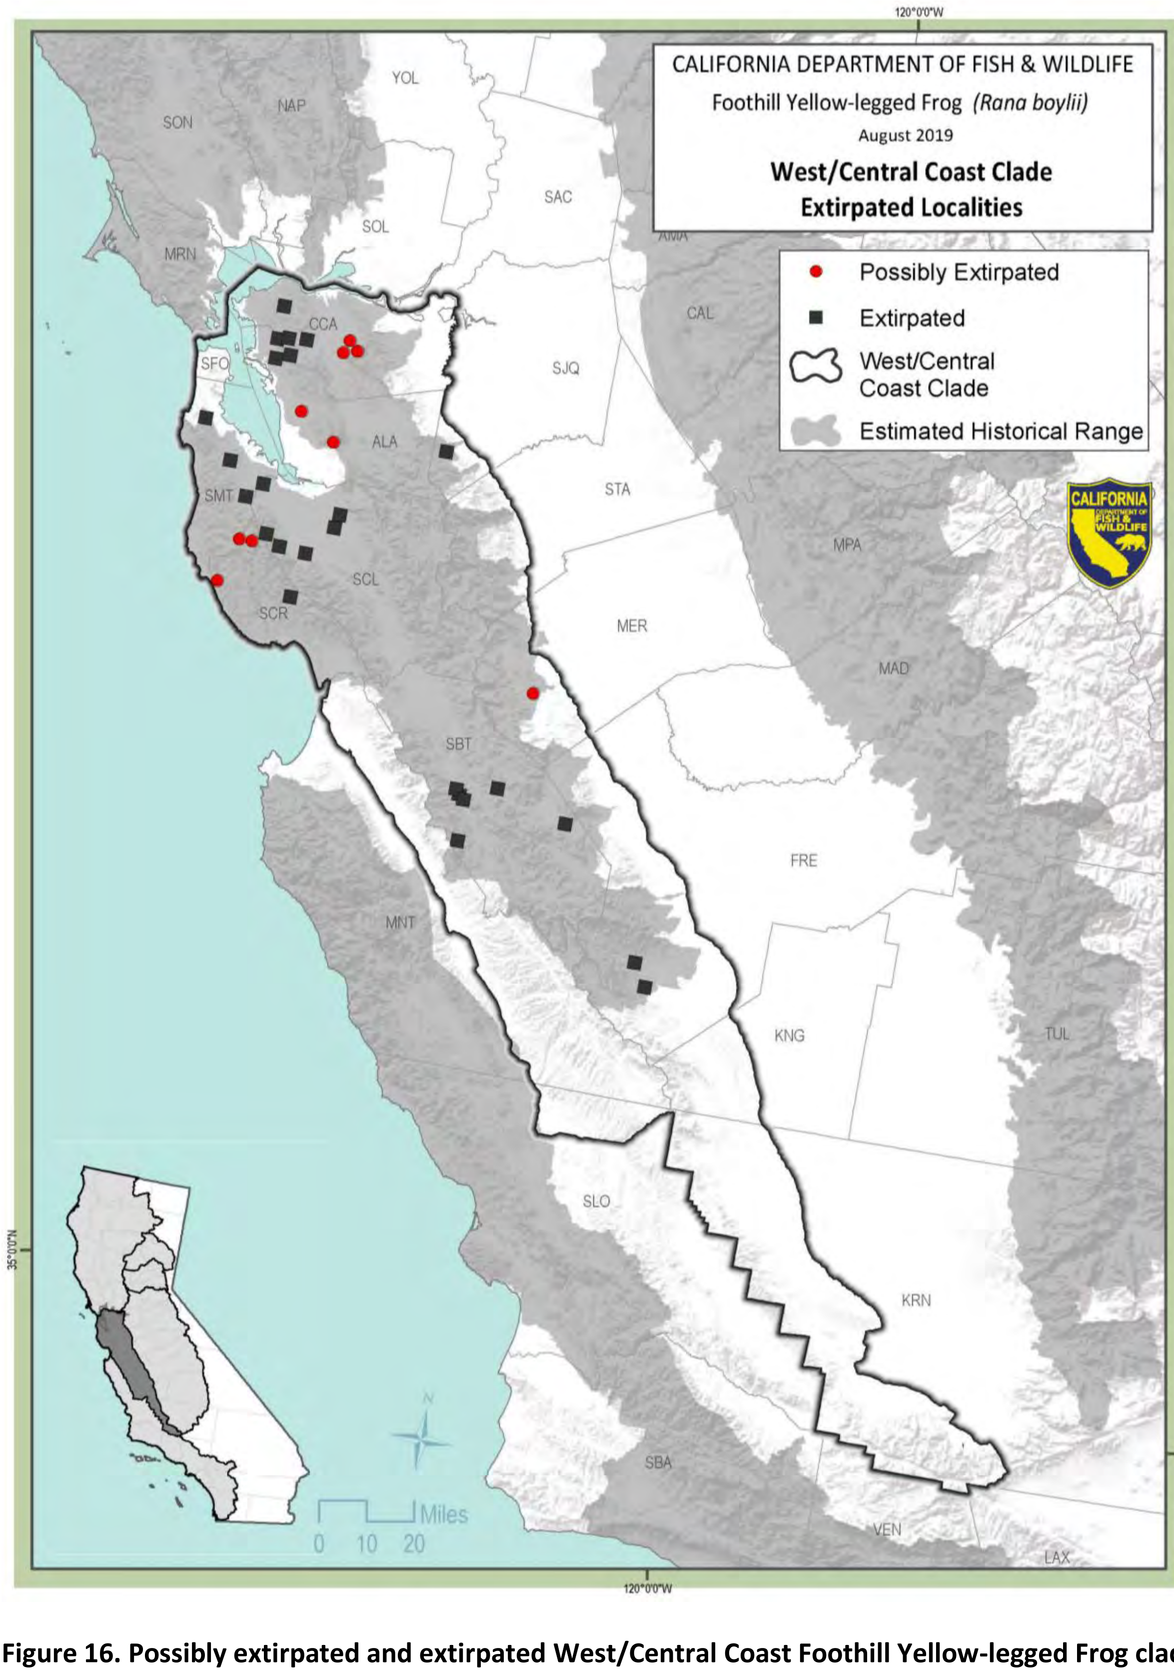

Figure 16. Possibly extirpated and extirpated West/Central Coast Foothill Yellow-legged Frog clade occurrences (CNDDB)

While historically-occupied lower elevation sites surrounding the San Francisco Bay and inland appear to be extirpated, there are (or were) some moderately abundant breeding populations remaining at higher elevations in Arroyo Hondo (Alameda County), Alameda Creek (Alameda and Santa Clara counties), Coyote and Upper Llagas creeks (Santa Clara County), and Soquel Creek (Santa Cruz County) with some scattered smaller populations also persisting in these counties (J. Smith pers. comm. 2016, 2017; CNDDB 2019). The Arroyo Hondo population is expected to lose approximately 1 mi of prime breeding habitat (i.e., supporting the highest density of egg masses on the creek) as the Calaveras Reservoir is refilled following its dam replacement project in 2019 (M. Grefsrud pers. comm. 2019). The Alameda Creek and Coyote Creek populations recently underwent large-scale mortality events, so their numbers may be lower than what is currently reported in the CNDDB (Adams et al. 2017a, Kupferberg and Catenazzi 2019). However, during 2019 surveys, Foothill Yellow-legged Frog egg mass density along Coyote Creek, including the location of the 2018 die-off, was comparable to those reported 15 years ago, although there may be a time lag before population-level effects are detected (S. Kupferberg pers. comm. 2019). Foothill Yellow-legged Frogs may be extirpated from Corral Hollow Creek in San Joaquin County, but a single individual was observed five years ago further up the drainage in Alameda County within an Off-Highway Vehicle park (CNDDB 2019). Few recent sightings of Foothill Yellow-legged Frogs in the east-flowing creeks are documented. They may still be extant in the headwaters of Del Puerto Creek (western Stanislaus County), but the records further downstream indicate bullfrogs (known predators and disease reservoirs) are moving up the system (Ibid.). Several locations in southern San Benito, western Fresno, and eastern Monterey counties have relatively recent (2000 and later) detections (Ibid.). However, while many of these sites supported somewhat large populations in the 1990s, the more recent records report fewer than ten individuals (Ibid.). The exception is a Monterey County site where 25 to 30 juveniles were observed in 2012 (Ibid.).

3.2.7 Southwest/South Coast Clade

Few early records exist for the Southwest/South Coast clade. Storer (1923) reported that Foothill Yellow-legged Frogs were collected for the first time in Monterey County in 1919 and that a specimen collected by Cope in 1889 in Santa Barbara and listed as *Rana temporaria pretiosa* may refer to the Foothill Yellow-legged Frog because as previously mentioned, the taxonomy of this species changed several times over the first century after it was named. Widespread extirpations occurred decades ago, detected primarily in the 1960s and 1970s, in southern California (Adams et al. 2017b). As a result, genetic samples were largely unavailable; nevertheless, the current known range of this clade is presumed to include the Coast Range west of the Salinas River from Monterey Bay in Monterey County south to the Transverse Range across to the San Gabriel Mountains in Los Angeles County. The Petition included references to museum specimens, collected below the putative elevation range of the Southern Mountain Yellow-legged Frog in Orange, San Bernardino, and San Diego counties, that should be examined to determine a conclusive identification. If the specimens from México were indeed Foothill Yellow-legged Frogs, additional historical populations in southern California cannot be completely ruled out. For management purposes and the Department’s listing recommendation, and based on the best available science, the boundaries of the Southwest/South Coast clade include the following whole counties: Orange, Santa Barbara, and Ventura. The eastern extent of this clade in Los

Angeles, Riverside, San Bernardino, and San Diego is bounded by the following subbasins: Los Angeles, San Diego, San Gabriel, San Jacinto, San Luis Rey-Escondido, Santa Ana, Santa Clara, and Santa Margarita. Monterey County west of Highway 101 and San Luis Obispo County south and west of Highways 101 and 46 are also part of this clade (Figure 6).

Figure 17 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, BIOS, and personal communications that are color coded by the most recent date of detection. Foothill Yellow-legged Frogs had been widespread and fairly abundant in this area until the late 1960s but were rapidly extirpated throughout the southern Coast Ranges and western Transverse Ranges by the mid-1970s (Sweet 1983, Adams et al. 2017b). Now the species has disappeared from nearly all know historically occupied locations (Figure 18), and only two populations from this clade are known to be extant, both located near the border of Monterey and San Luis Obispo counties (S. Sweet pers. comm. 2017, McCartney-Melstad et al. 2018, Peek 2018, CNDDB 2019). These populations appear to be extremely small and rapidly losing genetic diversity, making them at high risk of extirpation (McCartney-Melstad et al. 2018, Peek 2018).

4.0 FACTORS AFFECTING ABILITY TO SURVIVE AND REPRODUCE

"The fortunes of the boylii *population fluctuate with those of the stream"* - Tracy I. Storer, 1925

Several past and ongoing activities have changed the watersheds upon which Foothill Yellow-legged Frogs depend, and many interact with each other exacerbating their adverse impacts. With such an expansive range in California, the degree and severity of these impacts on the species often vary by location. To the extent feasible, based on the best scientific information available, those differences are discussed below.

4.1 Dams, Diversions, and Water Operations

Foothill Yellow-legged Frogs evolved in a Mediterranean climate with predictably cool wet winters and hot dry summers; their life cycle is adapted to these conditions. In California and other areas with a Mediterranean climate, human demands for water are at the highest when runoff and precipitation are lowest, and annual water supply varies significantly but always follows the general pattern of peak discharge declining to base flow in the late spring or summer (Grantham et al. 2010). The Foothill Yellow-legged Frog's life cycle depends on this flow pattern and the specific habitat conditions it produces (see the Breeding and Rearing Habitat section). Dams are ubiquitous, but not evenly distributed, in California. Figure 19 depicts the locations of dams under the jurisdiction of the Army Corps of Engineers (ACOE) and the California Department of Water Resources (DWR). Figure 20 depicts the number of surface diversions per PLSS section within the Foothill Yellow-legged Frog's range (eWRIMS 2019).

Dam operations frequently change the amount, timing, and frequency of water availability; water temperature, depth, and velocity; the downstream capacity to transport sediment; and channel morphology, all of which can result in dramatic consequences for the Foothill Yellow-legged Frog's ability to survive and successfully reproduce. Several studies comparing Foothill Yellow-legged Frog

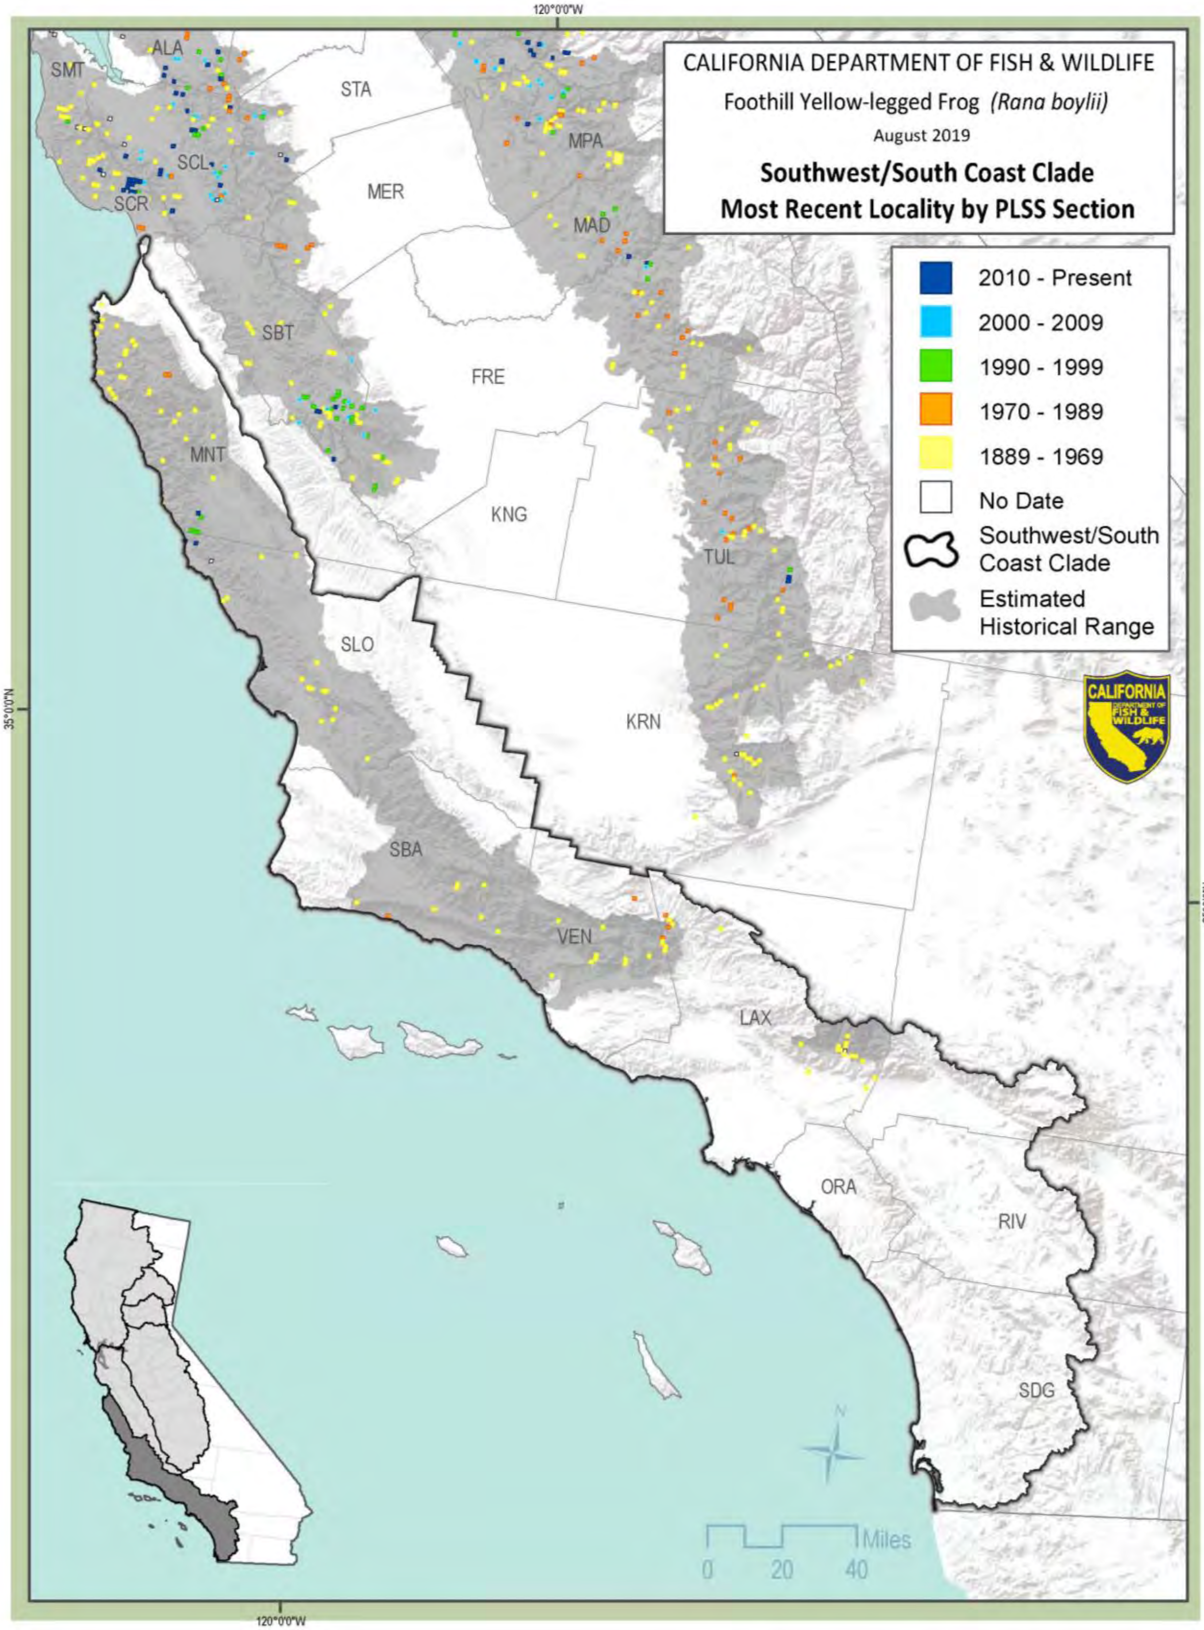

Figure 17. Southwest/South Coast clade observations from 1889-2019 by most recent sighting in a Public Land Survey System section (ARSSC, BIOS, CNDDB)

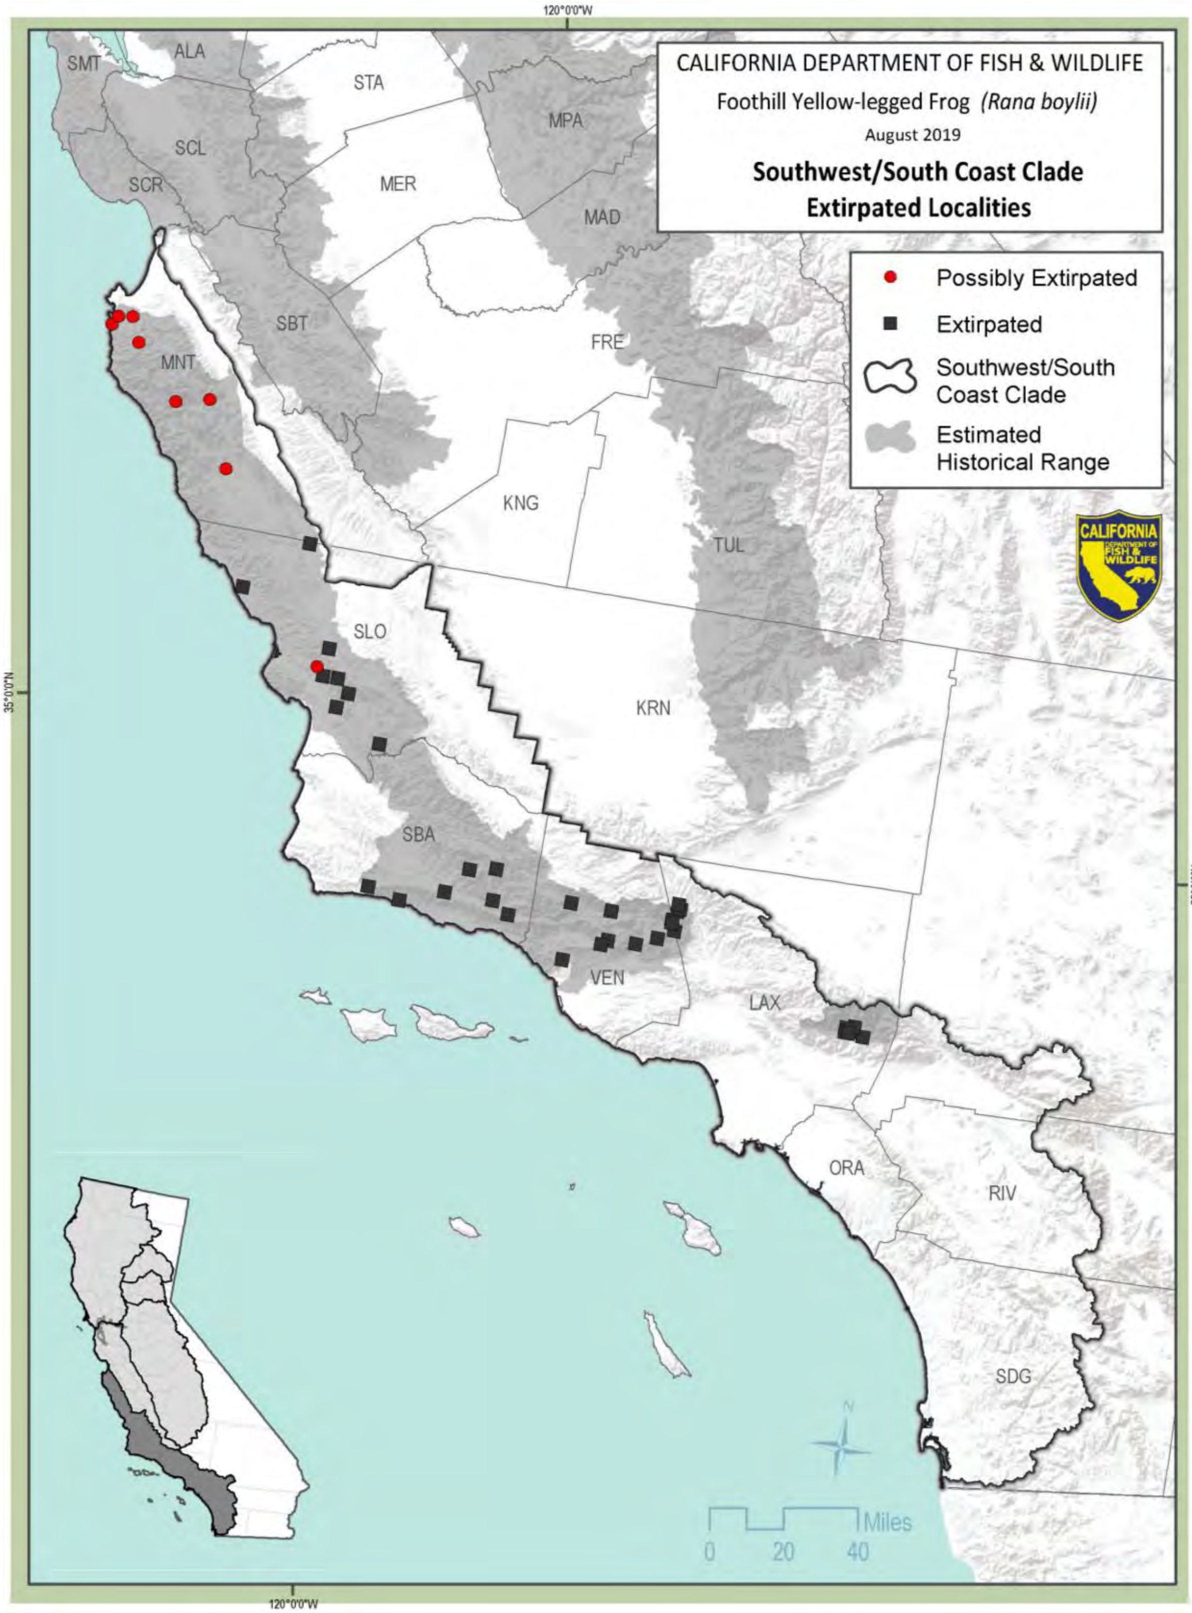

Figure 18. Possibly extirpated and extirpated Southwest/South Coast Foothill Yellow-legged Frog clade occurrences (CNDDB)

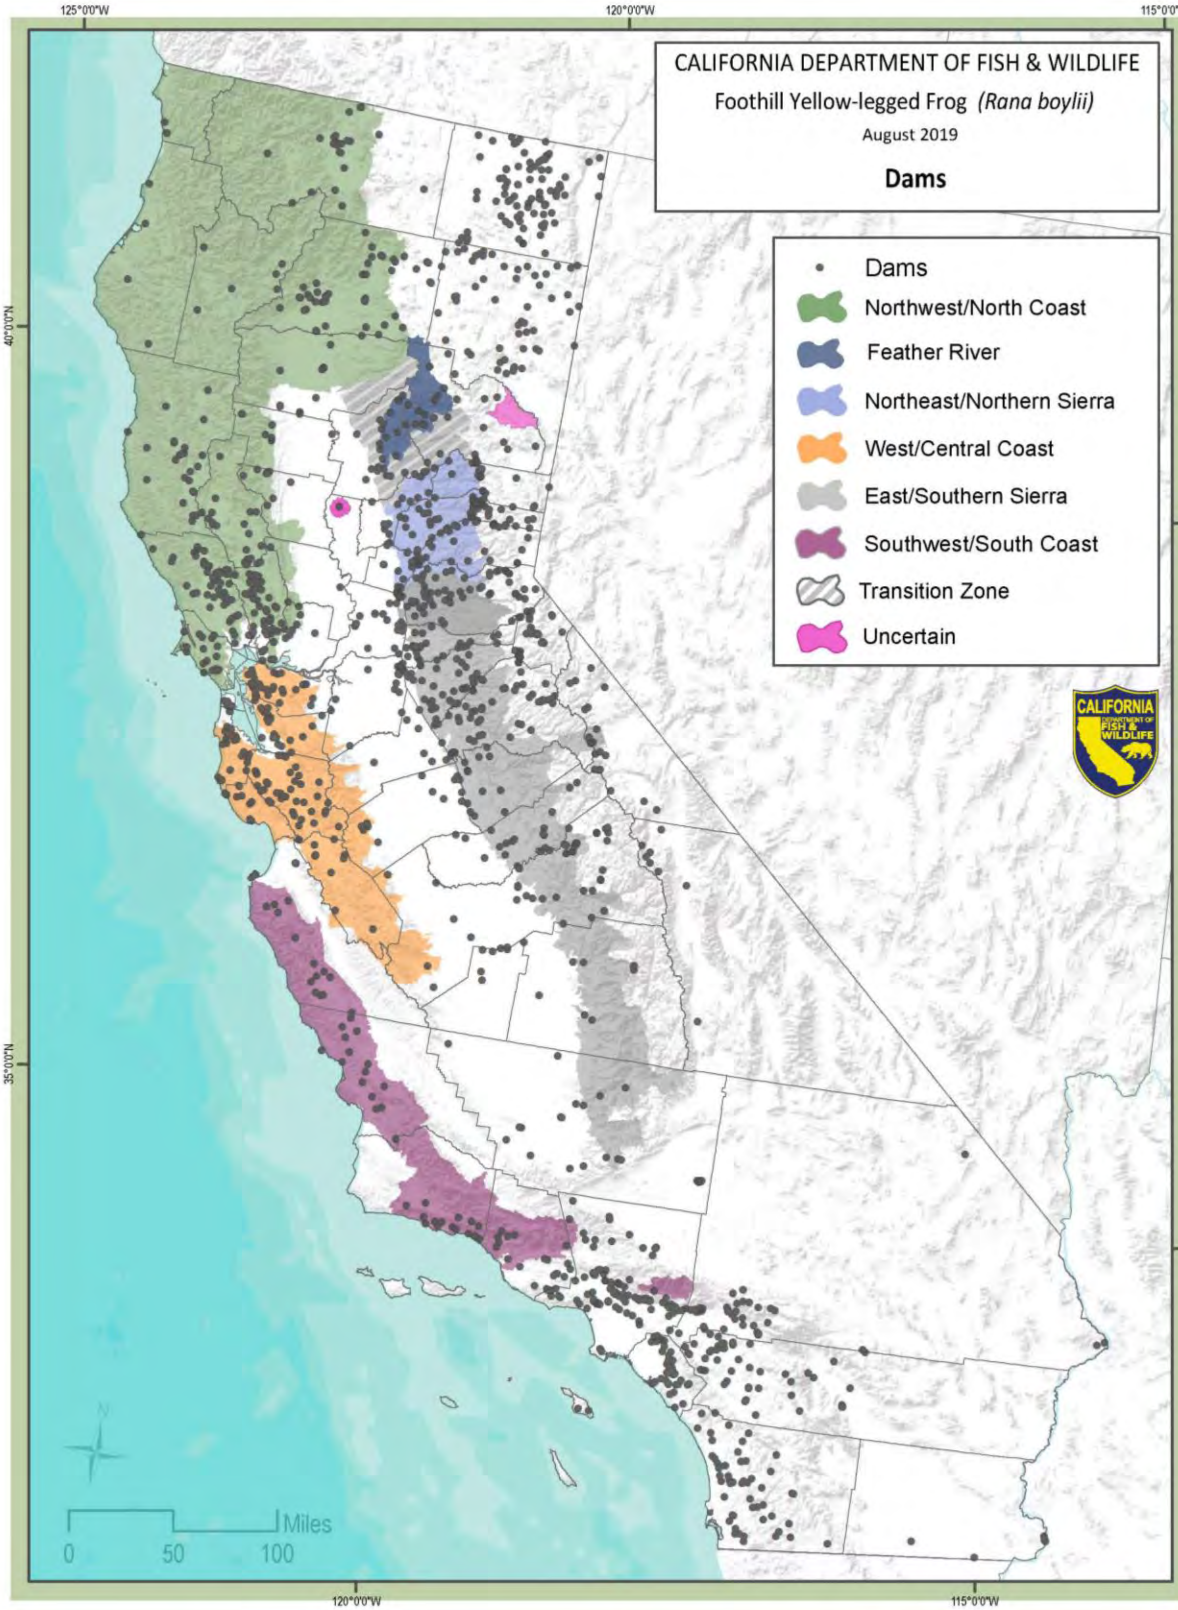

Figure 19. Locations of dams under the jurisdiction of the U.S. Army Corps of Engineers and the California Department of Water Resources in California (DWR, FRS)

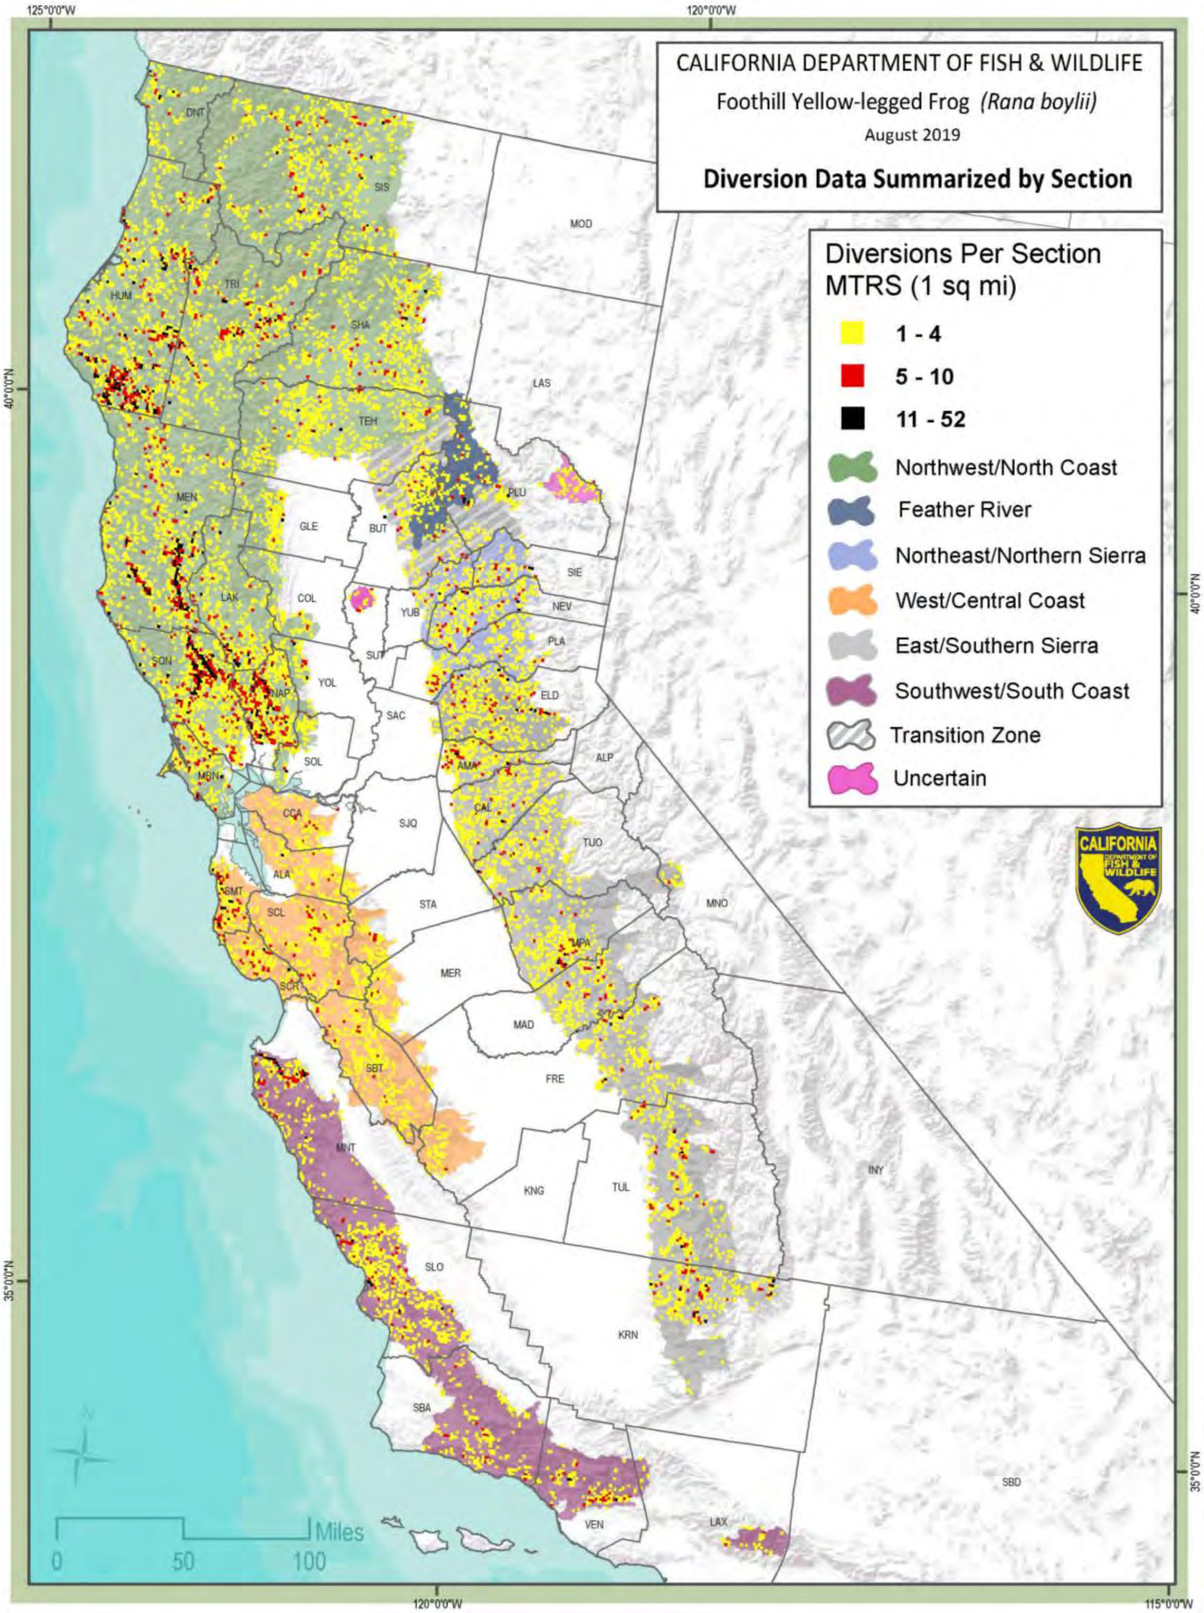

Figure 20. Number of surface water diversions per Public Land Survey System section within the Foothill Yellow-legged Frog's range in California (eWRIMs)

populations in regulated and unregulated reaches within the same watershed investigated potential dam-effects. These studies demonstrated that dams and their operations can result in several factors that contribute to population declines and possible extirpation. These factors include confusing breeding cues, scouring and stranding of egg masses and tadpoles, reducing the quality and quantity of breeding and rearing habitat, diminishing tadpole growth rate, creating barriers to gene flow, and supporting the establishment and spread of non-native species (Hayes et al. 2016). In addition, as previously discussed in the Population Structure and Genetic Diversity section, subpopulations of Foothill Yellow-legged Frogs on regulated rivers are more genetically isolated, and the type of water operations (hydropeaking vs. bypass flows) significantly affects the degree of connectivity and associated gene flow among them (Peek 2010, 2018; R. Peek pers. comm. 2019b). Both the Middle Fork of the American River and the Tuolumne River have hydropeaking reaches, and the Foothill Yellow-legged Frogs occupying them show marked genetic divergence and evidence of genetic bottlenecking (Peek 2018, R. Peek pers. comm. 2019b). Figure 21 depicts the locations of hydropower generating dams within and around the Foothill Yellow-legged Frog's range in California.

As discussed in the Seasonal Activity and Movements section, cues for Foothill Yellow-legged Frogs to start breeding include water temperature and velocity, two features altered by dams. Some dam operations result in reduced flows that are more stable over the course of a year than under unimpaired conditions, while others can result elevated and highly variable flows (R. Peek pers. comm. 2019a). In addition, dam operators are frequently required to maintain thermally appropriate water temperatures and flows for cold water adapted salmonids (USFWS and Hoopa Valley Tribe 1999, Wheeler et al. 2014). For example, late-spring and summer water temperatures on the mainstem Trinity River below Lewiston Dam have been reported to be up to 20°F cooler than average pre-dam temperatures, while average winter temperatures are slightly warmer (USFWS and Hoopa Valley Tribe 1999). As a result, Foothill Yellow-legged Frogs breed later in the season on the mainstem Trinity River compared to six nearby tributaries, and some mainstem reaches may never attain the minimum temperature required for successful breeding (Wheeler et al. 2014, Snover and Adams 2016). In addition, annual discharges past Lewiston Dam have been 10-30% of pre-dam flows and do not mimic the natural hydrograph (Lind et al. 1996). In other regulated rivers like the Middle Fork American, the water level can fluctuate nearly 3 ft in several hours, and higher than natural flows may be released for extended periods of time before returning to base flows (Peek 2010).

Aseasonal discharges from dams occur for several reasons including increased flow in late-spring and early summer to facilitate outmigration of salmonids, channel maintenance pulse flows, short-duration releases for recreational whitewater boating, rapid reductions after a spill (uncontrolled flows released down a spillway when reservoir capacity is exceeded) to retain water for power generation or water supply later in the year, peaking flows for hydropower generation, and sustained releases to maintain the seismic integrity of the dam (Lind et al. 1996, Jackman et al. 2004, Kupferberg et al. 2011b, Kupferberg et al. 2012, Snover and Adams 2016). The results of a Foothill Yellow-legged Frog population viability analysis (PVA) suggest that the likelihood a population will persist is very sensitive to early life stage mortality; the 30-year probability of extinction increases significantly with high levels of egg or tadpole scouring or stranding (Kupferberg et al. 2009c). For instance, in 1991 and 1992, all egg masses

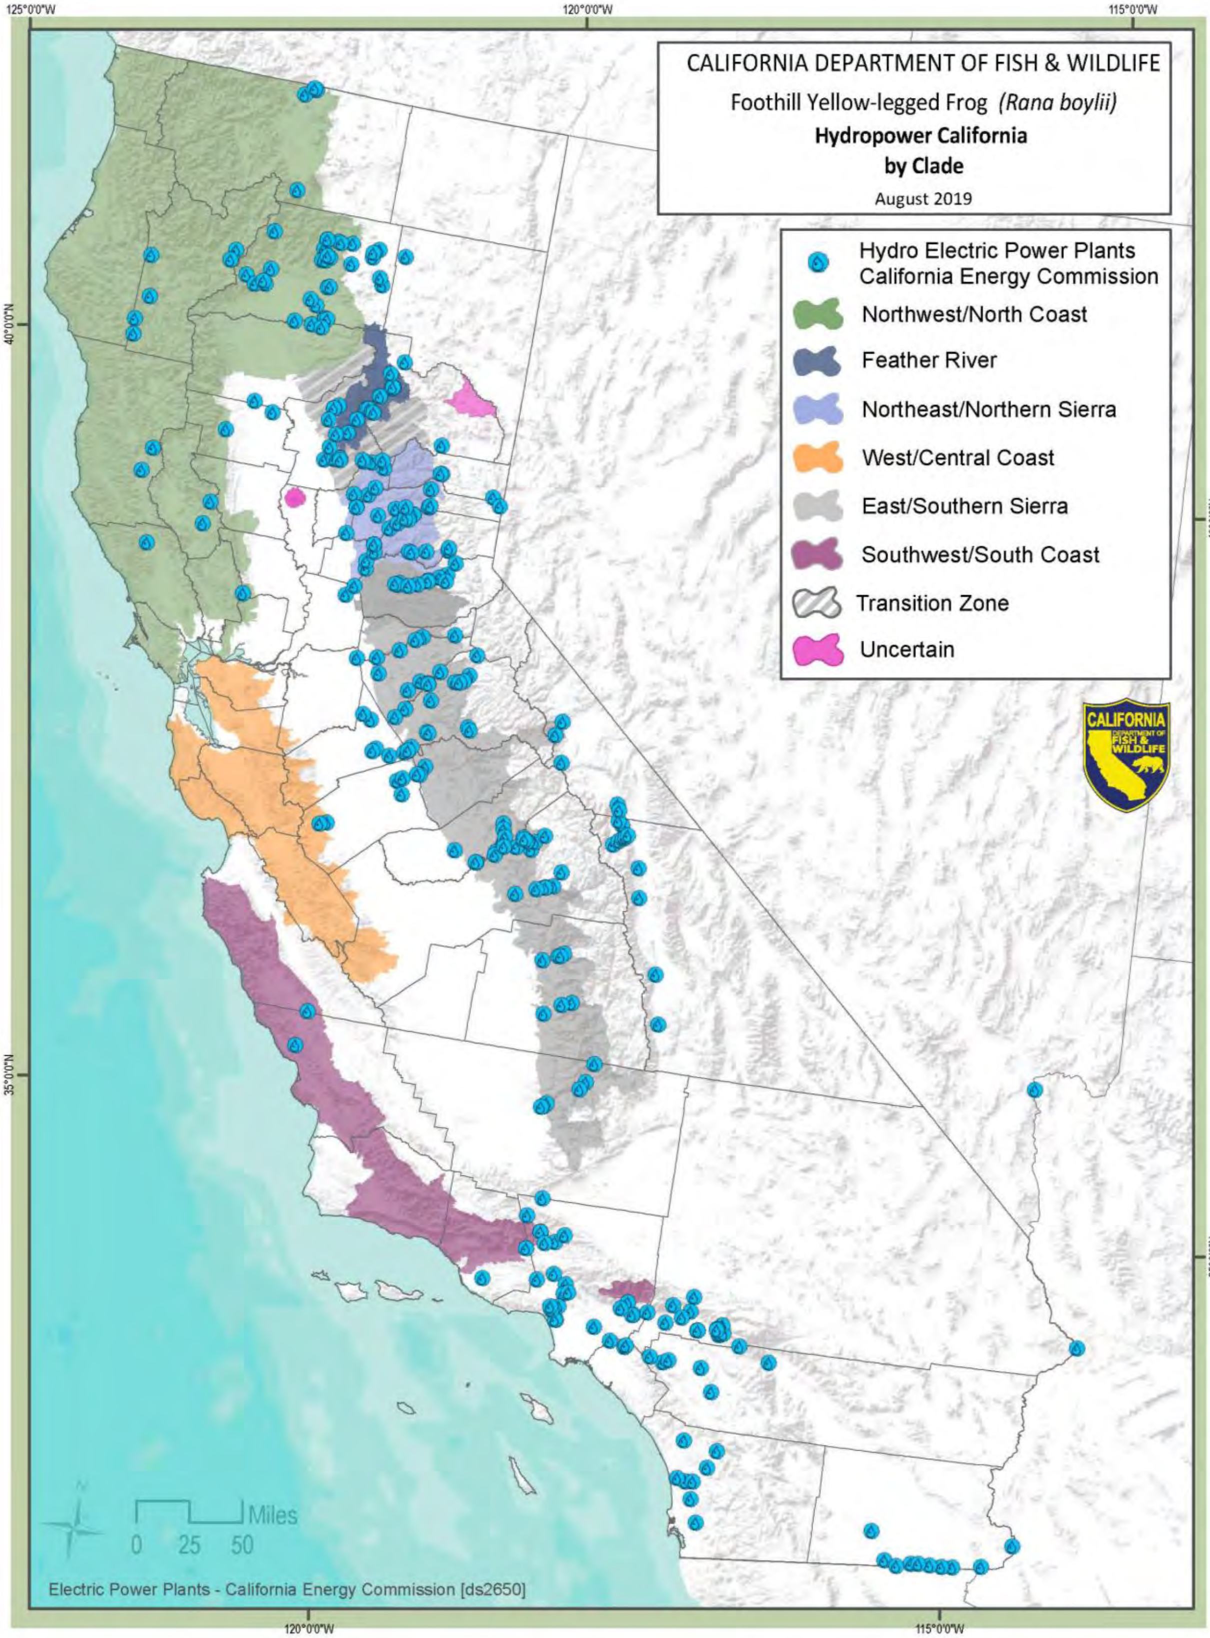

Figure 21. Locations of hydropower generating dams (BIOS)

laid before high flow releases to encourage outmigration of salmonids on the Trinity River were scoured away (Lind et al. 1996). According to the PVA, even a single annual pulse flow such as this, or for recreational boating, can result in a three- to five-fold increase in the 30-year extinction risk based on amount of tadpole mortality experienced (Kupferberg et al. 2009c). Management after natural spills can also lead to substantial mortality. For example, in 2006, Foothill Yellow-legged Frogs on the North Fork Feather River bred during a prolonged spill, and the rapid recession below Cresta Dam that followed stranded and desiccated all the eggs laid (Kupferberg et al. 2009b). Rapid flows can also increase predation risk if tadpoles are forced to seek shelter under rocks where crayfish and other invertebrate predators are more common or if they are displaced into the water column where their risk of predation by fish is greater (Ibid.).

The overall decrease in flows and frequency of large winter floods below dams can produce extensive changes to Foothill Yellow-legged Frog habitat quality. They reduce the formation of river bars that are regularly used as breeding habitat, and they create deeper and steeper channels with less complexity and fewer warm, calm, shallow edgewater habitats for tadpole rearing (Lind et al. 1996, Wheeler and Welsh 2008, Kupferberg et al. 2011b, Wheeler et al. 2014). For example, 26 years after construction of the Lewiston Dam on the Trinity River, habitat changes for 39 mi immediately downstream of the dam were evaluated (Lind et al. 1996). Riparian vegetation went from covering 30% of the riparian area pre-dam to 95% (Ibid.). Additionally, river bars made up 70% of the pre-dam riparian area compared to 4% post-dam, amounting to a 94% decrease in available Foothill Yellow-legged Frog breeding habitat (Ibid.).

Several features of riverine habitat below dams can decrease tadpole growth rate and other measures of fitness. As ectotherms, Foothill Yellow-legged Frogs require temperatures that support their metabolism, food conversion efficiency, growth, and development, and these temperatures may not be reached until late in the season, or not at all, when the water released is colder than their lower thermal limit (Kupferberg et al. 2011a, Catenazzi and Kupferberg 2013, Wheeler et al. 2014). Colder temperatures and higher flows reduce time spent feeding and food assimilation efficiency, resulting in slower growth and development (Kupferberg et al. 2011a,b; Catenazzi and Kupferberg 2018). Large bed-scouring winter floods promote greater *Cladophora glomerata* blooms, the filamentous green alga that dominates primary producer biomass during the tadpole rearing season (Power et al. 2008, Kupferberg et al. 2011a). The period of most rapid tadpole growth often coincides with blooms of highly nutritious and more easily assimilated epiphytic diatoms, so reduced flows can have food-web impacts on tadpole growth and survival (Power et al. 2008, Kupferberg et al. 2011a, Catenazzi and Kupferberg 2018). In addition, colder temperatures and fluctuating summer flows, such as those released for hydropower generation, can reduce the amount of algae available for grazing and can change the algal assemblage to one dominated by mucilaginous stalked diatoms like *Didymosphenia geminata* that have low nutritional value (Spring Rivers Ecological Sciences 2003, Kupferberg et al 2011a, Yarnell et al. 2013, Furey et al. 2014). Altered temperatures, flows, and food quality can contribute to slower growth and development, longer time to metamorphosis, smaller size at metamorphosis, and reduced body condition, which adversely impact fitness (Kupferberg et al. 2011b, Catenazzi and Kupferberg 2018).

As previously discussed, genetic divergence and diversity are strongly affected by river regulation (Peek 2010, 2018; Stillwater Sciences 2012). Foothill Yellow-legged Frogs primarily use watercourses as movement corridors, so the reservoirs created behind dams are often uninhabitable and represent barriers to gene flow (Bourque 2008; Peek 2010, 2018). This decreased connectivity can lead to loss of genetic diversity, which can reduce a species' ability to adapt to changing conditions (Palstra and Ruzzante 2008).

Decreased winter discharge below dams facilitates establishment and expansion of invasive bullfrogs, whose tadpoles require overwintering and are not well-adapted to flooding events (Lind et al. 1996, Doubledee et al. 2003). Where they occur, bullfrogs tend to dominate areas more altered by dam operations than less impaired areas, which support a higher proportion of native species (Moyle 1973, Fuller et al. 2011). In addition to downstream effects, the reservoirs created behind dams directly inundate and eliminate lotic (flowing) Foothill Yellow-legged Frog habitat, typically do not retain natural riparian communities due to fluctuating water levels, are often managed for human activities not compatible with the species' needs, and act as a source of introduced species upstream and downstream (Brode and Bury 1984, PG&E 2018). Moyle and Randall (1998) identified characteristics of sites with low native biodiversity in the Sierra Nevada foothills; they were often drainages that had been dammed and diverted in lower- to middle-elevations and dominated by introduced fishes and bullfrogs. Even small-scale operations can have significant effects. Some farming operations divert water during periods of high flows and store it in small impoundments for use during low flow-high demand times; these ponds can serve as sources for introduced species like bullfrogs to spread into areas where the habitat would otherwise be unsuitable (Kupferberg 1996b).

The mechanisms described above result in the widespread pattern of greater Foothill Yellow-legged Frog density in unregulated rivers and in reaches far enough downstream of a dam to experience minimal effects from it (Lind et al. 1996, Kupferberg 1996a, Bobzien and DiDonato 2007, Peek 2010). Foothill Yellow-legged Frog abundance in unregulated rivers averages five times greater than population abundance downstream of large dams (Kupferberg et al. 2012). Figure 22 depicts a comprehensive collection of egg mass density data, where at least four years of surveys have been undertaken, showing much lower abundance in regulated rivers (Peek and Kupferberg 2016). In California, Foothill Yellow-legged Frog presence is associated with an absence of dams or with only small dams far upstream (Lind 2005, Kupferberg et al. 2012). Hydropower generation from Sierra Nevada rivers accounts for nearly half its statewide production and about 9% of all electrical power used in California (Dettinger et al. 2018). Every major stream below approximately 2,000 ft in the Sierra Nevada has at least one large reservoir (≥100,000 ac-ft), and many have multiple medium and small ones (Hayes et al. 2016). Because of this, Catenazzi and Kupferberg (2017) posit that the dam-effect on Foothill Yellow-legged Frog populations is likely greater in the Sierra Nevada than the Coast Range because in the former dams are more often constructed in a series along a river and spaced close enough together that suitable breeding temperatures may never be attained in the intervening reaches.

4.2 Pathogens and Parasites

Perhaps the most widely recognized amphibian disease is chytridiomycosis, which is caused by the fungal pathogen *Batrachochytrium dendrobatidis* (Bd). Implicated in the decline of over 500 amphibian species, including 90 presumed extinctions, it represents the greatest recorded loss of biodiversity

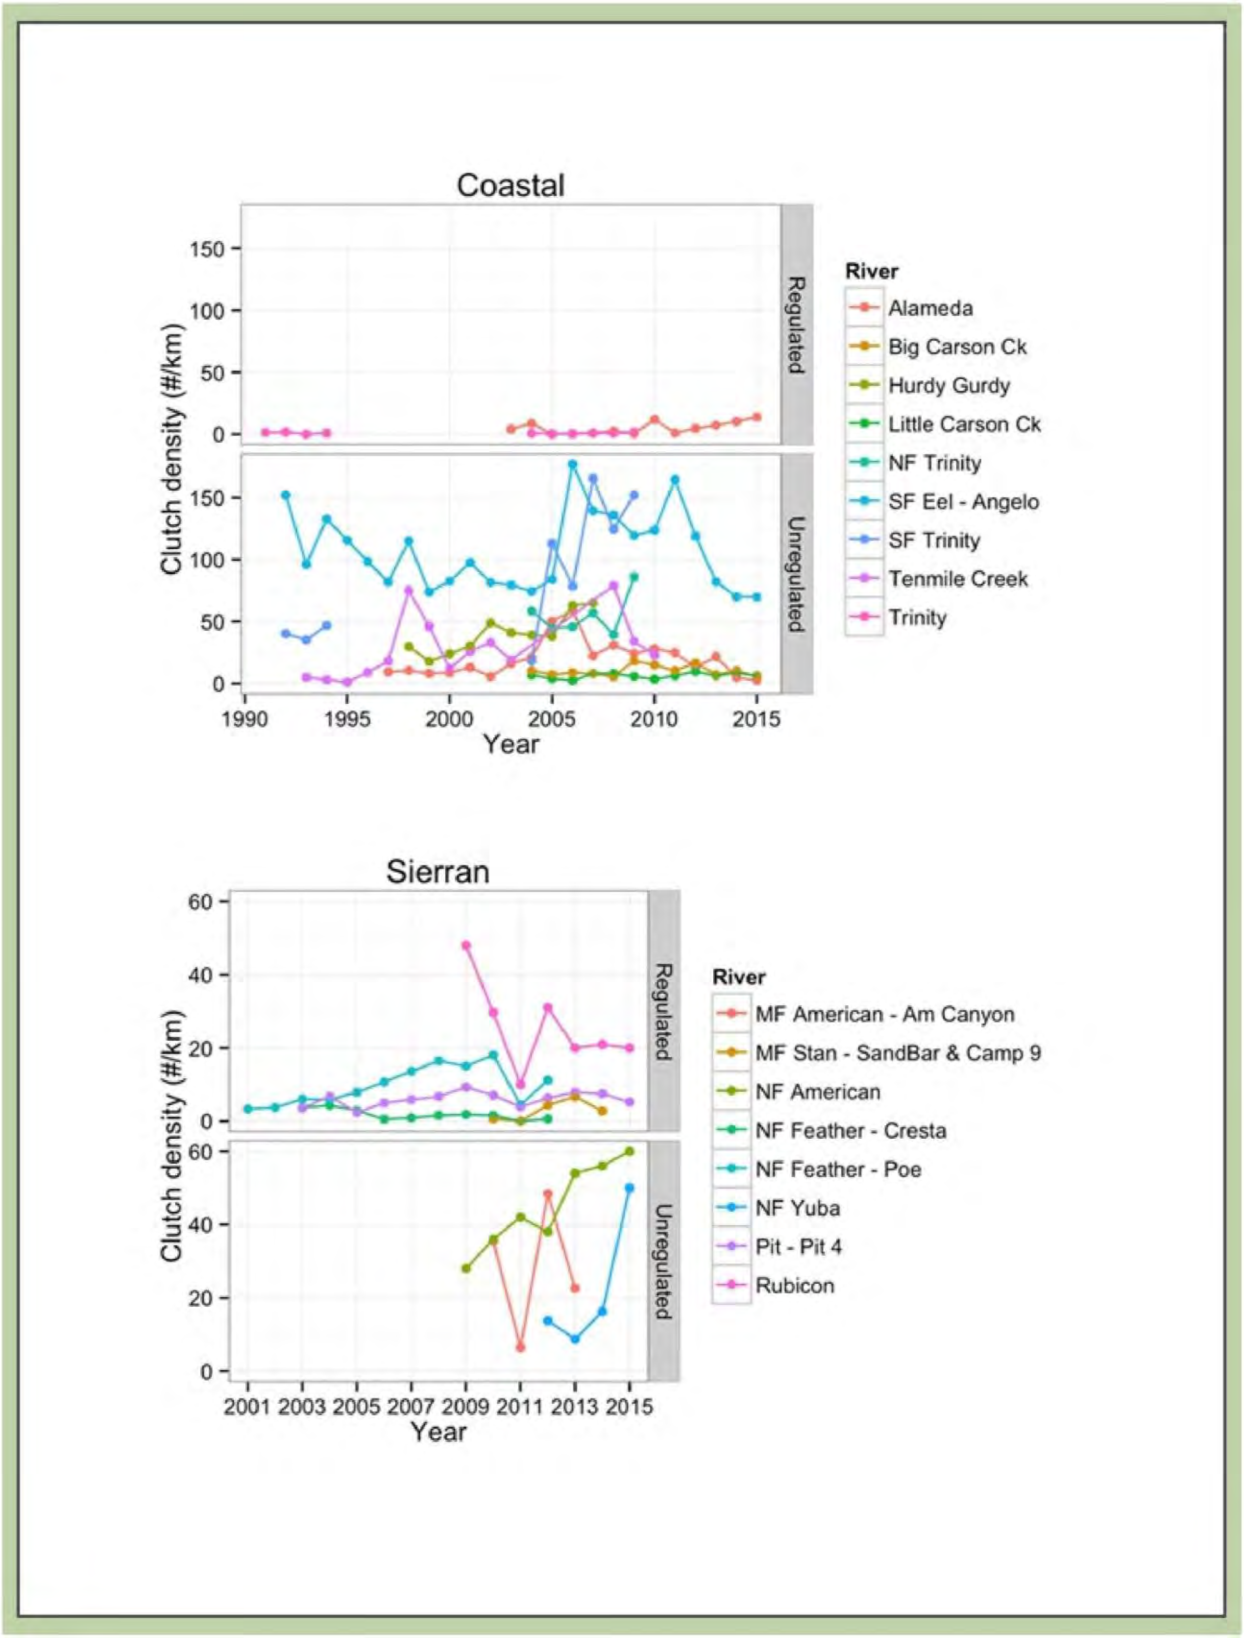

Figure 22. Foothill Yellow-legged Frog Egg mass density estimates along the coast from 1990-2015 and the Sierra Nevada from 2001-2015 (Peek and Kupferberg 2016)

attributable to a disease (Scheele et al. 2019). The global trade in American Bullfrogs (primarily for food) is connected to the disease's spread because the species can persist with low-level Bd infections without developing chytridiomycosis (Yap et al. 2018). Previous studies suggested Foothill Yellow-legged Frogs may not be susceptible to Bd-associated mass mortality; skin peptides strongly inhibited growth of the fungus in the lab, and the only detectable difference between Bd+ and Bd- juvenile Foothill Yellow-legged Frogs was slower growth (Davidson et al. 2007). At Pinnacles National Park in 2006, 18% of post-metamorphic Foothill Yellow-legged Frogs tested positive for Bd; all were asymptomatic and at least one Bd+ Foothill Yellow-legged Frog subsequently tested negative, demonstrating an ability to shed the fungus (Lowe 2009). However, recent studies have found historical evidence of Bd contributing to the extirpation of Foothill Yellow-legged Frogs in southern California, an acute die-off in 2013 in the Alameda Creek watershed, and another in 2018 in Coyote Creek (Adams et al. 2017a,b; Kupferberg and Catenazzi 2019). Evaluation of museum specimens indicated a lower Bd prevalence (proportion of individuals infected) in Foothill Yellow-legged Frogs than most other co-occurring amphibians in southern California in the first part of the 20th century, but it spiked in the 1970s just prior to the last observation of an individual in 1977 (Adams et al. 2017b). Two museum specimens collected in 1966, one from Santa Cruz County and the other from Alameda County, provide the earliest evidence of Bd in Foothill Yellow-legged Frogs in central California (Padgett-Flohr and Hopkins 2009). In contrast to the southern California results, Foothill Yellow-legged Frogs possessed the highest Bd prevalence among all amphibians tested in coastal Humboldt County in 2013 and 2014; however, zoospore (the aquatic dispersal agent) loads were well below the presumed lethal density threshold (Ecoclub Amphibian Group et al. 2016).

In addition to bullfrogs, the native Pacific Treefrog (*Pseudacris regilla*) seems immune to the lethal effects of chytridiomycosis, and owing to its broad ecological tolerances, more terrestrial lifestyle, and relatively large home range size and dispersal ability, the species is ubiquitous across California (Padgett-Flohr and Hopkins 2009). In a laboratory experiment, Bd-infected Pacific Treefrogs shed an average of 68 zoospores/min, making them the prime candidate for spreading and maintaining Bd in areas where bullfrogs do not occur (Padgett-Flohr and Hopkins 2009, Reeder et al. 2012). In the wild in Sixty Lakes Basin (Fresno County), Pacific Treefrog populations persisted at 100% of sites where the Southern Mountain Yellow-legged Frog had been extirpated from 72% of its formerly occupied sites due to a Bd outbreak (Reeder et al. 2012). This is consistent with the results of a model that incorporated Bd habitat suitability, host availability, and invasion history in North America, which concluded west coast mountain ranges were at the greatest risk from the disease (Yap et al. 2018).

Several other pathogens and parasites have been associated with Foothill Yellow-legged Frogs, but none have been ascribed to large-scale mortality events. Another fungus, a water mold (*Saprolegnia* sp.) carried by fish, is an important factor in amphibian embryo mortality in the Pacific Northwest (Blaustein et al. 1994, Kiesecker and Blaustein 1997). Fungal infections of Foothill Yellow-legged Frog egg masses, potentially from *Saprolegnia*, have been observed in the mainstem Trinity River (Ashton et al. 1997). *Saprolegnia* infection is more likely to occur in ponds and lakes, particularly if stocked by hatchery-raised fish into previously fishless areas and when frogs use communal oviposition sites, so it likely does not represent a major source of mortality in Foothill Yellow-legged Frogs (Blaustein et al. 1994, Kiesecker and Blaustein 1997). However, they may be more susceptible to *Saprolegnia* infection when exposed to other environmental stressors that compromise their immune defenses (Blaustein et al. 1994, Kiesecker and Blaustein 1997).

The trematode parasite *Ribeiroia ondatrae* is responsible for limb malformations in ranids (Stopper et al. 2002). *Ribeiroia ondatrae* was detected on a single Foothill Yellow-legged Frog during a study on malformations, but its morphology was normal (Kupferberg et al. 2009a). The results of the study instead linked malformations in Foothill Yellow-legged Frog tadpoles and young-of-year to the Anchor Worm (*Lernaea cyprinacea*), a parasitic copepod from Eurasia (Ibid.). Prevalence of malformations was low, under 4% of the population in both years of study, but there was a pattern of infected individuals metamorphosing at a smaller size, which as previously mentioned can have implications on fitness (Ibid.). Three other species of helminths (parasitic worms) were encountered during the study (*Echinostoma* sp., *Manodistomum* sp., and *Gyrodactylus* sp.); their relative impact on their hosts is unknown, but at least one Foothill Yellow-legged Frog had 700 echinostome cysts in its kidney (Ibid.). Bursey et al. (2010) discovered 13 species of helminths in and on Foothill Yellow-legged Frogs from Humboldt County. Most are common in anurans, and some are generalists with multiple possible hosts, but studies on their impact on Foothill Yellow-legged Frogs are lacking (Ibid.).

4.3 Introduced Species

Species not native to an area, but introduced, can alter food webs and ecosystem processes through predation, competition, hybridization, disease transmission, and habitat modification. Native species lack evolutionary history with introduced species, and early life stages of native anurans are particularly susceptible to predation by aquatic non-native species (Kats and Ferrer 2003). Because introduced species often establish in highly modified habitats, it can be difficult to differentiate between impacts from habitat degradation and the introduced species (Fisher and Shaffer 1996). However, native amphibians have been frequently found successfully reproducing in heavily altered habitats when introduced species were absent, suggesting introduced species themselves can impose an appreciable adverse effect (Ibid.). Numerous introduced species have been documented to adversely impact Foothill Yellow-legged Frogs or are suspected of doing so.

American Bullfrogs were introduced to California from the eastern U.S. around the turn of the 20th century, likely in response to overharvest of native ranids by the frog-leg industry that accompanied the Gold Rush (Jennings and Hayes 1985). Nearly 50 years ago, Moyle (1973) reported that distributions of Foothill Yellow-legged Frogs and bullfrogs in the Sierra Nevada foothills were nearly mutually exclusive. He speculated that bullfrog predation and competition may be causal factors in their disparate distributions in addition to the habitat degradation from dams and diversions that facilitated the bullfrog invasion in the first place. In a study along the South Fork Eel River and one of its tributaries, Foothill Yellow-legged Frog abundance was nearly an order of magnitude (10 times) lower in reaches where bullfrogs were well established (Kupferberg 1997a). At a site in Napa Valley, after bullfrogs were eradicated, Foothill Yellow-legged Frogs, among other native species, recolonized the area (Wilcox and Alvarez 2019). In a mesocosm experiment, Foothill Yellow-legged Frog tadpole survival in the presence of bullfrog tadpoles was half that of control enclosures containing only Foothill Yellow-legged Frogs, and they weighed approximately one-quarter less at metamorphosis (Kupferberg 1997a). The mechanism for these declines appeared to be the reduction of high-quality algae by bullfrog tadpole grazing, as opposed to any behavioral or chemical interference (Ibid.). Adult bullfrogs, which can get very large (3.5-6.0 inches), also directly consume Foothill Yellow-legged Frogs, including adults (Moyle 1973, Crayon 1998, Powell et al. 2016).

As discussed briefly in the Pathogens and Parasites section, American Bullfrogs act as reservoirs and vectors of the lethal chytrid fungus. In museum specimens from both southern and central California, Bd was detected in bullfrogs before it was detected in Foothill Yellow-legged Frogs in the same area (Padgett-Flohr and Hopkins 2009, Adams et al. 2017b). During a die-off from chytridiomycosis that commenced in 2013, Bd prevalence and load in Foothill Yellow-legged Frogs was positively predicted by bullfrog presence (Adams et al. 2017a). A similar die-off in 2018 from a nearby county appears to be related to transmission by bullfrogs as well (Kupferberg and Catenazzi 2019). In addition, male Foothill Yellow-legged Frogs have been observed amplexing female bullfrogs, which may not only constitute wasted reproductive effort but could serve to increase their likelihood of contracting Bd (Lind et al. 2003a). In fact, adult males were more likely to be infected with Bd than females or juveniles during the recent die-off in Alameda Creek (Adams et al. 2017a). African Clawed Frogs (*Xenopus laevis*) have also been implicated in the spread of Bd in California because, like bullfrogs, they are asymptomatic carriers (Padgett-Flohr and Hopkins 2009). However, African Clawed-Frog distribution only minimally overlaps with the Foothill Yellow-legged Frog's range unlike the widespread bullfrog (Stebbins and McGuinness 2012).

Hayes and Jennings (1986) observed a negative association between the abundance of introduced fish and Foothill Yellow-legged Frogs. Rainbow trout (*Onchorynchus mykiss*) and green sunfish (*Lepomis cyanellus*) are suspected of destroying egg masses (Van Wagner 1996). Bluegill sunfishes (*L. macrochirus*) are likely predators; in captivity when offered eggs and tadpoles of two ranid species, they consumed both life stages but a significantly greater number of tadpoles (Werschkul and Christensen 1977). Common hatchery-stocked fish like brook (*Salvelinus fontinalis*) and rainbow trout commonly carry *Saprolegnia* (Blaustein et al. 1994). In addition, presence of non-native fish can facilitate bullfrog invasions by reducing the density of macroinvertebrates that prey on their tadpoles (Adams et al. 2003). Foothill Yellow-legged Frog tadpoles raised from eggs from sites with and without smallmouth bass (*Micropterus dolomieu*) did not differ in their responses to exposure to the non-native, predatory bass and a native, non-predatory fish (Paoletti et al. 2011). This result suggests that Foothill Yellow-legged Frogs have not yet evolved a recognition of bass as a threat, which makes them more vulnerable to predation (Ibid.).

Introduced into several areas within the Coast Range and Sierra Nevada, signal crayfish have been recorded preying on Foothill Yellow-legged Frog egg masses and are suspected of preying on their tadpoles based on observations of tail injuries that looked like scissor snips (Riegel 1959, Wiseman et al. 2005). The introduced red swamp crayfish (*Procambarus clarkii*) likely also preys on Foothill Yellow-legged Frogs. Because Foothill Yellow-legged Frogs evolved with the native Shasta Crayfish (*Pacifastacus fortis*) in some parts of northern California, frogs from those areas may more effectively avoid crayfish predation than in other parts of the state where they are not native (Riegel 1959, USFWS 1998, Kats and

Ferrer 2003). The Foothill Yellow-legged Frog's naiveté to crayfish was demonstrated in a study that showed they did not change behavior when exposed to signal crayfish chemical cues; however, once the crayfish was released and consuming Foothill Yellow-legged Frog tadpoles, the survivors, likely reacting to chemical cues from dead tadpoles, exhibited a predator-avoidance behavior (Kerby and Sih 2015).

4.4 Sedimentation

Several anthropogenic activities, some of which are described in greater detail below, can artificially increase sedimentation into waterways occupied by Foothill Yellow-legged Frogs and adversely impact biodiversity (Moyle and Randall 1998). These activities include but are not limited to mining, agriculture, overgrazing, timber harvest, and poorly constructed roads (Ibid.). Increased fine sediments can substantially degrade Foothill Yellow-legged Frog habitat quality. Heightened turbidity decreases light penetration that phytoplankton and other aquatic plants require for photosynthesis (Cordone and Kelley 1961). When silt particles fall out of the water column, they can destroy algae by covering the bottom of the stream (Ibid.). Algae are not only important for Foothill Yellow-legged Frog tadpoles as forage but also for oxygen production (Ibid.). Sedimentation may impede attachment of egg masses to substrate (Ashton et al. 1997). The effect of silt accumulation on embryonic development is unknown, but it does make them less visible, which could decrease predation risk (Fellers 2005). Fine sediments can fill interstitial spaces between rocks that tadpoles use for shelter from high velocity flows and cover from predators and that serve as sources for aquatic invertebrate prey for post-metamorphic Foothill Yellow-legged Frogs (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b).

4.5 Mining

Current mining practices, as well as legacy effects from historical mining operations, may adversely impact Foothill Yellow-legged Frogs through contaminants, direct mortality, habitat destruction and degradation, and behavioral disruption. While mercury in streams can result from atmospheric deposition, storm-induced runoff of naturally occurring mercury, agricultural runoff, and geothermal springs, runoff from historical mine sites mobilizes a significant amount of mercury (Foe and Croyle 1998, Alpers et al. 2005, Hothem et al. 2010). Beginning in the mid-1800s, extensive mining occurred in the Coast Range to supply mercury for gold mining in the Sierra Nevada, causing widespread contamination of both mountain ranges and the rivers in the Central Valley (Foe and Croyle 1998). Studies on Foothill Yellow-legged Frog tissues collected from the Cache Creek (Coast Ranges) and Greenhorn Creek (Sierra Nevada) watersheds revealed mercury bioaccumulation concentrations as high as 1.7 and 0.3 ppm, respectively (Alpers et al. 2005, Hothem et al. 2010). For context, the U.S. Environmental Protection Agency's mercury criterion for issuance of health advisories for fish consumption is 0.3 ppm; concentrations exceeded this threshold in Foothill Yellow-legged Frog tissues at 62% of sampling sites in the Cache Creek watershed (Hothem et al. 2010). Bioaccumulation of this powerful neurotoxin can cause deleterious impacts on amphibians including inhibited growth, decreased survival to metamorphosis, increased malformations, impaired reproduction, and other sublethal effects (Zillioux et al. 1993, Unrine et al. 2004). In a study measuring Sierra Nevada watershed health, Moyle and Randall (1998) reportedly found very low biodiversity in streams that were heavily polluted by acidic water leaching from historical mines. Acidic drainage measured as low as pH 3.4 from some mined areas in the northern Sierra Nevada (Alpers et al. 2005).

Widespread suction dredging for gold occurred in the Foothill Yellow-legged Frog's California range until enactment of a moratorium on issuing permits in 2009 (Hayes et al. 2016). Suction dredging vacuums up the contents of the streambed, passes them through a sluice box to separate the gold, and then deposits the tailings on the other side of the box (Harvey and Lisle 1998). While most habitat disturbance is localized and minor, it can be especially detrimental if it degrades or destroys breeding and rearing habitat through direct disturbance or sedimentation (Ibid.). In addition, this activity can lead to direct mortality of early life stages through entrainment, and those eggs and tadpoles that do survive passing through the suction dredge may experience greater mortality due to subsequent unfavorable physiochemical conditions and possible increased predation risk (Ibid.). Suction dredging can also reduce the availability of invertebrate prey, although this impact is typically short-lived (Ibid.). Suction dredging alters stream morphology, and relict tailing ponds can serve as breeding habitat for bullfrogs in areas that would not normally support them (Fuller et al. 2011). However, in some areas these mining holes have reportedly benefited Foothill Yellow-legged Frogs by creating cool persistent pools through the summer at one Sierra Nevada site that adult females appeared to prefer (Van Wagner 1996). Senate Bill 637 (2015) directs the Department to work with the State Water Resources Control Board (SWRCB) to develop a statewide water quality permit that would authorize the use of vacuum or suction dredge equipment in California under conditions set forth by the two agencies. SWRCB staff, in coordination with Department staff, are in the process of collecting additional information to inform the next steps that will be taken by the SWRCB (SWRCB 2019).

Instream aggregate (gravel) mining continues today and can have similar impacts to suction dredge mining by removing, processing, and relocating stream substrates (Olson and Davis 2009). This type of mining typically removes bars used as Foothill Yellow-legged Frog breeding habitat and reduces habitat heterogeneity by creating flat wide channels (Kupferberg 1996a, Yarnell 2005). When listed salmonids are present, typically mining must be conducted above the wetted edge, but this practice can create perennial off-channel bullfrog breeding ponds (M. van Hattem pers. comm. 2018).

4.6 Agriculture

California is the nation's largest agricultural producer and exporter (CDFA 2018a). Direct loss of Foothill Yellow-legged Frog habitat from wildland conversion to agriculture is likely rare overall because the typically rocky riparian areas they inhabit are usually not conducive to farming, but removal of riparian vegetation directly adjacent to streams for agriculture is more common and widespread. The U.S. Department of Agriculture classifies 9.6 million ac in California as cropland, which amounts to less than 10% of the state's land area, and 70% of this occurs in the Central Valley between Redding and Bakersfield (Martin et al. 2018). In addition, several indirect impacts can adversely affect Foothill Yellow-legged Frogs at substantial distances from agricultural operations such as effects from runoff (sediments and agrochemicals), drift and deposition of airborne pollutants, water diversions, and creation of novel habitats like impoundments that facilitate spread of detrimental non-native species. As sedimentation and introduced species impacts were previously discussed, this section instead focuses on the other possible adverse impacts.

4.6.1 Agrochemicals

Many species of amphibians, particularly ranids, have experienced declines throughout California, but the most dramatic declines have occurred in the Sierra Nevada east of the San Joaquin Valley where 60% of the total pesticide usage in the state was sprayed (Sparling et al. 2001). Agrochemicals applied to crops in the Central Valley can volatilize, travel through the atmosphere, and deposit in higher elevations (LeNoir et al. 1999). Pesticide concentrations diminish as elevations increase in the lower foothills but change little from 1,750 to 6,300 ft, which coincides with the Foothill Yellow-legged Frog's elevational range (Ibid). Foothill Yellow-legged Frog absence at historically occupied sites in California significantly correlated with agricultural land use within 3.1 mi (Davidson et al. 2002). Figure 23 depicts the positive relationship between Foothill Yellow-legged Frog declines and the amount of upwind agriculture, suggesting airborne agrochemicals may be a contributing factor (Ibid.). Cholinesterase-inhibitors (most organophosphates and carbamates), which disrupt nerve impulse transmission, were more strongly associated with population declines than other pesticide types (Davidson 2004). Olson and Davis (2009) and Lind (2005) also reported a negative correlation between Foothill Yellow-legged Frog presence and proximity and quantity of nearby agriculture in Oregon and across the species' entire range, respectively.

Lethal and sublethal effects of agrochemicals on amphibians can take two general forms: direct toxicity and food-web effects. Sublethal doses of agrochemicals can interact with other environmental stressors to reduce fitness. Foothill Yellow-legged Frog tadpoles showed significantly greater vulnerability to the lethal and sublethal effects of carbaryl than Pacific Treefrogs (Kerby and Sih 2015). An inverse relationship exists between carbaryl concentration and Foothill Yellow-legged Frog activity, and their 72-hr LC_{50} (concentration at which 50% die) measured one-fifth that of Pacific Treefrogs (Ibid.). Carbaryl slightly decreased Foothill Yellow-legged Frog development rate, but it significantly increased susceptibility to predation by signal crayfish despite nearly no mortality in the pesticide- and predator-only treatments (Ibid.). Sparling and Fellers (2009) also found Foothill Yellow-legged Frogs were significantly more sensitive to pesticides (chlorpyrifos and endosulfan in this study) than Pacific Treefrogs; their 96-hr LC_{50} was nearly five-times less than for treefrogs. Endosulfan was nearly 121 times more toxic to Foothill Yellow-legged Frogs than chlorpyrifos, and water samples from the Sierra Nevada have contained endosulfan concentrations greater than the LC_{50} for the species in some parts of the species' range (Ibid.). Sublethal effects included smaller body size, slower development rate, and increased time to metamorphosis (Ibid.). Sparling and Fellers (2007) determined the organophospates chlorpyrifos, malathion, and diazinon can harm Foothill Yellow-legged Frog populations, and their oxon derivatives (the resultant compounds once they begin breaking down in the body) were 10 to 100 times more toxic than their respective parental forms.

Extrapolating the results of studies on other ranids to Foothill Yellow-legged Frogs should be undertaken with caution; however, those studies can demonstrate additional potential adverse impacts of exposure to agrochemicals. Relyea (2005) discovered that Roundup®, a common herbicide, could cause rapid and

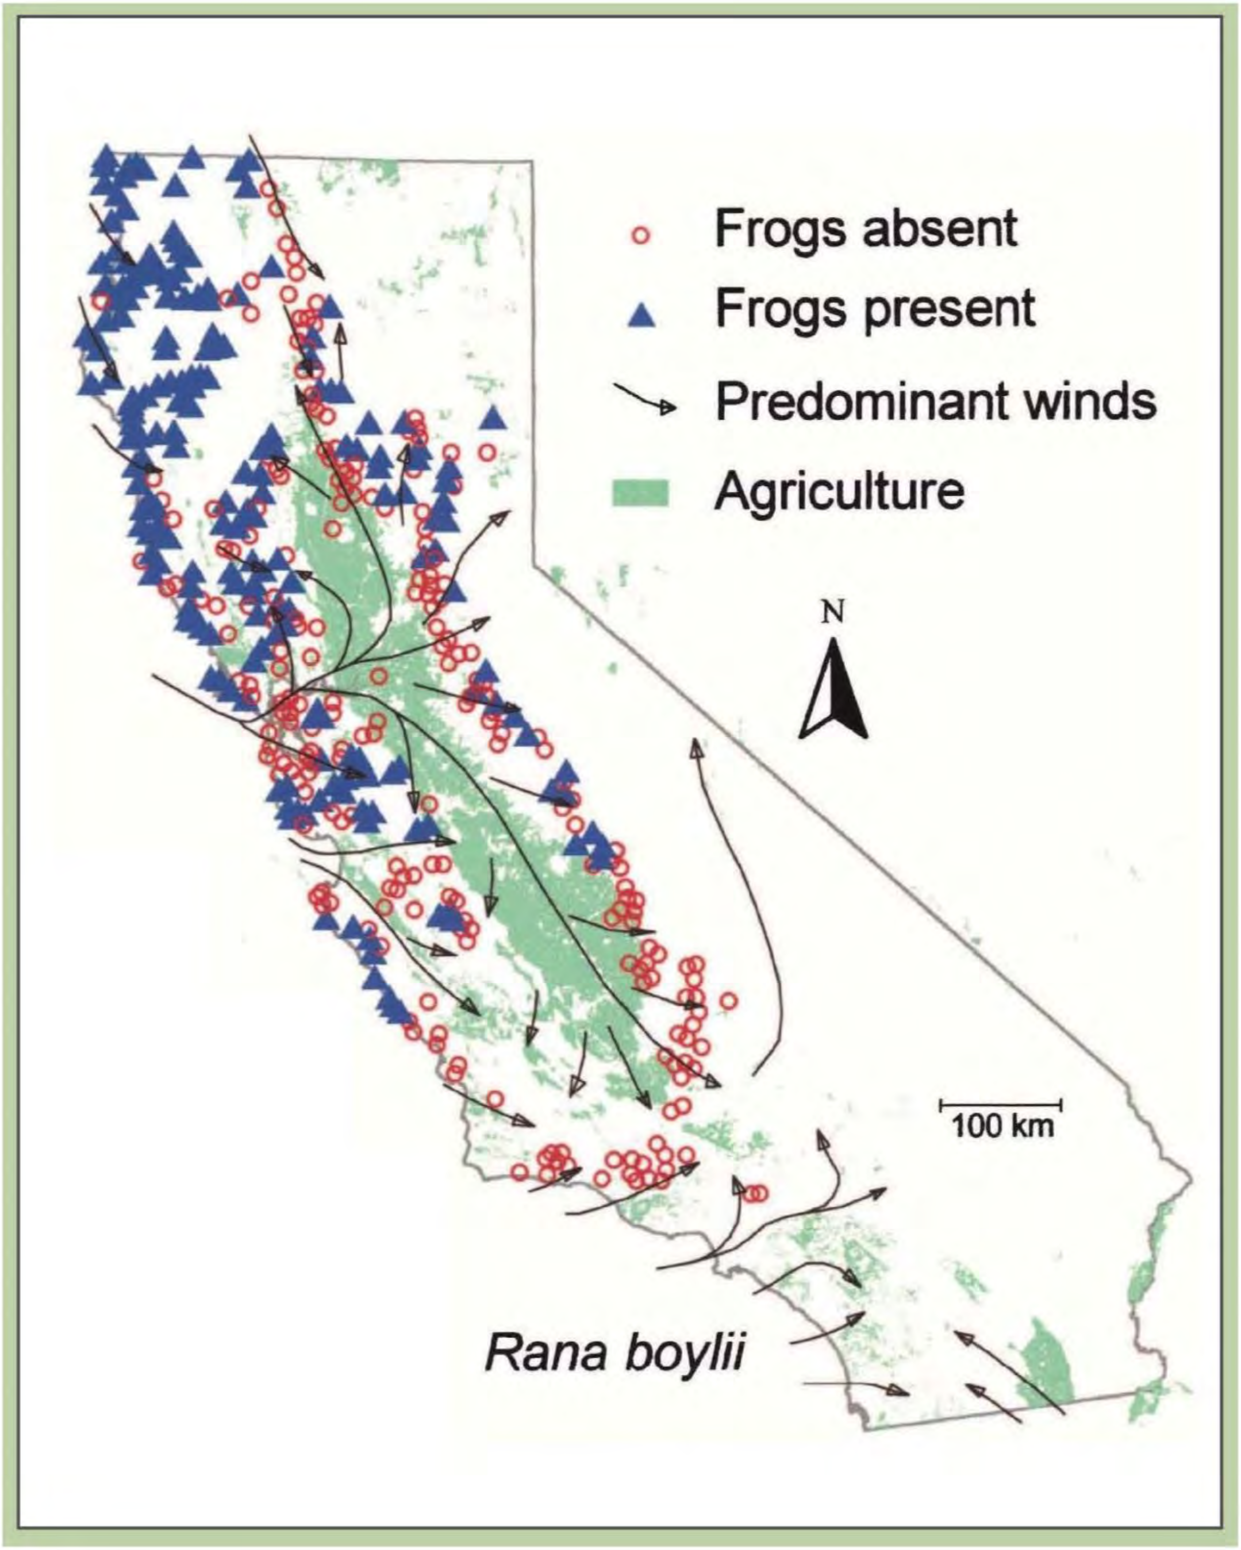

Figure 23. Relationship of Foothill Yellow-legged Frog occupancy to agriculture and prevailing winds from Davidson et al. (2002)

widespread mortality in amphibian tadpoles through direct toxicity, and overspray at the manufacturer's recommended application concentrations would be highly lethal. Atrazine, another common herbicide, has been implicated in disrupting reproductive processes in male Northern Leopard Frogs (Rana pipiens) by slowing gonadal development, inducing hermaphroditism, and even producing oocytes (eggs) (Hayes et al. 2003). However, recent research on sex reversal in wild populations of Green Frogs (R. clamitans) suggests the phenomenon may be a relatively common natural process unrelated to environmental contaminants, requiring more research (Lambert et al. 2019). Malathion, a common organophosphate insecticide, that rapidly breaks down in the environment, applied at low concentrations caused a trophic cascade that resulted in reduced growth and survival of two species of ranid tadpoles (Relyea and Diecks 2008). Malathion caused a reduction in the amount of zooplankton, which resulted in a bloom of phytoplankton and an eventual decline in periphyton, an important food source for tadpoles (Ibid.). In contrast, Relyea (2005) found that some insecticides increased amphibian tadpole survival by reducing their invertebrate predators. Runoff from agricultural areas can contain fertilizers that input nutrients into streams and increase productivity, but they can also result in harmful algal blooms (Cordone and Kelley 1961). In addition, exposure to pesticides can result in immunosuppression and reduce resistance to the parasites that cause limb malformations (Kiesecker 2002, Hayes et al. 2006).

4.6.2 Cannabis

An estimated 60-70% of the cannabis (*Cannabis indica* and *C. sativa*) used in the U.S. from legal and illegal sources is grown in California, and most comes from the Emerald Triangle, an area comprised of Humboldt, Mendocino, and Trinity counties (Ferguson 2019). Small-scale illegal cannabis farms have operated in this area since at least the 1960s but have expanded rapidly since the passage of the Compassionate Use Act in 1996, particularly trespass grows on public land primarily by Mexican cartels (Mallery 2010, Bauer et al. 2015). Like other forms of agriculture, it involves clearing the land, diverting water, and using herbicides and pesticides; however, in addition, many of these illicit operations use large quantities of fertilizers and highly toxic banned pesticides to kill anything that may threaten the crop, and they leave substantial amounts of non-biodegradable trash and human excrement (Mallery 2010, Thompson et al. 2014, Carah et al. 2015).

Measurements of environmental impacts of illegal cannabis grows have been hindered by the difficult and dangerous nature of accessing many of these sites; however, some analyses have been conducted, often using aerial images and GIS. An evaluation of 54% of watersheds within and bordering Humboldt County revealed that while cannabis grow sites are generally small (<1.2 ac) and comprised a tiny fraction of the study area (301 ac), they were widespread (present in 83% of watersheds) but unevenly distributed, indicating impacts are concentrated in certain watersheds (Butsic and Brenner 2016, Wang et al. 2017). The results also showed that 68% of grows were ≤0.3 mi from developed roads, 23% were located on slopes steeper than 30%, and 5% were within 328 ft of critical habitat for threatened salmonids (Butsic and Brenner 2016). These characteristics suggest wildlands adjacent to cannabis cultivations are at heightened risk of habitat fragmentation, erosion, sedimentation, landslides, and impacts to waterways critical to imperiled species (Ibid.).

A separate analysis in the same general area estimated potentially significant impacts from water diversions alone. Cannabis requires a substantial amount of water during the growing season, so it is often cultivated near sources of perennial surface water for irrigation, commonly diverting from springs and headwater streams (Bauer et al. 2015). In the least impacted of the study watersheds, Bauer et al. (2015) calculated that diversions for cannabis cultivation could reduce the annual seven-day low flow by up to 23%, and in some of the heavily impacted watersheds, water demands for cannabis could exceed surface water availability. If not regulated carefully, cannabis cultivation could have substantial impacts on sensitive aquatic species like Foothill Yellow-legged Frogs in watersheds in which it is concentrated.

For context, cannabis cultivation was responsible for approximately 1.1% of forest cover lost within study watersheds in Humboldt County from 2000 to 2013, while timber harvest accounted for 53.3% (Wang et al. 2017). Cannabis requires approximately two times as much water per day as wine grapes, the other major irrigated crop in the region (Bauer et al. 2015). Impacts from cannabis cultivation have been observed by Foothill Yellow-legged Frog researchers working on the Trinity River and South Fork Eel River in the form of lower flows in summer, increased egg stranding, and more algae earlier in the season in recent years (S. Kupferberg and M. Power pers. comm. 2015; D. Ashton pers. comm. 2017; S. Kupferberg, M. van Hattem, and W. Stokes pers. comm. 2017). In addition, Gonsolin (2010) reported illegal cannabis cultivations on four headwater streams that drained into his study area along Coyote Creek, three of which were occupied by Foothill Yellow-legged Frogs. The cultivators had removed vegetation adjacent to the creeks, terraced the slopes, diverted water, constructed small water impoundments, poured fertilizers directly into the impoundments, and applied herbicides and pesticides, as evidenced by leftover empty containers littering the site.

Commercial sale of cannabis for recreational use became legal in California on January 1, 2018, through passage of the Control, Regulate and Tax Adult Use of Marijuana Act (2016), and with it an environmental permitting system and habitat restoration fund was established. The number of applications for temporary licenses per watershed is depicted in Figure 24. Two of the expected outcomes of passage of this law were that the profit-margin on growing cannabis would fall to the point that it would discourage illegal trespass grows and move the bulk of the cultivation out of remote forested areas into existing agricultural areas like the Central Valley (CSOS 2016). However, until cannabis is legalized at the federal level, these results may not occur since banks are reluctant to work with growers due to federal prohibitions subjecting them to prosecution for money laundering (ABA 2019). Additional details on cannabis permitting at the state level can be found under the Existing Management section.

4.6.3 Vineyards

Vineyard operators historically built on-stream dams and removed almost all the surrounding riparian vegetation to make room for vines and for ease of irrigation (M. van Hattem pers. comm. 2019). They still divert a substantial amount of water for irrigation, and they build on- and off-stream impoundments that support bullfrogs (Ibid.). The acreage of land planted in wine grapes in California began rising dramatically in the 1970s and now accounts for 90% of wine produced in the U.S. (Geisseler and Horwath 2016, Alston et al. 2018). The number of wineries in California rose from approximately 330 to

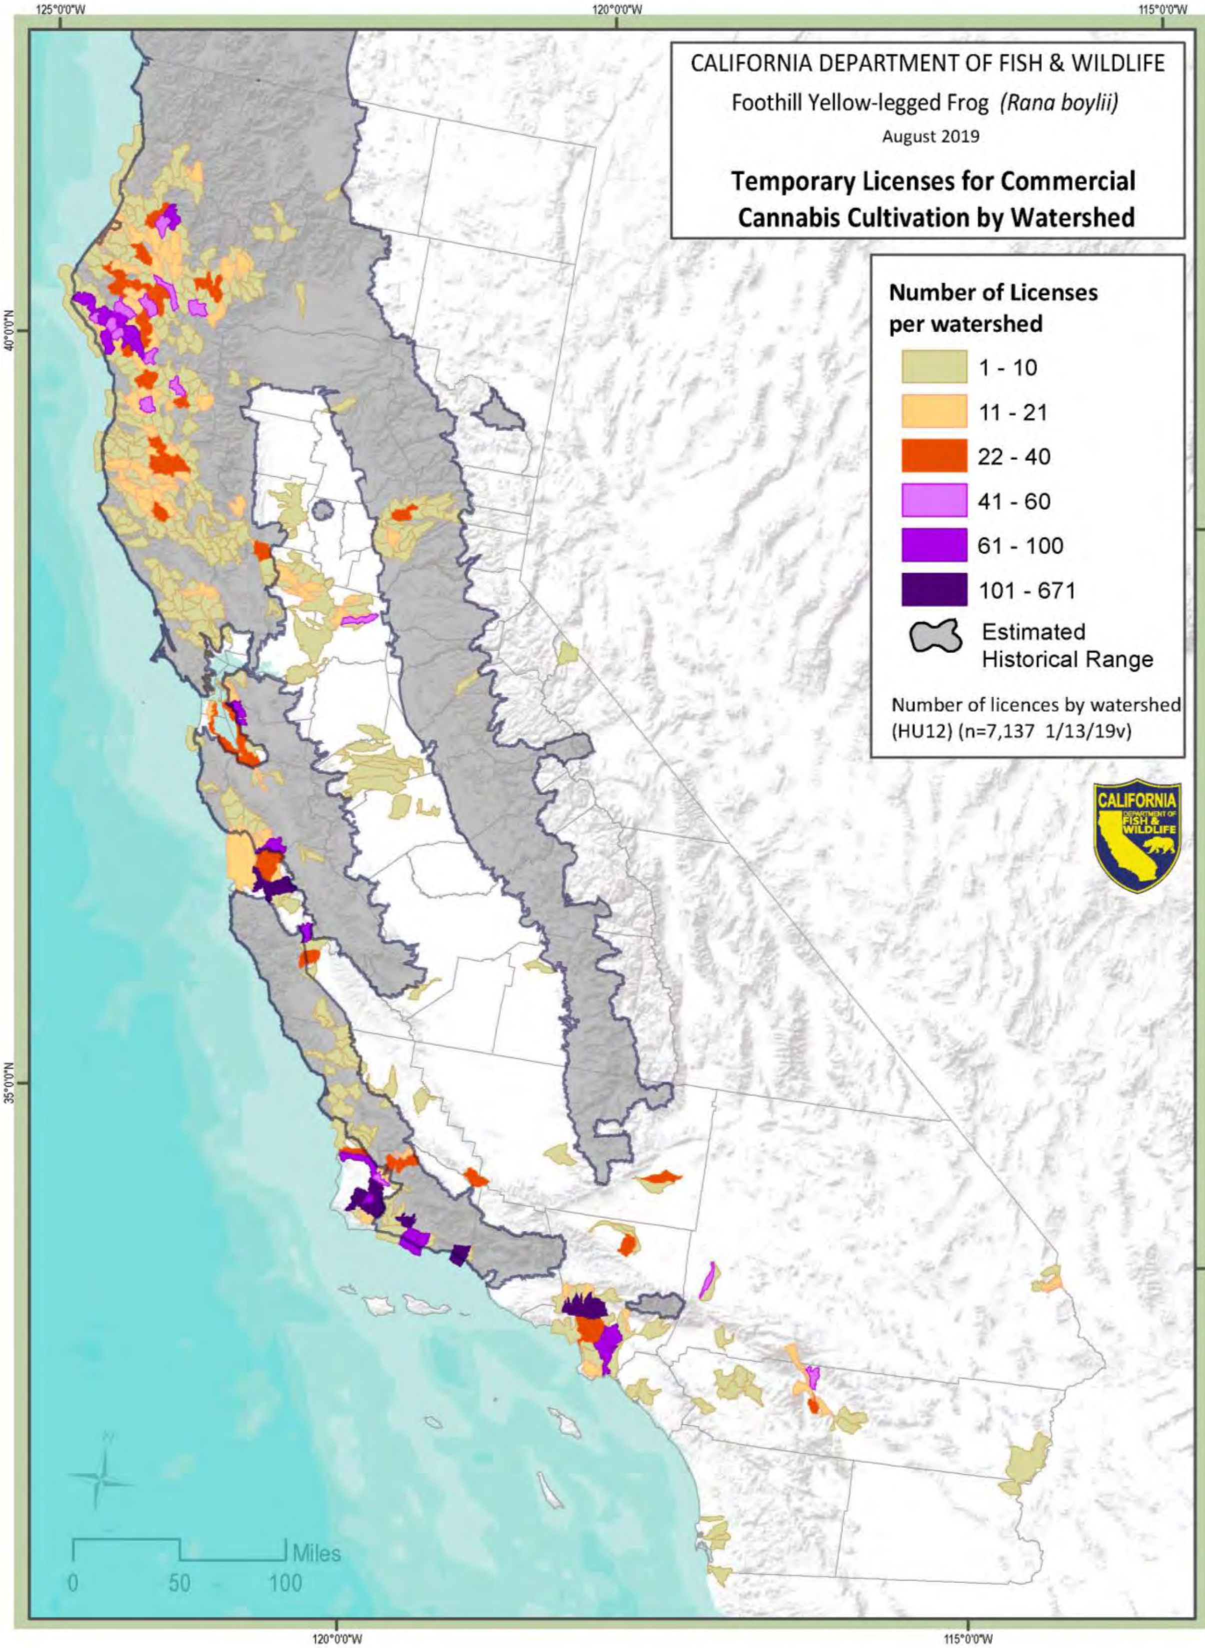

Figure 24. Cannabis cultivation temporary licenses by watershed in California (CDFA, NHD)

nearly 2,500 between 1975 and 2006; however, expansion slowed and has reversed slightly recently with 60,000 ac, or 6.5% of total area planted, removed between 2015 and 2017 (Volpe et al. 2010, CDFA 2018b). In 2015, 857,000 ac were planted in grapes with 70% located in the San Joaquin Valley; 66%, 21%, and 13% were planted in wine, raisin, and table grapes, respectively (Alston et al. 2018).

Expansion of wineries in the coastal counties converted natural areas such as oak woodlands and forests to vineyards (Merenlender 2000, Napa County 2010). The area of Sonoma County covered in grapes increased by 32% from 1990 to 1997, and 42% of these new vineyards were planted above 328 ft with 25% on slopes greater than 18% (Merelender 2000). For context, only 18% of vineyards planted before 1990 occurred above 328 ft and less than 6% on slopes greater than 18% (Ibid.). This conversion took place on approximately 1,909 ac of conifer and dense hardwood forest, 7,229 ac of oak grassland savanna, and 367 ac of shrubland (Ibid.). Recent expansion of oak woodland conversion to vineyards in Napa County was highest in its eastern hillsides (Napa County 2010). Napa County estimates that between 2,682 and 3,065 ac of woodlands will be converted to vineyards between 2005 and 2030 (Ibid.). For context, 733 ac were converted from 1992 to 2003 (Ibid.). In addition, wine grapes were second only to almonds in terms of overall quantity of pesticides applied in California in 2016, but the quantity per unit area 2.6 lb/ac was 160% greater for the wine grapes (CDPR 2018). Vineyard expansion into hillsides has continued into sensitive headwater areas, and like cannabis cultivation, even small vineyards can have substantial impacts on Foothill Yellow-legged Frog habitat through sedimentation, water diversions, spread of harmful non-native species, and agrochemical contamination (Merelender 2000, K. Weiss pers. comm. 2018).

4.6.4 Livestock Grazing

Livestock grazing can be an effective habitat management tool, including control of riparian vegetation encroachment into important Foothill Yellow-legged Frog breeding habitat, but overgrazing can significantly degrade the environment (Siekert et al. 1985). Cattle display a strong preference for riparian areas and have been implicated as a major source of habitat damage in the western U.S., where the adverse impacts of overgrazing on riparian vegetation are intensified by arid and semi-arid climates (Behnke and Raleigh 1978, Kauffman and Krueger 1984, Belsky et al. 1999). The severity of grazing impacts on riparian systems can be influenced by the number of animals, duration and time of year, substrate composition, and soil moisture (Benhke and Raleigh 1978, Kauffman et al. 1983, Marlow and Pogacnik 1985, Siekert et al. 1985). In addition to habitat damage, cattle can directly trample any life stage of Foothill Yellow-legged Frog.

Signs of overgrazing include impacts to the streambanks such as increased slough-offs and cave-ins that collapse undercuts used as refuge by Foothill Yellow-legged Frogs (Kauffman et al. 1983). Overgrazing reduces riparian cover and increases erosion and sedimentation, which as described above can result in silt degradation of breeding, rearing, and invertebrate food-producing areas (Cordone and Kelley 1961, Behnke and Raleigh 1978, Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). Loss of streamside and instream vegetative cover and changes to channel morphology can increase water temperatures and velocities (Behnke and Raleigh 1978). Water quality can be affected by increased turbidity and nutrient input from excrement, and seasonal water quantity can be impacted through changes to channel morphology (Belsky et al. 1999). In addition, increased nutrients and temperatures can promote blooms of harmful cyanobacteria like *Microcystis aeruginosa*, which releases a toxin when it expires that can cause liver damage to amphibians as well as other animals including humans (Bobzien and DiDonato 2007, Zhang et al. 2013).

While some recent studies indicate livestock grazing continues to damage stream and riparian ecosystems, its impact on Foothill Yellow-legged Frogs in California is unknown (Belsky et al. 1999, Hayes et al. 2016). In Oregon, the species' presence was correlated with significantly less grazing than where they were absent according to Borisenko and Hayes's 1999 report (as cited in Olson and Davis 2009). However, Fellers (2005) reported that apparently some Coast Range foothill populations occupying streams draining east into the San Joaquin Valley were doing well at the time of publication despite being heavily grazed.

4.7 Urbanization and Road Effects

Habitat conversion and fragmentation combined with modified environmental disturbance regimes can substantially jeopardize biological diversity (Tracey et al. 2018). This threat is most severe in areas like California with Mediterranean-type ecosystems that are biodiversity hot spots, fire-prone, and heavily altered by human land use (Ibid.). From 1990 to 2010, the fastest-growing land use type in the conterminous U.S. was new housing construction, which rapidly expanded the wildland-urban interface (WUI), where houses and natural vegetation meet or intermix on the landscape (Radeloff et al. 2018).

Of several variables tested, proportion of urban land use within a 3.1 mi radius of a site was associated with Foothill Yellow-legged Frog declines (Davidson et al. 2002). Lind (2005) also found significantly less urban development nearby and upwind of sites occupied by Foothill Yellow-legged Frogs, suggesting pollutant drift may be a contributing factor. Changes in wildfires may also contribute to the species' declines; 95% of California's fires are human-caused, and wildfire issues are greatest at the WUI (Syphard et al. 2009, Radeloff et al. 2018). Population density, intermix WUI (where wildland and development intermingle as opposed to an abrupt interface), and distance to WUI explained the most variability in fire frequency (Syphard et al. 2007). In addition to wildfires, habitat loss, and fragmentation, urbanization can impact adjacent ecosystems through non-native species introduction, native predator subsidization, and disease transmission (Bar-Massada et al. 2014).

Projections show growth in California's population to 51 million people by 2060, from approximately 40 million currently (PPIC 2019). This will increase urbanization, the WUI, and habitat fragmentation. The Department of Finance projects the Inland Empire, the San Joaquin Valley, and the Sacramento metropolitan area will be the fastest-growing regions of the state over the next several decades (Ibid.). This puts the greatest pressure in areas outside of the Foothill Yellow-legged Frog's range; however, because the environmental stressors associated with urbanization can span far beyond its physical footprint, they may still adversely affect the species.

Highways are frequently recognized as barriers to dispersal that fragment habitats and populations; however, single-lane roads can pose significant risks to wildlife as well (Cook et al. 2012, Brehme et al. 2018). Foothill Yellow-legged Frogs are at risk of being killed by vehicles when roads are located near their habitat (Cook et al. 2012, Brehme et al. 2018). Fifty-six juvenile Foothill Yellow-legged Frogs were found on a road adjacent to Sulphur Creek (Mendocino County), seven of which had been struck and killed (Cook et al. 2012). When fords (naturally shallow areas) are used as vehicle crossings, they can create sedimentation and poor water quality, and when the fords are gravel or cobble bars used by Foothill Yellow-legged Frogs for breeding, their use could result in direct mortality (K. Blanchard pers. comm. 2018, R. Bourque pers. comm. 2018).

Construction of culverts under roads to keep vehicles out of the streambed can result in varying impacts. In some cases, they can impede dispersal, trap frogs, and create deep scoured pools that support predatory fish and frogs, but when properly constructed, they can facilitate frog movement up and down the channel with reduced road mortality (Van Wagner 1996, GANDA 2008, C. Dillingham pers. comm. 2019). In addition, those scoured pools can provide habitat for Foothill Yellow-legged Frogs in areas where premature drying is a threat and non-native species are absent (M. Grefsrud pers. comm. 2019). Culverts can also act in a similar way to a natural waterfall and impede upstream migration of non-native fish and crayfish (Kerby et al. 2005). An evaluation of the relative impact of roads on 166 native California amphibians and reptiles, through barriers to movement and direct mortality, concluded that Foothill Yellow-legged Frogs, at individual and population levels, were at moderate risk in aquatic habitat but very low risk of impacts in terrestrial habitat (Brehme et al. 2018). For context, all chelonids (turtles and tortoises), 72% of snakes, 50% of anurans, 18% of lizards, and 17% of salamander species in California were ranked as having a high or very high risk of negative road impacts in the same evaluation (Ibid.).

Poorly constructed roadways near rivers and streams can result in substantial erosion and sedimentation, leading to reduced amphibian densities (Welsh and Ollivier 1998). Proximity of roads to Foothill Yellow-legged Frog habitat contributes to petrochemical runoff and poses the threat of spills (Ashton et al. 1997). A diesel spill on Hayfork Creek (Trinity County) resulted in mass mortality of Foothill Yellow-legged Frog tadpoles and partial metamorphs (Bury 1972). Roads have also been implicated in the spread of disease and may have aided in the spread of Bd in California (Adams et al. 2017b).

Frogs use auditory and visual cues to defend territories and attract mates, and some studies reveal that realistic levels of traffic noise can impede transmission and reception of these signals (Bee and Swanson 2007). Some male frogs have been observed changing the frequency of their calls to increase the distance they can be heard over traffic noise, but if females have evolved to recognize lower pitched calls as signs of superior fitness, this potential trade-off between audibility and attractiveness could have implications for reproductive success (Parris et al. 2009). In a separate study, traffic noise caused a change in male vocal sac coloration and an increase in stress hormones, which changed sexual selection processes and suppressed immunity (Troïanowski et al. 2017). Because Foothill Yellow-legged Frogs mostly call underwater and are not known to use color displays, communication cues may not be adversely affected by traffic noise, but their stress response is unknown.

4.8 Timber Harvest

Because Foothill Yellow-legged Frogs tend to remain close to the water channel (i.e., within the riparian corridor) and current timber harvest practices minimize disturbance in riparian areas for the most part, adverse effects from timber harvest are expected to be relatively low (Hayes et al. 2016, CDFW 2018b). However, some activities have a potential to negatively impact Foothill Yellow-legged Frogs or their habitat, including direct mortality and increased sedimentation during construction and decommissioning of watercourse crossings and infiltration galleries, tree felling, log hauling, and entrainment by water intakes or desiccation of eggs and tadpoles through stranding from dewatering during drafting operations (CDFW 2018b,c). In addition to impacts previously described under the Sedimentation and Urbanization and Road Effects sections, when silt runoff into streams is accompanied by organic materials, such as logging debris, impaired water quality can result, including reduced dissolved oxygen, which is important in embryonic and tadpole development (Cordone and Kelley 1961).

Because Foothill Yellow-legged Frogs are heliotherms (i.e, they bask in the sun to raise their body temperature) and sensitive to thermal extremes, some moderate timber harvest may benefit the species (Zweifel 1955, Fellers 2005). Ashton (2002) reported 85% of his Foothill Yellow-legged Frog observations occurred in second-growth forests (37-60 years post-harvest) as opposed to late-seral forests and postulated that the availability of some open canopy areas played a major part in this disparity. Foothill Yellow-legged Frogs are typically absent in areas with closed canopy (Welsh and Hodgson 2011). Reduced canopy also raises stream temperatures, which could improve tadpole development and promote algal and invertebrate productivity in otherwise cold streams (Olson and Davis 2009; Catenazzi and Kupferberg 2013,2017).

4.9 Recreation

Several types of recreation can adversely impact Foothill Yellow-legged Frogs, and some are more severe and widespread than others. Increased and intensified recreation in streams was one of the main potential factors identified by herpetologists as contributing to disappearance of Foothill Yellow-legged Frogs in southern California (Adams et al. 2017b). The greater number of people traveling into the backcountry may have facilitated the spread Bd to these areas, and while no evidence shows stress from disturbance or other environmental pressures increases susceptibility to Bd, the stress hormone corticosterone has been implicated in immunosuppression (Hayes et al. 2003, Adams et al. 2017b).

The amount of Foothill Yellow-legged Frog habitat disturbed by off-highway motor vehicles (OHV) throughout its range in California is unknown, but its impacts can be significant, particularly in areas with small isolated populations (Kupferberg et al. 2009c, Kupferberg and Furey 2015). An example is the Carnegie State Vehicular Recreation Area (CSVRA), located in the hills southwest of Tracy in the Corral Hollow Creek watershed (Alameda and San Joaquin counties). The above-described road effects apply: sedimentation, crushing along trail crossings, and potential noise effects (Ibid.). In addition, dust suppression activities employed by CSVRA use magnesium chloride, which has the potential to harm developing embryos and tadpoles (Karraker et al. 2008, Hopkins et al. 2013, OHMVRC 2017). Based on museum records, Foothill Yellow-legged Frogs were apparently abundant in Corral Hollow Creek, but they are extremely rare now and are already extirpated or at risk of extirpation (Kupferberg et al. 2009c, Kupferberg and Furey 2015).

Motorized and non-motorized recreational boating can also impact Foothill Yellow-legged Frogs. The impacts of jet boat traffic were investigated in Oregon; in areas with frequent use and high wakes breaking on shore, Foothill Yellow-legged Frogs were absent (Borisenko and Hayes 1999 as cited in Olson and Davis 2009). This wake action had the potential to dislodge egg masses, strand tadpoles, disrupt adult basking behavior, and erode shorelines (Ibid.). Jet boat tours and races on the Klamath River (Del Norte and Humboldt counties) may have an impact on Foothill Yellow-legged Frog use of the mainstem (M. van Hattem pers. comm. 2019). In addition, using gravel bars as launch and haul out sites for boat trailers, kayaks, or river rafts can result in direct loss of egg masses and tadpoles or damage to breeding and rearing habitat and can disrupt post-metamorphic frog behavior (Ibid.). As described above, pulse flows released for whitewater boating in the late spring and summer can result in scouring and stranding of egg masses and tadpoles (Borisenko and Hayes 1999 as cited in Olson and Davis 2009, Kupferberg et al. 2009b). The nearshore velocities of these pulse flows are greater than those that resulted in stunted growth and increased vulnerability to predation in Foothill Yellow-legged Frog tadpoles under experimental conditions (Kupferberg et al. 2011b).

Hiking, horse-riding, camping, fishing, and swimming, particularly in sensitive breeding and rearing habitat, can also adversely impact Foothill Yellow-legged Frog populations (Borisenko and Hayes 1999 in Olson and Davis 2009). Because Foothill Yellow-legged Frog breeding activity was being disturbed and egg masses were being trampled by people and dogs using Carson Falls (Marin County), the land manager established an educational program, including employing docents on weekends that remind people to stay on trails and tread lightly to try to reduce the loss of Foothill Yellow-legged Frog reproductive effort (Prado 2005). In addition, within his study site, Van Wagner (1996) reported that a property owner moved rocks that were being used as breeding habitat to create a swimming hole. The extent to which this is more than a small, local problem is unknown, but as the population of California increases, recreational pressures in Foothill Yellow-legged Frog habitat are likely to increase commensurately.

4.10 Drought

Drought is a common phenomenon in California and is characterized by lower than average precipitation. Lower precipitation in general results in less surface water, and water availability is critical for obligate stream-breeding species. Even in the absence of drought, a positive relationship exists between precipitation and latitude within the Foothill Yellow-legged Frog's range in California, and mean annual precipitation has a strong influence on Foothill Yellow-legged Frog presence at historically occupied sites (Davidson et al. 2002, Lind 2005). Figure 25 depicts the recent historical annual average precipitation across the state as well as during the most recent drought and how they differ. Southern California is normally drier than northern California, but the severity of the drought was even greater in the south.

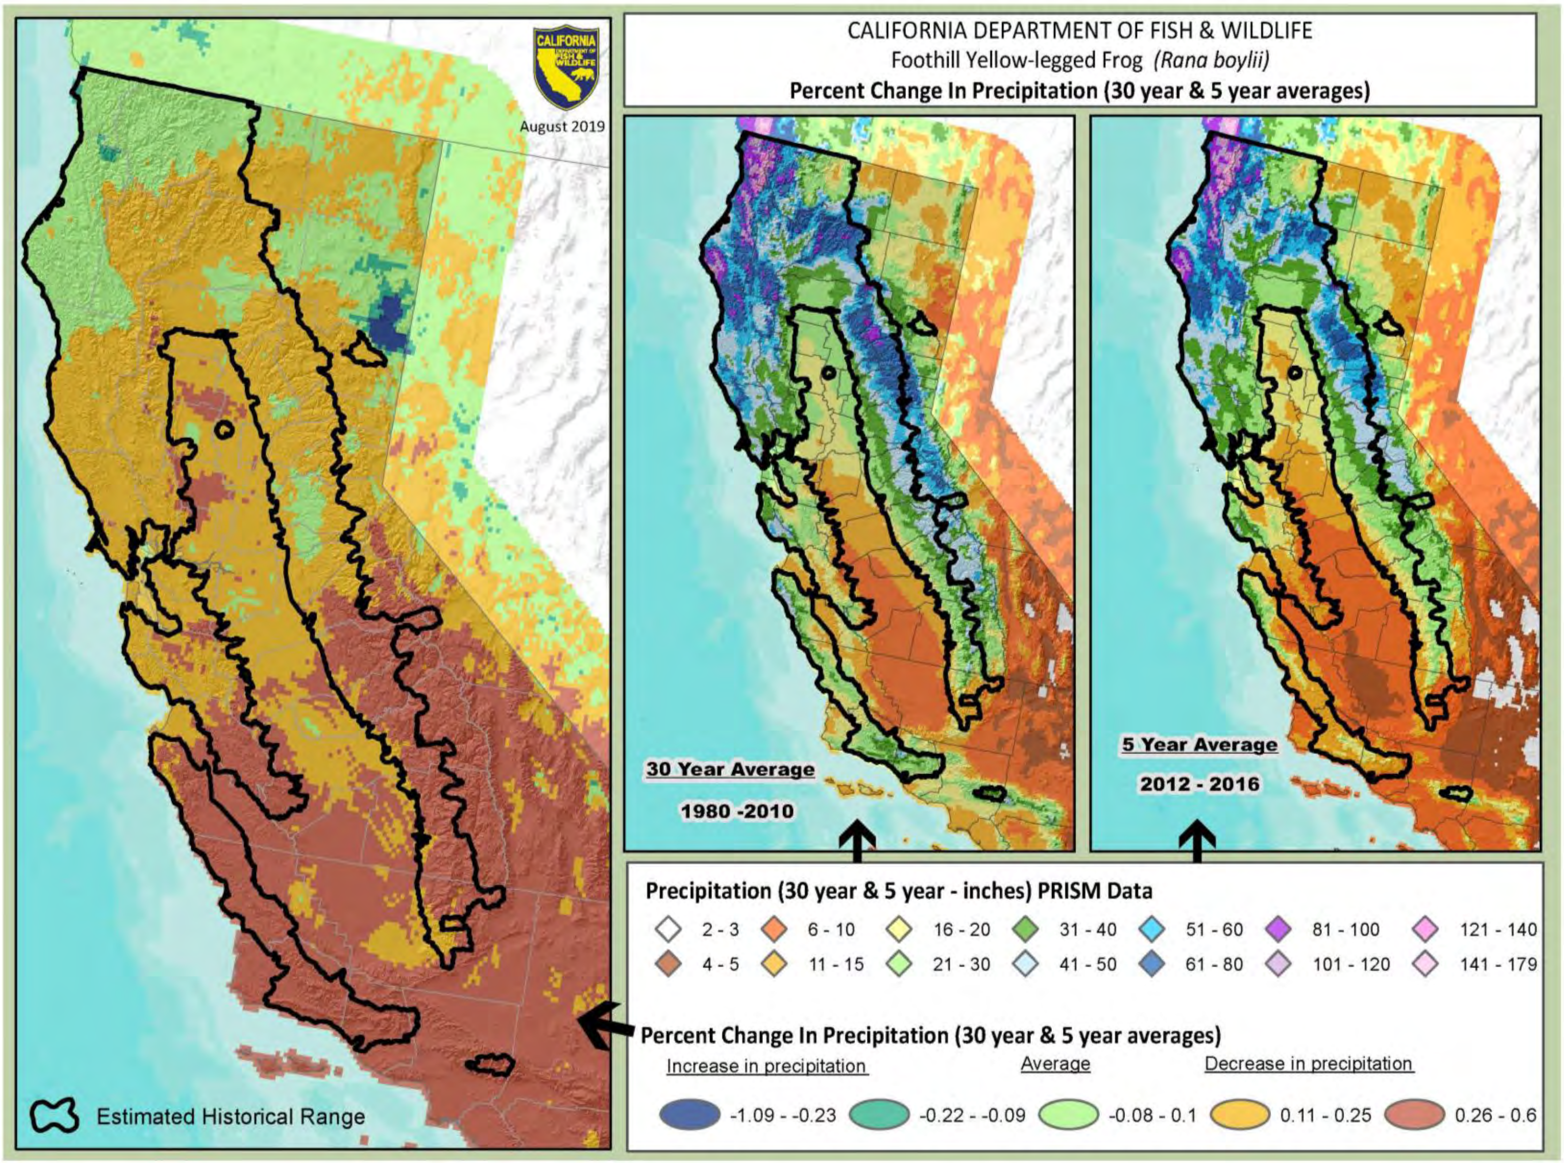

Figure 25. Change in precipitation from recent 30-year average and 5-year drought (PRISM)

Reduced precipitation can result in deleterious effects to Foothill Yellow-legged Frogs beyond the obvious premature drying of aquatic habitat. When stream flows recede during the summer and fall, sometimes the isolated pools that stay perennially wet are the only remaining habitat. This phenomenon concentrates aquatic species, resulting in several potentially significant adverse impacts. Stream flow volume was negatively correlated with Bd load during a recent chytridiomycosis outbreak in the Alameda Creek watershed (Adams et al. 2017a). The absence of high peak flows in winter coupled with wet years allowed bullfrogs to expand their distribution upstream, and the drought-induced low flows in the fall concentrated them with Foothill Yellow-legged Frogs in the remaining drying pools (Ibid.). This mass mortality event appeared to have been the result of a combination of drought, disease, and dam effects (Ibid.). This die-off occurred in a regulated reach that experiences heavy recreational use, and crayfish and bass are present (Ibid.). Despite these threats, the density of breeding females in this reach was greater in 2014 and 2015 than in the unregulated reach upstream because the latter dried completely before tadpoles could metamorphose during the preceding drought years (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015).

In addition to increasing the spread of pathogens, drought-induced stream drying can increase predation and competition by introduced fish and frogs in the pools they are forced to share (Moyle 1973, Hayes and Jennings 1988, Drost and Fellers 1996). This concentration in isolated pools can also result in increased native predation as well as facilitate spread of Bd. An aggregation of six adult Foothill Yellow-legged Frogs was observed perched on a rock above an isolated pool in the summer where a gartersnake was foraging on tadpoles; this close contact may reduce evaporative water loss when they are forced out of the water during high temperatures, but it can also increase disease transmission risk (Leidy et al. 2009.). Gonsolin (2010) also documented a late summer aggregation of juvenile Foothill Yellow-legged Frogs out of water during extremely high temperatures. In addition, drought-induced low flow, high water temperatures, and high densities of tadpoles were associated with outbreaks of malformation-inducing parasitic copepods (Kupferberg et al. 2009a).

Premature stream drying caused or worsened by drought can result in stranding egg masses and tadpoles, but in some situations, it can also benefit Foothill Yellow-legged Frogs. For example, if pools stay wet long enough to support metamorphosis, complete drying at the end of the season may eliminate introduced species like warm water fish and bullfrogs (Bogan et al. 2019). Foothill Yellow-legged Frogs adapted to drought conditions by initiating breeding earlier and shortening the period over which they oviposit (Kupferberg 1996a, Yarnell et al. 2013). Moyle (1973) noted that the only intermittent streams occupied by Foothill Yellow-legged Frogs in the Sierra Nevada foothills had no bullfrogs. At a long-term study site in upper Coyote Creek in early fall 2014, at the height of the most severe drought in over a millennium, remnant pools in the upper watershed provided important refuge for native species (Griffin and Anchokaitis 2014, Bogan et al. 2019). Foothill Yellow-legged Frogs were widely distributed and relatively abundant in the remnant pools, and non-native species were absent in all but one (Bogan et al. 2019). The Foothill Yellow-legged Frog abundance was much lower than reported a decade earlier; it appeared to have never recovered from the 2007-2009 drought (Gonsolin 2010, J. Smith pers. comm. 2015). However, in 2016 after a relatively wet winter, Foothill Yellow-legged

Frogs bred en masse, and only a single adult bullfrog was detected, which was an unusually low number for that area (CDWR 2016, J. Smith pers. comm. 2016).

Drought can also exacerbate the effects of other environmental stressors. During the most recent severe drought, tree mortality increased dramatically from 2014 to 2017 and reached approximately 129 million dead trees (OEHHA 2018). Multiple years of high temperatures and low precipitation left them weakened and more susceptible to pathogens and parasites (Ibid.). Vast areas of dead and dying trees are more prone to severe wildfires, and they lose their carbon sequestration function while also emitting methane, which is an extremely damaging greenhouse gas (CNRA 2016). Post-wildfire storms can result in erosion of fine sediments from denuded hillsides into the stream channel (Florsheim et al. 2017). If the storms are short in duration and peak discharges are low magnitude, as happens during droughts, flows may be insufficient to transport the material downstream, extending the duration of habitat degradation (Ibid.). Reduced rainfall may also infiltrate the debris leading to subsurface flows rather than the surface water Foothill Yellow-legged Frogs require (Ibid.). Extended droughts increase risk of the stream being uninhabitable or inadequate for breeding for multiple years, which would result in population-level impacts and possible extirpation (Ibid.).

4.11 Wildland Fire and Fire Management

Fire is an important element for shaping and maintaining the species composition and integrity of many California ecosystems (Syphard et al. 2007, SBFFP 2018). Prior to European settlement, an estimated 4.5 to 12 million ac burned annually (4-11% of total area of the state), ignited both deliberately by Native Americans and through lightning strikes (Keeley 2005, SBFFP 2018). The impacts of wildland fires on Foothill Yellow-legged Frogs are poorly understood and likely vary significantly across the species' range with differences in climate, vegetation, soils, stream-order, slope, frequency, and severity (Olson and Davis 2009). Mortality from direct scorching is unlikely because Foothill Yellow-legged Frogs are highly aquatic, and most wildfires occur during the dry period of the year when the frogs are most likely to be in or near the water (Pilliod et al. 2003, Bourque 2008). Field observations support this presumption; sightings of post-metamorphic Foothill Yellow-legged Frogs immediately after fires in the northern Sierra Nevada and North Coast indicate they are not very vulnerable to the direct effects of fire (S. Kupferberg and R. Peek pers. comm. 2018). Similarly, Foothill Yellow-legged Frogs were observed two months, and again one year, after a low- to moderate-intensity fire burned an area in the southern Sierra Nevada in 2002, and the populations were extant and breeding as recently as 2017 (Lind et al. 2003b, CNDDB 2019). While water may provide a refuge from fire, it is also possible for temperatures during a fire, or afterward due to increased solar exposure, to near or exceed a threshold that results in lethal or sublethal harm; this would likely impact embryos and tadpoles with limited dispersal abilities (Pilliod et al. 2003).

Intense fires remove overstory canopy, which provides insulation from extreme heat and cold, and woody debris that increases habitat heterogeneity (Pilliod et al. 2003, Olson and Davis 2009). If this happens frequently enough, it can permanently change the landscape. For example, frequent high-severity burning of crown fire-adapted ecosystems can prevent forest regeneration since seeds require sufficient time between fires to mature, and repeated fires can deplete the seed bank (Stephens et al.

2014). Smoke and ash change water chemistry through increased nutrient and heavy metal inputs that can reach concentrations harmful to aquatic species during the fire and for days, weeks, or years thereafter (Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Erosion rates on granitic soils, which make up a large portion of the Foothill Yellow-legged Frog's range, can be over 60 times greater in burned vs. unburned areas and can increase sedimentation for over 10 years (Megahan et al. 1995, Hayes et al. 2016). In some cases, post-fire nutrient inputs into streams could benefit Foothill Yellow-legged Frogs through increased productivity and more rapid growth and development (Pilliod et al. 2003). While the loss of leaf litter that accompanies fire alters the food web, insects are expected to recolonize rapidly, and the lack of cover could increase their vulnerability to predation by Foothill Yellow-legged Frogs (Ibid.).

Low-intensity fires likely have no adverse effect on Foothill Yellow-legged Frogs (Olson and Davis 2009). If they occur in areas with dense canopy, wildfires can improve habitat quality for Foothill Yellow-legged Frogs by reducing riparian cover, providing areas to bask, and increasing habitat heterogeneity, which is likely to outweigh any adverse effects from some fire-induced mortality (Russell et al. 1999, Olson and Davis 2009). In a preliminary analysis of threats to Foothill Yellow-legged Frogs in Oregon, proximity to stand-replacing fires was not associated with absence (Olson and Davis 2009).

Euro-American colonization of California significantly altered the pattern of periodic fires with which California's native flora and fauna evolved through fire exclusion, land use practices, and development (OEHHA 2018). Fire suppression can lead to canopy closure, which reduces habitat quality by limiting thermoregulatory opportunities (Olson and Davis 2009). In addition, fire suppression and its subsequent increase in fuel loads combined with expanding urbanization and rising temperatures have resulted in a greater likelihood of catastrophic stand-replacing fires that can significantly alter riparian systems for decades (Pilliod et al. 2003). Firebreaks, in which vegetation is cleared from a swath of land, can result in similar impacts to roads and road construction (Ibid.). Fire suppression can also include bulldozing within streams to create temporary reservoirs for pumping water, which can cause more damage than the fire itself to Foothill Yellow-legged Frogs in some cases (S. Kupferberg and R. Peek pers. comm. 2018). In addition, fire suppression practices can involve applying hundreds of tons of ammonia-based fire retardants and surfactant-based fire suppressant foams from air tankers and fire engines (Pilliod et al. 2003). Some of these chemicals are highly toxic to some anurans (Little and Calfee 2000).

Fire suppression has evolved into fire management with a greater understanding of its importance in ecosystem health (Keeley and Syphard 2016). Several strategies are employed including prescribed burns, mechanical fuels reduction, and allowing some fires to burn instead of extinguishing them (Pilliod et al. 2003). Like wildfires themselves, fire management strategies have the potential to benefit or harm Foothill Yellow-legged Frogs. Prescribed fires and mechanical fuels removal lessen the likelihood of catastrophic wildfires, but they can also result in loss of riparian vegetation, excessive sedimentation, and increased water temperatures (Ibid.). Salvage logging after a fire may result in similar impacts to timber harvest but with higher rates of erosion and sedimentation (Ibid.). A balanced approach to wildland fires is likely to have the greatest beneficial impact on species and ecosystem health (Stephens et al. 2012).

4.12 Floods and Landslides

As previously described, Foothill Yellow-legged Frog persistence is highly sensitive to early life stage mortality (Kupferberg et al. 2009c). While aseasonal dam releases are a major source of egg mass and tadpole scouring, storm-driven floods are also capable of inducing the same effects (Ashton et al. 1997). Van Wagner (1996) concluded that the high discharge associated with heavy rainfall could account for a significant source of mortality in post-metamorphic Foothill Yellow-legged Frogs as well as eggs and tadpoles; he observed two adult females and several juveniles swept downstream with fatal injuries post-flooding. Severe flooding, specifically two 500-year flood events in early 1969 in Evey Canyon (Los Angeles County), resulted in massive riparian habitat destruction (Sweet 1983). Prior to the floods, Foothill Yellow-legged Frogs were widespread and common, but only four subsequent sightings were documented between 1970 and 1974 and none since (Sweet 1983, Adams 2017b). Sweet (1983) speculates that because Foothill Yellow-legged Frogs overwinter in the streambed in that area, the floods may have reduced the population's abundance below an extinction threshold. Four other herpetologists interviewed about Foothill Yellow-legged Frog extirpations in southern California listed severe flooding as a likely cause (Adams et al. 2017b).

As mentioned above, landslides are a frequent consequence of post-fire rainstorms and can result in lasting impacts to stream morphology, water quality, and Foothill Yellow-legged Frog populations. On the other hand, Olson and Davis (2009) suggest that periodic landslides can have beneficial effects by transporting woody debris into the stream that can increase habitat complexity and replace sediments that are typically washed downstream over time. Whether a landslide is detrimental or beneficial is likely heavily influenced by amount of precipitation and the underlying system. As previously described, too little precipitation could lead to prolonged loss of habitat through failure to transport material downstream, and too much precipitation can result in large-scale habitat destruction and direct mortality.

4.13 Climate Change

Foothill Yellow-legged Frogs evolved over millions of years through repeated droughts, flooding, and fires, but relatively recent anthropogenic habitat fragmentation and degradation have reduced the species' ability to recolonize sites where they have been extirpated by these events. Cumulatively, the threats and stressors Foothill Yellow-legged Frogs encounter over much of their range in California jeopardize their persistence in currently occupied areas. Climate change is expected to exacerbate many of these impacts.

Global climate change threatens biodiversity and may lead to increased frequency and severity of drought, wildfires, flooding, and landslides (Williams et al. 2008, Keely and Syphard 2016). Data show a consistent trend of warming temperatures in California and globally; 2014 was the warmest year on record, followed by 2015, 2017, and 2016 (OEHHA 2018). Climate model projections for annual temperature in California in the 21st century range from 2.7 to 8.1°F greater than the 1961-1990 mean (Cayan et al. 2008). Precipitation change projections are less consistent than those for temperature, but recent studies indicate increasing variability in precipitation and increasingly dry conditions in California resulting from increased evaporative water loss primarily due to rising temperatures (Cayan et al. 2005, Williams et al. 2015, OEHHA 2018). Precipitation variability and proportion of dry years were negatively associated with Foothill Yellow-legged Frog presence in a range-wide analysis (Lind 2005). In addition, low precipitation intensified the adverse effects of dams on the species (Ibid.).

California recently experienced the longest drought since the U.S. Drought Monitor began reporting in 2000 (NIDIS 2019). Figure 26 depicts that California experienced drought effects in at least a portion of the state for 376 consecutive weeks until it broke on March 5, 2019 (Ibid.). The most intense period occurred during the week of October 28, 2014 when D4 (the most severe drought category) affected 58.4% of California's land area (Ibid.). A recent modeling effort using data on historical droughts, including the Medieval megadrought between 1100 and 1300 CE, indicates the mean state of drought from 2050 to 2099 in California will likely exceed the Medieval-era drought, under both high and moderate greenhouse gas emissions models (Cook et al. 2015). The probability of a multidecadal (35 yr) drought occurring during the late 21st century is greater than 80% in all models used by Cook et al. (2015). If correct, this would represent a climatic shift that not only falls outside of contemporary variability in aridity but would also be unprecedented in the past millennium (Ibid.).

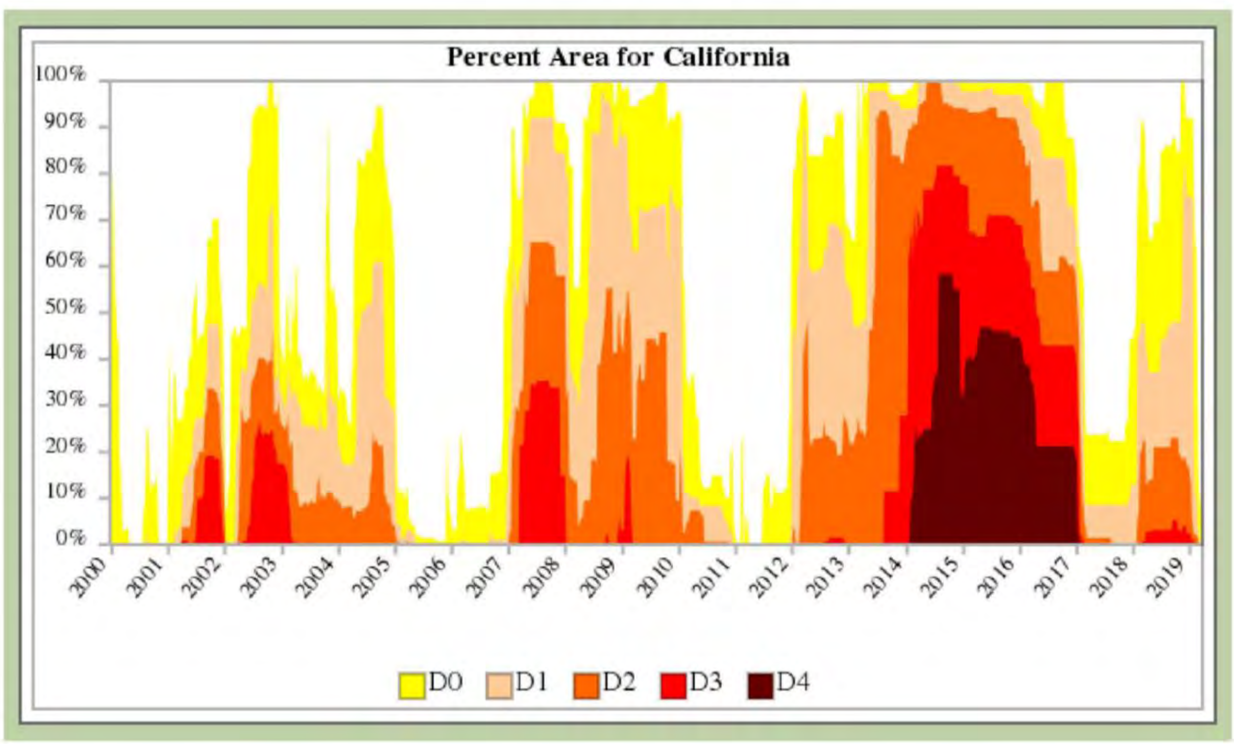

Figure 26. Palmer Hydrological Drought Indices 2000-2019 (NIDIS)

As a result of increasing temperatures, a decreasing proportion of precipitation falls as snow, resulting in more runoff from rainfall during the winter and a shallower snowpack that melts more rapidly (Stewart 2009). A combination of reduced seasonal snow accumulation and earlier streamflow timing significantly reduces surface water storage capacity and increases the risk for winter and spring floods, which may require additional and taller dams and alterations hydropower generation flow regimes

(Cayan et al. 2005, Knowles et al. 2006, Stewart 2009). The reduction in snowmelt volume is expected to impact the northern Sierra (Feather, Yuba, and American River watersheds) to a greater extent than the southern portion (Young et al. 2009). The earlier shift in peak snowmelt timing is predicted to exceed four to six weeks across the entire Sierra Nevada, depending on the amount of warming that occurs this century (Ibid.). In addition, the snow water equivalent is predicted to significantly decline by 2070-2099 over the 1961-1990 average in the Trinity, Sacramento, and San Joaquin drainages from -32% to -79%, and effectively no snow is expected to fall below 3,280 ft in the high emissions/sensitive model (Cayan et al. 2008).

The earlier shift of snowmelt and lower water content will result in lower summer flows, which will intensify the competition for water among residential, agricultural, industrial, and environmental needs (Field et al. 1999, Cook et al. 2015). In unregulated systems, as long as water is present through late summer, an earlier hydrograph recession that triggers Foothill Yellow-legged Frog breeding could result in a longer time to grow larger prior to metamorphosis, which is expected to improve survival (Yarnell et al. 2010, Kupferberg 2011b). However, if duration from peak to base flow shortens, it can result in increased sedimentation and reduced habitat complexity in addition to stranding (Yarnell et al. 2010).

Fire frequency relates to temperature, fuel loads, and fuel moisture (CCSP 2008). Therefore, increasing periods of drought combined with extreme heat and low humidity that stress or kill trees and other vegetation create ideal conditions for wildland fires (Ibid). Not surprisingly, the area burned by wildland fires over the western U.S. increased since 1950 but rose rapidly in the mid-1980s (Westerling et al. 2006, OEHHA 2018). As temperatures warmed and snow melted earlier, large-wildfire frequency and duration increased, and wildfire seasons lengthened (Westerling et al. 2006, OEHHA 2018). With increased fire frequency comes the heightened risk of landslides and extended periods of habitat unsuitability.

In California, latitude is inversely correlated with temperature and annual area burned, but the climate-fire relationship is substantially different across the state, and future wildfire regimes are difficult to predict (Keeley and Syphard 2016). For example, the relationship between spring and summer temperature and area burned in the Sierra Nevada is highly significant but not in southern California (Ibid.). Climate has a greater influence on fire regimes in mesic environments than arid, and the most influential climatological factor (e.g., precipitation, temperature, season, or their interactions) shifts over time (Ibid.). Nine of the 10 largest fires in California since 1932 have occurred in the past 20 years, four within the past two years (Figure 27; CAL FIRE 2019). However, it is possible this trend will not continue; climate- and wildfire-induced changes in vegetation could reduce wildfire severity in the future (Parks et al. 2016).

Wildfires themselves can accelerate the effects of climate change. Wildfires emit short-lived climate pollutants like black carbon (soot) and methane that are tens to thousands of times greater than carbon dioxide (the main focus of greenhouse gas reduction) in terms of warming effect and are responsible for 40% or more of global warming to date (CNRA 2016). Healthy forests can sequester large amounts of carbon from the atmosphere, but recently carbon emissions from wildfires have exceeded their uptake by vegetation in California (Ackerly et al. 2018).

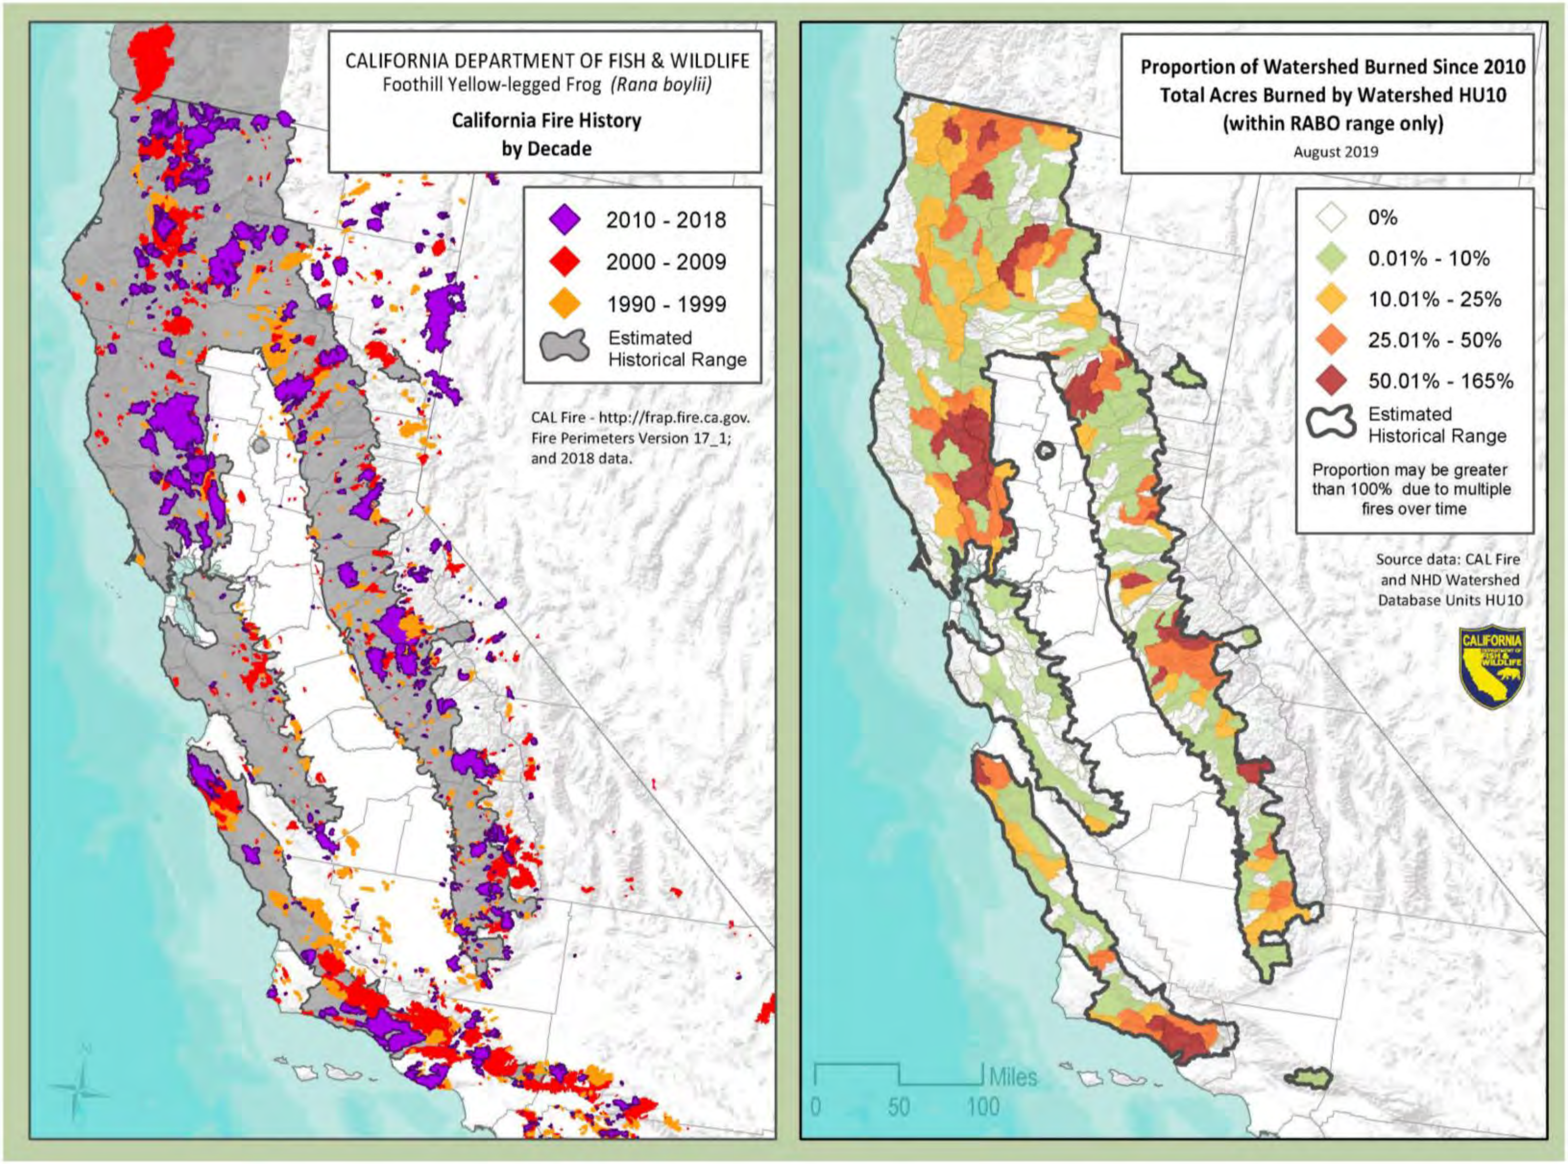

Figure 27. Fire history (1990-2018) and proportion of watershed burned (2010-2018) in California (CAL FIRE, NHD)

With increased variability and changes in precipitation type, magnitude, and timing comes more variable and extreme stream flows (Mallakpour et al. 2018). Models for stream flow in California project higher high flows, lower low flows, wetter rainy seasons, and drier dry seasons (Ibid.). The projected water cycle extremes are related to strengthening El Niño and La Niña events, and both severe flooding and intense drought are predicted to increase by at least 50% by the end of the century (Yoon et al. 2015). These changes increase the likelihood of Foothill Yellow-legged Frog egg mass and tadpole scouring and stranding. However, the severity of these phenomena will vary because an area's underlying geology and lithology affect subsurface water storage capacity, which influences base flows and the degree to which these more frequent extreme weather events will impact Foothill Yellow-legged Frogs (S. Kupferberg pers. comm. 2019). For instance, springs can provide persistent water and a buffer against some drought effects, and areas with low subsurface storage capacity are less affected by changes in rainfall (Hahm et al. 2019, S. Kupferberg pers. comm. 2019).

A species' vulnerability to climate change is a function of its sensitivity to climate change effects, its exposure to them, and its ability to adapt its behaviors to survive with them (Dawson et al. 2011). Myriad examples exist of species shifting their geographical distribution toward the poles and higher elevations as well as changing their growth and reproduction with increases in temperature over time (Parmesan and Yohe 2003, Moritz et al. 2008). However, in many places, fragmentation of suitable habitat by anthropogenic barriers (e.g., urbanization, agriculture, and reservoirs) limits a species' ability to shift its range (Pounds et al. 2007). The proportion of sites historically occupied by Foothill Yellow-legged Frogs that are now extirpated increases significantly on a north-to-south latitudinal gradient and at drier sites within California, suggesting climate change may contribute to the spatial pattern of the species' declines (Davidson et al. 2002).

An analysis of the climate change sensitivity of 195 species of plants and animals in northwestern North America revealed that, as a group, amphibians and reptiles were estimated to be the most sensitive (Case et al. 2015). Nevertheless, examples exist of amphibians adjusting their breeding behaviors (e.g., calling and migrating to breeding sites) to occur earlier in the year as global warming increases (Beebee 1995, Gibbs and Breisch 2001). Because of the rapid change in temperature, Beebee (1995) posits these are examples of behavioral and physiological plasticity rather than natural selection. However, for species with short generation times or in areas less affected by climate change, populations may be able to undergo evolutionary adaptation to the changing local environmental conditions (Hoffman and Sgrò 2011).

As previously described in the Seasonal Activity and Movements section, Foothill Yellow-legged Frog breeding is closely tied to water temperature, flow, and stage, and the species already adjusts its timing of oviposition by as much as two months in the same location during different water years, so the species may have enough inherent flexibility to reduce their vulnerability to predicted climate changes. The species appears fairly resilient to drought, fire, and flooding, at least in some circumstances. For example, after the 2012-2016 drought, the Loma Fire in late 2016, and severe winter flooding and landslides in 2016 and 2017, Foothill Yellow-legged Frog adults and metamorphs, as well as aquatic insects and rainbow trout, were abundant throughout Upper Llagas Creek in fall of 2017, and the substrate consisted of generally clean gravels and cobbles with only a slight silt coating in some pools (J.

Smith pers. comm. 2017). The frogs and fish likely took refuge in a spring-fed pool, and the heavy rains scoured the fine sediments that eroded downstream (Ibid.). These refugia from the effects of climate change reduce the species' exposure, thereby reducing their vulnerability (Case et al. 2015).

Climate change models that evaluate the Foothill Yellow-legged Frog's susceptibility from a species and habitat perspective yield mixed results. An investigation into the possible effects of climate on California's native amphibians and reptiles used ecological niche models, future climate scenarios, and general circulation models to predict species-specific climatic suitability in 2050 (Wright et al. 2013). The results suggested approximately 90-100% of localities currently occupied by Foothill Yellow-legged Frogs are expected to remain climatically suitable in that time, and the proportion of currently suitable localities predicted to change ranges from -20% to 20% (Ibid.). However, a second study, performed by the same research team using a subset of these models, found that 66.4% of currently occupied cells will experience reduced environmental suitability in 2050 (Warren et al. 2014). This analysis included 90 species of native California mammals, birds, reptiles, and amphibians. For context, over half of the taxa were predicted to experience >80% reductions, a consistent pattern reflected across taxonomic groups (Ibid.). Similarly, a third examination, using comparable methods but focusing on the Plumas National Forest (primarily Plumas County with portions of Butte and Sierra counties), found that most of the area will be of the lowest climatic suitability (least and low, in this study) for Foothill Yellow-legged Frogs by 2070 and that each future climate scenario was significantly different from the current model (Bedwell 2018).

A fourth analysis investigated the long-term risk of climate change by modeling the relative environmental stress a vegetative community would undergo in 2099 given different climate and greenhouse gas emission scenarios (Thorne et al. 2016). This model does not incorporate any Foothill Yellow-legged Frog-specific data; it strictly projects climatic stress levels vegetative communities would experience within the species' range boundaries (Ibid.). Unsurprisingly, higher emissions scenarios resulted in a greater proportion of habitat undergoing climatic stress (Figure 28). Perhaps counterintuitively, the warm and wet scenario resulted in a greater amount of stress than the hot and dry scenario. When high emissions and warm and wet changes are combined, a much greater proportion of the vegetation communities will experience "non-analog" conditions, those outside of the range of conditions currently known in California (Ibid.).

4.14 Habitat Restoration and Species Surveys

Potential conflicts between managing riverine habitat below dams for both cold water adapted salmonids and Foothill Yellow-legged Frogs was discussed previously. In addition to problems with temperatures and pulse flows, some stream restoration projects aimed at physically creating or improving salmonid habitat can also adversely affect the frogs. For example, boulder deflectors were placed in Hurdygurdy Creek (Del Norte County) to create juvenile steelhead rearing habitat; deflectors change broad, shallow, low-velocity reaches into narrower, deeper, faster reaches preferred by the fish (Fuller and Lind 1992). Foothill Yellow-legged Frogs were documented using the restoration reach as breeding habitat annually prior to placement of the boulders, but no breeding was detected in the following three years, suggesting this project eliminated the conditions the frogs require (Ibid.). At

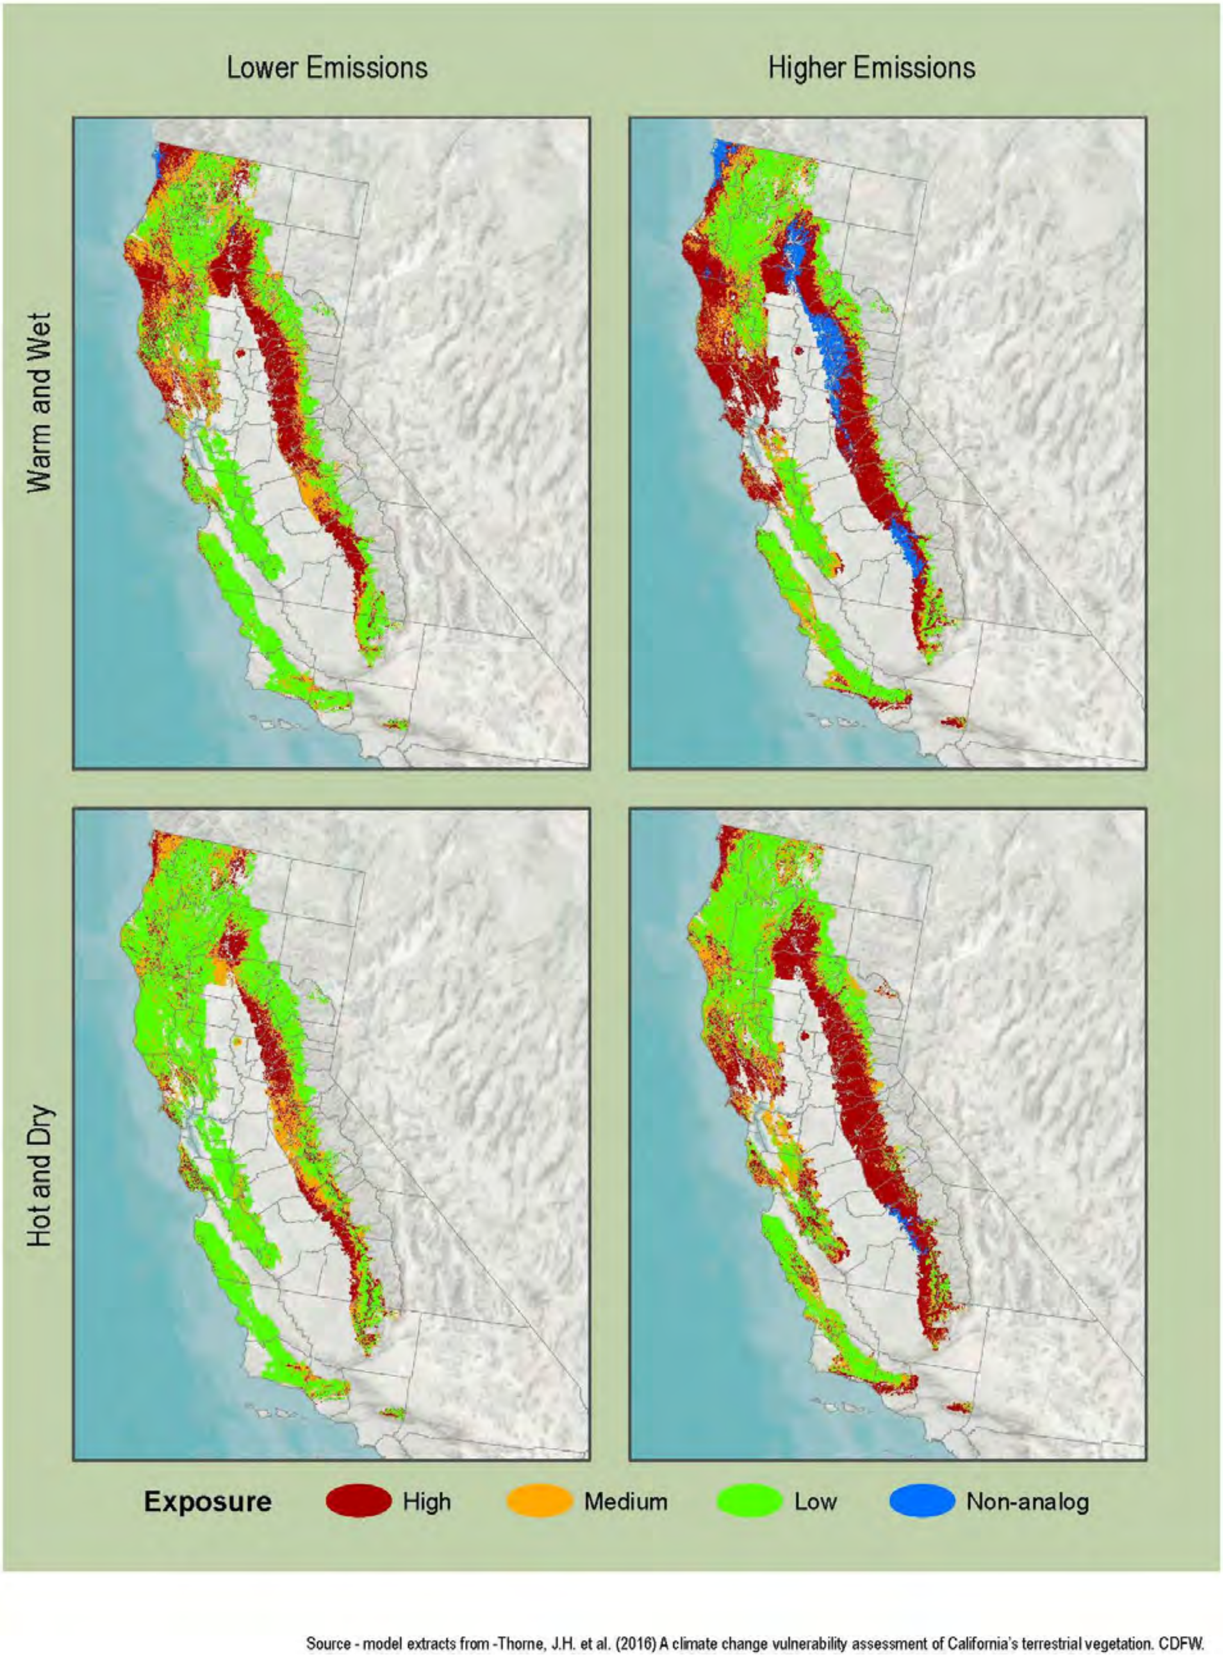

Figure 28. Vegetative community exposure to climate change in 2099 based on Thorne et al. (2016)

another location, a fish passage structure to facilitate salmonid migration above the Alameda Creek Diversion Dam was recently constructed on a Foothill Yellow-legged Frog lek site (M. Grefsrud pers. comm. 2019). The structure blocks a migratory pathway between overwintering habitat in hillside springs and seeps and the creek and creates a potential trap for frogs that fall into the structure (S. Kupferberg pers. comm. 2019). Use of rotenone to eradicate non-native fish as part of a habitat restoration project is rare, but if it is applied in streams occupied by Foothill Yellow-legged Frogs, it can kill tadpoles but is unlikely to impact post-metamorphic frogs (Fontenot et al. 1994). Metamorphosing tadpoles may be able to stay close enough to the surface to breathe air and survive but may display lethargy and experience increased susceptibility to predation (Ibid.).

Commonly when riparian vegetation is removed, regulatory agencies require a greater amount to be planted as mitigation to offset the temporal loss of habitat. This practice can have adverse impacts on habitat suitability for Foothill Yellow-legged Frogs. It is especially problematic where flood suppression by dams has resulted in encroachment into the active channel by riparian trees whose roots bind sediment and steepen the bank slopes (S. Kupferberg pers. comm. 2019). Foothill Yellow-legged Frogs have been observed moving into areas where trees were recently removed, and they are known to avoid heavily shaded areas (Lind et al. 1996, Welsh and Hodgson 2011, M. Grefsrud pers. comm. 2019).

Biologists and other stream researchers can inadvertently harm Foothill Yellow-legged Frogs. When working in Foothill Yellow-legged Frog habitat, in-stream surveyors can trample egg masses or larvae if they are not careful, and those rock-hopping on shore can unknowingly crush post-metamorphic stages that often take cover under streamside rocks (S. Kupferberg pers. comm. 2019). One method for sampling fish is electroshocking, which runs a current through the water that stuns the fish temporarily allowing them to be captured. Post-metamorphic frogs are unlikely to be killed by electroshocking; however, at high frequencies (60 Hz), they may experience some difficulty with muscle coordination for a few days (Allen and Riley 2012). This could increase their risk of predation. At 30 Hz, there were no differences between frogs that were shocked and controls (Ibid.). Tadpoles are more similar to fish in tail musculature and spinal structure and are at higher risk of injuries; however, researchers who reported observing stunned tadpoles noted they appeared to recover completely within several seconds (Ibid.). Adverse effects to Foothill Yellow-legged Frogs from electrofishing may only happen at frequencies higher than those typically used for fish sampling (Ibid.).

4.15 Small Population Sizes

Small populations are at greater risk of extirpation, primarily because the effects of demographic, environmental, and genetic stochasticity are disproportionately greater than they are on large populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). Consequently, any of the threats previously discussed will likely have an even greater adverse impact on small populations of Foothill Yellow-legged Frogs. This risk of extinction from genetic stochasticity is amplified when connectivity between the small populations, and thus gene flow, is impeded (Fahrig and Merriam 1985, Taylor et al. 1993, Lande and Shannon 1996, Palstra and Ruzzante 2008). Genetic diversity provides capacity to evolve in response to environmental changes, and the “rescue effect” of gene flow is important in minimizing probability of local extinction (Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). However, the rescue effect is diminished in conditions of high local environmental stochasticity of recruitment or survival (Eriksson et al. 2014). In addition, populations living near their physiological limits and lacking adaptive capacity may not be able to evolve in response to rapid changes (Hoffmann and Sgrò 2011). Furthermore, while pathogens or parasites rarely result in host extinction, they can increase that likelihood in small populations by driving the host populations below a critically low threshold, beneath which demographic stochasticity can lead to extinction, even if they possess the requisite genetic diversity to adapt to a changed environment (Gomulkiewicz and Holt 1995, Adams et al. 2017b).

A Foothill Yellow-legged Frog PVA revealed that, even with no dam effects considered (e.g., slower growth and increased egg and tadpole mortality), populations occurring along a hypothetical 6.2 mi reach were four times more likely to go extinct within 30 years when using the starting average density of adult females in regulated rivers (2.9/mi) compared to the starting average density of adult females from unregulated rivers (20/mi) (Kupferberg et al. 2009c). When the density of females in sparse populations was used (1.3/mi), the 30-year risk of extinction increased 13-fold (Ibid.). With dam effects, a number of the risk factors above contribute to the additional probability of local extinction such as living near their lower thermal tolerance and reduced recruitment and survival from scouring and stranding flows, poor food quality, and increased predation and competition (Kupferberg 1997a; Hoffmann and Sgrò 2011; Kupferberg et al. 2011a,b; Kupferberg et al. 2012; Eriksson et al. 2014). These factors act synergistically, contributing in part to the small size, high divergence, and low genetic diversity exhibited by many Foothill Yellow-legged Frog populations located in highly regulated watersheds (Kupferberg et al. 2012, Peek 2018).

5.0 EXISTING MANAGEMENT

5.1 Land Ownership within the California Range

Using the Department's Foothill Yellow-legged Frog presumed historical range boundary (Figure 1) and the California Protected Areas Database (CPAD), a GIS dataset of lands that are owned in fee title and protected for open space purposes by over 1,000 public agencies or non-profit organizations, the total area of the species' range in California comprises 33,656,857 ac (CPAD 2019, CWHR 2019). Approximately 37% is owned by federal agencies, 80% of which (10,060,100 ac) is managed by the Forest Service (Figure 29). Department of Fish and Wildlife-managed lands, State Parks, and other State agency-managed lands constitute around 2.6% of the range. The remainder of the range includes <1% Tribal lands, 2.3% other conserved lands (e.g., local and regional parks), and 57% private and government-managed lands that are not protected for open space purposes. It is important to note that even if included in the CPAD, a property's management does not necessarily benefit Foothill Yellow-legged Frogs. For example, the primary focus of many parks is to provide various types of recreation, which as previously described can have significantly adverse impacts on the species, and most BLM and Forest Service land is managed for multiple uses (e.g., timber harvest, mining, grazing, recreation).

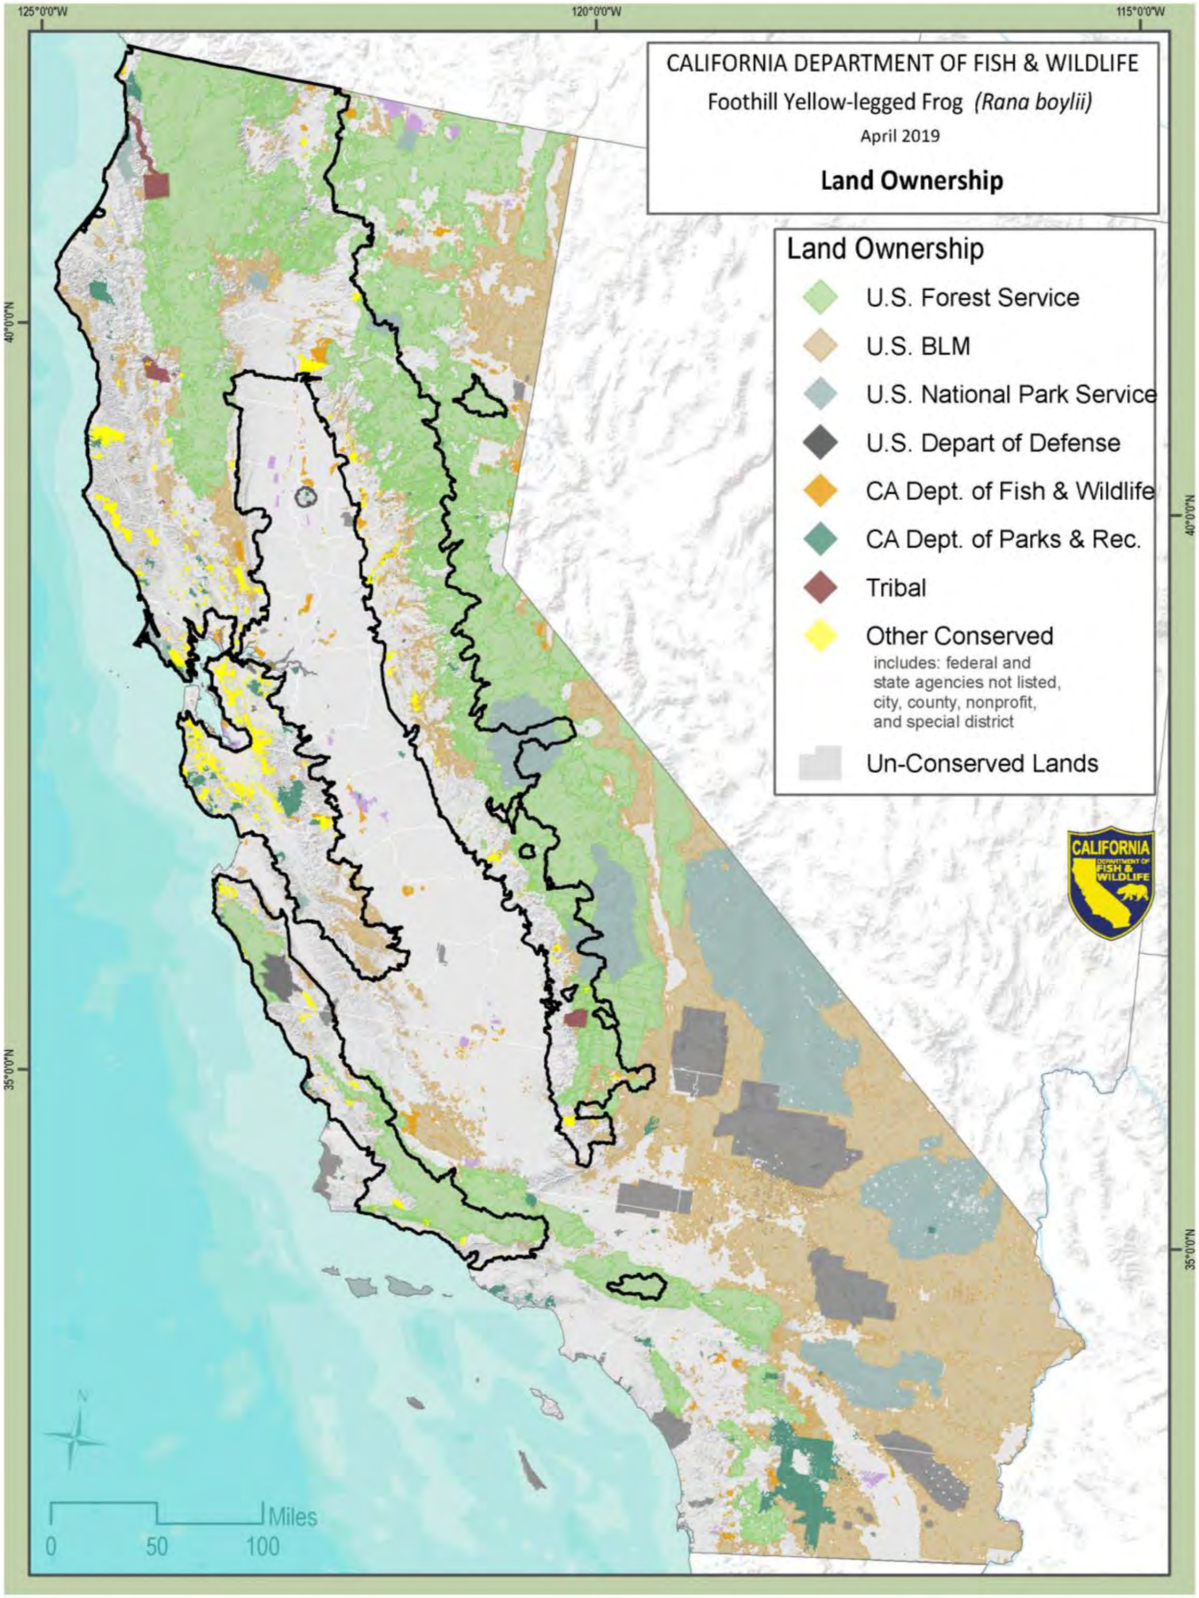

Figure 29. Conserved, Tribal, and other lands within the estimated historical range of Foothill Yellow-legged Frogs in California (BLM, CMD, CPAD, CWHR, DOD)

However, in some cases, changes in management to conserve the species may be easier to undertake on publicly-managed conserved lands than on private lands or public lands not classified as conserved.

5.2 Statewide Laws

The laws and regulations governing land use within the Foothill Yellow-legged Frog's range vary by ownership. Several state and federal environmental laws apply to activities undertaken in California that may provide some level of protection for Foothill Yellow-legged Frogs and their habitat. The following is not an exhaustive list.

5.2.1 National Environmental Policy Act and California Environmental Quality Act

Most federal land management actions must undergo National Environmental Policy Act of 1969 (NEPA; 42 U.S.C. § 4321, et seq.) analysis. NEPA requires federal agencies to document, consider alternatives, and disclose to the public the impacts of major federal actions and decisions that may significantly impact the environment. As a BLM and Forest Service Sensitive Species, impacts to Foothill Yellow-legged Frogs are considered during NEPA analysis; however, the law has no requirement to minimize or mitigate adverse effects.

The California Environmental Quality Act (CEQA) is similar to NEPA; it requires state and local agencies to identify, analyze, and consider alternatives, and to publicly disclose environmental impacts from projects over which they have discretionary authority (Pub. Resources Code § 21000 et seq.). CEQA differs substantially from NEPA in requiring mitigation for significant adverse effects to a less than significant level unless overriding considerations are documented. CEQA requires an agency find that projects may have a significant effect on the environment if they have the potential to substantially reduce the habitat, decrease the number, or restrict the range of any rare, threatened, or endangered species (Cal. Code Regs., tit. 14, §§ 15065(a)(1), 15380.). CEQA establishes a duty for public agencies to

avoid or minimize such significant effects where feasible (Cal. Code regs., tit. 14, § 15021). Impacts to Foothill Yellow-legged Frogs, as an SSC, should be identified, evaluated, disclosed, and mitigated or justified under the Biological Resources section of an environmental document prepared pursuant to CEQA. However, a lead agency is not required to make a mandatory finding of significance conclusion for a project unless it determines on a project-specific basis that the species meets the CEQA criteria for rare, threatened, or endangered.

5.2.2 Clean Water Act and Porter-Cologne Water Quality Control Act

The Clean Water Act originated in 1948 as the Federal Water Pollution Control Act of 1948. It was heavily amended in 1972 and became known as the Clean Water Act (CWA). The purpose of the CWA was to establish regulations for the discharge of pollutants into waters of the United States and establish quality standards for surface waters. Section 404 of the CWA forbids the discharge of dredged or fill material into waters and wetlands without a permit from the ACOE. The CWA also requires an alternatives analysis, and the ACOE is directed to issue their permit for the least environmentally damaging practicable alternative. The definition of waters of the United States has changed substantially over time based on Supreme Court decisions and agency rule changes.

The Porter-Cologne Water Quality Act was established by the State in 1969 and is similar to the CWA in that it establishes water quality standards and regulates discharge of pollutants into state waters, but it also administers water rights, which regulate water diversions and extractions. The SWRCB and nine Regional Water Boards share responsibility for implementation and enforcement of Porter-Cologne as well as the CWA's National Pollutant Discharge Elimination System permitting.

5.2.3 Federal and California Wild and Scenic Rivers Acts

In 1968, the U.S. Congress passed the federal Wild and Scenic Rivers Act (WSRA) (16 U.S.C. § 1271, et seq.) which created the National Wild and Scenic River System. The WSRA requires the federal government to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The WSRA prohibits the federal government from building, licensing, funding or otherwise aiding in the building of dams or other project works on rivers or segments of designated rivers. The WSRA does not give the federal government control of private property including development along protected rivers.

California's Wild and Scenic Rivers Act was enacted in 1972 so rivers that "possess extraordinary scenic, recreational, fishery, or wildlife values shall be preserved in their free-flowing state, together with their immediate environments, for the benefit and enjoyment of the people of the state." (Pub. Res. Code, § 5093.50). Designated waterways are codified in Public Resources Code sections 5093.50-5093.70. In 1981, most of California's designated Wild and Scenic Rivers were adopted into the federal system. Currently in California, 2,000 mi of 23 rivers are protected by the WSRA, most of which are located in the northwest. Foothill Yellow-legged Frogs have been observed in 11 of the 17 designated rivers within their range (CNDDB 2019).

5.2.4 Lake and Streambed Alteration Agreements

Fish and Game Code Section 1602 requires entities to notify the Department of activities that "divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake." If the activity may substantially adversely affect an existing fish and wildlife resource, the Department may enter into a lake or streambed alteration agreement with the entity that includes reasonable measures necessary to protect the fish or wildlife resource (Fish & G. Code, §1602, subd. (a)(4)(B)). A lake or stream alteration agreement does not authorize take of species listed as candidates, threatened, or endangered under CESA (see Protection Afforded by Listing for CESA compliance requirements).

5.2.5 Medicinal and Adult-Use Cannabis Regulation and Safety Act

The commercial cannabis cultivation industry is unique in that any entity applying for an annual cannabis cultivation license from California Department of Food and Agriculture (CDFA) must include "a copy of any final lake or streambed alteration agreement…or written verification from the California Department of Fish and Wildlife that a lake or streambed alteration agreement is not required" with their license application (Cal. Code Regs., tit. 3, § 8102, subd. (v)). The SWRCB also enforces the laws related to waste discharge and water diversions associated with cannabis cultivation (Cal. Code Regs., tit. 3, § 8102, subd. (p)).

5.2.6 Forest Practice Act

The Forest Practice Act was originally enacted in 1973 to ensure that logging in California is undertaken in a manner that will also preserve and protect the State's fish, wildlife, forests, and streams. This law and the regulations adopted by the California Board of Forestry and Fire Protection pursuant to it are collectively referred to as the Forest Practice Rules. The Forest Practice Rules implement the provisions of the Forest Practice Act in a manner consistent with other laws, including CEQA, Porter-Cologne, CESA, and the Timberland Productivity Act of 1982. The California Department of Forestry and Fire Protection enforces these laws and regulations governing logging on private land.

5.2.7 Federal Power Act

The Federal Power Act and its major amendments are implemented and enforced by FERC and require licenses for dams operated to generate hydropower. One of the major amendments of the Federal Power Act required that these licenses "shall include conditions for the protection, mitigation and enhancement of fish and wildlife including related spawning grounds and habitat" (ECPA 1986). Hydropower licenses granted by FERC are usually valid for 30-50 years. If a licensee wants to renew their license, it must file a Notice of Intent and a pre-application document five years before the license expires to provide time for public scoping, any potentially new studies necessary to analyze project impacts and alternatives, and preparation of environmental documents. The applicant must officially apply for the new license at least two years before the current license expires.

As a federal agency, FERC must comply with federal environmental laws prior to issuing a new license or relicensing an existing hydropower project, which includes NEPA and ESA. As a result of environmental compliance or settlement agreements formed during the relicensing process, some operations have been modified and habitat restored to protect fish and wildlife. For example, the Lewiston Dam relicensing resulted in establishment of the Trinity River Restoration Program, which takes an ecosystem-approach to studying dam effects and protecting and restoring fish and wildlife populations downstream of the dam (Snover and Adams 2016). Similarly, relicensing of the Rock Creek-Cresta Project on the North Fork Feather River resulted in establishment of a multi-stakeholder Ecological Resources Committee (ERC). As a result of the ERC's studies and recommendations, pulse flows for whitewater boating were suspended for several years following declines of Foothill Yellow-legged Frogs, and the ERC is currently working toward augmenting the population in an attempt to increase abundance to a viable level.

5.3 Administrative and Regional Plans

5.3.1 Forest Plans

NORTHWEST FOREST PLAN

In 1994, BLM and the Forest Service adopted the Northwest Forest Plan to guide the management of over 37,500 mi^2 of federal lands in portions of northwestern California, Oregon, and Washington. The Northwest Forest Plan created an extensive network of forest reserves including Riparian Reserves. Riparian Reserves apply to all land designations to protect riparian dependent resources. With the exception of silvicultural activities consistent with Aquatic Conservation Strategy objectives, timber harvest is not permitted within Riparian Reserves, which can vary in width from 100 to 300 ft on either side of streams, depending on the classification of the stream or waterbody (USDA FS and BLM 1994). Fuel treatment and fire suppression strategies and practices implemented within these areas are designed to minimize disturbance.

SIERRA NEVADA FOREST PLAN

Land and Resource Management Plans for forests in the Sierra Nevada were changed in 2001 by the Sierra Nevada Forest Plan Amendment and subsequently adjusted through a supplemental Environmental Impact Statement and Record of Decision in 2004, referred to as the Sierra Nevada Framework (USDA FS 2004). This established an Aquatic Management Strategy with goals including maintenance and restoration of habitat to support viable populations of riparian-dependent species; spatial and temporal connectivity for aquatic and riparian species within and between watersheds to provide physically, chemically, and biologically unobstructed movement for their survival, migration, and reproduction; instream flows sufficient to sustain desired conditions of riparian, aquatic, wetland, and meadow habitats; the physical structure and condition of streambanks and shorelines to minimize erosion and sustain desired habitat diversity; and prevention of new introductions of invasive species and reduction of invasive species impacts that adversely affect the viability of native species. The Sierra Nevada Framework also includes Riparian Conservation Objectives and associated standards and guidelines specific to aquatic-dependent species, including the Foothill Yellow-legged Frog.

5.3.2 Resource Management Plans

Sequoia, Kings Canyon, and Yosemite National Parks fall within the historical range of the Foothill Yellow-legged Frog, but the species has been extirpated from these areas. The guiding principles for managing biological resources on National Park Service lands include maintenance of animal populations native to park ecosystems (Hayes et al. 2016). They also commit the agency to work with other land managers on regional scientific and planning efforts and maintenance or reintroduction of native species to the parks including conserving Foothill Yellow-legged Frogs in the Sierra Nevada (USDI NPS 1999 as cited in Hayes et al. 2016). A Sequoia and Kings Canyon National Parks Resource Management Plan does not include specific management goals for Foothill Yellow-legged Frogs, but it does include a discussion of the factors leading to the species' decline and measures to restore the integrity of aquatic ecosystems (Ibid.). The Yosemite National Park Resource Management Plan includes a goal of restoring

Foothill Yellow-legged Frogs to the Upper Tuolumne River below Hetch Hetchy Reservoir (USDI NPS 2003 as cited in Hayes et al. 2016).

5.3.3 FERC Licenses

Dozens of hydropower dams have been relicensed in California since 1999, and several are in the process of relicensing (FERC 2019). In addition to following the Federal Power Act and other applicable federal laws, Porter-Cologne Water Quality Act requires non-federal dam operators to obtain a Water Quality Certification (WQC) from the SWRCB. Before it can issue the WQC, the SWRCB must consult with the Department regarding the needs of fish and wildlife. Consequently, SWRCB includes conditions in the WQC that seek to minimize adverse effects to native species, and Foothill Yellow-legged Frogs have received some special considerations due to their sensitivity to dam operations during these licensing processes. As discussed above, the typical outcome is formation of an ERC-type group to implement the environmental compliance requirements and recommend changes to flow management to reduce impacts. The degree to which these considerations and modifications to dam operations results in its desired effect to protect healthy Foothill Yellow-legged Frog populations varies by site, but the myriad impacts from dams are difficult to overcome, and genetic evidence suggests populations in these highly regulated watersheds are fragmented and losing diversity (Peek 2018, S. Kupferberg pers. comm. 2019).

Foothill Yellow-legged Frog-specific requirements in license agreements fall into three general categories: data collection, modified flow regimes, and standard best management practices. Brief examples of each are described.

DATA COLLECTION

When little is known about the impacts of different flows and temperatures on Foothill Yellow-legged Frog occupancy and breeding success, data are collected and analyzed to inform recommendations for future modifications to operations such as temperature trigger thresholds. These surveys include locating egg masses and tadpoles, monitoring temperatures and flows, and recording their fate (e.g., successful development and metamorphosis, displacement, desiccation) during different flow operations and different water years. Examples of licenses with these conditions include the Lassen Lodge Project (FERC 2018), Rock Creek-Cresta Project (FERC 2009a), and El Dorado Project (EID 2007).

MODIFIED FLOW REGIMES

When enough data exist to understand the effect of different operations on Foothill Yellow-legged Frog occupancy and success, license conditions may include required minimum seasonal instream flows, specific thermal regimes, gradual ramping rates to reduce the likelihood of early life stage scour or stranding, freshet releases (winter/spring flooding simulation) to maintain riparian processes, and cancellation or prohibition of recreational pulse flows during the breeding season. Examples of licenses with these conditions include the Poe Hydroelectric Project (SWRCB 2017), Upper American Project (FERC 2014), and Pit 3, 4, 5 Project (FERC 2007b).

BEST MANAGEMENT PRACTICES

Efforts to reduce the impacts from maintenance activities and indirect operations include selective herbicide and pesticide application, aquatic invasive species monitoring and control, erosion control, and riparian buffers. Examples of licenses with these conditions include the South Feather Project (SWRCB 2018), Spring Gap-Stanislaus Project (FERC 2009b), and the Chili Bar Hydroelectric Project on the South Fork American River (FERC 2007a).

5.3.4 Habitat Conservation Plans and Natural Community Conservation Plans

Non-federal entities can obtain authorization for take of federally threatened and endangered species incidental to otherwise lawful activities through development and implementation of a Habitat Conservation Plan (HCP) pursuant to Section 10 of the ESA. The take authorization can extend to species not currently listed under the ESA but which may become listed as threatened or endangered over the term of the HCP, which is often 25-75 years. California's companion law, the Natural Community Conservation Planning Act of 1991, takes a broader approach than either CESA or ESA. A Natural Community Conservation Plan (NCCP) identifies and provides for the protection of plants, animals, and their habitats, while allowing compatible and appropriate economic activity. There are currently four HCPs that include Foothill Yellow-legged Frogs as a covered species, two of which are also NCCPs.

HUMBOLDT REDWOOD (FORMERLY PACIFIC LUMBER) COMPANY

The Humboldt Redwood Company (HRC) HCP covers 211,700 ac of private Coast Redwood and Douglas-fir forest in Humboldt County (HRC 2015). It is a 50-year HCP/incidental take permit (ITP) that was executed in 1999, revised in 2015 as part of its adaptive management strategy, and expires on March 1, 2049. The HCP includes an Amphibian and Reptile Conservation Plan and an Aquatics Conservation Plan with measures designed to sustain viable populations of Foothill Yellow-legged Frogs and other covered aquatic herpetofauna. These conservation measures include prohibiting or limiting tree harvest within Riparian Management Zones (RMZ), controlling sediment by maintaining roads and hillsides, restricting controlled burns to spring and fall in areas outside of the RMZ, conducting effectiveness monitoring throughout the life of the HCP, and use the data collected to adapt monitoring and management plans accordingly.

Watershed assessment surveys include observations of Foothill Yellow-legged Frogs and have documented their widespread distribution on HRC lands with a pattern of fewer near the coast in the fog belt and more inland (S. Chinnici pers. comm. 2017). The watersheds within the property are largely unaffected by dam-altered flow regimes or non-native species, so aside from the operations described under Timber Harvest above that are minimized to the extent feasible, the focus on suitable temperatures and denser canopy cover for salmonids may reduce habitat suitability for Foothill Yellow-legged Frogs over time (Ibid.).

San Joaquin County Multi-Species Habitat Conservation and Open Space Plan

The San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) is a 50-year HCP/ITP that was signed by the USFWS on November 14, 2000 (San Joaquin County 2000). The SJMSCP covers almost all of San Joaquin County except federal lands, a few select projects, and some properties with certain land uses, roughly 900,000 ac. At the time of execution, approximately 172 ac of habitat within the SJMSCP area in the southwest portion of the county were considered occupied by Foothill Yellow-legged Frogs with another 4,484 ac classified as potential habitat, but it appears the species had been considered extirpated before then (Jennings and Hayes 1994, San Joaquin County 2000, Lind 2005). The HCP estimates around 8% of the combined modeled habitat would be converted to other uses over the permit term, but the establishment of riparian preserves with buffers around Corral Hollow Creek, where the species occurred historically, was expected to offset those impacts (San Joaquin County 2000, SJCOG 2018). However, the HCP did not require surveys to determine if Foothill Yellow-legged Frogs are benefiting from its conservation measures (M. Grefsrud pers. comm. 2019).

East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan

The East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan (ECCC HCP/NCCP) is a multi-jurisdictional 30-year plan adopted in 2007 that covers over 174,018 ac in eastern Contra Costa County (Jones & Stokes 2006). The Foothill Yellow-legged Frog appears to be extirpated from the ECCC HCP/NCCP area (CNDDB 2019). Nevertheless, suitable habitat was mapped, and impacts were estimated at well under 1% of both breeding and migratory habitat (Jones & Stokes 2006). One of the HCP/NCCP's objectives is acquiring high-quality Foothill Yellow-legged Frog habitat that has been identified along Marsh Creek (Ibid.). In 2017, the Viera North Peak 160 ac property was acquired that possesses suitable habitat for Foothill Yellow-legged Frogs (ECCCHC 2018).

Santa Clara Valley Habitat Plan

The Santa Clara Valley Habitat Plan (SCVHP) is a 50-year HCP/NCCP covering over 519,506 ac in Santa Clara County (ICF 2012). As previously mentioned, Foothill Yellow-legged Frogs appear to have been extirpated from lower elevation sites, particularly below reservoirs in this area. Approximately 17% of modeled Foothill Yellow-legged Frog habitat, measured linearly along streams, was already permanently preserved, and the SCVHP seeks to increase that to 32%. The maximum allowable habitat loss is 7 mi permanent loss and 2 mi temporary loss, while 104 mi of modeled habitat is slated for protection. By mid-2018, 8% of impact area had been accrued and 3% of habitat protected (SCVHA 2019).

Green Diamond Aquatic Habitat Conservation Plan

Green Diamond Resources Company has an Aquatic Habitat Conservation Plan (AHCP) covering 400,000 ac of their land that is focused on cold water adapted species, but many of the conservation measures are expected to benefit Foothill Yellow-legged Frogs as well (K. Hamm pers. comm. 2017). Examples include slope stability and road management measures to reduce stream sedimentation from erosion and landslides, and limiting water drafting during low flow periods with screens over the pumps to avoid entraining animals (Ibid.). Although creating more open canopy areas and warmer water temperatures is not the goal of the AHCP, the areas that are suitable for Foothill Yellow-legged Frog breeding are likely to remain that way because they are wide channels that receive sufficient sunlight (Ibid.).

6.0 SUMMARY OF LISTING FACTORS

CESA's implementing regulations identify key factors relevant to the Department's analyses and the Fish and Game Commission's decision on whether to list a species as threatened or endangered. A species will be listed as endangered or threatened if the Commission determines that the species' continued existence is in serious danger or is threatened by any one or any combination of the following factors: (1) present or threatened modification or destruction of its habitat; (2) overexploitation; (3) predation; (4) competition; (5) disease; or (6) other natural occurrences or human-related activities (Cal. Code Regs., tit. 14, § 670.1, subd. (i).

This section provides summaries of information from the foregoing sections of this status review, arranged under each of the factors to be considered by the Commission in determining whether listing is warranted.

6.1 Present or Threatened Modification or Destruction of Habitat

Most of the factors affecting the Foothill Yellow-legged Frog's ability to survive and reproduce discussed above involve habitat destruction or degradation. The most widespread, and potentially most significant, threats are associated with dams and their flow regimes, particularly in areas where they are concentrated and occur in a series along a river. Dams and the way they are operated can have up- and downstream impacts to Foothill Yellow-legged Frogs. They can result in aseasonal or asynchronous breeding cues, scouring and stranding of egg masses and tadpoles, reduction in quality and quantity of breeding and rearing habitat, slower tadpole growth rate, barriers to gene flow among populations, and establishment and spread of non-native species (Hayes et al. 2016). These impacts appear to be most severe when the dam is operated for the generation of hydropower that use hydropeaking and pulse flows (Kupferberg et al. 2009c, Peek 2018). Foothill Yellow-legged Frog abundance below dams is an average of five times lower than in unregulated rivers (Kupferberg et al. 2012). The number, height, and distance upstream of dams in a watershed influenced whether Foothill Yellow-legged Frogs still occurred at sites that were occupied in 1975 (Ibid.). Water diversions for agricultural, industrial, and municipal uses also reduce the availability and quality of Foothill Yellow-legged Frog habitat. Dams are concentrated in the Bay Area, Sierra Nevada, and southern California (Figure 19), while hydropower plants are densest in the northern and central Sierra Nevada (Figure 21).

With predicted increases in the human population, ambitious renewable energy targets, higher temperatures, and more extreme and variable precipitation falling increasingly as rain rather than snow, the need for more and taller dams and water diversions for hydropower generation, flood control, and water storage and delivery is not expected to abate in the future. California voters approved Proposition 1, the Water Quality, Supply and Infrastructure Improvement Act of 2014, which dedicated $2.7 billion to water storage projects (PPIC 2018). In 2018, the California Water Commission approved funding for four new dams in California: expansion of Pacheco Reservoir (Santa Clara County), expansion of Los

Vaqueros Reservoir (Contra Costa County), Temperance Flat Dam (new construction) on the San Joaquin River (Fresno County), and the off-stream Sites Reservoir (new construction) diverting the Sacramento River (Colusa County) (CWC 2019). No historical records of Foothill Yellow-legged Frogs from the Los Vaqueros or Sites Reservoir areas exist in the CNDDB, and one historical (1950) collection is documented from the Pacheco Reservoir area (CNDDB 2019). However, the proposed Temperance Flat Dam site is downstream of one of the only known extant populations of Foothill Yellow-legged Frogs in the East/Southern Sierra clade (Ibid.).

The other widespread threat to Foothill Yellow-legged Frog habitat is climate change. While drought, wildland fires, floods, and landslides are natural, and ostensibly necessary, disturbance events for preservation of native biodiversity, climate change is expected to result in increased frequency and severity of these events in ways that may exceed species' abilities to adapt (Williams et al. 2008, Hoffmann and Sgrò 2011, Keely and Syphard 2016). These disturbance events, which can lead to local extirpations, will occur across a landscape of mostly fragmented and small populations, so the likelihood of natural recolonization will be highly impaired (S. Kupferberg pers. comm. 2019). Climatic changes in flow regime can lead to increased competition, predation, and disease transmission as species become concentrated in areas that remain wet into the late summer (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Loss of riparian vegetation from wildland fires can result in increased stream temperatures or concentrations of nutrients and trace heavy metals that inhibit growth and survival (Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Stream sedimentation from landslides following fire or excessive precipitation can destroy or degrade breeding and rearing habitat (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). At least some models predict unprecedented dryness in the latter half of the century (Cook et al. 2015). The effects of climate change will be realized across the Foothill Yellow-legged Frog's range, and the severity of these effects will likely differ in ways that are difficult to predict. However, the impacts from extended droughts will likely be greatest in the areas that are naturally more arid, the lower elevations and latitudes of southern California and the foothills surrounding the Central Valley (Figure 25), although some models suggest the stress to vegetation communities may be relatively high in the North Coast (Figure 28).

While most future urbanization is predicted to occur in areas outside of the Foothill Yellow-legged Frog's range, it has already contributed to the loss and fragmentation of Foothill Yellow-legged Frog habitat in California. In addition, the increased predation, wildland fires, introduced species, road mortality, disease transmission, air and water pollution, and disturbance from recreation that can accompany urbanization expand its impact far beyond its physical footprint (Davidson et al. 2002, Syphard et al. 2007, Cook et al. 2012, Bar-Massada et al. 2014). Within the Foothill Yellow-legged Frog's historical range, these effects appear most significant and extensive in terms of population extirpations in southern California and the San Francisco Bay Area.

Several other activities have the potential to destroy or degrade Foothill Yellow-legged Frog habitat, but they are less common across the range. They also tend to have relatively small areas of impact, although they can be significant in those areas, particularly if populations are already small and declining. These include impacts from mining, cannabis cultivation, vineyard expansion, overgrazing, timber harvest, recreation, and some stream habitat restoration projects (Harvey and Lisle 1998, Belsky et al. 1999, Merelender 2000, Pilliod et al. 2003, Bauer et al. 2015, Kupferberg and Furey 2015).

6.2 Overexploitation

Foothill Yellow-legged Frogs are not threatened by overexploitation. There is no known pet trade for Foothill Yellow-legged Frogs (Lind 2005). During the massive frog harvest that accompanied the Gold Rush, some Foothill Yellow-legged Frogs were collected, but because they are relatively small and have irritating skin secretions, there was much less of a market for them (Jennings and Hayes 1985). Within these secretions is a peptide with antimicrobial activity that is particularly potent against *Candida albicans*, a human pathogen that has been developing resistance to traditional antifungal agents (Conlon et al. 2003). However, the peptide's therapeutic potential is limited by its strong hemolytic activity (destroys red blood cells), so further studies will focus on synthesizing analogs that can be used as antifungals, and collection of significant numbers of Foothill Yellow-legged Frogs for lab cultures is not expected (Ibid.).

Like all native California amphibians, collection of Foothill Yellow-legged Frogs is unlawful without a permit from the Department. They may only be collected for scientific, educational, or propagation reasons through a Scientific Collecting Permit (Fish & G. Code § 1002 et seq.). The Department has the discretion to limit or condition the number of individuals collected or handled to ensure no significant adverse effects. Incidental harm from authorized activities on other aquatic species can be avoided or minimized by the inclusion of special terms and conditions in permits.

6.3 Predation

Predation is a likely contributor to Foothill Yellow-legged Frog population declines where the habitat is degraded by one or many other risk factors (Hayes and Jennings 1986). Predation by native gartersnakes can be locally substantial; however, it may only have an appreciable population-level impact if the availability of escape refugia is diminished. For example, when streams dry and only pools remain, Foothill Yellow-legged Frogs are more vulnerable to predation by native and non-native species because they are concentrated in a small area, often with little aquatic cover.

Several studies have demonstrated the synergistic impacts of predators and other stressors. Foothill Yellow-legged Frogs, primarily as demonstrated through studies on tadpoles, are more susceptible to predation when exposed to some agrochemicals, cold water, high velocities, excess sedimentation, and even the presence of other species of predators (Harvey and Lisle 1998, Adams et al. 2003, Olson and Davis 2009, Kupferberg et al. 2011b, Kerby and Sih 2015, Catenazzi and Kupferberg 2018). Foothill Yellow-legged Frog tadpoles appear to be naïve to chemical cues from some non-native predators; they have not evolved those species-specific predator avoidance behaviors (Paoletti et al. 2011). Furthermore, early life stages are often more sensitive to environmental stressors, making them more vulnerable to predation, and Foothill Yellow-legged Frog population dynamics are highly sensitive to egg and tadpole mortality (Kats and Ferrer 2003, Kupferberg et al. 2009c). Predation pressure is likely positively associated with proximity to anthropogenic changes in the environment, so in more remote or pristine places, it probably does not have a serious population-level impact.

6.4 Competition

Intra- and interspecific competition in Foothill Yellow-legged Frogs has been documented. Intraspecific male-to-male competition for females has been reported (Rombough and Hayes 2007, Wilcox and Alvarez 2019). Observations include physical aggression and a non-random mating pattern in which larger males were more often engaged in breeding (Rombough and Hayes 2007, Wheeler and Welsh 2008). A behavior resembling clutch-piracy, where a satellite male attempts to fertilize already laid eggs, has also been documented (Rombough and Hayes 2007). These acts of competition play a role in population genetics, but they likely do not result in serious physical injury or mortality. Intraspecific competition among Foothill Yellow-legged Frog tadpoles was negligible (Kupferberg 1997a).

Interspecific competition appears to have a greater possibility of resulting in adverse impacts. Kupferberg (1997a) did not observe a significant change in tadpole mortality for Foothill Yellow-legged Frogs raised with Pacific Treefrogs compared to single-species controls. However, when reared together, Foothill Yellow-legged Frog tadpoles lost mass, while Pacific Treefrog tadpoles increased mass (Kerby and Sih 2015). As described previously under Introduced Species, Foothill Yellow-legged Frog tadpoles experienced significantly higher mortality and smaller size at metamorphosis when raised with bullfrog tadpoles (Kupferberg 1997a). The mechanism of these declines appeared to be exploitative competition (as opposed to interference) through the reduction of available algal resources from bullfrog tadpole grazing in the shared enclosures (Ibid.).

The degree to which competition threatens Foothill Yellow-legged Frogs likely depends on the number and density of non-native species in the area rather than intraspecific competition, and co-occurrence of Foothill Yellow-legged Frog and bullfrog tadpoles may be somewhat rare since the latter tends to breed in lentic (still water) environments (M. van Hattem pers. comm. 2019). Interspecific competition with other native species may have some minor adverse consequences on fitness.

6.5 Disease

Currently, the only disease known to pose a serious risk to Foothill Yellow-legged Frogs is Bd. Until 2017, the only published studies on the impact of Bd on Foothill Yellow-legged Frogs suggested it could reduce growth and body condition but was not lethal (Davidson et al. 2007, Lowe 2009, Adams et al. 2017b). However, two recent mass mortality events caused by chytridiomycosis proved they are susceptible to lethal effects, at least under certain conditions like drought-related concentration and presence of bullfrogs (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Some evidence indicates disease may have played a principal role in the disappearance of the species from southern California (Adams et al. 2017b). Bd is likely present in the environment throughout the Foothill Yellow-legged Frog's range, and with bullfrogs and treefrogs acting as carriers, it will remain a threat to the species; however, given the dynamics of the two recent die-offs in the San Francisco Bay area, the probability of future outbreaks may be greater in areas where the species is under additional stressors like drought and introduced species (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Therefore, as with predation, Foothill Yellow-legged Frogs are less likely to experience the adverse impacts of diseases in more remote areas with fewer anthropogenic changes to the environment.

6.6 Other Natural Events or Human-Related Activities

Agrochemicals, particularly organophosphates that act as endocrine disruptors, can travel substantial distances from the area of application through atmospheric drift and have been implicated in the disappearance and declines of many species of amphibians in California including Foothill Yellow-legged Frogs (LeNoir et al. 1999, Davidson 2004, Lind 2005, Olson and Davis 2009). Foothill Yellow-legged Frogs appear to be significantly more sensitive to the adverse impacts of some pesticides than other native species (Sparling and Fellers 2009, Kerby and Sih 2015). These include smaller body size, slower development rate, increased time to metamorphosis, diminished immune response, and greater vulnerability to predation and malformations (Kiesecker 2002, Hayes et al. 2006, Sparling and Fellers 2009, Kerby and Sih 2015). Some of the most dramatic declines experienced by ranids in California occurred in the Sierra Nevada east of the San Joaquin Valley, where over half of the state's total pesticide usage occurs (Sparling et al. 2001).

Many Foothill Yellow-legged Frog populations are small, isolated from other populations, and possess low genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). Genetic diversity is important in providing a population the capacity to evolve in response to environmental changes, and connectivity among populations is important for gene exchange and in minimizing probability of local extinction (Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). Small populations are at much greater risk of extirpation primarily through the disproportionate impact of demographic, environmental, and genetic stochasticity than robust populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). Based on a Foothill Yellow-legged Frog PVA, populations in regulated rivers face a 4- to 13-fold greater extinction risk in 30 years than populations in unregulated rivers due to smaller population sizes (Kupferberg et al. 2009c). The threat posed by small population sizes is significant and the general pattern shows increases in severity from north to south; however, many sites, primarily in the northern Sierra Nevada, in watersheds with large hydropower projects are also at high risk.

7.0 PROTECTION AFFORDED BY LISTING

It is the policy of the State to conserve, protect, restore and enhance any endangered or threatened species and its habitat (Fish & G. Code, § 2052). The conservation, protection, and enhancement of listed species and their habitat is of statewide concern (Fish & G. Code, § 2051(c)). "Take" is defined for CESA purposes as hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill (Fish & G. Code, § 86). The Fish and Game Code provides the Department with related authority to authorize "take" of species listed as threatened or endangered under certain circumstances (see, e.g., Fish & G. Code, §§ 2081, 2081.1, 2086, & 2835).

If the Foothill Yellow-legged Frog is listed under CESA, impacts of take caused by activities authorized through ITPs must be minimized and fully mitigated according to state standards (Fish & G. Code, § 2081, subd. (b)). These standards typically include protection of land in perpetuity with an easement, development and implementation of a species-specific adaptive management plan, and funding through an endowment to pay for long-term monitoring and maintenance to ensure the mitigation land meets performance criteria. Obtaining an ITP is voluntary. The Department cannot force compliance; however, any person violating the take prohibition may be criminally and civilly liable under state law.

Additional protection of Foothill Yellow-legged Frogs following listing would be expected to occur through state and local agency environmental review under CEQA. CEQA requires affected public agencies to analyze and disclose project-related environmental effects, including potentially significant impacts on rare, threatened, and endangered species. In common practice, potential impacts to listed species are examined more closely in CEQA documents than potential impacts to unlisted species. Where significant impacts are identified under CEQA, the Department expects project-specific avoidance, minimization, and mitigation measures to benefit the species. State listing, in this respect, and consultation with the Department during state and local agency environmental review under CEQA would be expected to benefit the Foothill Yellow-legged Frog in terms of reducing impacts from individual projects, which might otherwise occur absent listing.

For some species, CESA listing may prompt increased interagency coordination, particularly between the National Marine Fisheries Service and the Department, and the likelihood that state and federal land and resource management agencies will allocate funds toward protection and recovery actions. In the case of the Foothill Yellow-legged Frog, some multi-agency efforts exist, often associated with FERC license requirements, to improve habitat conditions and augment declining populations. The USFWS is leading an effort to develop range-wide and regional Foothill Yellow-legged Frog conservation strategies, and CESA listing may result in increased priority for limited conservation funds such as State Wildlife Grants and funding opportunities connected to level of imperilment on the International Union for Conservation of Nature's Red List.

8.0 LISTING RECOMMENDATION

CESA directs the Department to prepare this report regarding the status of the Foothill Yellow-legged Frog in California based upon the best scientific information available (Fish & G. Code, § 2074.6). CESA also directs the Department based on its analysis to indicate in the status report whether the petitioned action (i.e., listing as threatened) is warranted (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

Under CESA, an endangered species is defined as "a native species or subspecies…which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish & G. Code, § 2062). A threatened species is defined as "a native species or subspecies…that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]" (Fish and G. Code, § 2067).

The Legislature left to the Department and the Commission, which are responsible for providing the best scientific information and for making listing decisions, respectively, the interpretation of what constitutes a "species or subspecies" under CESA. (*Cal. Forestry Assn. v. Cal. Fish and G. Com.* (2007) 156

Cal.App.4th 1535, 1548-49). Courts should give a “great deal of deference” to Commission listing determinations supported by Department scientific expertise (*Central Coast Forest Assn. v. Fish & G. Com.* (2018) 18 Cal. App. 5th 1191, 1198-99). The Commission’s authority to list necessarily includes discretion to determine what constitutes a species or subspecies (*Id*. at p. 1237). The Commission’s determination of which populations to list under CESA goes beyond genetics to questions of policy (*Ibid*.).

As described above, genetic divergence among populations and genetic diversity within those populations are critical to species protection. Genetic divergence indicates the amount of time that population lineages have been separated. Effective conservation strategies often identify the most divergent clades in a group of lineages as key management units. While it can be difficult to determine when populations within species have sufficiently differentiated to be considered separate species or subspecies, the population-genetics approach using the fixation index F_{ST} is the most widely used summary measure of population divergence. The high divergence values calculated for F_{ST} for Foothill Yellow-legged Frog suggest a long history of reproductive isolation for the six clades described. Further, genetic diversity provides information on population health and indicates the extent to which populations have the capacity to adapt to changing condition. Amphibians may be particularly vulnerable to the effects of low genetic diversity. The levels of genetic diversity within the six Foothill Yellow-legged Frog clades differed significantly, largely following a north-to-south pattern, and the significant reductions in connectivity and genetic diversity over short evolutionary periods raises concerns with respect to population viability and persistence.

A population of organisms considered distinct for conservation purposes based on scientific analysis of the reproductive isolation and genetic differences between population groups is eligible for listing under CESA (see *Cal. Forestry Assn. v. Cal. Fish and G.*, supra, 156 Cal.App.4th 1535 [upholding the Commission’s listing of two evolutionarily significant units of Coho Salmon]. The Department has recognized that similar populations of a species can be grouped for efficient protection of bio- and genetic diversity (*Id*. at p. 1546-47). Further, genetic structure and biodiversity in California populations are important because they foster enhanced long-term stability (*Id*. at p. 1547). Diversity spreads risk and supports redundancy in the case of catastrophes, provides a range of raw materials that allow adaptation and persistence in the face of long-term environmental change, and leads to greater abundance (*Ibid*.). In consideration of the scientific information contained herein, the Department has determined that each of the six Foothill Yellow-legged Frog genetic clades described in this status report— Northwest/North Coast, Feather River, Northeast/Northern Sierra, East/Southern Sierra, West/Central Coast, and Southwest/South Coast—qualify as a “species or subspecies” under CESA and listing the Foothill Yellow-legged Frog by genetic clade is the prudent approach due to the disparate degrees of imperilment among them. The Department, based on the best science, included areas where the historical range is uncertain, but populations may be discovered within the defined clade boundaries (Figure 6). The Department includes and makes the following recommendation in this status report as submitted to the Commission in an advisory capacity based on the best available science.

NORTHWEST/NORTH COAST: Not warranted at this time.

Clade-level Summary: This is the largest clade with the most robust populations (highest densities) and the greatest genetic diversity. This area is the least densely populated by humans; contains relatively few hydropower dams, particularly further north; and has the highest precipitation in the species' California range. The species is still known to occur in most, if not all, historically occupied watersheds; presumed extirpations are mainly concentrated in the southern portion of the clade around the heavily urbanized San Francisco Bay area. The proliferation of cannabis cultivation, particularly illicit grows in and around the Emerald Triangle, the apparent increase in severe wildland fires in the area, and potential climate change effects are cause for concern, so the species should remain a Priority 1 SSC here with continued monitoring for any change in its status.

FEATHER RIVER: Threatened.

Clade-level Summary: This is the smallest clade and has a high density of hydropower dams. It also recently experienced one of the largest, most catastrophic wildfires in California history. Despite these threats, Foothill Yellow-legged Frogs appear to continue to be relatively broadly distributed within the clade, although with all the dams in the area, most populations are likely disconnected. The area is more mesic and experienced less of a change in precipitation in the most recent drought than the clades south of it. The clade is remarkable genetically and morphologically as it is the only area where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs overlap and can hybridize. The genetic variation within the clade is greater than the other clades except for the Northwest/North Coast. Most of the area within the clade's boundaries is Forest Service-managed, and little urbanization pressure or known extirpations exist in this area. Recent FERC licenses in this area require Foothill Yellow-legged Frog specific conservation, which to date has included cancelling pulse flows, removing encroaching vegetation, and translocating egg masses and in situ head-starting to augment a population that had recently declined.

NORTHEAST/NORTHERN SIERRA: Threatened.

Clade-level Summary: The Northeast/Northern Sierra clade shares many of the same threats as the Feather River clade (e.g., relatively small area with many hydropower dams). The area is also more mesic and experienced less of a change in precipitation during the recent drought than more southern clades. However, this pattern may not continue as some models suggest loss of snowmelt will be greater in the northern Sierra Nevada, and one of the climate change exposure models suggests that a comparatively large proportion of the lower elevations will experience climatic conditions not currently known from the area (i.e., non-analog) by the end of the century. Recent surveys suggest the area continues to support several populations of the species, some of which seem to remain robust, with a fairly widespread distribution. However, genetic analyses from several watersheds suggest many of these populations are isolated and diverging, particularly in regulated reaches with hydropeaking flows.

EAST/SOUTHERN SIERRA: Endangered.

Clade-level Summary: Like the Southwest/South Coast clade, widespread extirpations in this area were observed as early as the 1970s. Dams and introduced species were credited as causal factors in these declines in distribution and abundance, and mining and disease may also have contributed. This area is relatively arid, and drought effects appear greater here than in northern areas that exhibit both more precipitation and a smaller difference between drought years and the historical average. There is a relatively high number of hydropower generating dams in series along the major rivers in this clade and at least one new proposed dam near one of the remaining populations. This area is also the most heavily impacted by agrochemicals from the San Joaquin Valley.

WEST/CENTRAL COAST: Endangered.

Clade-level Summary: Foothill Yellow-legged Frogs appear to be extirpated from a relatively large proportion of historically occupied sites within this clade, particularly in the heavily urbanized northern portion around the San Francisco Bay. In the northern portion of the clade, nearly all the remaining populations (which may be fewer than a dozen) are located above dams, which line the mountains surrounding the Bay Area, and two are known to have undergone recent disease-associated die-offs. These higher elevation sites are more often intermittent or ephemeral streams than the lower in the watersheds. As a result, the more frequent and extreme droughts that have dried up large areas may have contributed to recent declines. Illegal cannabis cultivation, historical mining effects, overgrazing, and recreation likely contributed to declines and may continue to threaten remaining populations.

SOUTHWEST/SOUTH COAST: Endangered.

Clade-level Summary: The most extensive extirpations have occurred in this clade, and only two known extant populations remain. Both are small with apparently low genetic diversity, making them especially vulnerable to extirpation. This is also an area with a large human population, many dams, and naturally arid, fire-prone environments, particularly in the southern portion of the clade. Introduced species are widespread, and cannabis cultivation is rivaling the Emerald Triangle in some areas (e.g., Santa Barbara County). Introduced species, expanded recreation, disease, and flooding appear to have contributed to the widespread extirpations in southern California over 40 years ago.

9.0 MANAGEMENT RECOMMENDATIONS

The Department has evaluated existing management recommendations and available literature applicable to the management and conservation of the Foothill Yellow-legged Frog to arrive at the following recommendations. These recommendations, which represent the best available scientific information, are largely derived from the Foothill Yellow-legged Frog Conservation Assessment, the California Energy Commission’s Public Interest Energy Research Reports, the Recovery Plans of West Coast Salmon and Steelhead, and the California Amphibian and Reptile Species of Special Concern (Kupferberg et al. 2009b,c, 2011a; NMFS 2012, 2013, 2014, 2016; Hayes et al. 2016; Thomson et al. 2016).

9.1 Conservation Strategies

Maintain current distribution and genetic diversity by protecting existing Foothill Yellow-legged Frog populations and their habitats and providing opportunities for increased connectivity and gene flow. Increase abundance to viable levels in populations at risk of extirpation due to small sizes, when appropriate, through in situ or ex situ captive propagation and translocations. Use habitat suitability and hydrodynamic habitat models to identify historically occupied sites that may currently support Foothill Yellow-legged Frogs or could with minor habitat improvements or modified management. Investigate the utility of using other amphibians as indicators of whether a site may be able to support Foothill Yellow-legged Frogs like the presence of Pacific Treefrogs or newts (*Taricha* spp.). Re-establish extirpated populations in suitable habitat through captive propagation and translocations. Prioritize areas in the southern portions of the species' range where extirpations and loss of diversity have been the most severe.

If establishing reserves, prioritize areas containing high genetic variation in Foothill Yellow-legged Frogs (and among various native species) and climatic gradients where selection varies over a small geographical area. Environmental heterogeneity can provide a means of maintaining phenotypic variability which increases the adaptive capacity of populations as conditions change. These reserves should provide connectivity to other occupied areas to facilitate gene flow and allow for ongoing selection to fire, drought, thermal stresses, and changing species interactions.

9.2 Research and Monitoring

Attempt to rediscover potentially remnant populations in areas where they are considered extirpated, prioritizing the southern portions of the species' range. Collect environmental DNA in addition to conducting visual encounter surveys to improve detectability. Concurrently assess presence of threats and habitat suitability to determine if future reintroductions may be possible. Collect genetic samples from any Foothill Yellow-legged Frogs captured for use in landscape genomics analyses and possible future captive propagation and translocation efforts. Attempt to better clarify clade boundaries where there is uncertainty. Study whether small populations are at risk of inbreeding depression, whether genetic rescue should be attempted, and if so, whether that results in hybrid vigor or outbreeding depression.

Continue to evaluate how water operations affect Foothill Yellow-legged Frog population demographics. Support and coordinate existing monitoring efforts and establish more long-term monitoring programs in regulated and unregulated (reference) rivers across the species' range, but particularly in areas like the Sierra Nevada where most large hydropower dams in the species' range are concentrated. Assess whether the timing of pulse flows influences population dynamics, particularly whether early releases have a disproportionately large adverse effect by eliminating the reproductive success of the largest, most fecund females, who appear to breed earlier in the season. Investigate survival rates in poorly understood life stages, such as tadpoles, young of the year, and juveniles. Determine the extent to which pulse flows contribute to displacement and mortality of post-metamorphic life stages.

Collect habitat variables that correlate with healthy populations to develop more site-specific habitat suitability and hydrodynamic models. Investigate the upstream and downstream extent of populations to document the conditions along the peripheries where marginal habitat becomes completely unsuitable. Study the potential synergistic effect of increased flow velocity and decreased temperature on tadpole fitness. Examine the relationship between changes in flow, breeding and rearing habitat connectivity, and scouring and stranding to develop site-specific, benign ramping rates. Incorporate these data and demographic data into future PVAs for use in establishing frog-friendly flow regimes in future FERC relicensing or license amendment efforts and habitat restoration projects. Ensure long-term funding for post-license restoration monitoring to evaluate attainment of expected results and for use in adapting management strategies accordingly.

Evaluate the distribution of other threats such as cannabis cultivation, vineyard expansion, livestock grazing, mining, timber harvest, and urbanization and roads in the Foothill Yellow-legged Frog's range. Study the short- and long-term effects of wildland fires and fire management strategies. Assess the extent to which these potential threats pose a risk to Foothill Yellow-legged Frog persistence in both regulated and unregulated systems.

Investigate how reach-level or short-distance habitat suitability and hydrodynamic models can be extrapolated to a watershed level. Study habitat connectivity needs such as the proximity of breeding sites and other suitable habitats along a waterway necessary to maintain gene flow and functioning meta-population dynamics.

9.3 Habitat Restoration and Watershed Management

Remove or modify physical barriers like dams and poorly constructed culverts and bridges to improve connectivity and natural stream processes. Remove anthropogenic features that support introduced predators and competitors such as abandoned mine tailing ponds that support bullfrog breeding. Where feasible, conduct active control and management efforts to decrease the abundance of bullfrogs, non-native fish, and crayfish (where they are non-native). In managed rivers, manipulate stream flows to negatively affect non-native species that are not adapted to a winter flood/summer drought flow regime. Where appropriate, construct natural barriers (e.g., boulders, waterfalls) to prevent upstream migration of crayfish and non-native fish.

Adopt a multi-species approach to channel restoration projects and managed flow regimes (thermal, velocity, timing) and mimic the natural hydrograph to the greatest extent possible. When this is impractical or infeasible, focus on minimizing adverse impacts by gradually ramping discharge up and down, creating and maintaining gently sloping and sun-lit gravel bars and warm calm edgewater habitats for tadpole rearing, and mixing hypolimnetic water (from the lower colder stratum in a reservoir) with warmer surface water before release if necessary to ensure appropriate thermal conditions for successful metamorphosis. Promote restoration and maintenance of habitat heterogeneity (different depths, velocities, substrates, etc.) and connectivity to support all life stages and gene flow. Avoid damaging Foothill Yellow-legged Frog breeding habitat when restoring habitat for other focal species like listed anadromous salmonids.

9.4 Regulatory Considerations and Best Management Practices

Develop range-wide minimum summer base flow requirements that protect Foothill Yellow-legged Frogs and their habitat with appropriate provisions to address regional differences using new more ecologically meaningful approaches such as percent-of-flow (or modified percent-of-flow) strategies for watersheds (e.g., Yarnell et al. 2013, Mierau et al. 2018). Limit water diversions during the dry season and construction of new in-stream dams by focusing on off-stream water storage strategies that are managed to prevent establishment of non-native predators and competitors.

Ensure and improve protection of riparian systems. Require maintenance of appropriate riparian buffers and canopy coverage (i.e., partly shaded) around occupied habitat or habitat that has been identified for potential future reintroductions. Restrict instream work to dry periods where possible. Prohibit fording in and around breeding habitat. Avoid working near streams after the first major rains in the fall when Foothill Yellow-legged Frogs may be moving upslope toward tributaries and overwintering sites. Use a 0.125 inch mesh screen on water diversion pumps and limit the rate and amount of water diverted such that depth and flow remain sufficient to support Foothill Yellow-legged Frogs of all life stages occupying the immediate area and downstream. Install exclusion fencing, where appropriate, being mindful that predators such as river otters may take advantage of the fencing to catch frogs (S. Kupferberg pers. comm. 2019). If Foothill Yellow-legged Frog relocation is required, conduct this activity early in the season because moving egg masses is easier than moving tadpoles.

Reduce habitat degradation from sedimentation, pesticides, herbicides, and other non-point source waste discharges from adjacent land uses, including along tributaries of rivers and streams. Limit mining to parts of rivers not used for oviposition, such as deeper pools or reaches with few tributaries, and at times of year when frogs are more common in tributaries (i.e., fall and winter). Manage recreational activities in or adjacent to Foothill Yellow-legged Frog habitat (e.g., OHV and hiking trails, camp sites, boating ingress/egress, flows, and speeds) in a way that minimizes adverse impacts. Siting cannabis grows in areas with better access to roads, gentler slopes, and ample water resources could significantly reduce threats to the environment. Determine which, when, and where agrochemicals should be restricted to reduce harm to Foothill Yellow-legged Frogs and other species. Ensure all new road crossings and modifications to existing crossings (bridges, culverts, fills, and other crossings) accommodate at least 100-year flood flows and associated bedload and debris.

9.5 Partnerships and Coordination

Establish collaborative partnerships with agencies, universities, and non-governmental organizations working on salmon and steelhead recovery and stream restoration. Anadromous salmonids share many of the same threats as Foothill Yellow-legged Frogs, and recovery actions such as barrier removal, restoration of natural sediment transport processes, reduction in pollution, and eradication of non-native predators should be planned and executed in a manner that benefits the frogs as well. Ensure Integrated Regional Water Management Plans and fisheries restoration programs take Foothill Yellow-legged Frog conservation into consideration during design, implementation, and maintenance.

Encourage local governments to place conditions on new developments to minimize negative impacts on riparian systems. Promote and implement initiatives and programs that improve water conservation use efficiency, reduce greenhouse gas emissions, promote sustainable agriculture and smart urban growth, and protect and restore riparian ecosystems. Shift reliance from on-stream storage to off-stream storage, resolve frost protection issues (water withdrawals), and ensure necessary flows for all life stages in all water years.

Establish a Department-coordinated staff and citizen scientist program to systematically monitor occupied stream reaches across the species' range.

9.6 Education and Enforcement

Support programs to provide educational outreach and local involvement in restoration and watershed stewardship, such as Project Wild, Adopt a Watershed, school district environmental camps, and other programs teaching the effects of human land and water use on Foothill Yellow-legged Frog survival.

Provide additional funding for increased law enforcement to reduce ecologically harmful stream alterations and water pollution and to ensure adequate protection for Foothill Yellow-legged Frogs at pumps and diversions. Identify and address illegal water diverters and out-of-compliance diverters, seasons of diversion, off-stream reservoirs, well pumping, and bypass flows to protect Foothill Yellow-legged Frogs. Prosecute violators accordingly. Provide additional environmental and enforcement staff for oversight of permit and environmental document compliance (i.e., fulfilling commitments in NEPA and CEQA documents to undertake activities to avoid, minimize, and mitigate adverse impacts; carrying out mitigation requirements in HCPs, NCCPs, FERC licenses; etc.).

10.0 ECONOMIC CONSIDERATIONS

The Department is charged in an advisory capacity in the present context to provide a written report and a related recommendation to the Commission based on the best scientific information available regarding the status of Foothill Yellow-legged Frog in California. The Department is not required to prepare an analysis of economic impacts (See Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

SUBJECT: NOTIFICATION OF STATUS REVIEW FOR FOOTHILL YELLOW-LEGGED FROG

To whom it may concern:

The California Department of Fish and Wildlife (Department) has initiated a status review of the Foothill Yellow-legged Frog (*Rana boylii*) pursuant to Fish and Game Code section 2074.6 and is providing this notice pursuant to Fish and Game Code section 2074.4 to solicit data and comments on the petitioned action from interested and affected parties.

The Department has initiated this status review following the Fish and Game Commission's (Commission) decision to accept for consideration the petition to list the species under the California Endangered Species Act (CESA) at its June 21, 2017 meeting. Having provided public notice (Cal. Reg. Notice Reg. 2017, No. 27-Z, pp. 986-987; Fish & G. Code, § 2074.2), the Foothill Yellow-legged Frog is now a candidate species under CESA. As a candidate species, the Foothill Yellow-legged Frog receives the same legal protection afforded to an endangered or threatened species (Fish & G. Code, § 2085).

The Department has 12 months to review the petition, evaluate the available information, and report back to the Commission whether or not the petitioned action is warranted. (Fish & G. Code, § 2074.6.) The Department's recommendation must be based on the best scientific information available to the Department. (Fish & G. Code, § 2074.6.)

Anyone with data or comments on the Foothill Yellow-legged Frog's ecology, genetics, life history, distribution, abundance, habitat, the degree and immediacy of threats to reproduction or survival, adequacy of existing management, and recommendations for management of the species, is hereby requested to provide such data or comments to:

California Department of Fish and Wildlife
Attn: Laura Patterson
1812 9th Street
Sacramento, California 95811
wildlifemgt@wildlife.ca.gov

Please submit two hard copies if submitting by surface mail. If submitting by email, please include "Foothill Yellow-legged Frog" in the subject heading.

Responses and information received by **August 31, 2017,** will be evaluated for incorporation in the Department's final report to the Commission. The Department's written report will indicate, based on the best scientific information available, whether the Department concludes that the petitioned action is warranted or not warranted. Receipt of the report will be placed on the agenda for the next available meeting of the Commission after delivery. The report will be made available to the public at that time. Following receipt of the Department's report, the Commission will allow a 30-day public comment period prior to taking any action on the Department's recommendation.

As a candidate species, the Foothill Yellow-legged Frog receives the same legal protection afforded to an endangered or threatened species under the California Endangered Species Act (Fish & G. Code, § 2085). Research on Foothill Yellow-legged Frog requires appropriate permits issued pursuant to Fish and Game Code Section 2081(a). Detection information on Foothill Yellow-legged Frogs should be sent to the California Natural Diversity Data Base at https://www.wildlife.ca.gov/Data/CNDDB/Submitting-Data.

Interested researchers or anyone with questions may contact Laura Patterson at 916-341-6981 or at the email or address above

SUBJECT: NOTIFICATION OF STATUS REVIEW FOR FOOTHILL YELLOW-LEGGED FROG

Dear Honorable Tribal Representative:

The California Department of Fish and Wildlife (Department) has initiated a status review of the Foothill Yellow-legged Frog (*Rana boylii*) pursuant to Fish and Game Code section 2074.6 and is providing this notice pursuant to Fish and Game Code section 2074.4 to solicit data and comments on the petitioned action from interested and affected Tribes. The Department has initiated this status review following the Fish and Game Commission's (Commission) decision to accept for consideration the petition to list the species under the California Endangered Species Act (CESA) at its June 21, 2017 meeting. Having provided public notice (Cal. Reg. Notice Reg. 2017, No. 27-Z, pp. 986-987; Fish & G. Code, § 2074.2), the Foothill Yellow-legged Frog is now a candidate species under CESA. As a candidate species, the Foothill Yellow-legged Frog receives the same legal protection afforded to an endangered or threatened species (Fish & G. Code, § 2085).

The Department has 12 months to review the petition, evaluate the available information, and report back to the Commission whether or not the petitioned action is warranted (Fish & G. Code, § 2074.6). The Department's recommendation must be based on the best scientific information available. The Department would welcome your Tribe to provide any data or comments on the species' ecology, genetics, life history, distribution, abundance, habitat, the degree and immediacy of threats to its reproduction or survival, the adequacy of existing management, and recommendations for management of the species.

Please provide such data or comments to "Attn: Laura Patterson" at the address in the letterhead. Please provide two hard copies if submitting by surface mail. Comments may also be sent via email to: wildlifemgt@wildlife.ca.gov. If submitting by email, please include "Foothill Yellow-legged Frog" in the subject heading. Please submit Foothill Yellow-legged Frog detection information to the California Natural Diversity Database at: https://www.wildlife.ca.gov/Data/CNDDB/Submitting-Data.

The Department respectfully requests your Tribe provide any responses and information before **August 31, 2017** to allow sufficient time to evaluate the information for possible incorporation in the Department's final status review report to the Commission. The written report will indicate, based on the best scientific information available, whether the Department concludes that the petitioned action is warranted or not warranted. Receipt of the status review report will be placed on the agenda for the next available Commission meeting after delivery. The report will be made available to the public at that time. Following receipt of the Department's report, the Commission will allow a 30-day public comment period prior to taking any action on the Department's recommendation.

The Department welcomes direct communication and consultation to discuss the status review of Foothill Yellow-legged Frog and to identify any impacts to Tribal interests or cultural resources. The Department is committed to open communication with your Tribe under its Tribal Communication and Consultation Policy, which is available through the Department's Tribal Affairs webpage at https://www.wildlife.ca.gov/General-Counsel/Tribal-Affairs.

If you would like more information on the Foothill Yellow-legged Frog status review, please contact Laura Patterson at 916-341-6981 or the Department via email at wildlifemgt@wildlife.ca.gov or at the address above. To request formal government-to-government consultation pursuant to the Department's Tribal Communication and Consultation Policy, please respond in writing to Tribal Liaison Nathan Voegeli by email tribal.liaison@wildlife.ca.gov or by mail to Department of Fish and Wildlife, 1416 9th Street, Suite 1341, Sacramento, CA 95814. Please designate and provide contact information for the appropriate Tribal lead person.

We look forward to your response and input on the Foothill Yellow-legged Frog status review.

Sincerely,

CDFW Seeks Information Related to Foothill Yellow-legged Frog

July 21, 2017

The California Department of Fish and Wildlife (CDFW) is seeking information relevant to a proposal to list the Foothill Yellow-legged Frog as a threatened species.

The Foothill Yellow-legged Frog (*Rana boylii*) inhabits lower elevation creeks, streams and rivers throughout the Klamath, Coast, Sierra Nevada and formerly the Transverse ranges of California. They can be found in a variety of habitat types such as chaparral, oak woodland, mixed coniferous forest, riparian sycamore and cottonwood forest, as well as wet meadows.

In December 2016, the Center for Biological Diversity submitted a petition to the California Fish and Game Commission to formally list the Foothill Yellow-legged Frog as threatened under the California Endangered Species Act. The listing petition described a variety of threats to the survival of Foothill Yellow-legged Frogs in California. These include direct and indirect impacts associated with dams, water diversions and development, invasive species, disease, climate change and other activities such as marijuana cultivation, timber harvest, mining, recreation, road building and urbanization. The Commission followed CDFW's recommendation and voted to advance the species to candidacy on June 21, 2017. The Commission published findings of this decision on July 7, 2017, triggering a 12-month period during which CDFW will conduct a status review to inform the Commission's decision on whether to list the species.

As part of the status review process, CDFW is soliciting information from the public regarding the Foothill Yellow-legged Frog's ecology, genetics, life history, distribution, abundance, habitat, the degree and immediacy of threats to reproduction or survival, adequacy of existing management and recommendations for management of the species. Comments, data and other information can be submitted in writing to:

California Department of Fish and Wildlife
Attn: Laura Patterson
1812 Ninth St.
Sacramento, CA 95811

Comments may also be submitted by email to wildlifemgt@wildlife.ca.gov. If submitting comments by email, please include "Foothill Yellow-legged Frog" in the subject heading.

All comments received by **Aug. 31, 2017** will be evaluated prior to submission of the CDFW report to the Commission. Receipt of the report will be placed on the agenda for the next available meeting of the Commission after delivery and the report will be made available to the public at that time. Following the receipt of the CDFW report, the Commission will allow a 30-day public comment period prior to taking any action on CDFW's recommendation.

The Center for Biological Diversity's listing petition and CDFW's petition evaluation for the Foothill Yellow-legged Frog are available at www.fgc.ca.gov/CESA/index.aspx#fylf.

Subject: Foothill Yellow-legged Frog

Laura,
I saw the TWS post on facebook about the call for information on Foothill Yellow-legged Frog. I'm not sure that I have much to add, but when I did my master's work in the Sutter Buttes I searched the creeks within the State Park for the species but never found them. I also confirmed the ID of the one specimen that is at Chico State from the Buttes.

My personal opinion is that if a FYLF population was present at the Sutter Buttes, the feral pigs have probably wiped them all out. All of the creeks I encountered during the summer were reduced to small pools,and those pools almost always were turned into pig wallows. That, along with other researchers not being recording the species other than the one specimen leads me to believe that they have been extirpated from the Buttes.

Anyway, that's probably all old news for you, but just in case it was useful I thought I would let you know.

Thanks and good luck!
Eric

From: Rosalind Helfand
Sent: Saturday, July 22, 2017 1:17 PM
To: Wildlife Management
Subject: Foothill Yellow-legged Frog - Attn Laura Patterson

Dear Ms. Patterson,

Hello. I'm submitting observations on Foothill Yellow-legged Frog habitat.

On October 7, 2016 at around 4pm, my husband and I observed and photographed three Foothill Yellow-legged Frogs in a shallow stream with clear water moving moderately fast feeding into the Smith River. This was not far from Stout Grove in Jedediah Smith Redwoods State Park.

The environment was very cool (although it was a very warm day in the sun) with dense trees and foliage and fully shaded at the time. The frogs both sat on rocks in the stream and hid in the water under tree debris (mostly bits of redwood tree) lining the sides of the stream.

The stream ran under a pedestrian bridge for a fairly heavily used trail and the frogs were found close to the bridge location -- both down and upstream.

It's clear that the habitat is fragile. If the stream were to dry up or be blocked or polluted, or if people were to walk in and around it regularly, it appears it would be a threat to the frogs.

We're happy to submit our photographs if desired.

Thank you!

I have been a California Fisherman for 45yrs. I have bought California Fishing licenses for 39yrs. I remember the good old days of fishing the San Gabriel River, Piru Creek, Cucamonga Creek and the Arroyo Seco Creek. So Cal trout fishing was good back in those days. That stupid frog ruined it, more people trout fish than watch that frog. That was a typical California maneuver wrecking something that was good for a bunch of the citizens to make a few people happy. I say lift the ban and start stocking the creeks again!

Subject: The possible listing of the Yellow legged frog as recommended by certain environmental groups

I must object to this listing of the yellow legged frog as endangered. Poor management of the perpetuation of the species is the problem and should be the recourse to improve numbers of the species. It has all ways been the California fish and game duty to help species survive, by devoting high intensity farming of the species at either hatcheries, or game farms. Then reintroducing the species back into the wild. I recommend using some of the game reserves to set up small eco-habitat, such as an open fenced terrarium of the perfect environment to provide advantages for the species to survive. The environmentalist are trying to destroy the right of the people to harvest the natural resources of public land to advance their communist agenda of government control over our lands. That The Fish and Wild life would be in collusion to their agenda of enemies of the rights of the people and traitors to the United States of America.
Proper management of out public lands require harvesting and fire breaks This designation would stop good land management of public lands. Creating an endangered species is the way environmentalists have created conditions of bad forest management , by creating a much more dangerous environment for all.

Subject: Yellow legged Frog

Dear Mrs. Patterson
I'd like to take a moment express my sincere concerns associated with the potential listing of the yellow legged frog. I have been employed as a peak ranger for more than a decade and deal daily with the many challenges associated with the rapidly increasing environmental regulations resulting from ESA listings such as the arroyo toad, the least turns vario and the SoCal steelhead. Additionally as and avid outdoorsmen, hunter and conservationists I have watched as rampant environmental regulations have reduced, limited and or all together taken away opportunity and access from the public. With that said I also recognize that ESA protections are important and am supportive of reasonable and practical regulations aimed at protecting endangered or threatened species.

However, in this case I am very concerned that this listing is nothing more than a veiled attack by the center for biological diversity to further limit recreational opportunities and to forward the environmental agenda of a small but powerful group of the states population. I challenge the commission to finally take a long hard look at the number of lawsuits filed by the center for biological diversity and to consider the fact that this organization along with 2 others has crippled the state and its residents with bogus environmental requests and lawsuits in an effort to advance their agenda. At what point will the commission take an actual hard look and start considering the balance of humans versus environmental regulation. As noted, I am supportive of reasonable regulation, but at this point in time I cannot support the listing of another species that i believe will only further limit my access to public lands because of the threats of organizations like center for biological diversity. I chsllenge the commission and other regulatory organizations to have a backbone. The ESA was intended to protect endangered species and to provide balance between and angered species and humans, and instead the pendulum has swung out of control because of the fear of litigation. I assure you the majority of tax layers would gladly spend money fight fight such aggeegious threats and claims and would rather do so then to have unreasonableand costly regulations placed on them.

I ask the commission that if they do take steps to list this species, that they do so with sound science and with a backbone. I hope that the commission takes the opportunity to make it clear to organizations like the center for biological diversity that they will not be influenced or controlled by the threat of litigation and that if listed regulations imposed will be based on balance between man and wildlife and that they will end this wildlife first attitude they have had in the past.

Sincerely
Clayton Strahan

This frog, and the enviro Nazi's of this state are ruining rural mountain economies!!! No fish planting in the rivers and streams means no tourists, no tourists mean no money for local business. What are WE supposed to do??? Are mountain economies to go extinct themselves, over this reptile??? NO MORE ENVIRO FACISM!!!!! PEOPLE NOT FROGS!!!! Theres nothing hard about it!

Since the ban on dredging I have only seen a decline in fish and wildlife populations AND a decrease in prosperity and population in these northern California communities. If we're really worried about the environment, how about not tunneling water to so. cal. for a start? How about leaving alone the folks who have lived off of and have taken good care of the lands up here in no. Cal? Why are "we" pretending to care about the environment and simultaneously publicly funding environmentally and economically destructive policies, programs and projects??? It's Naziism and it's affecting PEOPLE who are much more important to me than a yellow legged frog that has not been impacted at all by people carying on their business as they always have up here. Leave us alone and stop further restricting access to and use of OUR land.

This frog is classified near-threatened. If DFW lists it, all inland fishing in California will be destroyed. DFW barely analyzed the wild and misleading claims of the Center for Biodiversity since they were pre-disposed in favor of anything to block fishing and hunting and public use of lands.

Dear Nathan Voegeli,

The Tribe has received the project notification letter dated July 24, 2017, requesting interest and input regarding the Foothill Yellow-Legged Frog. We appreciate your effort to contact the Tribe. The Tribal Heritage Preservation Office staff has reviewed the project information. Based on the project details, the Tribe does not have any comments to provide at this time. Should the project be modified the Tribe respectfully requests project notification and the opportunity to review the project. Thank you for contacting the Tribe with this notice and the opportunity to provide comment.

Sincerely,
Buffy McQuillen

Hello Laura,

The person that is coordinating the placement of listed salmon above dams in the Central Valley is Brian Elliott. It is my understanding that NOAA has had studies completed on several rivers above dams where they think reintroductions may be successful. Those studies may have relatively current FYLF information in them. Brian may be able to expedite you receiving that information. Good Luck.

Re: Proposal to list Foothill Yellow-legged Frog (*Rana boylii)* as Threatened under California Endangered Species Act

To Whom It May Concern:

We write in support of the California Fish and Game Commission proposal to list *Rana boylii*, the Foothill yellow-legged frog (FYLF) as a threatened species under the California Endangered Species Act (CESA). The signers of this letter are part of the Friends of Tesla Park alliance, a group of individuals and organizations working to preserve public wildlands in southeastern Alameda County, in an area commonly referred to as the Tesla park land and Corral Hollow Creek watershed.

Public and open space lands are often-times assumed to provide sanctuary for species in decline. This letter demonstrates, using the biologically rich Corral Hollow Creek watershed (Fig. 1) as a case study, that unregulated, or under-regulated, activities on publicly owned lands can have significant, adverse impacts to FYLF, and thus they require protection under CESA. These frogs have long been known to occur in Corral Hollow Creek. Museum records of abundant FYLF populations date back to 1911 and continue through time until the last few decades[1]. The persistence of FYLF has become tenuous because of the destruction and modification of their fluvial habitat due to Off Highway Vehicle (OHV) use at the Carnegie State Vehicular Recreation Area (CSVRA). Proposed expansion of CSVRA into Tesla threatens future

[1] University of California, Berkeley Museum of Vertebrate Zoology. Available url [http://arctos.database.museum/SpecimenSearch.cfm] accessed 8/5/2015.

destruction of habitat that is currently intact. In this letter, we highlight the inadequacy of existing regulatory mechanisms within the California State Parks Off-Highway Motor Vehicle Recreation (OHMVR) Division to protect FYLF. We also highlight the vulnerability of small isolated populations to stochastic events that can lead to extirpation and the implications of climate change for FYLF.

Although we focus on the Corral Hollow Creek watershed, the threat posed by OHV use to this species on publicly owned land is not limited to this one location. Similar OHV related threats occur elsewhere in the range of FYLF including Frank Raines OHV Park (Stanislaus Co. along Del Puerto Creek), Hollister Hills State Vehicular Recreation Area, and the Clear Creek area managed by the Bureau of Land Management (San Benito Co.). There are other publicly owned lands that are not specifically designated for OHV use, but where OHV use is allowed in the watersheds either currently, or historically, occupied by FYLF. Included in this category are the various US National Forests[2] (e.g. in the foothills of the Sierra Nevada). Improved regulatory mechanisms are needed to halt the decline of this species and aid its recovery in the streams and rivers flowing through public lands.

[2] See list of US National Forests with OHV use at http://ohv.parks.ca.gov/?page_id=23140

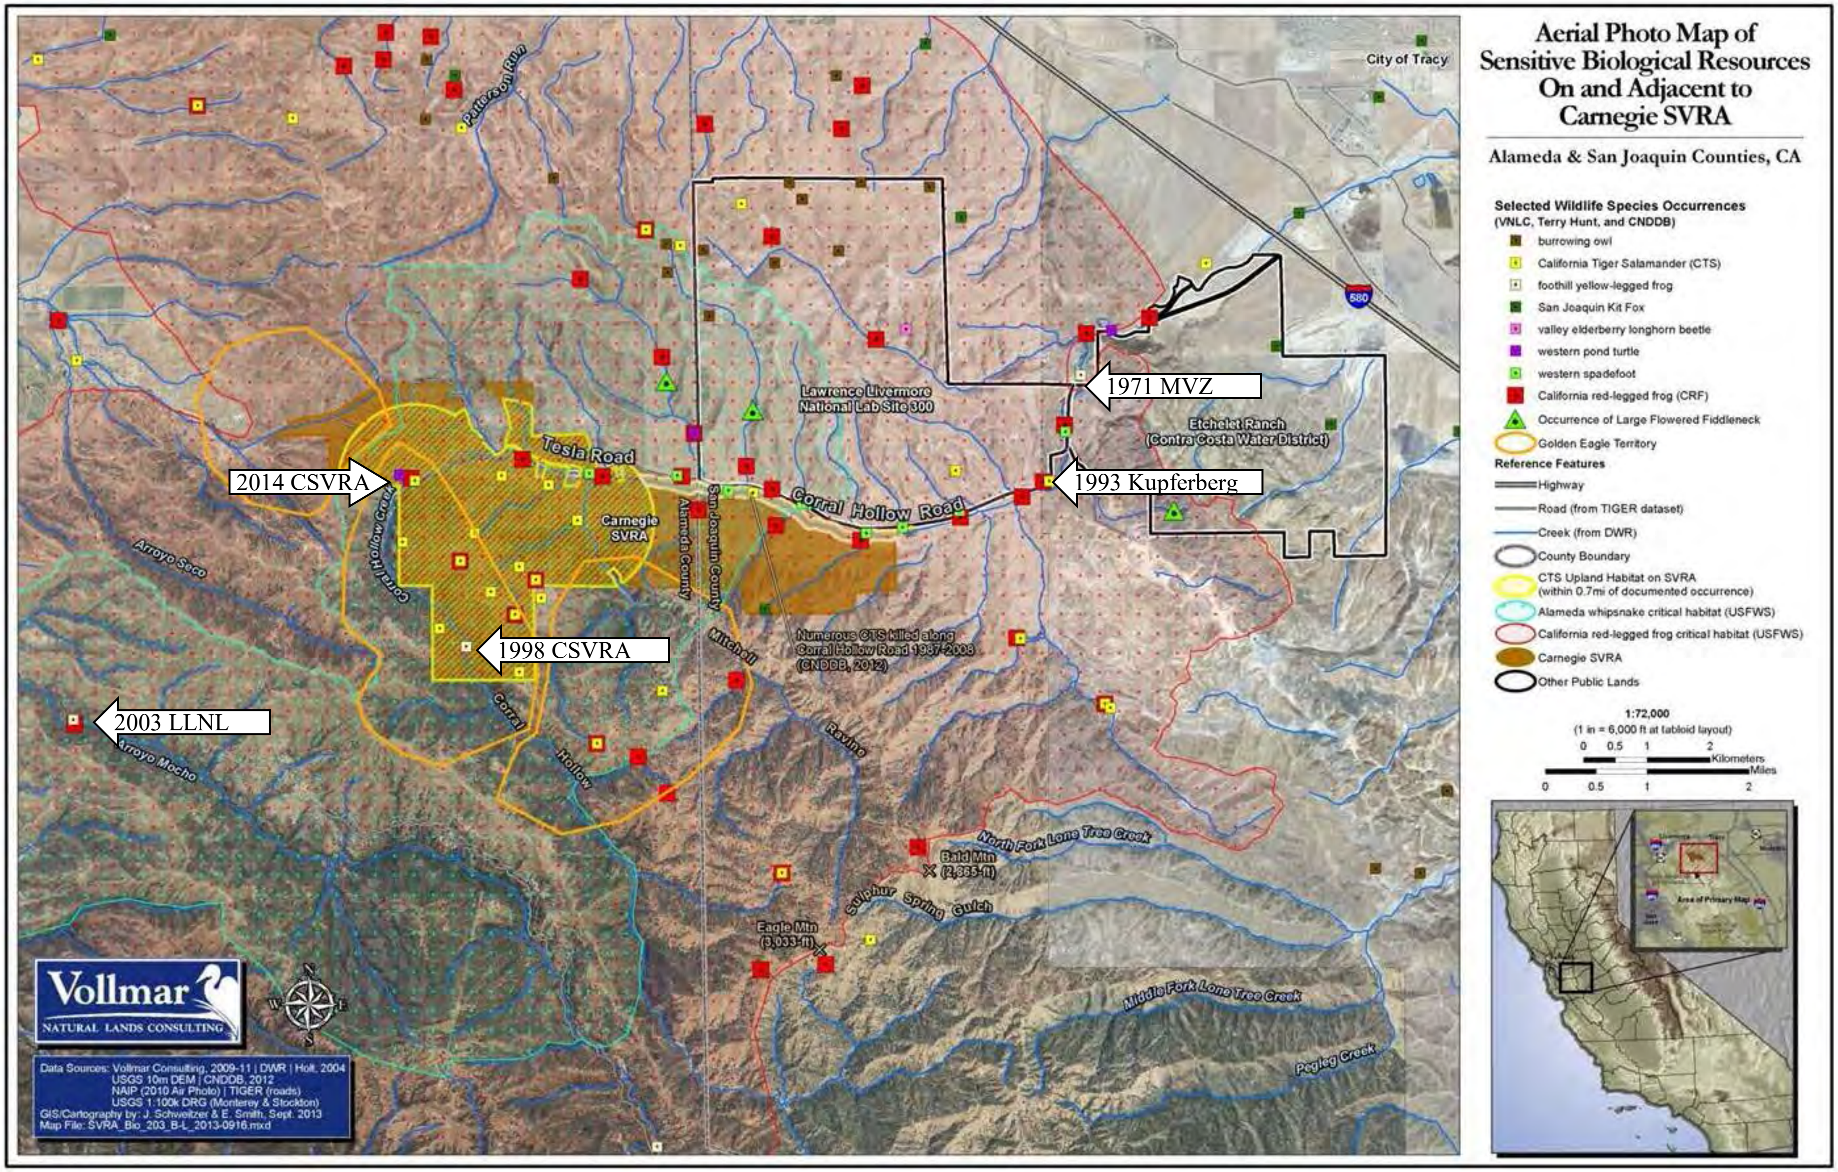

Figure 1 Locations (bold white arrows with years and observers) of Foothill yellow legged frogs observed in the Corral Hollow watershed and vicinity. THREATS TO FOOTHILL YELLOW-LEGGED FROGS IN CORRAL HOLLOW

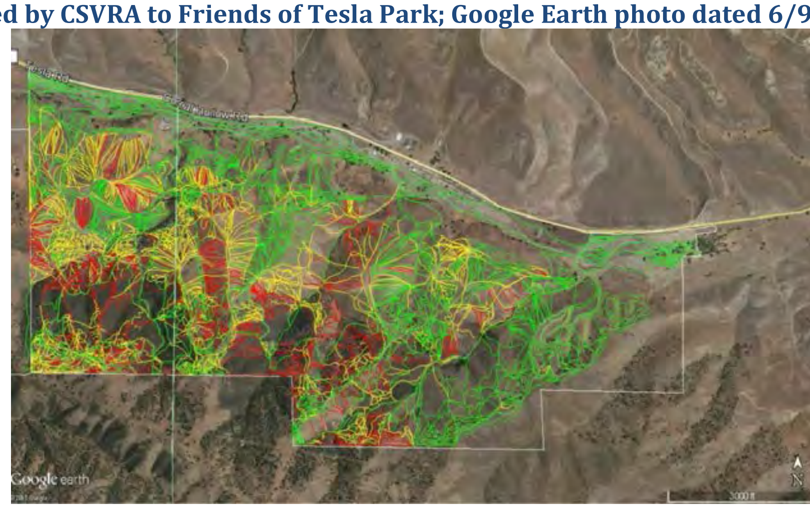
Multiple anthropogenic stressors are contributing to range wide declines of FYLF. Water diversion, extraction, and flow regulation pose major threats, with extirpation having occurred most frequently downstream of large dams[3], but declines have happened in free-flowing streams as well. Heavy erosion and transport of sediment to streams deteriorate conditions, can cause local extirpations[4], and subsequently isolate remaining populations.

1 SEDIMENTATION OF FLUVIAL HABITAT DUE TO OHV INDUCED EROSION

FYLF are now absent from historically occupied reaches of Corral Hollow Creek where OHV use occurs and downstream of the heavily sedimented reach. The stream reach where FYLF still occur is at risk of the same fate if OHV use expands. Twenty years ago, California State Parks purchased land upstream of the existing 1,575-acre CSVRA and is planning a 3,100-acre expansion. The present SVRA hosts at least 0.14 miles of trails per acre (Fig. 2).

Figure 2. Map view of CSVRA OHV trails and erosion status (lines shown as green, yellow, or red). GIS shapefile provided by CSVRA to Friends of Tesla Park; Google Earth photo dated 6/9/2014.



Extrapolation from this estimate of density yields a prediction of at least 447 miles of new OHV trails in the expansion area (*i.e.* 0.14 miles/acre *x* 3100 acres). This linear tally and extrapolation greatly under-represents the amount of de-vegetated area prone to erosion around all trails, not only those designated yellow and red by CSVRA, where severe soil loss occurs (Fig. 3). We believe that CESA protection of a species in the streams receiving the sediment will improve regulation of this detrimental activity.

Figure 3. Map view (left) comparing CSVRA-designated trails (lines) and ratings (red, yellow, green color coding) to area of barren surfaces visible in a background aerial image (6/9/2014 Google Earth); associated hillside-gully erosion (right, location of photograph shown by arrow, 4/1/2015).

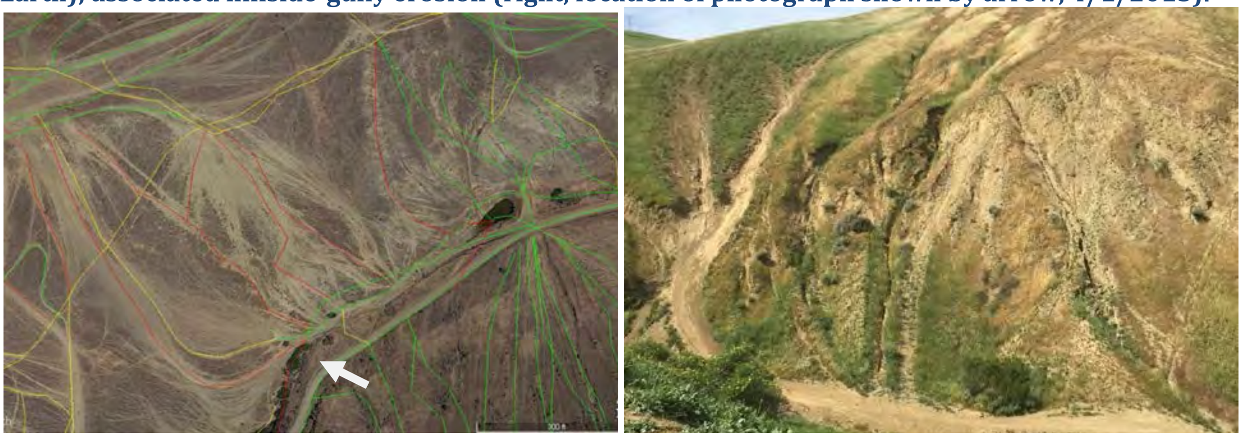

Figure 4. Pervasive hillside runoff concentrated in OHV trails where barren soils become over-saturated and erode in Carnegie SVRA (12/11/2014).

During storms, runoff bearing the fine sediment from the hillsides enters the creeks (Figs. 4, 5). The sediment buries the former stream channel, alters the channel's cross-sectional shape, and decreases the availability of suitable depth, velocity, and substrate habitats preferred by FYLF. These physical habitat features are central requirements for FYLF[5],[6]. As was noted in the Recovery Plan for California red-legged frogs regarding habitat quality in Corral Hollow Creek, "off-road vehicle activities upstream … are decreasing the suitability of the ecological reserve due to high rates of sedimentation during peak stream flows"[7].

Climate change will likely exacerbate the erosion problems. Rainfall patterns are changing from a continuous rainy season that recharges ground water and sustains baseflows to droughts punctuated by intense storms generating maximum runoff and peak streamflows. 'Atmospheric river' storms, such as the one that occurred in December 2014 (Fig. 5), now

contribute 80% of Bay Area annual rainfall, compared to 30-50% in the past[8]. Atmospheric rivers are bands of moisture laden air that extend across the Pacific Ocean from the tropics. Some global climate change experts, such as USGS hydrologist Mike Dettinger, predict that "under current climate scenarios, atmospheric rivers will hit Northern California twice as often by 2100 as they do now."[8]

Figure 5. Fine sediment discharge from OHV area to Corral Hollow Creek. (12/11/2014).

2 SMALL POPULATION SIZE AND ISOLATION

FYLF have been sporadically encountered in Corral Hollow Creek in Carnegie SVRA (2014[9], 1998[10], Fig. 1). Both observations were in the proposed CSVRA expansion area, upstream of the current riding area and reaches presently receiving excessively large loads of sediment. The recent sighting was of a single juvenile, which by virtue of its size had metamorphosed the previous summer/fall. This indicates that there is likely a breeding site in the vicinity, yet no appropriately timed and geographically extensive surveys have been conducted to determine the location of the breeding site. Without such information, SVRA expansion plans cannot be modified appropriately. Indeed, specific protection of FYLF was not addressed in the 2016 final EIR approved by CSVRA[11]. As an example of inadequate surveys, TRA Environmental Consultants conducted a survey on Oct. 17, 2013, when the reach was dry. Not surprisingly, no FYLF were detected.

FYLF were not historically sparse in Corral Hollow Creek, but their distribution appears to have become fragmented. The 2004 CSVRA Draft Habitat Conservation Plan (p. 6-13)[12], UC Berkeley Museum of Vertebrate Zoology specimens from 1971 (MVZ:Herp:98194), and a survey conducted in 1993 by Dr. Sarah Kupferberg (unpublished data via personal communication) report large numbers of tadpoles downstream of what is now CSVRA. The present rarity of FYLF in Corral Hollow Creek places them at risk of extirpation. A population projection model developed for this species[13] indicates extirpation is extremely sensitive to population size. The likelihood of recolonization after extirpation in Corral Hollow Creek is low because dispersal usually follows watercourses[14] and there are barriers both upstream and downstream of the extant FYLF. Upstream, there is a ridge separating the presently occupied site from the nearest extant population 4 miles away in Arroyo Mocho[15] (Fig. 1). Carnegie SVRA represents the downstream barrier.

3 NEED FOR CESA PROTECTION & IMPLEMENTATION OF CONSERVATION GUIDELINES

California ESA protection of FYLF would improve the implementation of conservation guidelines. The Draft Habitat Conservation Plan from 2004 was never adopted. Presently, the Natural Resource Management Guidelines in CSVRA's General Plan and FEIR approved and certified in October 2016 are insufficient to avoid or minimize impacts on FYLF because the buffer zone along Corral Hollow Creek is too narrow. Furthermore, tributaries are not protected from OHV use and crossings are allowed. Connectivity to seeps and off-channel water bodies is not accounted for. The General Plan and EIR assertion that a 'Limited Recreation Area' (≤ 150 feet on one or the other side of Corral Hollow Creek) would protect FYLF ignores the scientific literature about movement and dispersal in this species. CSVRA also does not consistently establish the 150-foot buffer and limited recreation does not exclude OHV use entirely. It has long been known that juveniles disperse away from natal streams and have been caught up to 600 feet away from a stream channel[16]. FYLF use small tributaries and seeps[17] and move from hundreds to thousands of meters in dendritic stream networks[18]. Development of a recovery plan for FYLF would ground guidelines in science. Further CSVRA is not generally meeting the 150-foot buffer standard within the existing SVRA.

4 CRITICAL HABITAT AND DISTINCT POPULATION SEGMENT

We believe that Corral Hollow Creek should be designated as critical habitat for FYLF given the location of the watershed within the species' geographic range and the potential for recovery in the publicly owned land if the expansion area can be designated as a preserve with no OHV use. At the latitude of the watershed, 37.6°, Lind[19] estimated that the frogs were missing from more than two thirds of historically occupied sites (Fig. 6). Analysis of mitochondrial DNA data strongly suggests that populations of FYLF at this latitude and further south in the Central California Coast Range constitute a distinct genetic lineage[20]. Samples from the nearby population in Arroyo Mocho were part of Lind et al.'s "Clade D", and we assume Corral Hollow frogs would fall in this lineage.

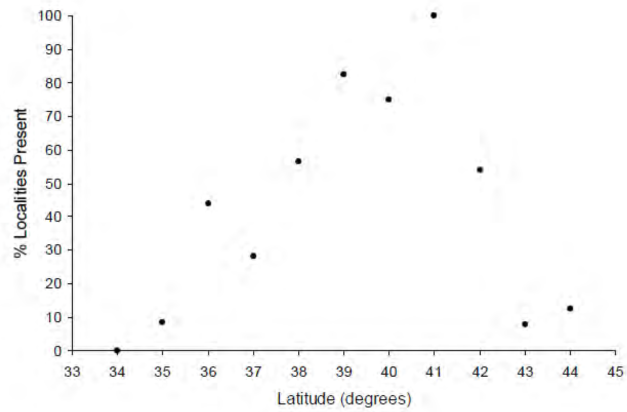

Figure 6. Percent of historic localities with FYLF present in relation to latitude (from Lind 2005).

We urge the California Fish and Game Commission to facilitate research efforts using contemporary nuclear DNA analysis techniques to verify that the Corral Hollow Creek population of FYLF is part of a Distinct Population Segment. Ryan Peek, Ph.D. candidate at UC Davis, is currently working on a project to extend the work of Lind et al.[16] using the same samples which have been maintained in a frozen archive. The most difficult aspect of the project is the logistics of collecting new tissue samples from additional populations of FYLF to fill in geographic sampling gaps. FYLF are often in remote and difficult to access locations. The listing process, status review, and assembly of a working group of scientists and public land managers could provide a unique opportunity to expedite the collection and delivery of tissue samples to Mr. Peek. An accurate assessment of Distinct Population Segments could be produced relatively quickly given a coordinated effort.

An additional geographic reason for designating the Tesla area as Critical Habitat is its location in both an east-west corridor connecting the xeric San Joaquin Desert biome and the mesic biome of the East Bay Hills and a north-south corridor in the Diablo Range (Fig. 7). If the Corral Hollow population of FYLF recovers under CESA protection, it could serve

5 CONCLUSION

Thank you for the opportunity to share our observations of a significant threat to FYLF that exists on publicly owned lands and should be taken into consideration when developing conservation strategies and making a listing determination under the California Endangered Species Act. The examples provided from CSVRA illustrate the significant threats to FYLF posed by OHV use. Because the management practices we have highlighted are OHMVR Division state-wide policies, it must be assumed that similar risks exist throughout the species range in California where OHV use occurs. If FYLF were protected by the California Endangered Species Act, management of OHV use and expansion of OHV use into sensitive areas could be more effectively regulated.

Given this case study and other information about the species, we urge California Fish and Game Commission to provide full protection to Foothill yellow-legged frog under the California Endangered Species Act including: (1) conducting a full status review of FYLF; (2) listing FYLF as threatened; and (3) designating the Corral Hollow Creek watershed as part of the Critical Habitat needed to maintain what will likely prove to be a Distinct Population Segment. The protection of FYLF habitat on the public land known as Tesla is particularly urgent given the degradation of habitat occurring downstream within the existing CSVRA.

Hello Laura,
I response to the call for information regarding Rana boylii I wanted to provide you with copies of reports and letters I have written in the past that are not as easily accessed as journal articles. It has recently come to my attention that links to the various CEC reports that were previously on a UC Davis website are no longer active and that the reports are also missing from the CEC's website. I am attaching files to this e-mail, but also wanted to generally offer my services in helping you track down material if you need it. For example I have hard copies of some Master's theses on boylii (Tom Van Wagner, Earl Gonsolin) that I could loan.

On another front entirely, I wanted to pass along a question from some salmonid fish researchers working at the Angelo Reserve where I do much of my work In the course of their electrofishing to catch pit-tagged steelhead, they routinely shock Rana boylii. They wanted to know if CDFW had guidance or recommendations. Should they go through sites and try to catch and remove frogs prior to shocking for fish to avoid 'by-catch' of frogs. I did not personally witness how the frogs reacted to elector-fishing, but they said that it looked pretty dramatic, the frogs go completely rigid, but as soon as the current is turned off they very rapidly swim away and disappear. They also wanted to know if the candidacy status would affect their reporting requirements on their scientific collecting permits. I understand that you are not the one granting SCP's for fisheries, but am wondering if the team of people who cover salmonid SCP's are in the loop, so to speak.

Please don't hesitate to ask if there are any ways that I can help in the information gathering process.

-sk

RE: Information relevant to a proposal to list the Foothill Yellow-legged Frog as threatened under the California Endangered Species Act.

Dear California Department of Fish and Wildlife:

Green Diamond Resource Company, California Timberlands Division (Green Diamond) is submitting information in response to your solicitation for material relevant to a proposal to list the foothill yellow-legged frog as threatened under the California Endangered Species Act.

Historical and current range and population levels: Foothill yellow-legged frogs (FYLF) have been documented since 1993 on Green Diamond California timberlands when aquatic surveys began in earnest and have a distribution that includes lotic habitats from relatively large rivers to zero-order (Strahler 1957) streams. Efforts to document the distribution of this species have included various types of biological assessment and monitoring surveys that have been conducted along watercourses throughout Green Diamond's California ownership (currently ~ 365,000 acres). Based on the information compiled to date, relatively large rivers and streams throughout Green Diamond's ownership (e.g., Van Duzen River, Eel River, Mad River, Redwood Creek, Klamath River, and Smith River) as well as lower portions of adjoining smaller tributaries (e.g., Cañon Creek, North Fork Mad River, Roach Creek, Tectah Creek, and Terwer Creek) provide suitable breeding habitats for FYLF. We have also documented that many adjoining tributaries to these breeding habitats are often occupied by adult and juvenile frogs and we believe these habitats provide suitable resources for juvenile rearing, summer foraging, and overwintering. During all but one of these survey types, observations of FYLF were supplemental to the survey objectives. One survey effort has been conducted by Green Diamond since 2008 to monitor trends in a subpopulation of FYLF in the Mad River watershed within timberlands owned by Green Diamond. Green Diamond biologists have been conducting the FYLF egg mass surveys annually and surveys are planned to continue.

This study has consisted of annual surveys along an approximate 2.2 km reach in the lower portion of the Mad River near Blue Lake, CA (Figure 1). Preliminary results from this study are presented below (Figure 2). Since initiation, 5,556 egg masses have been documented. The annual average density of egg masses over 10 years of surveys is 258 egg masses per km. These density estimates of egg masses equate to a minimum estimate of female FYLF that deposited the eggs (Wheeler and Welsh 2008).

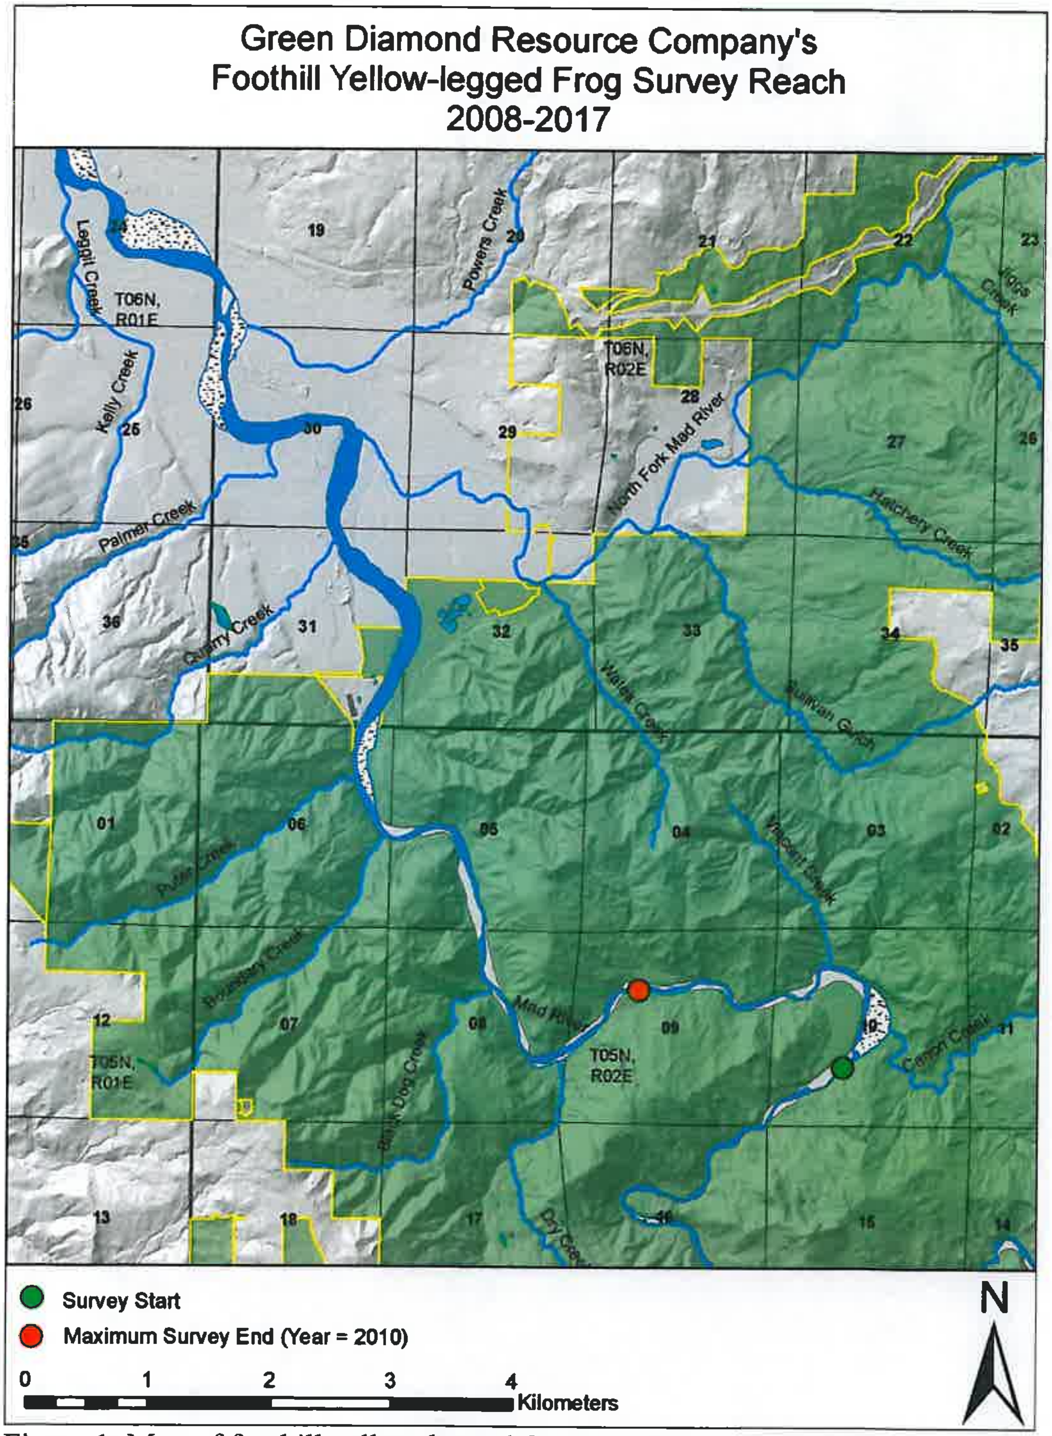

Figure 1. Map of foothill yellow-legged frog egg mass survey reach along the Mad River on Green Diamond California timberlands near Blue Lake, CA.

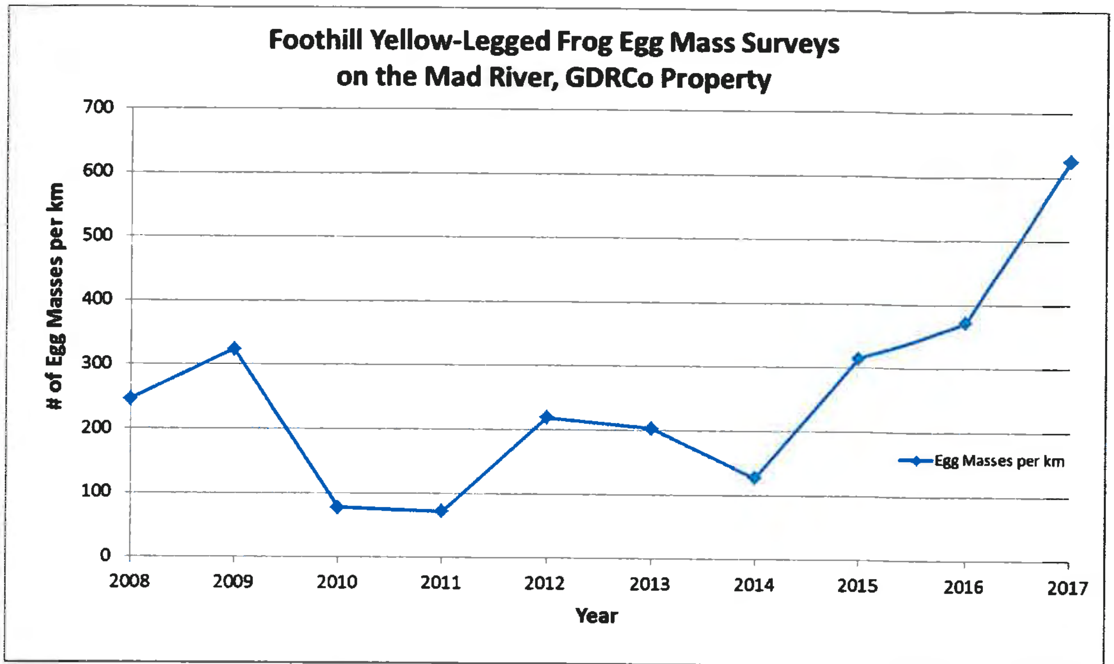

Figure 2. Foothill yellow-legged frog egg mass densities observed along the Mad River during annual survey efforts on Green Diamond California timberlands near Blue Lake, CA from 2008 to 2017.

In 2009, an egg mass density of 323.6 per km was the highest number documented for this monitoring project, which is also the highest density documented for the species (Bourque and Bettaso 2011). The 2017 survey exceeded that documented in 2009 with 625 egg masses per km. Based on the results of this annual survey, this population within the Mad River watershed appears to be very robust and has been increasing in numbers in recent years.

Past and ongoing conservation measures for species and its habitats:

In 2007, National Marine Fisheries Service and the U.S. Fish and Wildlife Service approved an Aquatic Habitat Conservation Plan and Candidate Conservation Agreement with Assurances (AHCP) for implementation on over 400,000 acres of Green Diamond's timberlands in northern California. Despite the FYLF not being among the six covered species in the AHCP, the conservation measures and riparian management measures of the plan also provide protections for FYLF habitat. Green Diamond's AHCP includes conservation measures for riparian management, slope stability, road management, and harvest-related ground disturbance that provide protections for FYLFs. The benefits of the riparian management measures are to maintain and enhance key riparian functions such as providing temperature control, nutrient inputs, channel stability, sediment control and large woody debris recruitment potential for streams. The slope stability measures are designed to minimize management-related landslides and sediment delivery to streams. The road management measures are designed to reduce sediment delivery into watercourses from road sources, including surface erosion from roads, road-related landslides and watercourse crossing failures. Additionally the road measures include water drafting provisions that limit drafting during low flows and provide screen specifications to avoid impinging animals. The harvest-related ground disturbance measures are designed to reduce sediment delivery to watercourses from harvest activities by minimizing soil disturbance, soil compaction, and with time-of-year operating restrictions. Collectively the measures were designed to avoid or address specific impacts and provide habitat improvements for the covered species but many of these measures should also serve to ensure the conservation of FYLF habitats.

While Green Diamond's AHCP is focused on cold-water adapted species and is not designed to create more open canopy situations with increased solar input and warmer water temperature conditions favorable to FYLF, the current conservation measures provide protection for FYLF habitats. The conditions along the larger watercourses that are breeding habitats are likely to remain suitable to FYLF due to the width of the watercourses and ample sunlight on these systems.

The benefits of Green Diamond's AHCP should be considered with any assessment of potential impacts of current forest practices on FYLF populations in north coastal California. In addition, the California Forest Practice Rules provide specific protection for watercourses and lakes during timber harvest activities that receive mandatory permits after a review by the lead agency, California Department of Forestry and Fire Protection. Green Diamond assesses potential FYLF habitat during the preparation and review of each timber harvest plan.

After considering the potential impacts of Green Diamond's current forest management practices on FYLF, we believe our existing management is effective at minimizing potential impacts to FYLF and their habitat. Additionally the FYLF population assessment that GDRCo conducts on a segment of stream along the Mad River suggests that this species has a large number of breeding females annually per km with pronounced increasing numbers in recent years.

Green Diamond appreciates the opportunity to provide comments and information to the California Department of Fish and Wildlife on FYLF distribution, abundance and adequacy of existing management strategies in managed timberlands of north coastal California for consideration during the status review for this species.

Sincerely,

Keith A. Hamm
Conservation Planning Manager
Green Diamond Resource Company

Subject: Foothill Yellow-legged Frog

Dear Ms. Patterson,

Sierra Streams Institute has collected data on foothill yellow-legged frog (*Rana boylii*) populations, habitat conditions, and anthropogenic impacts at several sites in the Bear and Yuba watersheds in the northern Sierra Nevada during the past two breeding seasons. We have also tested frogs for chytrid fungus at several sites in both watersheds, and have collaborated with Ryan Peek of UC Davis. We respectfully request that the results of these scientific studies be considered along with the other available statewide data in CDFW's 12-month status review for this species. We also request that Tom Van Wagner's data from studies in Clear Creek and Shady Creek be considered; it is our understanding that he will be submitting those data separately.

I have attached a preliminary report of Sierra Streams Institute's Bear River Watershed visual encounter surveys performed in 2016. Our 2017 data is currently being entered, QCed, and analyzed. I will submit the 2017 report by the end of October 2017. That report will contain substantial information about habitat conditions and impacts within the Bear River Watershed. It will also delineate the locations of foothill yellow-legged frogs observed within the footprint of the proposed Centennial Reservoir on the Bear River.

Sierra Streams Institute's 2017 report will also contain more information on our chytrid test methodology, coordinates of the sites where we collected skin swabs, and more. In the mean time, here is a brief summary of the chytrid results. All skin swab samples were tested for chytrid at the Amphibian Disease Lab at the San Diego Zoo.

Chytrid results for foothill yellow-legged frogs swabbed in spring/summer 2016 under the direct supervision of Ryan Peek and performed under his permit:

- Steephollow Creek upstream of its confluence with the Bear River and downstream of Lowell Hill Rd: 8/10 positive
- Bear River near the Chicago Park Powerhouse: 3/5 positive
- Greenhorn Creek near Hwy 174: 1/3 positive (the positive one was a California toad found dead at the water's edge; all other swabs this year were from foothill yellow-legged frogs)
- Clear Creek: 0/4 positive

Chytrid results for American bullfrogs swabbed in spring/summer 2015 under Sierra Streams Institute's scientific collecting permit:

- 3/3 tested positive at the confluence of Deer & Squirrel Creeks
- 1/1 tested positive on Squirrel Creek upstream of the Deer Creek confluence
- 3/5 tested positive on Deer Creek above Lake Wildwood
- 0/4 tested positive in Lower Scotts Flat Lake

With gratitude and best wishes,

Kristen Hein Strohm
Wildlife Biologist
Sierra Streams Institute

Subject: Foothill yellow legged frog

Im 73 years old and raised nearly 1 million dollars for CWA over 17 yrs (colusa crab cioppino dinners) i have barged 1 million salmon smolts to the golden gate .
I have a 65 ft comm. fishing vessel which i fished for 57 years.
I also farm 600 acres of rice in maxwell ca.
I have seen the egret and blue heron population multiply hundreds of times in the last 60 yrs. If you will go to youre frog pond at early and late hrs. You will see unbelievable tadpole and frog predation from these beautiful birds, i have watched the same animals reduce the bulfrog population to nearly zero in all waterways in sac valley.
Having always being extremely observant i know see these birds n huge flocks in coastal red legged frog habitate.
If you will spend a couple of hrs w field glases observing you eill see where all the frogs have gone. Sometimes by protecting one species you have inadvertantly upset natures way. Dont blame every one and everything, the answer is right in front of you!

Subject: Rana boylii request for information

Hi Laura,

Can you please accept this as my response to your request for information regarding the foothill yellow-legged frog, Rana boylii.

Rana boylii is considered to be a "Sensitive Species" and thus a focus of management planning by BLM.

Rana boylii is present on lands managed by Bureau of Land Management within the jurisdiction of the Central Coast Field Office.

We know them to be present in numerous creeks converging on San Benito Mountain within the Clear Creek Management Area in San Benito and western Fresno Counties.

I have also observed them frequently in Laguna Creek where it is forded by Coalinga Road in San Benito County. In the past two years I have not seen them there.

I have observed them in Cantua Creek on private and public lands in west Fresno County, most recently in 2013.

This summer I observed a small population in Jacalitos Creek, west Fresno County, in the Devil's Gate gorge.

I know them to be present in Del Puerto Creek, in Sulphur Creek (a tributary of Smith Creek on Mt. Hamilton) and in Soquel Creek in the Santa Cruz Mountains.

I have also observed them breeding in Cazadero Creek in Sonoma County.

A major concern of mine is that, should Clear Creek Management Area be re-opened to off-road vehicular use, as has been proposed in the US Congress, siltation and other effects of OHV will negatively impact the species. At present CCMA is closed to OHV use.

I would be happy to supply more precise locality data, and to elaborate on potential threats to any of the above-named populations, should you so desire.

Thank you for allowing me to contribute to this matter,

Mike Westphal
Ecologist
US Bureau of Land Management

Laura Patterson,

Attached are a number of reports from Redwood National Park of Yellow-legged frog monitoring or notes on Redwood Creek, Humboldt County, within the park.

The early reports (2001-2005) are deformed frog surveys on mainstem Redwood Creek between Forty-four Creek and Bond Creek confluences.

The 2016 summer steelhead report has information in the wildlife observed table that shows their occurrence when noted in the 24 mile survey Redwood Creek reach as well as numbers counted in a short reach from Lacks to Panther Creeks.

In a survey done this week (8/28/2017) of Redwood Creek from Forty-four Creek to Bond Creek, numbers of adults and young frogs are reported.

If you have any questions, please contact me at the phone number or email listed below.

Laura,
I have been quite busy in the field summer (with limited internet access), but would like to add my comments for your consideration in the FYLF listing decision. I will be more available (i.e., in the office) through the fall and winter if additional information is needed.

Thank you for your careful consideration during this review process.

Email: wildlifemgt@wildlife.ca.gov.
subject: "Foothill Yellow-legged Frog"

I am writing to provide California Department of Fish and Wildlife (CDFW) with information relevant to the current proposal to list the Foothill Yellow-legged Frog (*Rana boylii*, FYLF) as a threatened species under the California Endangered Species Act.

As you may know already, I have studied FYLF in Northern California for many years, and much of my work has focused on impacts related to downstream effects of dams and ways to improve flow management to reduce those impacts. And while those efforts have led to incremental benefits to populations downstream of dams, population recovery has been slow. Added pressures of climate change and the largely unregulated marijuana industry have potential to ameliorate any gains made by improved flow management for this already imperiled species.

Reproductive success of FYLF in my study areas in the Trinity River, Trinity County was very low this year. High flows in the Spring delayed onset breeding. Subsequently, rapidly descending hydrograph led to desiccation of nearly all eggmasses observed. I can provide a detailed report of our observations this summer once the data has been fully processed and reviewed following the end of the field season.

This comment period occurs during an especially busy time for us actively working in the field, so I am limited on time to provide a through summary of currently available information, but urge you to consult recent publications and consult with those involved in ongoing research with this species during your review. I will be in the field though much of September and the first half October, but should be much more available later autumn and through the winter. Please don't hesitate to contact me for additional information during the review process.

Thank you,

Don Ashton

Subject: Data and Comments on the Status Review of the Foothill Yellow-Legged Frog (*Rana boylii*)

Dear Ms. Patterson:

The California Fish and Game Commission voted to make Foothill Yellow-Legged Frog (*Rana boylii*) (FYLF) a "threatened" candidate species under the authority of the California Endangered Species Act at the June 2017 Commission meeting. As such, California Department of Fish and Wildlife (CDFW) is conducting a Status Review and accepting input for the species during its candidacy. The California Department of Forestry and Fire Protection (CAL FIRE) appreciates the opportunity to provide data and comments as you develop the Status Review for FYLF.

CAL FIRE is the lead agency that regulates timber harvesting activities on approximately seven million acres of private and state forestland in the State of California under the authority of the California Forest Practice Act and Rules. These rules are intended to preserve and protect fish, wildlife, and other natural and cultural resources. Additionally, CAL FIRE manages eight Demonstration State Forests, totaling about 71,000 acres. The forests are managed through the development of Timber Harvesting Plans (THP's) that address and mitigate potential impacts to listed and special status species. Typical THPs identify whether a proposed project is within the range of such a species, if habitat is present, and if individuals are known to be present. Mitigation and avoidance measures may then be proposed if any of those conditions exist.

According to the CDFW's Biogeographic Information and Observation System (BIOS), FYLF range layers indicate that all of the Demonstration State Forests are within the range of FYLF. For the most part, FYLF protocol or visual encounter surveys for the species have not been conducted on the Demonstration State Forests, with the exception of Soquel Demonstration State Forest (SDSF). SDSF is located in Santa Cruz County, where the East Branch of Soquel Creek and its tributaries flow through the Forest.

In the Center for Biological Diversity's "*Petition to List the Foothill Yellow-Legged Frog (Rana boylii) as Threatened Under the California Endangered Species Act*," population data ranging from 1992-2008 were reported for Soquel Creek from a California Natural Diversity Database (CNDDB) search in 2016, with the narrative qualification that populations were small to moderate. In order to provide current information and data, a local volunteer herpetology group in Santa Cruz has been conducting annual surveys for amphibians and reptiles, including FYLF, since 2011. As part of the conditions of their scientific collecting permit, results of the surveys are regularly submitted for inclusion in the CNDDB. For ease of access, an abbreviated version of the data with occurrence locations previously submitted to the CNDDB is attached as a table at the end of this letter. General information and photos of individuals, egg masses, and habitat from those surveys can also be found at the following location: naherp.com. The volunteer herpetologists plan to continue regular surveys and to provide their results to the CNDDB.

CAL FIRE looks forward to the findings of CDFW's Status Review and to providing further input. If you have any questions or comments regarding this letter, please contact CAL FIRE Forest Practice Biologist, Stacy Stanish at Anastasia.Stanish@fire.ca.gov or (916) 616-8643.

Sincerely,

HELGE ENG
Deputy Director
Resource Management

California Department of Fish and Wildlife
Attn: Laura Patterson
1812 Ninth St.
Sacramento, CA 95811

Dear Laura Patterson,

This letter is in response to the California Fish and Wildlife is seeking information that relates to its decision to accept for consideration the petition submitted to list foothill yellow-legged frog (FYLF) as a threatened species under the California Endangered Species Act.

Sierra Pacific Industries (SPI) has not done extensive surveys of its forestlands for FYLF, however we have identified FYLF in several streams over the last 20 years. In some instances SPI resource managers have re-surveyed areas after timber harvesting activities were completed. See the table below for the name of the stream where FYLF surveys have occurred, the number of individual FYLF observed and surveyor comments.

CA 2.2 Watershed	Year of Survey	Stream Name Surveyed	Visual Encounter Surveyor	Frog count	Egg mass count.	Comments
McCormick Creek	2017	Long Canyon Creek	Luke Wagner	6	0	N/A
McCormick Creek	2017	Griswold	Kym Underwood	12	0	N/A
Lower Panther Creek	2017	Unnamed Class II	Luke Wagner	1	0	N/A
5517.530301	2017	Near St. Catherine's creek	Joe King	3	0	N/A
5517.410101	2016	Trib. of Oregon Creek	Dario Davidson	2	0	N/A

Although the survey effort for FYLF is far from exhaustive the occurrences of FYLF on SPI forestland appear to be fairly wide spread. This brings into question how much of the available habitat along unregulated streams (streams not subjected to atypical flux flows from dam releases) has been surveyed. Should the Fish and Game Commission require that a more thorough sampling of FYLF habitat on unregulated streams be conducted prior to making a listing decision? A more thorough census of FYLF would provide a good basis for a listing decision and also that data could be used as baseline data for future population and adaptive management assessments.

In researching FYLF data sources to provide information for this letter, the Department's Natural Diversity Database (NDDB) has a large number of observations helpful for your analysis. But, some of the scientific studies conducted in California and cited in the Department's evaluation of the FYLF listing petition are not in the NDDB. Two examples, Bourque (2008) and Wheeler et al. (2015), contain occurrence location information which appear to be absent from NDDB. The locations of scientific studies used in the listing process should be added to the NDDB.

Internet websites, iNaturalist.org and www.naherp.com both contain recent reports of FYLF observations in California which would be relevant to the Department's analysis.

Federal Energy Regulatory Commission permit applications contain many references to FYLF for the various relicensing applications for dams in California. The Department should include information found in these documents.

The Department should consult with their fisheries staff biologists who presumably evaluate stream habitat in deciding when and where to plant fish for recreational fishing. Recent work to evaluate the effects of fish stocking on natural stream processes should include readily available information on frog presence or absence.

Kupferberg et al. (2008) state that the foothill yellow-legged frog's entire life cycle is associated with fluvial environments and adult frogs are almost always found close to water, from small creeks to large rivers, and often use cover within the stream as a primary refuge. Clutches of eggs are laid on in-channel substrates in spring or early summer, and larvae metamorphose in late summer or early fall prior to the onset of the next rainy season's floods. Bourque (2008) used radio telemetry to determine the distance male and female adult frogs moved away from the wetted channel. Bourque's results indicated that in the spring (April-June) and fall/winter (October-January) the maximum distance from water for both males and females was 10.7 m and 40 m respectively. Rombough (2006) indicates that overwintering habitat includes streams/rivers and in tributaries and at seeps along stream/river edges where frogs hide under woody debris and rocks along the stream margins.

Sierra Pacific Industries believes that the California Forest Practice rules provide appropriate protections for the FYLF in 14 CCR 916, 936, 956. In particular the protection measures from 936.4(b) state:

A combination of the rules, the plan, and mitigation measures shall provide protection for the following:

a. Water temperature control.

b. Streambed and flow modification by large woody debris.

c. Filtration of organic and inorganic material.

d. Upslope stability.

e. Bank and channel stabilization.

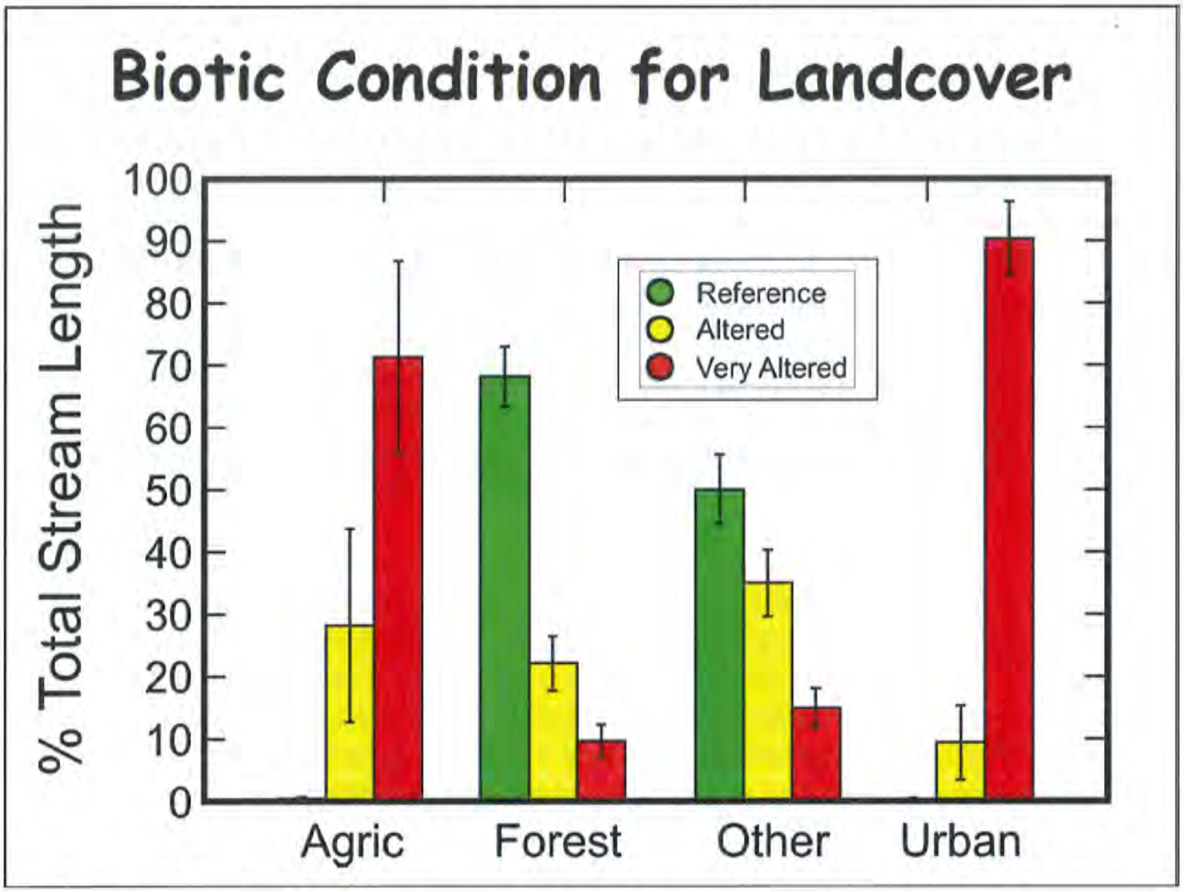
f. Spawning and rearing habitat for salmonids

g. Vegetation structure diversity for fish and wildlife habitat, possibly including but not limited to:

1. Vertical diversity
2. Migration corridor
3. Nesting, roosting, and escape
4. Food abundance
5. Microclimate modification
6. Snags
7. Surface cover"

The California Forest Practice Rules (CFPR) and their implementation through the Timber Harvest Plan (THP) process, which is a certified regulatory program under PRC 21080.5, include an interdisciplinary review team consisting of CAL FIRE (Lead Agency), Regional Water Quality Control Board, California Department of Fish and Wildlife, and California Geological Survey. The lead and responsible agencies assess each THP for its compliance with CFPR, Fish and Game codes, Porter Cologne Water Quality Control Act and CEQA. During THP implementation and following the completion of operations agencies perform regulatory compliance monitoring. In combination, the existing regulations, review, and state agency compliance monitoring means that there is a robust regulatory framework in place to protect FYLF. The Department should acknowledge the work of Registered Professional Foresters, private landowners, and departments and staff of California's Natural Resources Agency in protecting functioning watercourse habitats where FYLF occur.

Because timber harvesting is subject to a robust regulatory framework, timber harvesting should not be considered a significant threat to the ongoing survival of FYLF. The instream and near stream conditions on both industrial and non-industrial private timberlands have been assessed through the Surface Water Ambient Monitoring Program (SWAMP). The SWAMP program is implemented by CDFW scientists and the results from sampling from 2000-2007, as reported by Harrington (2012), is shown in the graphic below.



These SWAMP data provide a good indication of where the threat of habitat alteration exists. Independent of the CDFW SWAMP sampling SPI contracted with the CSU Chico Foundation to collect 35 additional benthic macroinvertebrate (BMI) samples on its timberlands between 2014 and 2016, including many areas that were salvaged logged following wildfire. These samples have all been archived in the California Environmental Data Exchange Network (CEDEN). The reason BMI samples were collected is because macroinvertebrates cannot escape pollution, macroinvertebrates have the capacity to integrate the effects of the stressors to which they are exposed, in combination and over time (US EPA website). Using the BMI samples SPI calculated the California Stream Condition Index (CSCI) scores and output using R scripts defined in Mazor et al. (2015). CSCI score categories were applied as defined in Rehn et al. (2015). Most (n = 29) of the 35 CSCI scores fell into the Likely Intact category with the remaining six samples scoring Possibly Altered. No sample fell into the Likely Altered or Very Likely Altered categories.

After review of the scientific literature on FYLF, it appears that what threatens its existence are water management activities downstream of the 1,250 dams in California under the jurisdiction of the California Department of Water Resources (CDWR 2017). Kupferberg et al. (2008) summarizes the impacts of dams succinctly. "Potential causes are many, but those related to dams and flow regulation are especially ubiquitous. Habitats have been destroyed and fragmented as river channels were converted to reservoirs. Alterations to the disturbance regime and sediment budget of dammed rivers have drastically modified the remaining river channel environment. Predation by nonnative predators such as bullfrogs (*Rana catesbeiana*), fish, and crayfish has increased as these invasive species flourished in California waterways subject to flow diversion and regulation (Moyle and Light 1996; Marchetti et al. 2004). As a result, *R. boylii* have either disappeared or declined to small population sizes relative to nearby populations in unregulated rivers within the same watershed (S. Kupferberg, personal observation, and unpublished USFS data)." Further study by Kupferberg et al. (2012) reports a comparative analysis between FYLF populations prior to 1975 and 1996-2010 on regulated and unregulated rivers in Oregon and California. Kupferberg et al. (2012) reports, "For California presence of dams in the upstream watershed was associated with an absence of frogs. Compared with sites where frogs were present, there were an average of 1.9, 1.6, and 2.1 times more dams (all sizes), large dams, and very large dams, respectively, upstream of sites where frogs were absent at the time of our study, but present before 1975."

Hayes et al. (2016) summaries the threat from dams in the following: "The most robust data implicate water development and diversions as the primary cause of declines in foothill yellow-legged frogs. Water development and diversions are a prominent risk because they result in hydrological changes that chronically affect several aspects of the frog's life history. Recent studies from both regulated and unregulated rivers have demonstrated that small-scale changes in local habitat conditions, such as water velocities, depths, and temperatures, which often result from water management activities and landscape-scale changes, can lead to (1) inconsistent environmental cues for breeding, (2) lower growth rates for tadpoles, (3) scouring or stranding of egg masses and tadpoles, (4) reductions of overall habitat suitability for breeding and rearing, (5) barriers to gene flow around reservoirs, and (6) establishment of nonnative predators in reservoirs that then spread into the rivers."

High intensity wildfire is another threat to FYLF. This is because where wildfires burn at high intensity it kills all the vegetation, removes the protective organic layer from the soil and creates a hydrophobic layer that impedes water infiltration and increases the rate of water run-off, which leads to accelerated sheet, rill and gully erosion. The soil transported downslope following an intense wildfire can cover over aquatic substrates limiting the reproductive success of FYLF (Yarnell 2015). Soil-embedded substrates reduce the amount of refugia for tadpoles to avoid high velocity water events (Hayes et al. 2016). While wildfires are unpredictable, one essential tool in limiting their intensity is to reduce vegetation density on upland slopes. The use of sustainable forestry practices to mitigate the potential impacts of high intensity wildfire on aquatic resources should be considered as a conservation measure for FYLF. It would be short-sighted to identify sustainable forestry practices as a threat under the current regulatory framework, since potential forestry related impacts are mitigated through the THP process, while at the same time these forestry activities can lead to beneficial or restorative effects for FYLF.

Bevers et al. (2004) estimated that for fuel modifications to effectively support fire suppression activities, approximately 54-88% of the landscape would need to receive fuel treatments (sustainable forestry practices). Because of the deleterious effects of high intensity fire, reducing fire severity should be a conservation goal of any listing action. With this in mind sustainable forestry practices should be viewed as a conservation action not a threat to the FYLF.

Sierra Pacific Industries believes the solution for ensuring the continued existence of FYLF in California is maintaining the hydrologic function of the streams and rivers downstream of water impoundments. We believe endangered species efforts should be focused on foothill areas generally below forested lands where marginally functioning populations of FYLF occur. We also encourage the implementation of sustainable forestry practices that reduce the risk of high intensity fires in a meaningful way.

Sincerely,

Cedric Twight
Regulatory Affairs Manager
Sierra Pacific Industries

Sacramento, CA 95811

SUBJECT: Foothill Yellow-Legged Frog

Dear Ms. Patterson:

The Placer County Water Agency (PCWA or Agency) owns and operates the Middle Fork American River Project (MFP), a multi-purpose water supply and hydro-electric development that was constructed by the people of Placer County to secure the water rights and resources necessary to provide for economic development within the county.

The Agency, like many other hydro-electric facility owners in the Sierra, recently completed a Federal Energy Regulatory Commission process to renew our operating license for the MFP. During this eight year long process, the Agency and its business partner the County of Placer spent a considerable amount of time, money and effort to study and protect the Foothill Yellow-legged frog. While this species has seen declines across much of its endemic range, it is locally abundant in the Rubicon and Middle Fork American River watersheds.

The Agency believes that three factors weigh against the immediate listing of the Foothill Yellow-legged frog under California endangered species act protection:

1. While some local populations have been studied extensively, like those in the American River watershed, other systems have received far less attention. We believe more study is warranted in watersheds statewide before a listing is recommended.

2. Many watersheds in the state that have hydro-electric projects present are being re-managed for the benefit of frogs. Specific management measures that decrease flow fluctuations during critical breeding and tadpole development stages that will benefit

frog reproduction and survival have been ordered by state and federal agencies in FERC relicensing proceedings. Many of these measures have only recently been operationalized, and require time and monitoring to assess their effectiveness. We suggest an intensive five year monitoring period beginning in 2018 (which most FERC licensees have agreed to undertake) in order to better understand how new license conditions will benefit frog populations.

3. The recent moratorium placed on suction dredging in California's streams will likely have a positive impact on frog populations. During the intensive study and monitoring period we recommend, an assessment can be made regarding the effectiveness of these new limitations.

Overall, we believe existing and forthcoming management actions should be given time to become operational and mature before a new regulatory process is undertaken. The sum total of upcoming management actions will positively benefit the species, and may make a State listing moot.

Sincerely,

PLACER COUNTY WATER AGENCY

Einar Maisch

Hello Laura,

I got this back from Butte County Planner Dan Breedon, I know its "late" but could be a useful trail to follow (And yes, I'm not complaining ☺). The attached document references occurrences in Butte county on pg. 5-104. The text on 5-104 also references "Appendix A" which shows the "Distribution and extent (areal or linear) of each covered species' modeled habitat located within the Plan Area (Appendix A; Table 5–4, Existing Extent Modeled Covered Species Habitat Types and Covered Plant Species Occurrences within CAZs and UPAs [see separate files])." http://www.buttehcp.com/BRCP-Documents/Formal-Public-Draft-EISEIR/index.html
The link will get you to Appendix A.

I hope this helps. Are there other Counties with HCP? Might be a treasure trove of information.
Good Luck. Cedric

Cedric,

Sorry I have been a bit backlogged. Got your message. I don't have any experience with this particular species. You may wish to speak with Chris Devine ad the Butte County Association of Governments. Chris is heading up the Butte Regional Conservation Plan http://www.buttehcp.com/index.html and may have some information to share.

You may want to check out the Conservation Strategy from the BRCP (attached, see page 5-104).

Dear Dr. Kupferberg:

RE: FOOTHILL YELLOW-LEGGED FROG (*RANA BOYLII*)
DEPARTMENT OF FISH AND WILDLIFE, PEER REVIEW STATUS REPORT

Thank you for agreeing to serve as a scientific peer reviewer for the Department of Fish and Wildlife's (Department) Draft Status Review of the Foothill Yellow-legged Frog (*Rana boylii*). A copy of this report, dated May 21, 2019, is enclosed for your use in that review. The Department seeks your expert analysis regarding the scientific validity of the report and its assessment of the status of the Foothill Yellow-legged Frog in California. **The Department would appreciate receiving your peer review input on or before June 21, 2019**.

The Department seeks your review as part of formal proceedings pending before the California Fish and Game Commission (Commission) under the California Endangered Species Act (CESA). As you may know, the Commission, as a constitutionally established entity distinct from the Department, exercises exclusive statutory authority under CESA to add species to the state lists of endangered and threatened species (Fish & G. Code, § 2070). The Department serves in an advisory capacity during listing proceedings, charged by the Fish and Game Code to use the best scientific information available to make related recommendations to the Commission (Fish & G. Code, § 2074.6).

The Commission first received the "Petition to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened" (Petition) on December 14, 2016 and published a formal notice of receipt on January 20, 2017 (Cal. Reg. Notice Register 2017, No. 3-Z, p. 46). On April 17, 2017, the Department provided the Commission with its "Evaluation of the Petition from the Center for Biological Diversity to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened under the California Endangered Species Act" to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5

& 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & (e).). Focusing on the information available to it relating to each of the relevant categories, the Department recommended to the Commission that the Petition be accepted.

The draft report forwarded to you today reflects the Department's effort to identify and analyze available scientific information regarding the status of Foothill Yellow-legged Frog in California. An endangered species is defined as "a native species or subspecies...which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish and G. Code, § 2062). A threatened species is defined as "a native species or subspecies...that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]" (Fish and G. Code, § 2067). At this time, the Department suggests listing the species under CESA is warranted for five of six recently described genetic clades based on the available science. The Department proposes to recommend endangered status for the South Coast, Central Coast, and Southern Sierra clades; threatened status for the Northern Sierra and Feather River clades; and "not warranted at this time" for the North Coast clade. We underscore, however, that scientific peer review plays a critical role in the Department's effort to develop and finalize its recommendations to the Commission as required by the Fish and Game Code.

Because of the importance of your effort, we ask you to focus your review on the scientific information regarding the status of Foothill Yellow-legged Frog in California. As with our own effort to date, your peer review of the science and analysis regarding each of the listing factors prescribed in CESA (Cal. Code Regs., Tit. 14, § 670.1(i)(1)(A)) (i.e., present or threatened habitat modification, overexploitation, predation, competition, disease, and other natural occurrences or human-related activities that could affect the species) are particularly important.

Please note the Department releases this peer review report to you solely as part of the peer review process, and it is not yet public.

For ease of review, I invite you to use "Track Changes" in Microsoft Word, or provide comments in list form by page number, section header, and paragraph.

Please submit your comments electronically to Laura Patterson, Senior Environmental Scientist (Specialist) with the Wildlife Branch at Laura.Patterson@wildlife.ca.gov or at the address in the letterhead above. If you have any questions, you may reach Laura Patterson by phone at (916) 341-6981.

If there is anything the Department can do to facilitate your review, please let me know. Thank you again for your contribution to the status review effort and the important input it provides during the Commission's related proceedings.

Sincerely,

Kari Lewis, Chief
Wildlife Branch

Dear Dr. Lind:

RE: FOOTHILL YELLOW-LEGGED FROG (*RANA BOYLII*)
DEPARTMENT OF FISH AND WILDLIFE, PEER REVIEW STATUS REPORT

Thank you for agreeing to serve as a scientific peer reviewer for the Department of Fish and Wildlife's (Department) Draft Status Review of the Foothill Yellow-legged Frog (*Rana boylii*). A copy of this report, dated May 21, 2019, is enclosed for your use in that review. The Department seeks your expert analysis regarding the scientific validity of the report and its assessment of the status of the Foothill Yellow-legged Frog in California. **The Department would appreciate receiving your peer review input on or before June 21, 2019**.

The Department seeks your review as part of formal proceedings pending before the California Fish and Game Commission (Commission) under the California Endangered Species Act (CESA). As you may know, the Commission, as a constitutionally established entity distinct from the Department, exercises exclusive statutory authority under CESA to add species to the state lists of endangered and threatened species (Fish & G. Code, § 2070). The Department serves in an advisory capacity during listing proceedings, charged by the Fish and Game Code to use the best scientific information available to make related recommendations to the Commission (Fish & G. Code, § 2074.6).

The Commission first received the "Petition to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened" (Petition) on December 14, 2016 and published a formal notice of receipt on January 20, 2017 (Cal. Reg. Notice Register 2017, No. 3-Z, p. 46). On April 17, 2017, the Department provided the Commission with its "Evaluation of the Petition from the Center for Biological Diversity to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened under the California Endangered Species Act" to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5

& 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & (e).). Focusing on the information available to it relating to each of the relevant categories, the Department recommended to the Commission that the Petition be accepted.

The draft report forwarded to you today reflects the Department's effort to identify and analyze available scientific information regarding the status of Foothill Yellow-legged Frog in California. An endangered species is defined as "a native species or subspecies…which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish and G. Code, § 2062). A threatened species is defined as "a native species or subspecies…that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]" (Fish and G. Code, § 2067). At this time, the Department suggests listing the species under CESA is warranted for five of six recently described genetic clades based on the available science. The Department proposes to recommend endangered status for the South Coast, Central Coast, and Southern Sierra clades; threatened status for the Northern Sierra and Feather River clades; and "not warranted at this time" for the North Coast clade. We underscore, however, that scientific peer review plays a critical role in the Department's effort to develop and finalize its recommendations to the Commission as required by the Fish and Game Code.

Because of the importance of your effort, we ask you to focus your review on the scientific information regarding the status of Foothill Yellow-legged Frog in California. As with our own effort to date, your peer review of the science and analysis regarding each of the listing factors prescribed in CESA (Cal. Code Regs., Tit. 14, § 670.1(i)(1)(A)) (i.e., present or threatened habitat modification, overexploitation, predation, competition, disease, and other natural occurrences or human-related activities that could affect the species) are particularly important.

Please note the Department releases this peer review report to you solely as part of the peer review process, and it is not yet public.

For ease of review, I invite you to use "Track Changes" in Microsoft Word, or provide comments in list form by page number, section header, and paragraph.

Please submit your comments electronically to Laura Patterson, Senior Environmental Scientist (Specialist) with the Wildlife Branch at Laura.Patterson@wildlife.ca.gov or at the address in the letterhead above. If you have any questions, you may reach Laura Patterson by phone at (916) 341-6981.

If there is anything the Department can do to facilitate your review, please let me know. Thank you again for your contribution to the status review effort and the important input it provides during the Commission's related proceedings.

Sincerely,

Kari Lewis, Chief

Hello Laura,
Please find attached my comments on the Draft Status Review and a marked up version of the manuscript using track changes that includes minor edits to the text.
Thank you for giving me the opportunity to be involved in such an important process.
I am very impressed with how thorough the document is. You may not have set out to provide an exhaustive review of the scientific literature, but I think that is what you have achieved. A job well done!
The vast majority of my specific comments are suggestions, not corrections, take them or leave them.
Kind Regards,
Sarah

Subject: Re: Peer Review Request: Foothill Yellow-legged Frog Status Review

Hello Laura,

I would be happy to participate and help with the review process. I do not have a financial conflict of interest. I will be in and out of the field during that time period, doing my annual breeding surveys but will do my best to ensure rapid turn around.

Regards,

Sarah

> The Fish and Game Commission (Commission) was petitioned to list the Foothill Yellow-legged Frog as threatened under the California Endangered Species Act (CESA) by the Center for Biological Diversity in December 2016. The California Department of Fish and Wildlife (Department) is tasked with writing a status review and providing a recommendation to the Commission on whether or not the best scientific information available supports the petitioner's position that listing is warranted. Part of the status review process is external peer review of the draft status review.

I am contacting you as a Foothill Yellow-legged Frog subject matter expert to request your participation in the peer review process. The Department expects the draft will be ready on for distribution to peer reviewers on or around May 17th. We would ask that you focus your review on the scientific information available regarding the status of Foothill Yellow-legged Frogs in California. Your peer review of the science and analysis regarding each of the listing factors prescribed in CESA (i.e., present or threatened habitat modification, overexploitation, predation, competition, disease, and other natural occurrences or human-related activities that could affect the species) is particularly valuable. We request that comments be submitted on or before one month from the date of receipt (on or around June 17th).

In addition, per the Department's Peer Review Policy (Department Bulletin 2017-03), I must ensure that you have no financial or other conflict of interest with the outcome or implications of the peer reviewed product.

Please respond to whether you are willing and able to participate in this important part of the listing determination process by Thursday April 11th.

Thank you for your consideration,

Laura

General Comments:

The draft STATUS REVIEW OF THE FOOTHILL YELLOW-LEGGED FROG (*Rana boylii*) IN CALIFORNIA is a scientifically sound and well-written document that very clearly summarizes the natural history of the species and outlines the current and future threats to its persistence throughout the state. The organization and progression of information and ideas are logical and straightforward in presentation. Complex concepts in ecology and population genetics are defined, and the needed background information on environmental change anticipated during an uncertain climate future is well summarized. The document accurately synthesizes knowledge from the scientific literature, reports, conference presentations, with observations from experienced field biologists and regulators who have been working with *Rana boylii* for many years. I have no criticisms with respect to presentation or interpretation of research and scientific information in the document. I have made minor suggestions with respect to wording and noted a few typographical errors in the body of the text. Overall, I find the background information sections titled BIOLOGY AND ECOLOGY, STATUS AND TRENDS IN CALIFORNIA, and FACTORS AFFECTING ABILITY TO SURVIVE AND REPRODUCE, to be comprehensive and insightful. The section covering the threats, SUMMARY OF LISTING FACTORS, is consistent with my knowledge of the species garnered over the past 25 years of field work and the scientific literature. My own research is correctly and accurately represented.

While environmental policy is not my academic area of expertise, I have observed firsthand the effects of water management and dam operations on *Rana boylii*, so am providing some opinions. These are offered as suggestions, not as needed changes. I think that the section entitled “EXISTING MANAGEMENT” could include more information about the shortcomings of the existing laws that contribute to the need for greater protection of *Rana boylii* under the California Endangered Species Act, CESA. One example is when a utility no longer wants to operate a dam and the dam becomes an ‘orphaned dam’ under FERC. Given the declining profitability of hydropower projects (especially for older dams/reservoirs) and the bankruptcy of PG&E, this may be a growing issue that dams may be operated on a somewhat *ad hoc* basis (i.e. not relicensed). During the limbo period while funds are raised for dam removal or a transfer to a different utility occurs, the needed studies to determine effects of operations on frogs (or other wildlife) don’t happen to inform any kind of adaptive management. I am not sure what laws govern the transfers to Dam Removal entities, such as happened with the multiple dams on the Klamath River that are now slated for removal. For example dam operations may proceed in ways known to be harmful to *Rana boylii*, such as pulsed flows after egg-laying has commenced, as is currently the case of Scott Dam on the Eel River now that the Potter Valley Project is an ‘orphan’.

With respect to the section titled LISTING RECOMMENDATION, I find that parsing designation by geographic region / clade is justified by the data presented. Because there are marked differences in the number of known populations, the range of populations’ sizes from sparse to robust, and the level of genetic differentiation across the state, I concur with the statement that listing “by genetic clade is the prudent approach due to the disparate degrees of imperilment”. I agree with the designation of ‘endangered’ for the West/Central Coast, the South/Southwest Coast, and the Southern Sierra clade because there are several risk factors at play, so few known populations in these regions, the remaining populations are small, and they are genetically distinct. I also agree with a special designation for the Feather, given the uniqueness of this clade and the extensive fragmentation due to the development of hydropower projects in the area.

In comparison, the abundance of large populations in the extended geographic area of the North Coast indicates that this clade is not at immediate risk of extirpation. Consequently, the decision to maintain the present designation of Species of Special Concern is reasonable. This strategy does have a drawback at the perimeter of such a large geographic region, where populations are sparser and disconnected. The option for a greater level of protection is lost. I suppose this trade-off is unavoidable, but I am concerned about the fate of populations in peripheral places like streams on Mt. Tamalpais in Marin County and the McCloud River in Shasta / Siskyou counties. My hope is that the efforts being made in Marin County to protect the populations there will continue without an elevation of the listing designation. The docent program and habitat restoration (e.g. canopy thinning) undertaken by the Marin Municipal Water District are excellent examples of stewardship.

Unfortunately, some utilities are less transparent and responsible than others. A book could be written about the ways in which the San Francisco Public Utilities Commission operates its facilities in the Alameda Creek watershed without making modifications or changes to protect the frogs and exploiting weaknesses in the regulatory framework. Over $40 million dollars were spent to build the fish passage structure mentioned on p. 68, while funds have yet to be allocated to improve habitat or conditions for frogs as was called for in the EIR for the Calaveras Dam replacement project. Furthermore, studies conducted on frogs that would have been useful in the preparation of this Status Review and that predicted negative impacts were never disseminated or made public, only retrievable through Public Records Act requests. The fish passage structure was built upstream of a natural barrier to fish passage, the steep bedrock canyon reach of Alameda Creek known as Little Yosemite. In order for steelhead to reach the large concrete structure, the frog breeding sites in Little Yosemite would have to be destroyed by construction of weirs and altering the water surface elevations of pools. SFPUC tried to exploit loopholes in the CEQA process by making a negative declaration of impact for the Little Yosemite project.

Another chapter in such a book would cover how the protected status / and unrealistic recovery plan for one species can endanger another. I am not sure how it would be incorporated into this document (and perhaps it is more appropriate during the public comment period), but an important question is how will biological conflicts between anadromous fish and frogs and jurisdictional conflicts between agencies (e.g. NMFS and CDFW) be resolved when salmonids are not the only endangered species in a river. Because *Rana boylii* occupy whole dendritic networks of streams, and their life cycle is so entwined with the hydrologic an geomorphic processes of fluvial habitats, an added benefit of protecting them is that there will likely be more thoughtful consideration made when multiple riverine species require accommodation in the same reach. I believe that protection of *Rana boylii* recommended in this Status Review will eventually lead to a more holistic management philosophy for California rivers and streams in the future.

<u>Specific comments:</u>

1. p. vi. The illustrations of Kevin Wiseman's pen and ink drawing and Isaac Chellman's photograph are beautiful – nice choices. I am curious where the frog is from, I have never seen one so overall golden in color. Maybe include the general location when giving credit for the photo?

2. **p. 5** This is trivial, but maybe worth mentioning that for a period of time species name was spelled *boylei*?

3. p. 10 Figure 4. For this figure's legend I think there are a couple of pieces of information that need adding. First, please specify what the numbers are next to each symbol. Is it numbers of pairs of individuals at the river distance on the x axis within the same river? Also I am assuming that these are all data from various rivers within the American River drainage. If not please include info from Ryan's thesis that would specify.

4. Table of predators. If you would like to add another pers comm. observation I have seen otters (a mom and a couple of her young) eating tadpoles on the Angelo Reserve where the tadpoles were concentrated in a side pool.

5. Figures 8, 9. There are very few blue dots (2010-present) for San Benito County, and several extirpated populations (black squares). So, out of curiosity I looked on i-naturalist and there were several. Problem is that the platform obscures the location / coordinates, so it is hard to know how the recent sightings jive with the ones in this map. Do you think that there is a way to reach out to the amateur naturalists to determine where the extant populations are in the region sparsely occupied by the West/Central Coast clade?

6. p. 26. Moraga Creek observation. This record came under scrutiny / was questioned when I was conducting surveys for East Bay Regional Park District not too many miles from Moraga Creek for a stream daylighting project they are planning for Alder and Leatherwood Cks, tributaries to San Leandro Creek. Marcia Grefsrud was going to reach out to the person (Jeff Drier) who made the sighting to see if he had photos. Not sure what she found out.

7. p. 26 Coyote Creek news. In spring 2019 I conducted breeding surveys in Coyote Creek in Henry Coe State Park covering a 3 km reach (including the pools where I found dead frogs fall of 2018). Over two visits I counted 80 clutches (ca. 26/km), but there were some already hatched tadpoles on the first visit and it was difficult to attribute how many clutches worth they were, so this count is an underestimate.

My search area was upstream of the reaches covered by Earl Gonsolin in 2004 and 2005, so comparisons are not exact. I checked Table 1 of his Master's thesis and the densities he recorded were

Lower Reach 2004=17.2, 2005=24.8

Upper Reach 2004= 12.6, 2005=17.9

So, in spite of the die-off I observed last fall, the reproductive output in 2019 doesn't necessarily indicate a drastic difference to the density of breeding adults relative to 15 years ago. However, the loss of juvenile frogs may become apparent in the future when that cohort would have reached breeding age.

8. p. 32. Surveys around / near Yosemite. SFPUC has surveyed the Tuolumne River, near Early Intake, which is not too many river miles downstream of the border with Yosemite National Park (in Stanislaus Natl forest). I received an email dated 6/26/18 from Alan Striegle reporting one clutch.

9. p. 54. Road effects. The pattern of fords / vehicle stream crossings being at breeding sites is something I have seen in many locations including in Mendocino National Forest on the Rice Fork Eel. I think this is also the case with trails – I think there is a popular mountain bike trail on MMWD land that crosses a stream at a breeding site.

10. p. 57. Channel modifications associated with temporary swimming holes. In public places, parks, etc. I see this all the time in the parts of Alameda Creek open to the public within the park. People are constantly building little dams across the channel with whatever cobbles and small boulders are available to create better swimming spots.

11. p. 59 paragraph starting with 'Rapidly receding…' I think this paragraph needs a more general topic sentence, because it covers other effects of drought beyond stranding. Maybe a sentence stating that the effects of droughts, and a 'whiplash' climate which vacillates between extremes of droughts and floods, can create a complex mix of positive and negative effects on FYLF. At Coyote Creek I wonder if part of the Bd outbreak dynamics were driven by the high densities associated with stream drying, which would be consistent with the effects of density seen in the Alameda Ck Bd outbreak.

12. p. 59. In reference to the recent drought, you may want to cite Bogan et al 2019 regarding the abundance of FYLF in remnant pools at Coyote Ck.
M. T. Bogan, R. A. Leidy, L. Neuhaus, C. J. Hernandez, S. M. Carlson. 2019. Biodiversity value of remnant pools in an intermittent stream during the great California drought. Aquatic Conservation https://doi.org/10.1002/aqc.3109

13. p. 60 Although salvage logging is discussed further on, it might be worth mentioning in this paragraph when bringing up the topic of erosion post-fire.

14. p. 62. I suggest adding a summary paragraph before moving on to climate change to pull together the implications of all the sources of mortality reviewed in the previous sections and segue to the next section in which the modeled increase in droughts is presented. When considered cumulatively, the sources of mortality that could lead to local extirpations are problematic because the process of re-colonization is short circuited when populations are un-naturally isolated and distant from one another. In many cases the drier and less predictable future, there will likely be no, or only very small source populations that could produce dispersers to found new populations after an extirpation. The management implication of the human modified landscape is that recolonization is going to depend on assisted migration. Generally, there is evidence to support the idea that FYLF are disturbance adapted, having evolved through many millennia of drought and floods and fires, and likely part of their success as a species has been the ability to have rapid population increases when new populations are founded. I think that capacity bodes well for the development of a recovery plan.

15. p. 64, paragraph 3. It might be worth mentioning here the role that local geology / lithology can play in either buffering or accentuating the impact of hydrologic change on FYLF. In basins with a large degree of springs and volcanic rock (like in the Pit River drainage) base flows remain higher than one might expect. Also in places with a lot of faulting, there can be springs that maintain some presence of above ground water. In other places, increased winter flooding / precipitation may not translate into any increase in summer base flows because there is simply limited sub-surface storage. I think this perspective about the importance of rock types may be really helpful in making decisions about recovery planning, and choosing which watersheds might have high likelihood of successful re-introduction or augmentation.

Hahm, W. J., Dralle, D. N., Rempe, D. M., Bryk, A. B., Thompson, S. E., Dawson, T. E., & Dietrich, W. E. (2019). Low subsurface water storage capacity relative to annual rainfall decouples Mediterranean plant productivity and water use from rainfall variability. *Geophysical Research Letters*.

16. p. 65 paragraph 5. I think the point about fragmentation is super important and salient – is there a way to give this idea more prominence? Perhaps as a conclusion to the climate change section? I am afraid it gets buried here in the middle of the section. I think that fragmentation, in addition to thwarting a pole ward range-shift response, will limit any upslope migration within a watershed. For many larger rivers in the Sierra moving to a higher elevation is not an option, the path is blocked by dams and reservoirs.

17. p. 69, bottom. It is tricky to include all State Park lands in the umbrella of land being protected because it includes the Off Highway Vehicular Recreation Areas, which are not truly protected with respect to conserving wildlife. Also the heavy recreation allowed in other state parks can also be an issue, I am thinking about 'Reggae on the River' and other such festivals in which there is very heavy use of river side habitats.

18. p. 70 The statement that **"**a property's management does not necessarily benefit Foothill Yellow-legged Frogs" requires some examples of the types of management being referred to. A general reader might not read between the lines here.

19. p. 73 Second to last paragraph about compliance requirements of Lake and Streambed Alteration Agreements. In my experience working in Alameda Creek, it seems like there are few repercussions when an entity either violates their LSA or lets their LSA expire, yet continues to work in the stream, or affect the stream. Perhaps it is not appropriate here to delve into the problems of lack of 'teeth' for enforcing agreements, but this is one of the shortcomings of existing protections that is relevant to the need for protection under CESA.

20. p. 75 Hetch Hetchy**.** Not sure it is worth mentioning under this section on laws and the Upper Tuolumne River, but SFPUC / Modesto Irrigation District operate outside of FERC scrutiny because of the Raker Act

https://www.nps.gov/yose/blogs/remember-hetch-hetchy-the-raker-act-and-the-evolution-of-the-national-park-idea.htm

21. **p. 75.** For the Chili Bar reference I suggest naming the river reaches, some readers many not know this refers to the reach of the South Fork American River that is a popular white water boating reach with pulsed flows. I think that it is worth noting the fate of the frogs at these sites. I may not be totally up to date about the status of the populations at that at these locations, but I believe they were or have become sparse / teetering on extirpation. One could infer that despite the incorporation of best management practices into the new licenses, the effects of small population size, which are outlined so clearly on p. 69, could not be overcome through BMP's alone.

22. **p. 84**. conservation funds. Would the state listing influence IUCN red list status? I know that there are certain conservation funding opportunities tied to IUCN status. It also might be worth stating here that listing status might improve the situation with respect to interactions with National Marine Fisheries Service, which acts with a singular mission to restore anadromous salmonids in California rivers, a goal which can at times be in conflict with conservation of other native taxa.

23. **p. 87, paragraph 2.** In addition to (or maybe as a component of) habitat suitability assessment, I wonder if it would be appropriate to use surrogates for FYLF. For example could Bd and pesticide residues be assessed in treefrogs or other local amphibians? Or to assess whether hydroperiod might be adequate, surveys to determine newts' ability to successfully reach metamorphosis at the site could serve as a proxy.

24. **p. 87 bottom** – metapopulation dynamics. I think that an element of the research needed on this topic should be to identify upstream and downstream boundaries of populations, to document the conditions where densities dwindle at the periphery of a distribution. I think the difference between marginal and completely unsuitable habitat requires better distinction.

25. **p. 88** off-stream water storage. As long as these water bodies are managed so they don't create habitat for bullfrogs and non-native fish, they are a good idea.

26. p. 89 barrier removal. This is a complicated recovery action that can have unintended consequences. In some cases though, rocks / hydraulic jumps that make a barrier to fish passage may actually create habitat for FYLF, or prevent the upstream migration of non natives like crayfish. Especially in step pool morphology channels, frogs may utilize the sites that are not passable by fish. Removing the barriers could allow non natives to move upstream (Kerby, J.L., Riley, S.P., Kats, L.B. and Wilson, P., 2005. Barriers and flow as limiting factors in the spread of an invasive crayfish (*Procambarus clarkii*) in southern California streams. *Biological Conservation*, *126*(3), pp.402-409.)

27. **p. 89, enforcement**. What about utilities or governmental or state agencies that are causing harm -- How does law enforcement apply to these larger entities when they violate a law or an agreement? For example SFPUC commissioned studies to be done to be incorporated into an HCP, but then did not release the reports that documented the negative impacts to *Rana boylii* and suspended the HCP process. They received their permits and rebuilt the Calaveras Dam, but did not comply or fulfill their obligations under existing environmental law. On p. 76 where HCP's and Natural Community Conservation Plans are discussed, I find that the authorized take does not always lead to an improvement or compensation elsewhere. Who are the HCP police?

ACKNOWLEDGMENTS

Laura Patterson prepared this report. Stephanie Hogan, Madeleine Wieland, and Margaret Mantor assisted with portions of the report, including the sections on Status and Trends in California and Existing Management. Kristi Cripe provided GIS analysis and figures. Review of a draft document was provided by the following California Department of Fish and Wildlife (Department) staff: Ryan Bourque, Marcia Grefsrud, and Mike van Hattem.

The Department is extremely grateful for the valuable comments provided on this report by the following peer reviewers: Dr. Sarah Kupferberg, Dr. Amy Lind, Dr. Jimmy McGuire, and Dr. Ryan Peek. The conclusions in this report are those of the Department and do not necessarily reflect those of the reviewers.

EXECUTIVE SUMMARY

[To be completed after external peer review]

REGULATORY SETTING

Petition Evaluation Process

A petition to list the Foothill Yellow-legged Frog (*Rana boylii*) as threatened under the California Endangered Species Act (CESA) was submitted to the Fish and Game Commission (Commission) on December 14, 2016 by the Center for Biological Diversity. Commission staff transmitted the petition to the Department of Fish and Wildlife (Department) pursuant to Fish and Game Code section 2073 on December 22, 2016 and published a formal notice of receipt of the petition on January 20, 2017 (Cal. Reg. Notice Register 2017, No. 3-Z, p. 46). A petition to list or delist a species under CESA must include "information regarding the population trend, range, distribution, abundance, and life history of a species, the factors affecting the ability of the population to survive and reproduce, the degree and immediacy of the threat, the impact of existing management efforts, suggestions for future management, and the availability and sources of information. The petition shall also include information regarding the kind of habitat necessary for species survival, a detailed distribution map, and any other factors that the petitioner deems relevant" (Fish & G. Code, § 2072.3).

On April 17, 2017, the Department provided the Commission with its evaluation of the petition, "Evaluation of the Petition from the Center For Biological Diversity to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened under the California Endangered Species Act," to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5 & 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & (e)). Focusing on the information available to the Department relating to each of the relevant categories, the Department recommended to the Commission that the petition be accepted.

At its scheduled public meeting on June 21, 2017, in Smith River, California, the Commission considered the petition, the Department's petition evaluation and recommendation, and comments received. The Commission found that sufficient information existed to indicate the petitioned action may be warranted and accepted the petition for consideration. Upon publication of the Commission's notice of its findings, the Foothill Yellow-legged Frog was designated a candidate species on July 7, 2017 (Cal. Reg. Notice Register 2017, No. 27-Z, p. 986).

Status Review Overview

The Commission's action designating the Foothill Yellow-legged Frog as a candidate species triggered the Department's process for conducting a status review to inform the Commission's decision on whether listing the species is warranted. At its scheduled public meeting on June 21, 2018, in Sacramento, California, the Commission granted the Department a six-month extension to complete the status review and facilitate external peer review.

This status review report is not intended to be an exhaustive review of all published scientific literature relevant to the Foothill Yellow-legged Frog; rather, it is intended to summarize the key points from the best scientific information available relevant to the status of the species. This final report, based upon the best scientific information available to the Department, is informed by independent peer review of a draft report by scientists with expertise relevant to the Foothill Yellow-legged Frog. This review is intended to provide the Commission with the most current information on the Foothill Yellow-legged Frog and to serve as the basis for the Department's recommendation to the Commission on whether the petitioned action is warranted. The status review report also identifies habitat that may be essential to continued existence of the species and provides management recommendations for recovery of the species (Fish & G. Code, § 2074.6). Receipt of this report is to be placed on the agenda for the next available meeting of the Commission after delivery. At that time, the report will be made available to the public for a 30-day public comment period prior to the Commission taking any action on the petition.

Federal Endangered Species Act Review

The Foothill Yellow-legged Frog is currently under review for possible listing as threatened or endangered under the federal Endangered Species Act (ESA) in response to a July 11, 2012 petition submitted by the Center for Biological Diversity. On July 1, 2015, the U.S. Fish and Wildlife Service (USFWS) published its 90-day finding that the petition presented substantial scientific or commercial information indicating that the petitioned action may be warranted and initiated a status review of the species (USFWS 2015). On March 16, 2016, the Center for Biological Diversity sued the USFWS to compel issuance of a 12-month finding on whether listing under the ESA is warranted. On August 30, 2016, the parties reached a stipulated settlement agreement that the USFWS shall publish its 12-month finding in the Federal Register on or before September 30, 2020 (*Center for Biological Diversity v. S.M.R. Jewell* (D.D.C. Aug. 30, 2016, No. 16-CV-00503)).

BIOLOGY AND ECOLOGY

Species Description and Life History

> *"In its life-history* boylii *exhibits several striking specializations which are in all probability related to the requirements of life of a stream-dwelling species"* – Tracy I. Storer, 1925

The Foothill Yellow-legged Frog is a small- to medium-sized frog; adults range from 38 to 81 mm (1.5-3.2 in) snout to urostyle length (SUL) with females attaining a larger size than males and males possessing paired internal vocal sacs (Zweifel 1955, Nussbaum et al. 1983, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs are typically gray, brown, olive, or reddish with brown-black flecking and mottling, which generally matches the substrate of the stream in which they reside (Nussbaum et al. 1983, Stebbins and McGinnis 2012). They often have a pale triangle between the eyes and snout and broad dark bars on the hind legs (Zweifel 1955, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs have a relatively squat body and granular skin, giving them a rough appearance similar to a toad, and fully webbed feet with slightly expanded toe tips (Nussbaum et al. 1983). The tympanum is also rough

and relatively small compared to congeners at around one-half the diameter of the eye (Zweifel 1955). The dorsolateral folds (glandular ridges extending from the eye area to the rump) in Foothill Yellow-legged Frogs are indistinct compared to other western North American ranids (Stebbins and McGinnis 2012). Ventrally, the abdomen is white with variable amounts of dark mottling on the chest and throat, which are unique enough to be used to identify individuals (Marlow et al. 2016). As their name suggests, the underside of their hind limbs and lower abdomen are often yellow; however, individuals with orange and red have been observed within the range of the California Red-legged Frog (*Rana draytonii*), making hindlimb coloration a poor diagnostic characteristic for this species (Jennings and Hayes 2005).

Adult females likely lay one clutch of eggs per year and may breed every year (Storer 1925, Wheeler et al. 2006). Foothill Yellow-legged Frog egg masses resemble a compact cluster of grapes approximately 45 to 90 mm (1.8-3.5 in) in diameter length-wise and contain anywhere from around 100 to over 3,000 eggs (Kupferberg et al. 2009c, Hayes et al. 2016). The individual embryos are dark brown to black with a lighter area at the vegetative pole and surrounded by three jelly envelopes that range in diameter from approximately 3.9 to 6.0 mm (0.15-0.25 in) (Storer 1925, Zweifel 1955, Hayes et al. 2016).

Foothill Yellow-legged Frog tadpoles hatch out around 7.5 mm (0.3 in) long and are a dark brown or black (Storer 1925, Zweifel 1955). They grow rapidly to 37 to 56 mm (1.5-2.2 in) and turn olive with a coarse brown mottling above and an opaque silvery color below (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012). Their eyes are positioned dorsally when viewed from above (i.e., within the outline of the head), and their mouths are large, downward-oriented, and suction-like with several tooth rows (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012, Hayes et al. 2016). Foothill Yellow-legged Frogs metamorphose at around 14-17 mm (0.55-0.67 in) SUL (Fellers 2005). Sexual maturity is attained at around 30-40 mm (1.2-1.6 in) SUL and 1-2 years for males and around 40-50 mm (1.6-2.0 in) SUL and 3 years for females, although in some populations this has been accelerated by a year (Zweifel 1955, Kupferberg et al. 2009c, Breedveld and Ellis 2018). During the breeding season, males can be distinguished from females by the presence of nuptial pads (swollen darkened thumb bases that aid in holding females during amplexus) and calling, which frequently occurs underwater but sometimes from the surface (MacTague and Northen 1993, Stebbins 2003, Silver 2017).

The reported lifespan of Foothill Yellow-legged Frogs varies widely by study. Storer (1925) and Van Wagner (1996) estimated a maximum age of 2 years for both sexes and the vast majority of the population. Breedveld and Ellis (2018) calculated the typical lifespan of males at 3-4 years and 5-6 years for females. Bourque (2008), using skeletochronology, found an individual over 7 years old and a mean age of 4.7 and 3.6 years for males and females, respectively. Drennan et al. (2015) estimated maximum age at 13 years for both sexes in a Sierra Nevada population and 12 for males and 11 for females in a Coast Range population.

Range and Distribution

Foothill Yellow-legged Frogs historically ranged from the Willamette River drainage in Oregon west of the Sierra-Cascade crest to at least the San Gabriel River drainage in Los Angeles County, California (Figure 1; Zweifel 1955, Stebbins 2003). In addition, a disjunct population was reported from 2,040 m

Figure 1. Foothill Yellow-legged Frog historical range (adapted from CWHR, Loomis [1965], Nussbaum et al. [1983])

(6,700 ft) in the Sierra San Pedro Mártir, Baja California Norte, México (Loomis 1965). In California, the species occupies foothill and mountain streams in the Klamath, Cascade, Sutter Buttes, Coast, Sierra Nevada, and Transverse ranges from sea level to 1,940 m (6,400 ft), but generally below 1,525 m (5,000 ft) (Hemphill 1952, Nussbaum et al. 1983, Stebbins 2003, Olson et al. 2016). Zweifel (1955) considered Foothill Yellow-legged Frogs to be present and abundant throughout their range where streams possessed suitable habitat.

Taxonomy and Phylogeny

Foothill Yellow-legged Frogs belong to the family Ranidae (true frogs), which inhabits every continent except Antarctica and contains more than 700 species (Stebbins 2003). The species was first described by Baird (1854) as *Rana boylii*. After substantial taxonomic uncertainty with respect to its relationship to other ranids (frogs in the family Ranidae) and several name changes over the next century, the Foothill Yellow-legged Frog (*R. boylii* with no subspecific epithet) was eventually recognized as a distinct species again by Zweifel (1955, 1968). The phylogenetic relationships among the western North American *Rana* spp. have been revised several times and are still not entirely resolved (Thomson et al. 2016). The Foothill Yellow-legged Frog was previously thought to be most closely related to the higher elevation Mountain Yellow-legged Frog (*R. muscosa*) (Zweifel 1955; Green 1986a,b). However, genetic analyses undertaken by Macey et al. (2001) and Hillis and Wilcox (2005) suggest they are more closely related to Oregon Spotted Frogs (*R. pretiosa*) and Columbia Spotted Frogs (*R. luteiventris*), respectively.

Population Structure and Genetic Diversity

Foothill Yellow-legged Frog populations exhibit varying levels of partitioning and genetic diversity ~~at different~~depending on the spatial ~~scales~~scale of comparison. At the coarse landscape level across the species' extant range, McCartney-Melstad et al. (2018) recovered five deeply divergent, geographically cohesive, genetic clades (Figure 2), while Peek (2018) recovered six (Figure 3). Genetic divergence is the process of speciation; it is a measure of the number of mutations accumulated by populations over time from a shared ancestor that differentiate them from the other populations in a species. When genetic divergence among clades is large enough, it can be used as a tool to define new species or subspecies.

The geographic breaks among the five clades were similar between the studies, but Peek (2018) identified a separate deeply divergent genetic clade in the Feather River watershed that is distinct from the rest of the northern Sierra Nevada clade. The five clades ~~the two studies shared~~(common to both studies) include the following [Note: naming conventions follow McCartney-Melstad et al. (2018) and Peek (2018)]:

(1) Northwest/North Coast: north of San Francisco Bay in the Coast Ranges and east into Tehama County;
(2) Northeast/Northern Sierra: northern El Dorado County (North Fork American River watershed, includes Middle Fork) and north in the Sierra Nevada to southern Plumas County (Upper Yuba River watershed);

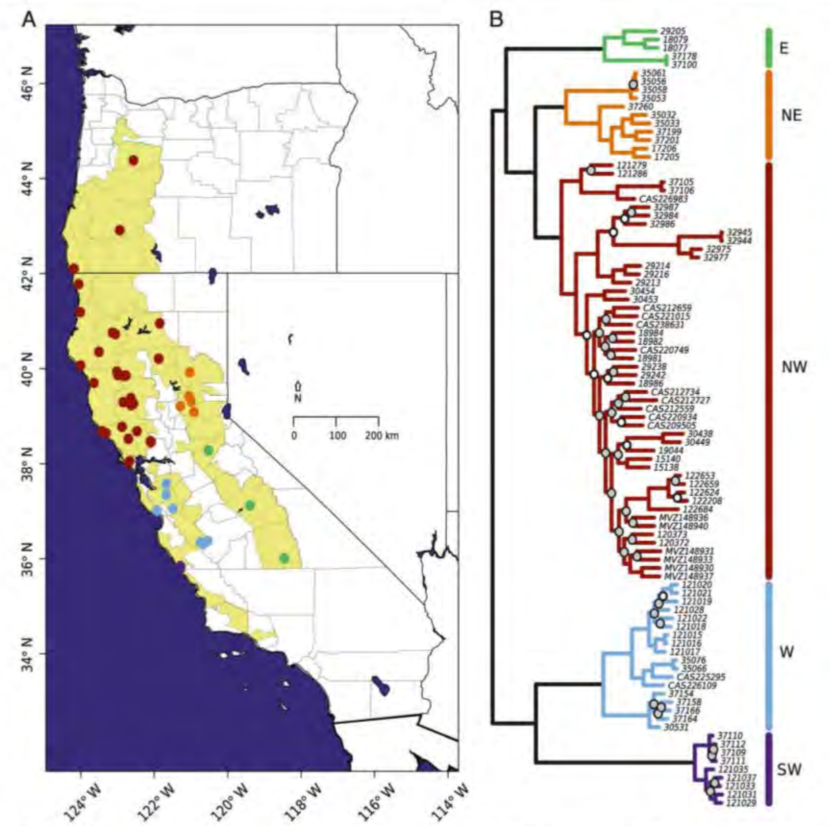

Fig. 1 a Map of *Rana boylii* sample localities. County outlines are shown within California and Oregon. Light yellow indicates the IUCN range map of *R. boylii*, excluding a small disjunct population at Sierra San Pedro Martir, Baja California, Mexico. Dots are colored by major grouping as determined in the **b** RAxML phylogeny, with midpoint rooting. Nodes without dots received >95% bootstrap support, those with white dots received <95% but greater than or equal to 75% bootstrap support, while nodes with gray dots received <75% bootstrap support

Figure 2. Foothill Yellow-legged Frog clades by McCartney-Melstad et al. (2018)

(3) East/Southern Sierra: El Dorado County (South Fork American River watershed) and south in the Sierra Nevada [no samples from Amador County were tested, but they would most likely fall within this clade because it is located between two other populations that occur within this clade];

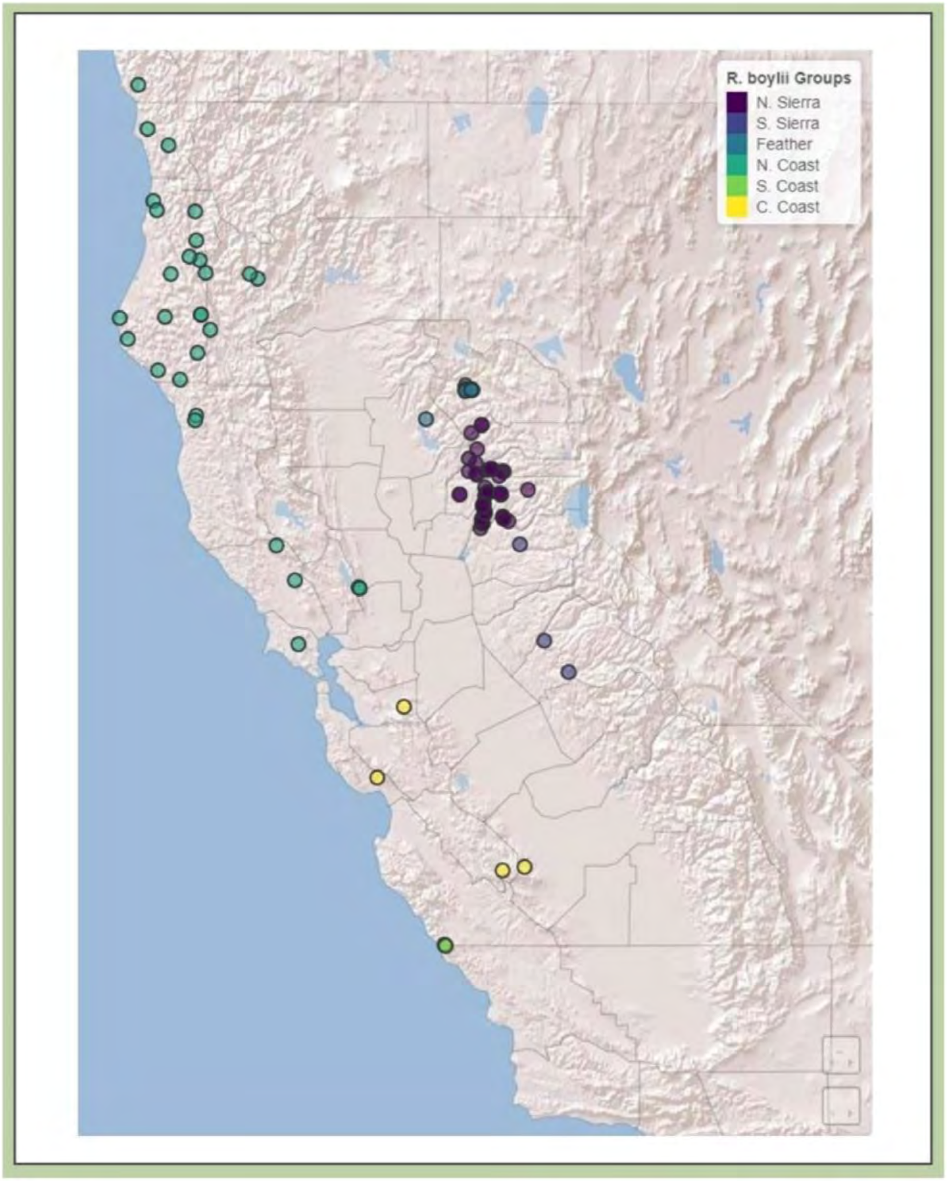

Figure 3. Foothill Yellow-legged Frog clades by Peek (2018)

(4) West/Central Coast: south of San Francisco Bay in the Coast Ranges to San Benito and Monterey counties, presumably east of the San Andreas Fault/Salinas Valley;

(5) Southwest/South Coast presumably west of the San Andreas Fault/Salinas Valley in Monterey County and south in the Coast Ranges.

The Feather River clade is found primarily in Plumas and Butte counties (Peek 2018). Peek's analysis found that this clade is as distinct as the rest of the Sierra Nevada as a cohesive group and all the coastal populations as one group, meaning it was found to be deeply divergent from the rest of the clades. McCartney-Melstad et al. (2018) also recognized the Feather River watershed as distinct from the rest of the northern Sierra but not as deeply divergent from the other clades as Peek. The Feather River watershed is also the only known location where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs (*R. sierrae*) co-occur and where two F1 hybrids (50% ancestry from each species) were found (Peek 2018). In addition, Peek's modeling results only weakly supported dividing the West/Central Coast and Southwest/South Coast groups into separate clades.

Previous work conducted by Lind et al. (2011) found a somewhat similar pattern, that populations on the periphery of the species' range are considerably genetically divergent from the rest of the range. Their results suggested that hydrologic regions and river basins were important landscape features that influenced the genetic structure of Foothill Yellow-legged Frog populations. However, using more modern genomic techniques, McCartney-Melstad et al. (2018) found nearly twice the variation among the five phylogenetic clades than among drainage basins, indicating other factors contributed to current population structure. They report that the depth of genetic divergence among Foothill Yellow-legged Frog clades exceeds that of any anuran (frog or toad) for which similar data are available and recommend using them as management units instead of the previously suggested watershed boundaries.

Levels of genetic diversity within the clades differed significantly. Genetic diversity gives species the ability to adapt to changing conditions (i.e., evolve), and its loss often signals extreme population and range reductions as well as potential inbreeding depression that can reduce survival and reproductive success (Lande and Shannon 1996, Hoffmann and Sgrò 2011, McCartney-Melstad et al. 2018). Loss of genetic diversity in Foothill Yellow-legged Frogs largely follows a north-to-south pattern with the southern clades (Southwest/South Coast and East/Southern Sierra) possessing the least amount (McCartney-Melstad et al. 2018, Peek 2018). In addition, these study results demonstrate that Foothill Yellow-legged Frogs have lost genetic diversity over time across their entire range except for the large Northwest/North Coast clade, which appears to have undergone a relatively recent population expansion (McCartney-Melstad et al. 2018, Peek 2018).

At a watershed scale, Dever (2007) found that tributaries to rivers and streams are important for preserving genetic diversity, and populations separated by more than 10 km (6.2 mi) show signs of genetic isolation. In other words, even in the absence of anthropogenic barriers to dispersal (e.g., dams and reservoirs), individuals located more than 10 km (6.2 mi) are not typically considered part of a single interbreeding population (Olson and Davis 2009). Peek (2011, 2018) reported that at this finer-scale, population structure and genetic diversity appear to be more strongly influenced by river regulation type (i.e., dammed or undammed) than to geographic distance or watershed boundaries. In general, regulated (dammed) rivers had limited gene flow and higher genetic divergence among subpopulations compared with unregulated (undammed) rivers (Peek 2011, 2018). In addition, differences in water flow regimes within regulated rivers affected connectivity (Peek 2011, 2018). Subpopulations in hydropeaking reaches, in which pulsed flows are used for electricity generation or whitewater boating, exhibited significantly lower gene flow than those in bypass reaches where water is diverted from upstream in the basin down to power generating facilities (Figure 4; Peek 2018). River regulation had a greater influence on genetic differentiation among sites than geographic distance in the Alameda Creek watershed as well (Stillwater Sciences 2012). Reduced connectivity among sites leads to lower gene flow and a loss of genetic diversity through genetic drift, which can diminish adaptability to changing environmental conditions (Palstra and Ruzzante 2008). Peek (2011) posits that given the *R. boylii* species group is estimated to be 8 million years old (Macey et al. 2001), the significant reductions in connectivity and genetic diversity over short evolutionary time periods in regulated rivers (often less than 50 years from the time of dam construction) is cause for concern with respect to population viability and persistence, particularly when combined with small population sizes.

Habitat Associations and Use

> *"These frogs are so closely restricted to streams that it is unusual to find one at a greater distance from the water than it could cover in one or two leaps."* – Richard G. Zweifel, 1955

Foothill Yellow-legged Frogs inhabit rivers and streams ranging from primarily rain-fed (coastal populations) to primarily snow-influenced (most Sierra Nevada and Klamath-Cascade populations) from headwater streams to large rivers (Bury and Sisk 1997, Wheeler et al. 2014). Occupied rivers and streams flow through a variety of vegetation types including hardwood, conifer, and valley-foothill riparian forests; mixed chaparral; and wet meadows (Hayes et al. 2016). Because the species is so widespread and can be found in so many types of habitats, the vegetation community is likely less important in determining Foothill Yellow-legged Frog occupancy and abundance than the aquatic biotic and abiotic conditions in the specific river, stream, or reach (Zweifel 1955). The species is an obligate stream-breeder, which sets it apart from other western North American ranids (Wheeler et al. 2014). Foothill Yellow-legged Frog habitat is generally characterized as partly-shaded, shallow, perennial rivers and streams with a low gradient and rocky substrate that is at least cobble-sized (Zweifel 1955, Hayes and Jennings 1988). However, the use of intermittent and ephemeral streams by post-metamorphic Foothill Yellow-legged Frogs may not be all that uncommon in some parts of the species' range in California (R. Bourque pers. comm. 2019). The species has been reported from some atypical habitats as well, including ponds, isolated pools in intermittent streams, and meadows along the edge of streams that lack a rocky substrate (Fitch 1938, Zweifel 1955, J. Alvarez pers. comm. 2017, CDFW 2018a).

As stream-breeding poikilotherms (animals whose internal temperature varies with ambient temperature), appropriate flow velocity, temperature, and water availability are critically important to Foothill Yellow-legged Frogs (Kupferberg 1996a, Van Wagner 1996, Wheeler et al. 2006, Lind et al. 2016). Habitat quality is also influenced by hydrologic regime (regulated vs. unregulated), substrate, presence of non-native predators and competitors, water depth, and availability of high-quality food and basking sites (Lind et al. 1996, Yarnell 2005, Wheeler et al. 2006, Catenazzi and Kupferberg 2017). Habitat suitability and use vary by life stage, sex, geographic location, watershed size, and season and

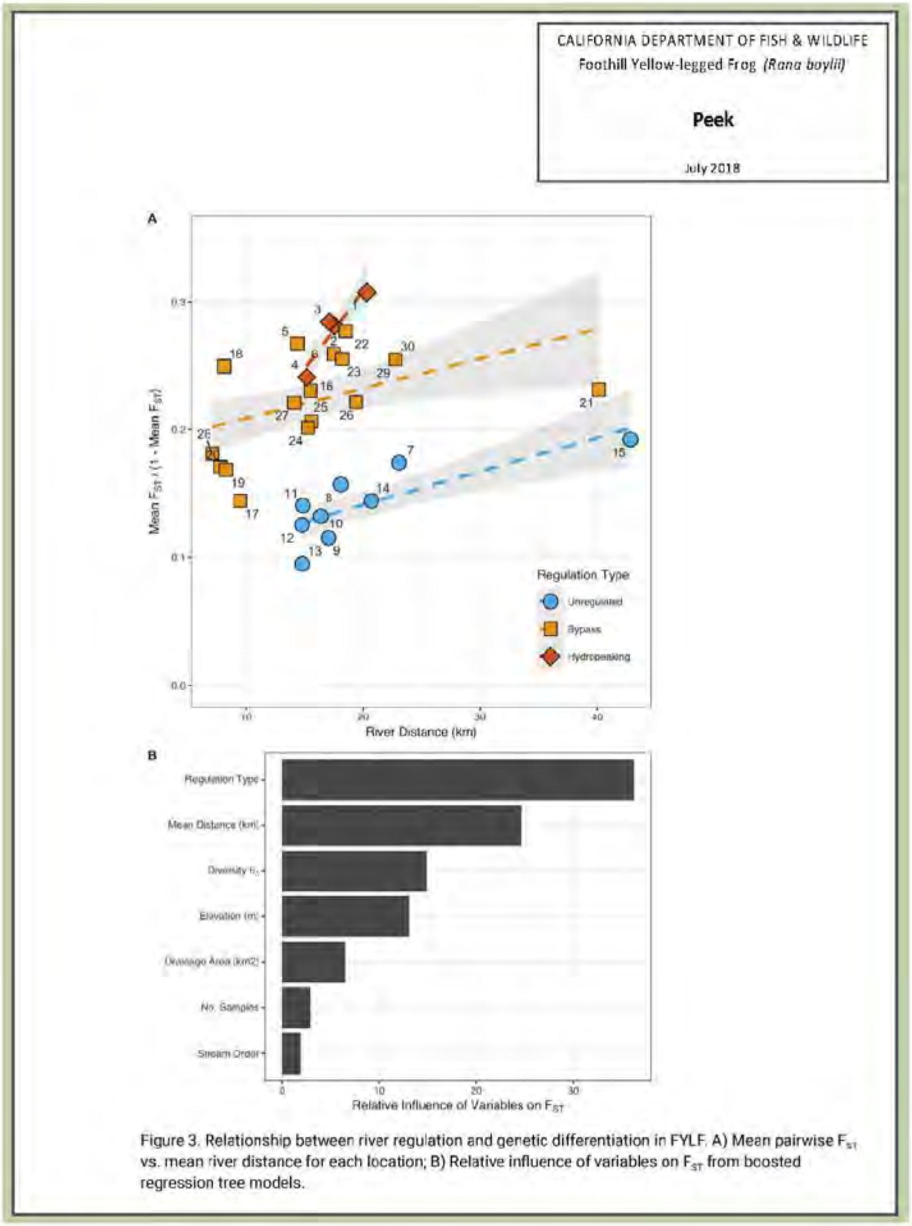

Figure 3. Relationship between river regulation and genetic differentiation in FYLF. A) Mean pairwise F_{ST} vs. mean river distance for each location; B) Relative influence of variables on F_{ST} from boosted regression tree models.

Figure 4. River regulation's relative influence on genetic differentiation from Peek (2018)

can generally be categorized as breeding and rearing habitat, nonbreeding active season habitat, and overwintering habitat (Van Wagner 1996, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011, Hayes et al. 2016, Catenazzi and Kupferberg 2017). Yarnell (2005) located higher densities of Foothill Yellow-legged Frogs in areas with greater habitat heterogeneity and suggested that they were selecting for sites that possessed the diversity of habitats necessary to support each life stage within a relatively short distance.

Breeding and Rearing Habitat

Suitable breeding habitat must be connected to suitable rearing habitat for metamorphosis to be successful. When this connectivity exists, as flows decline through the season, tadpoles can follow the receding shoreline into areas of high productivity and lower predation risk as opposed to becoming trapped in isolated pools with a high risk of overheating, desiccation, and predation (Kupferberg et al. 2009c).

Several studies on Foothill Yellow-legged Frog breeding habitat, carried out across the species' range in California, reported similar findings. Foothill Yellow-legged Frogs select oviposition (egg-laying) sites within a narrow range of depths, velocities, and substrates and exhibit fidelity to breeding sites that consistently possess suitable microhabitat characteristics over time (Kupferberg 1996a, Bondi et al. 2013, Lind et al. 2016). At a coarse-spatial scale, breeding sites in rivers and large streams are often located near the confluence of tributary streams in sunny, wide, shallow reaches (Kupferberg 1996a, Yarnell 2005, GANDA 2008, Peek 2011). These areas are highly productive compared to cooler, deeper, closed-canopy sites (Catenazzi and Kupferberg 2013). At a fine-spatial scale, females prefer to lay eggs in low velocity areas dominated by cobble- and boulder-sized substrates, often associated with sparsely-vegetated point bars (Kupferberg 1996a, Lind et al. 1996, Van Wagner 1996, Bondi et al. 2013, Lind et al. 2016). They tend to select areas with less variable, more stable flows, and in areas with higher flows at the time of oviposition, they place their eggs on the downstream side of large cobblestones and boulders, which protects them from being washed away (Kupferberg 1996a, Wheeler et al. 2006).

Appropriate rearing temperatures are vital for successful metamorphosis. Tadpoles grow faster and larger in warmer water to a point (Zweifel 1955; Catenazzi and Kupferberg 2017, 2018). Zweifel (1955) conducted experiments on embryonic thermal tolerance and determined that the critical low was approximate 6°C (43°F), and the critical high was around 26°C (79°F). Welsh and Hodgson (2011) determined that best the single variable for predicting Foothill Yellow-legged Frog presence was temperature since none were observed below 13°C (55°F), but numbers increased significantly with increasing temperature. Catenazzi and Kupferberg (2013) measured tadpole thermal preference at 16.5-22.2°C (61.7-72.0°F), and the distribution of Foothill Yellow-legged Frog populations across a watershed was consistent within this temperature range. ~~At~~ When the daily average temperatures during the warmest month of the year were below 16°C (61°F), tadpoles were absent under closed canopy and scarce even with an open canopy (Ibid.). Catenazzi and Kupferberg (2017) found regional differences in apparently suitable breeding temperatures. Inland populations from primarily snowmelt-fed systems with relatively cold water were relegated to reaches that are warmer on average during the warmest 30 days of the year than coastal populations in the chiefly rainfall-fed, and thus warmer, systems (17.6-

24.2°C [63.7-75.6°F] vs. 15.7-22.0°C [60.3-71.6°F], respectively). However, experiments on tadpole thermal preference demonstrated that individuals from different source populations selected similar rearing temperatures, which presumably optimized development (Ibid.). In regulated systems, where water released from dams is often colder than normal, suitable rearing temperatures downstream may be limited (Wheeler et al. 2014, Catenazzi and Kupferberg 2017).

Appropriate flow velocities are also critical for survival to metamorphosis. The velocity at which Foothill Yellow-legged Frog egg masses shear away from the substrate they are adhered to varies according to factors such as depth and degree to which the eggs are sheltered (Spring Rivers Ecological Sciences 2003). This critical velocity is expected to decrease as the egg mass ages due to their reduced structural integrity of the protective jelly envelopes (Hayes et al. 2016). Short-duration increases in flow velocity may be tolerated if the egg masses are somewhat sheltered, but sustained high velocities increase the likelihood of detachment (Kupferberg 1996a, Spring Rivers Ecological Sciences 2003). Hatchlings and tadpoles about to undergo metamorphosis are relatively poor swimmers and require especially slow, stable flows during these stages of development (Kupferberg et al. 2011b). Tadpoles respond to increasing flows by swimming against the current to maintain position for a short period of time and eventually swimming to the bottom and seeking refuge in the rocky substrate's interstitial spaces (Ibid.). When tadpoles are exposed to repeated increases in velocities, their growth and development are delayed (Ibid.). Under experimental conditions, the critical velocity at which tadpoles were swept downstream ranged between 20 and 40 cm/s (0.66-1.31 ft/s); however, as they reach metamorphosis it decreases to as low as 10 cm/s (0.33 ft/s) (Ibid.).

Nonbreeding Active Season Habitat

Post-metamorphic Foothill Yellow-legged Frogs utilize a more diverse range of habitats and are much more dispersed during the nonbreeding active season than the breeding season. Microhabitat preferences appear to vary by location and season, but some patterns are common across the species' range. Foothill Yellow-legged Frogs tend to remain close to the water's edge (average < 3 m [10 ft]); select sunny areas with limited canopy cover; and are often associated with riffles and pools (Zweifel 1955, Hayes and Jennings 1988, Van Wagner 1996, Welsh et al. 2005, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011). Adequate water, food resources, cover from predators, ability to thermoregulate (e.g., presence of basking sites and cool refugia), and absence of non-native predators are important components of nonbreeding active season habitat (Hayes and Jennings 1988, Van Wagner 1996, Catenazzi and Kupferberg 2013).

Overwintering Habitat

Overwintering habitat varies depending on local conditions, but as with the rest of the year, Foothill Yellow-legged Frogs are most often found in or near water where they can forage and take cover from predators and high discharge events (Storer 1925, Zweifel 1955). In larger streams and rivers, Foothill Yellow-legged Frogs are often found along tributaries during the winter where the risk of being displaced by heavy flows is reduced (Kupferberg 1996a, Gonsolin 2010). Bourque (2008) found 36.4% of adult females used intermittent and ephemeral tributaries during the overwintering season. Van

Wagner (1996) located most overwintering frogs using pools with cover such as boulders, root wads, and woody debris. During high flow events, they moved to the stream's edge and took cover under vegetation like sedges (*Carex* sp.) or leaf litter (Ibid.). Rombough (2006) found most Foothill Yellow-legged Frogs under woody debris along the high-water line and often using seeps along the stream-edge, which provided them with moisture, a thermally stable environment, and prey.

Exceptions to the pattern of remaining near the stream's edge during winter have been reported. Cook et al. (2012) observed dozens of juvenile Foothill Yellow-legged Frogs traveling over land, as opposed to using riparian corridors. They were found using upland habitats with an average distance of 71.3 m (234 ft) from water (range: 16-331 m [52-1,086 ft]) (Ibid.). In another example, a single subadult that was found adjacent to a large wetland complex 830 m (2,723 ft) straight-line distance from the wetted edge of the Van Duzen River, although it is possible the wetland was connected to the river via a spillway or drainage that may have served as the movement corridor (CDFW 2018a, R. Bourque pers. comm. 2019).

Seasonal Activity and Movements

Because Foothill Yellow-legged Frogs occupy areas with relatively mild winter temperatures, they can be active year-round, although at low temperatures (< 7°C [44 °F], they become lethargic (Storer 1925, Zweifel 1955, Van Wagner 1996, Bourque 2008). They are active both day and night, and during the day adults are often observed basking on warm objects such as sun-heated rocks, although this is also when their detectability is highest (Fellers 2005, Wheeler et al. 2005). By contrast, Gonsolin (2010) tracked radio-telemetered Foothill Yellow-legged Frogs under substrate a third of the time and underwater a quarter of the time, although nearly all his detections of frogs without transmitters were basking.

Adult Foothill Yellow-legged Frogs migrate from their overwintering sites to breeding habitat in the spring, often from a tributary to its confluence with a larger stream or river. In areas where tributaries dry down, juveniles also make this downstream movement (Haggarty 2006). When the tributary itself is perennial and provides suitable breeding habitat, the frogs may not undertake these long-distance movements (Gonsolin 2010). Cues for adults to initiate this migration to breeding sites are somewhat enigmatic and vary by location, elevation, and amount of precipitation (S. Kupferberg and A. Lind pers. comm. 2017). They can also include day length, water temperature, and sex (GANDA 2008, Gonsolin 2010, Yarnell et al. 2010, Wheeler et al. 2018). Males initiate movements to breeding sites where they congregate in leks (areas of aggregation for courtship displays), and females arrive later and over a longer period (Wheeler and Welsh 2008, Gonsolin 2010). Most males utilize breeding sites associated with their overwintering tributaries, but some move substantial distances to other sites and may use more than one breeding site in the same season (Wheeler and Welsh 2006, GANDA 2008).

While the predictable hydrograph in California consists of wet winters with high flows and dry summers with low flows, the timing and quantity of seasonal discharge can vary significantly from year to year. The timing of oviposition can influence offspring growth and survival. Early breeders risk scouring of egg masses from their substrate by late spring storms in wet years or desiccation if waters recede rapidly, but when they successfully hatch, tadpoles benefit from a longer growing season, which can enable them to metamorphose at a larger size and increase their likelihood of survival (Railsback et al. 2016).

Later breeders are less likely to have their eggs scoured away or desiccated because flows are generally more stable, but they have fewer mate choices, and their tadpoles have a shorter growing period before metamorphosis, reducing their chance of survival (Ibid.). Some evidence indicates larger females, who coincidentally lay larger clutches, breed earlier (Kupferberg et al. 2009c, Gonsolin 2010). Consequently, early season scouring or stranding of egg masses or tadpoles can disproportionately impact the population's reproductive output because later breeders produce fewer and smaller eggs per clutch (Kupferberg et al. 2009c, Gonsolin 2010).

Timing of oviposition is often a function of water temperature and flow, but it consistently occurs on the descending limb of the hydrograph which corresponds to high winter discharge gradually receding toward low summer baseflow (Kupferberg 1996a, GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010, Yarnell et al. 2010). Under natural conditions, the timing coincides with intermittent tributaries drying down and increases in algal blooms that provide forage for tadpoles (Haggarty 2006, Power et al. 2008). At lower elevations, breeding can start in late March or early April, and at mid-elevations, breeding typically occurs in mid-May to mid-June (Gonsolin 2010, S. Kupferberg and A. Lind pers. comm. 2017). The time of year a population initiates breeding can vary by a month among water years, occurring later at deeper sites when colder water becomes warmer (Wheeler et al. 2018). In wetter years, delayed breeding into early July can occur in some colder snowmelt systems (S. Kupferberg and A. Lind pers. comm. 2017, GANDA 2018).

A population's period of oviposition can also vary from two weeks to three months, meaning they could be considered explosive breeders at some sites and prolonged breeders at others (Storer 1925, Zweifel 1955, Van Wagner 1996, Ashton et al. 1997, Wheeler and Welsh 2008). Water temperature typically warms to over 10°C (50°F) before breeding commences (GANDA 2008, Gonsolin 2010, Wheeler et al. 2018). Wheeler and Welsh (2008) observed Foothill Yellow-legged Frogs breeding when flows were below 0.6 m/s (2 ft/s), pausing during increased flows until they receded, and GANDA (2008) reported breeding initiated when flow decreased to less than 55% above baseflow.

Male Foothill Yellow-legged Frogs spend more time at breeding sites during the season than females, many of whom leave immediately after laying their eggs (GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010). Daily movements are usually short (< 0.3 m [1 ft]), but some individuals travel substantial distances: median 70.7 m/d (232 ft/d) in spring and 37.1 m/d (104 ft/day) in fall/winter, nearly always using streams as movement corridors (Van Wagner 1996, Bourque 2008, Gonsolin 2010). The maximum reported movement rate is 1,386 m/d (0.86 mi/d), and the longest seasonal (post-breeding) daily distance reported is 7.04 km (4.37 mi) by a female that traveled up a dry tributary and over a ridge before returning to and moving up the mainstem creek (Bourque 2008). Movements during the non-breeding season are typically in response to drying channels or during rain events (Bourque 2008, Gonsolin 2010, Cook et al. 2012).

Hatchling Foothill Yellow-legged Frogs tend to remain with what is left of the egg mass for several days before dispersing into the interstitial spaces in the substrate (Ashton et al. 1997). They often move downstream in areas of moderate flow and will follow the location of warm water in the channel throughout the day (Brattstrom 1962, Ashton et al. 1997, Kupferberg et al. 2011a). Tadpoles usually

metamorphose in late August or early September (S. Kupferberg and A. Lind pers. comm. 2017). Twitty et al. (1967) reported that newly metamorphosed Foothill Yellow-legged Frogs mostly migrated upstream, which may be an evolutionary mechanism to return to their natal site after being washed downstream (Ashton et al. 1997).

Home Range and Territoriality

Foothill Yellow-legged Frogs exhibit a lek-type mating system in which males aggregate at the breeding site and establish calling territories (Wheeler and Welsh 2008, Bondi et al. 2013). The species has a relatively large calling repertoire for western North American ranids with seven unique vocalizations recorded (Silver 2017). Some of these can be reasonably attributed to territory defense and mate attraction communications (MacTeague and Northen 1993, Silver 2017). Physical aggression among males during the breeding season has been reported (Rombough and Hayes 2007, Wheeler and Welsh 2008). In addition, Wheeler and Welsh (2008) observed a non-random mating pattern in which males engaged in amplexus with females were larger than males never seen in amplexus, suggesting either physical competition or female preference for larger individuals. Very little information has been published on Foothill Yellow-legged Frog home range size. Wheeler and Welsh (2008) studied males during a 17-day period during breeding season and classified some of them "site faithful" based on their movements and calculated their home ranges. Two-thirds of males tracked were site faithful, and their mean home range size was 0.58 m^2 (SE = 0.10 m^2; 6.24 ft^2 [SE = 1.08 ft^2]) (Ibid.). In contrast, perhaps because the study took place over a longer time period, Bourque (2008) reported approximately half of the males he tracked during the spring were mobile, and the other half were sedentary. The median distances traveled along the creek (a proxy for home range size since they rarely leave the riparian corridor) for mobile and sedentary males were 149 m (489 ft) and 5.5 m (18 ft), respectively.

Diet and Predators

Foothill Yellow-legged Frog diet varies by life stage and likely body size. Tadpoles graze on periphyton (algae growing on submerged surfaces) scraped from rocks and vegetation and grow faster, and to a larger size, when it contains a greater proportion of epiphytic diatoms with nitrogen-fixing endosymbionts (*Epithemia* spp.), which are high in protein and fat (Kupferberg 1997b, Fellers 2005, Hayes et al. 2016, Caten~~n~~azzi and Kupferberg 2017). Tadpoles may also forage on necrotic tissue from dead bivalves and other tadpoles, or more likely the algae growing on them (Ashton et al. 1997, Hayes et al. 2016). Post-metamorphic Foothill Yellow-legged Frogs primarily feed on a wide variety of terrestrial arthropods but also some aquatic invertebrates (Fitch 1936, Van Wagner 1996, Haggarty 2006). Most of their diet consists of insects and arachnids (Van Wagner 1996, Haggarty 2006, Hothem et al. 2009). Haggarty (2006) did not identify any preferred taxonomic groups, but she noted larger Foothill Yellow-legged Frogs consumed a greater proportion of large prey items compared to smaller individuals, suggesting the species may be gape-limited generalist predators. Hothem et al. (2009) found mammal hair and bones in a Foothill Yellow-legged Frog. Adult Foothill Yellow-legged Frogs, like many other ranids, also cannibalize conspecifics (Wiseman and Bettaso 2007). In the fall when young-of-year are abundant, they may provide an important source of nutrition for adults prior to overwintering (Ibid.).

Foothill Yellow-legged Frogs are preyed upon by several native and introduced species, including each other as described above. Some predators target specific life stages, while others may consume multiple stages. Several species of gartersnakes (genus *Thamnophis*) are the primary and most widespread group of native predators on Foothill Yellow-legged Frogs tadpoles through adults is (Fitch 1941, Fox 1952, Zweifel 1955, Lind and Welsh 1994, Ashton et al. 1997, Wiseman and Bettaso 2007, Gonsolin 2010). Table 1 lists other known and suspected predators of Foothill Yellow-legged Frogs.

Table 1. Confirmed and potential Foothill Yellow-legged Frog predators in California in addition to gartersnakes (*Thamnophis* spp.)

Common Name	Scientific Name	Classification	Native	Prey Life Stage(s)	Sources
Caddisfly (larva)	*Dicosmoecus gilvipes*	Insect	Yes	Embryos (eggs)	Rombough and Hayes 2005
Dragonfly (nymph)	*Aeshna walker*	Insect	Yes	Larvae	Catenazzi and Kupferberg 2018
Waterscorpion	*Ranatra brevicollis*	Insect	Yes	Larvae	Catenaazi and Kupferberg 2018
Signal Crayfish	*Pacifastacus leniusculus*	Crustacean	No	Embryos (eggs) and Larvae	Rombough and Hayes 2005; Wiseman et al. 2005
Speckled Dace	*Rhinichthys osculus*	Fish	Yes	Larvae	Rombough and Hayes 2005
Reticulate Sculpin	*Cottus perplexus*	Fish	Yes	Larvae	Rombough and Hayes 2005
Sacramento Pike Minnow	*Ptychocheilus grandis*	Fish	Yes*	Embryos (eggs) and Adults	Ashton and Nakamoto 2007
Sunfishes	Family Centrachidae	Fish	No	Larvae	Moyle (1973); Hayes and Jennings 1986
Catfishes	Family Ictaluridae	Fish	No	Larvae	Moyle (1973); Hayes and Jennings 1986
Rough-skinned Newt	*Taricha granulosa*	Amphibian	Yes	Embryos (eggs)	Evenden 1948
California Giant Salamander	*Dicamptodon ensatus*	Amphibian	Yes	Larvae	Fidenci 2006
American Bullfrog	*Rana catesbeiana*	Amphibian	No	Larvae to Adults	Crayon 1998; Hothem et al. 2009
California Red-legged Frog	*Rana draytonii*	Amphibian	Yes	Larvae to Adults	Gonsolin 2010
American Robin	*Turdus migratorius*	Bird	Yes	Larvae	Gonsolin 2010
Common Merganser	*Mergus merganser*	Bird	Yes	Larvae	Gonsolin 2010
American Dipper	*Cinclus mexicanus*	Bird	Yes	Larvae	Ashton et al. 1997
Mallard	*Anas platyrhynchos*	Bird	Yes	Adults	Rombough et al. 2005
Raccoon	*Procyon lotor*	Mammal	Yes	Larvae to Adults	Zweifel 1955; Ashton et al. 1997
River Otter	*Lontra canadensis*	Mammal	Yes	Adults	T. Rose pers. comm. 2014

* Introduced to the Eel River, location of documented predation; Foothill Yellow-legged Frogs are extirpated from most areas of historical range overlap

STATUS AND TRENDS IN CALIFORNIA

Administrative Status

Sensitive Species

The Foothill Yellow-legged Frog is listed as a Sensitive Species by the U.S. Bureau of Land Management (BLM) and U.S. Forest Service (Forest Service). These agencies define Sensitive Species as those species that require special management consideration to promote their conservation and reduce the likelihood and need for future listing under the ESA.

California Species of Special Concern

The Department's Species of Special Concern (SSC) designation is similar to the federal Sensitive Species designation. It is administrative, rather than regulatory in nature, and intended to focus attention on animals at conservation risk. The designation is used to stimulate needed research on poorly known species and to target the conservation and recovery of these animals before they meet the CESA criteria for listing as threatened or endangered (Thomson et al. 2016). The Foothill Yellow-legged Frog is listed as a Priority 1 (highest risk) SSC (Ibid.).

Trends in Distribution and Abundance

Range-wide in California

Range is the general geographical area in which an organism occurs. For purposes of CESA and this Status Review, the range is the species' California range (*Cal. Forestry Assn. v. Cal. Fish and Game Com.* (2007) 156 Cal.App.4th 1535, 1551). Systematic, focused, range-wide assessments of Foothill Yellow-legged Frog distribution and abundance are rare, both historically and contemporarily. A detailed account of what has been documented within the National Parks and National Forests in California can be found in Appendix 3 of the *Foothill Yellow-legged Frogs Conservation Assessment in California* (Hayes et al. 2016).

Most Foothill Yellow-legged Frog records are incidental observations made during stream surveys for ESA-listed salmonids and simply document presence at a particular date and location, although some include counts or estimates of abundance by life stage. This makes assessing trends in distribution and abundance difficult despite a relatively large number of observations compared to many other species tracked by the California Natural Diversity Database (CNDDB). The CNDDB contained 2,366 Foothill Yellow-legged Frog occurrences in its March 2019 edition, 500 of which are documented from the past 5 years.

A few wide-ranging survey efforts that included Foothill Yellow-legged Frogs exist. Reports from early naturalists suggest Foothill Yellow-legged Frogs were relatively common in the Coast Ranges as far south as central Monterey County, in eastern Tehama County, and in the foothills in and near Yosemite National Park (Grinnell and Storer 1924, Storer 1925, Grinnell et al. 1930, Martin 1940). In addition to

these areas, relatively large numbers of Foothill Yellow-legged Frogs (17-35 individuals) were collected at sites in the central and southern Sierra Nevada and the San Gabriel Mountains between 1911 and 1950 (Hayes et al. 2016). Widespread disappearances of Foothill Yellow-legged Frog populations were documented as early as the 1970s and 80s in southern California, the southern Coast Range, and the central and southern Sierra Nevada foothills (Moyle 1973, Sweet 1983).

Twenty-five years ago, the Department published the first edition of *Amphibians and Reptile Species of Special Concern in California* (Jennings and Hayes 1994). The authors revisited hundreds of localities that had historically been occupied by Foothill Yellow-legged Frogs between 1988 and 1991 and consulted local experts to determine presumed extant or extirpated status. Based on these survey results and stressors observed on the landscape, they considered Foothill Yellow-legged Frogs endangered in central and southern California south of the Salinas River in Monterey County. They considered the species threatened in the west slope drainages of the Cascade Mountains and Sierra Nevada east of the Central Valley, and they considered the remainder of the range to be of special concern (Ibid.).

Fellers (2005) and his field crews conducted surveys for Foothill Yellow-legged Frogs throughout California. They visited 804 sites across 40 counties with suitable habitat within the species' historical range. They detected at least one individual at 213 sites (26.5% of those surveyed) over 28 counties. They located Foothill Yellow-legged Frogs in approximately 40% of streams in the North Coast, 30% in the Cascade Mountains and south of San Francisco in the Coast Range, and 12% in the Sierra Nevada. Fellers estimated population abundance was 20 or more adults at only 14% of the sites where the species was found and noted the largest and most robust populations occurred along the North Coast. In addition, to determine status of Foothill Yellow-legged Frogs across the species' range and potential causes for declines, Lind (2005) used previously published status accounts, species expert and local biologist professional opinions, and field visits to historically occupied sites between 2000-2002. She determined that Foothill Yellow-legged Frogs had disappeared from 201 of 394 of the sites, representing just over 50%. The coarse-scale trend in California is one of greater population declines and extirpations in lower elevations and latitudes (Davidson et al. 2002).

Few site-specific population trend data are available from which to evaluate status. However, long-term monitoring efforts often use egg mass counts as a proxy to estimate adult breeding females. The results of these studies often reveal extreme interannual variability in number of egg masses laid (Ashton et al. 2010, S. Kupferberg and M. Power pers. comm. 2015, Peek and Kupferberg 2016). In a meta-analysis of egg mass count data collected across the species' range in California over the past 25 years, Peek and Kupferberg (2016) reported declines in two unregulated rivers and an increase in another. Their models did not detect any significant trends in abundance across different locations or regulation type (dammed or undammed); however, high interannual variability can render trend detection difficult. Interannual variability was substantially greater in regulated rivers vs. unregulated; the median coefficient of variation was 66.9% and 41.6%, respectively (Ibid.). The greater variability in regulated rivers decreases the probability of detecting significant declines, and coupled with low abundance, it can lead to populations dropping below a density necessary for persistence without detection, resulting in extirpation.

Regional differences in Foothill Yellow-legged Frog persistence across its range have been recognized for nearly 50 years (i.e., more extirpations documented in the south). Because of these differences and the recent availability of new landscape genomic data, more detailed descriptions of trends in Foothill Yellow-legged Frog population distribution and abundance in California are evaluated by clade below. Figure 5 depicts Foothill Yellow-legged Frog localities across all clades in California by the most recent confirmed sighting in the datasets available to the Department within a Public Lands Survey System (PLSS) section. "Transition Zones" are those areas where the exact clade boundaries are unknown due to a lack of samples. In addition, while not depicted as an area of uncertainty, no genetic samples have been tested south of the extant population in northern San Luis Obispo County, in the Sutter Buttes in Sutter County, or northeastern Plumas County. It is possible there were historically more clades than currently understood.

Caution should be exercised in comparing the following observation data across the species' range and across time since survey effort and reporting are not standardized. These data can be useful for making some general inferences about distribution, abundance, and trends. For instance, assuming the observation correctly identifies the species, the date on the record is the last time the species was confirmed to have occurred at that location. However, this only works in the affirmative. For example, at a site where the last time the species was seen was 75 years ago, the species may still persist there if no one has surveyed it since the original observation. CNDDB staff use information on land use conversion, follow-up visits, and biological reports to categorize an occurrence location as "extirpated" or "possibly extirpated".

Northwest/North Coast Clade

This clade extends from north of San Francisco Bay through the Coast Range and Klamath Mountains to the northern limit of the Foothill Yellow-legged Frog's range and east through the Cascade Range. It includes Del Norte, Siskiyou, Humboldt, Trinity, Shasta, Tehama, Mendocino, Glenn, Colusa, Lake, Sonoma, Napa, Yolo, Solano, and Marin counties. This clade covers the largest geographic area and contains the greatest amount of genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). In addition, it is the only clade with an increasing trend in genetic diversity (Peek 2018).

Early records note the comparatively high abundance of Foothill Yellow-legged Frogs in this area. Storer (1925) described Foothill Yellow-legged Frogs as very common in many of Coast Range streams north of San Francisco Bay, and Cope (1879,1883 as cited in Hayes et al. 2016) noted they were "rather abundant in the mountainous regions of northern California." In addition, relatively large collections occurred over short periods of time in this region in the late 1800s and the first half of the 20th century (Hayes et al. 2016). Nineteen were taken over two weeks in 1893 along Orrs Creek, a tributary to the Russian River, and 40 from near Willits (both in Mendocino County) in 1911; 112 were collected over three days at Skaggs Spring (Sonoma County) in 1911; 57 were taken in one day along Lagunitas Creek (Marin County) in 1928; and 50 were collected in one day near Denny (Trinity County) in 1955 (Ibid.).

A few long-term Foothill Yellow-legged Frog egg mass monitoring efforts undertaken within this clade's boundaries found densities vary significantly, often based on river regulation type, and documented

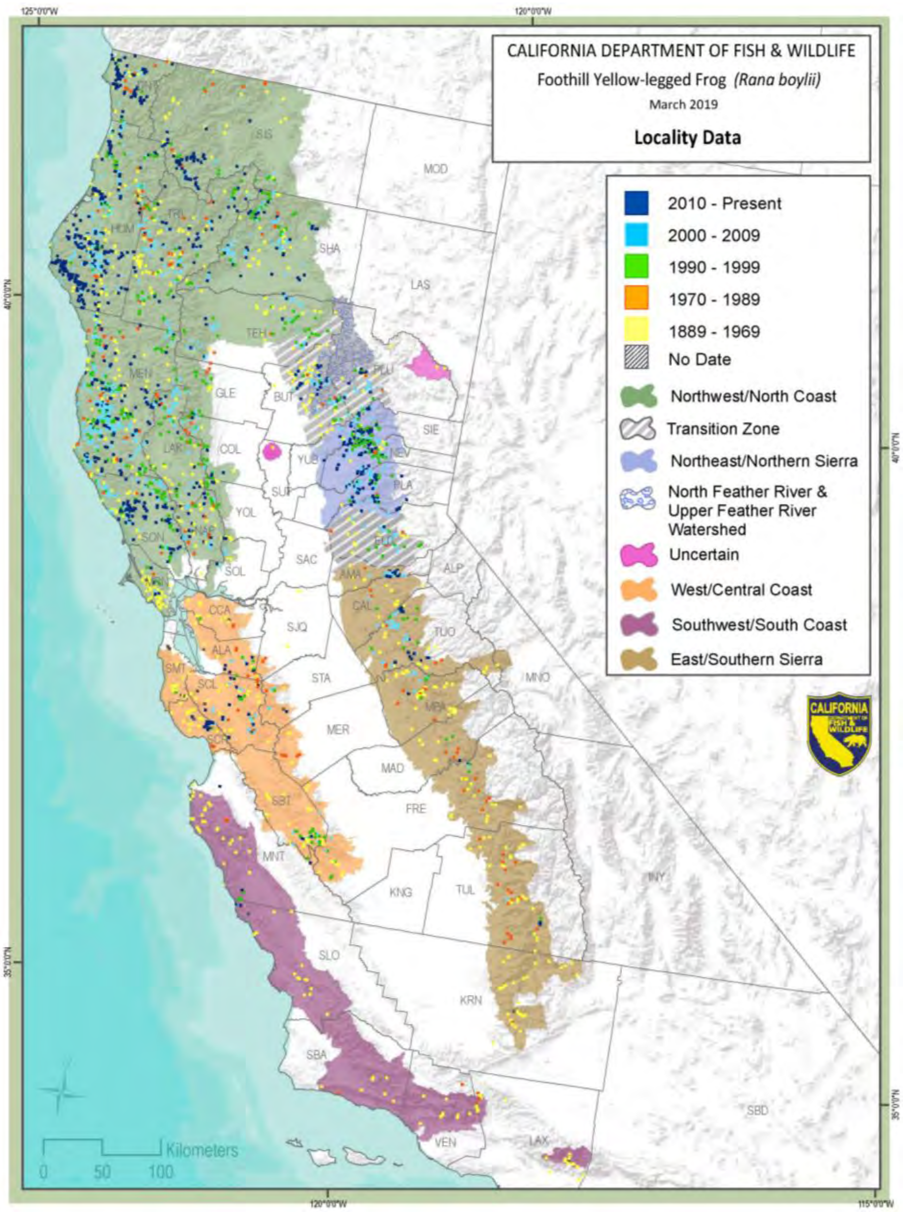

Figure 5. Foothill Yellow-legged Frog occurrence data from 1889-2019 overlaying the six clades by most recent sighting in a Public Lands Survey System section (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

several robust populations. The Green Diamond Resources Company has been monitoring a stretch of the Mad River near Blue Lake (Humboldt County) since 2008 (GDRC 2018). The greatest published density of Foothill Yellow-legged Frog egg masses was documented here in 2009 at 323.6 egg masses/km (520.7/mi) (Bourque and Bettaso 2011). However, in 2017, surveyors counted 625.1 egg masses/km (1,006/mi) along the same reach (GDRC 2018). At its lowest during this period, egg mass density was calculated at 71.54/km (115.1/mi) in 2010, although this count occurred after a flooding even that likely scoured over half of the egg masses laid that season (GDRC 2018, R. Bourque pers. comm. 2019). During a single day survey in 2017 along approximately 2 km (1.3 mi) of Redwood Creek in Redwood National Park (Humboldt County), 2,009 young and 126 adult Foothill Yellow-legged Frogs were found (D. Anderson pers. comm. 2017). Some reaches of the South Fork Eel River (Mendocino County) also support high densities of Foothill Yellow-legged Frogs. Kupferberg (pers. comm. 2018) recorded 206.9 and 106.2 egg masses/km (333 and 171/mi) along two stretches in 2016, and 201.7 and 117.5 egg masses/km (324 and 189/mi) in 2017. However, other reaches yielded counts as low as 6.1 and 8.4 egg masses/km (9.8 and 13.5/mi) (Ibid.). In the Angelo Reserve (an unregulated reach), the 24-year mean density was 109 egg masses/km (175.4/mi) (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015). In contrast, a 10-year mean density of egg masses below Lewiston Dam on the Trinity River (Trinity County) was 0.89/km (1.43/mi) (Ibid.).

Figure 6 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, Biological Information Observation System datasets, and personal communications that are color coded by the most recent date of detection. Within this clade, Foothill Yellow-legged Frogs were observed in at least 343 areas in the past 5 years (CNDDB 2019). The species remains widespread within many watersheds, although most observations only verify presence, or fewer than ten individuals or egg masses are recorded (Ibid.). Documented extirpations are comparatively rare, but also likely undetected or under-reported, and nearly all occurred just north of the high-populated San Francisco Bay area (Figure 7; Ibid.).

West/Central Coast

This clade extends south from the San Francisco Bay through the Diablo Range and down the peninsula through the Santa Cruz and Gabilan Mountains in the Coast Range east of the Salinas Valley. It includes most of Contra Costa, Alameda, San Mateo, Santa Cruz, Santa Clara, and San Benito counties; western San Joaquin, Stanislaus, Merced, and Fresno counties; and a small portion of eastern Monterey County. Records of Foothill Yellow-legged Frogs occurring south of San Francisco Bay did not exist until specimens were collected in 1918 around what is now Pinnacles National Park in San Benito County, and little information exists on historical distribution and abundance within this clade (Storer 1923).

Within this clade, Foothill Yellow-legged Frogs were observed in at least 24 areas in the past five years (Figure 8; CNDDB 2019). Documented and possible extirpations are concentrated around the San Francisco Bay and sites at the southern portion of the clade's range, although these may not have been resurveyed since their original observations in the 1940s through 1960s, except for a site in Pinnacles National Park that was surveyed in 1994 (Figure 9; Ibid.). In addition, although not depicted,

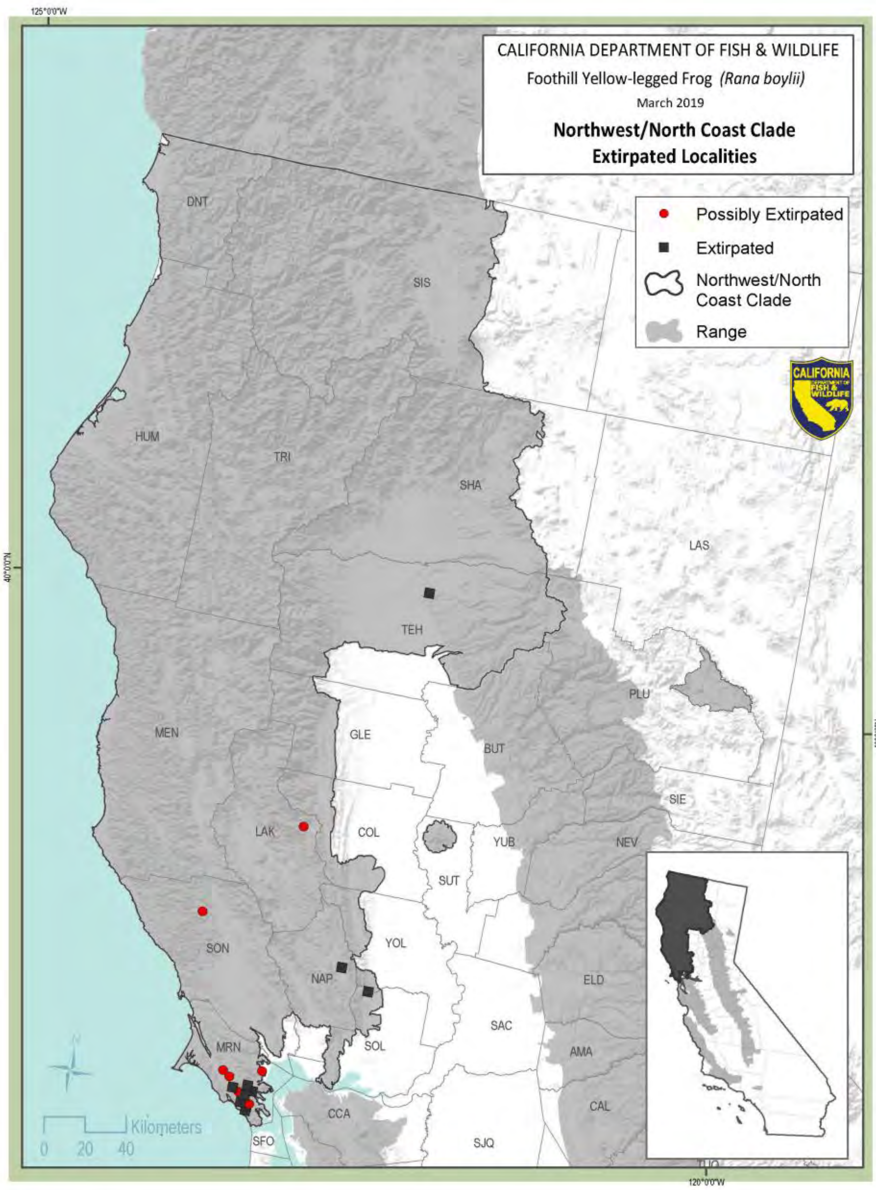

Figure 7. Possibly extirpated and extirpated Northwest/North Coast Foothill Yellow-legged Frog clade sites (CNDDB)

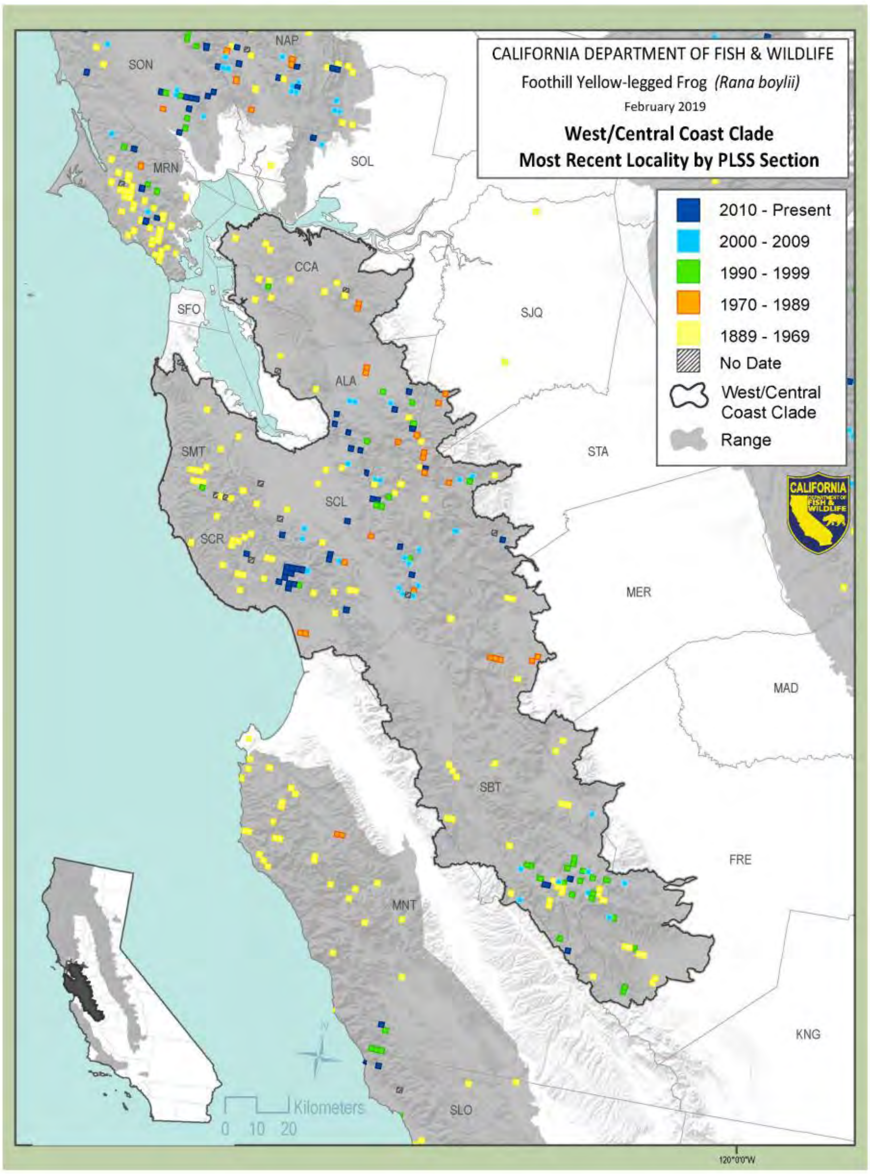

Figure 8. Close-up of West/Central Coast clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

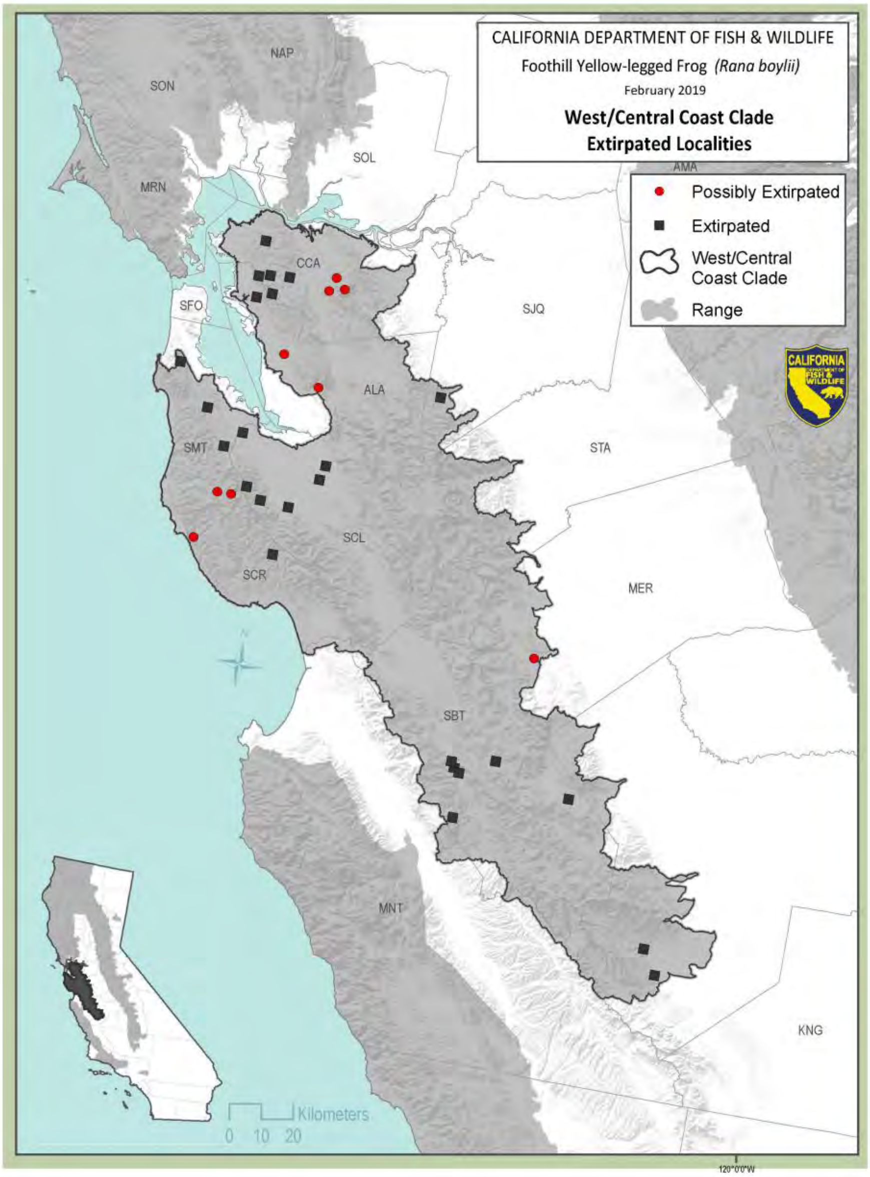

Figure 9. Possibly extirpated and extirpated West/Central Coast Foothill Yellow-legged Frog clade sites (CNDDB)

two populations on Arroyo Mocho and Arroyo Valle south of Livermore (Alameda County) are also likely extirpated (M. Grefsrud pers. comm. 2019).

The San Francisco Bay Area is heavily urbanized. Foothill Yellow-legged Frogs may be gone from Contra Costa County; eight of the nine CNDDB records from the county are museum specimens collected between 1891 and 1953, and the most recent observation was two adults in a plunge pool in an intermittent tributary to Moraga Creek in 1997. No recent (2010 or later) observations exist from San Mateo County (Ibid.). Historically occupied lower-elevation sites surrounding the San Francisco Bay and inland appear to be extirpated, but there are (or were) some moderately abundant breeding populations remaining at higher elevations in Arroyo Hondo (Alameda County), Alameda Creek (Alameda and Santa Clara counties), Coyote and Upper Llagas creeks (Santa Clara County), and Soquel Creek (Santa Cruz County) with some scattered smaller populations also persisting in these counties (J. Smith pers. comm. 2016, 2017; CNDDB 2019). The Alameda Creek and Coyote Creek populations recently underwent large-scale mortality events, so their numbers are likely substantially lower than what is currently reported in the CNDDB (Adams et al. 2017a, Kupferberg and Catenazzi 2019). In addition, the Arroyo Hondo population will lose approximately 1.6 km (1 mi) of prime breeding habitat (i.e., supported the highest density of egg masses on the creek) as the Calaveras Reservoir is refilled following its dam replacement project in 2019 (M. Grefsrud pers. comm. 2019). Foothill Yellow-legged Frogs may be extirpated from Corral Hollow Creek in San Joaquin County, but a single individual was observed five years ago further up the drainage in Alameda County within an Off-Highway Vehicle park (CNDDB 2019). Few recent sightings of Foothill Yellow-legged Frogs in the east-flowing creeks are documented. They may still be extant in the headwaters of Del Puerto Creek (western Stanislaus County), but the records further downstream indicate bullfrogs (known predators and disease reservoirs) are moving up the system (Ibid.). Several locations in southern San Benito, western Fresno, and eastern Monterey counties have relatively recent (2000 and later) detections (Ibid.). However, while many of these sites supported somewhat large populations in the 1990s, the more recent records report fewer than ten individuals (Ibid.). The exception is a Monterey County site where around 25 to 30 were observed in 2012 (Ibid.).

Southwest/South Coast

Widespread extirpations occurred decades ago, primarily in the 1960s and 1970s, in this area (Adams et al. 2017b). As a result, genetic samples were largely unavailable, and the boundaries are speculative. The clade is presumed to include the Coast Range from Monterey Bay south to the Transverse Range across to the San Gabriel Mountains. This clade includes portions of Monterey, San Luis Obispo, Santa Barbara, Ventura, and Los Angeles counties. Storer (1923) reported that Foothill Yellow-legged Frogs were collected for the first time in Monterey County in 1919 and that a specimen collected by Cope in 1889 in Santa Barbara and listed as *Rana temporaria pretiosa* may refer to the Foothill Yellow-legged Frog because as previously mentioned, the taxonomy of this species changed several times over the first century after it was named.

Foothill Yellow-legged Frogs had been widespread and fairly abundant in this area until the late 1960s (Figure 10) but were rapidly extirpated throughout the southern Coast Ranges and western Transverse

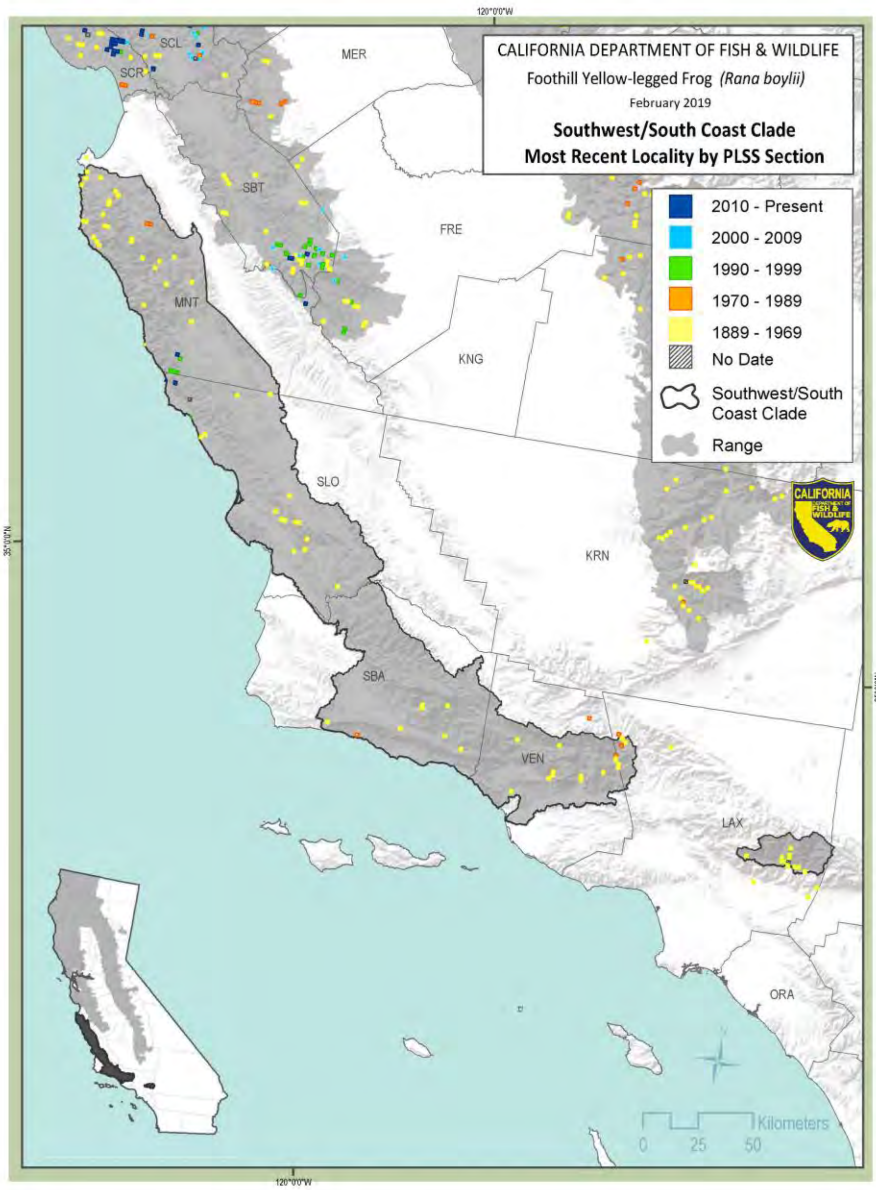

Figure 10. Close-up of Southwest/South Coast clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

Ranges by the mid-1970s (Figure 11; Sweet 1983, Adams et al. 2017b). Only two known extant populations exist from this clade, located near the border of Monterey and San Luis Obispo counties (S. Sweet pers. comm. 2017, McCartney-Melstad et al. 2018, Peek 2018, CNDDB 2019). They appear to be extremely small and rapidly losing genetic diversity, making them at high risk of extirpation (McCartney-Melstad et al. 2018, Peek 2018).

Northeast/Feather River and Northern Sierra

The exact clade boundaries in the Sierra Nevada are unclear and will require additional sampling and testing to define (Figure 12). The Northeast clade presumably encompasses the Feather River and Northern Sierra clades. The Feather River clade is located primarily in Plumas and Butte counties. The Northern Sierra clade roughly extends from the Feather River watershed south to the Middle Fork American River. It includes portions of El Dorado, Placer, Nevada, Sierra, and Plumas counties. It may also include portions of Amador, Butte, and eastern Tehama counties. No genetic samples were available to test in the Sutter Buttes or the disjunct population in northeastern Plumas County to determine which clades they belonged to before they were extirpated (Figure 13; Olson et al. 2016, CNDDB 2019).

In general, there is a paucity of historical Foothill Yellow-legged Frog data for west-slope Sierra Nevada streams, particularly in the lower elevations of the Sacramento Valley, and no quantitative abundance data exist prior to major changes in the landscape (i.e., mining, dams, and diversions) or the introduction of non-native species (Hayes et al. 2016). Foothill Yellow-legged Frogs have been collected frequently from the Plumas National Forest area in small numbers from the turn of the 20th century through the 1970s (Ibid.). Estimates of relative abundance are not clear from the records, but they suggest the species was somewhat widespread in this area.

More recently, Foothill Yellow-legged Frog populations in the Sierra Nevada have been the subject of a substantial number of surveys and focused research associated with recent and ongoing relicensing of hydroelectric power generating dams by the Federal Energy Regulatory Commission (FERC). Consequently, Foothill Yellow-legged Frogs have been observed in at least 30 areas in Plumas and Butte counties (roughly the Feather River clade) over the past five years (CNDDB 2019). As with the rest of the range, most records are observations of only a few individuals; however, many observations occurred over multiple years, and in some cases all life stages were observed over multiple years (Ibid). The populations appear to persist even with the small numbers reported. The only long-term consistent survey effort has been occurring on the North Fork Feather River along the Cresta and Poe reaches (GANDA 2018). The Cresta reach's subpopulation declined significantly in 2006 and never recovered despite modification of the flow regime to reduce egg mass and tadpole scouring and some habitat restoration (Ibid.). A pilot project to augment the Cresta reach's subpopulation through in situ captive rearing was initiated in 2017 (Dillingham et al. 2018). It resulted in the highest number of young-of-year Foothill Yellow-legged Frogs recorded during fall surveys since researchers started keeping count (Ibid.). The number of egg masses laid in the Poe reach varies substantially year-to-year from a low of 26 in 2001 to a high of 154 in 2015 and back down to 36 in 2017 (GANDA 2018).

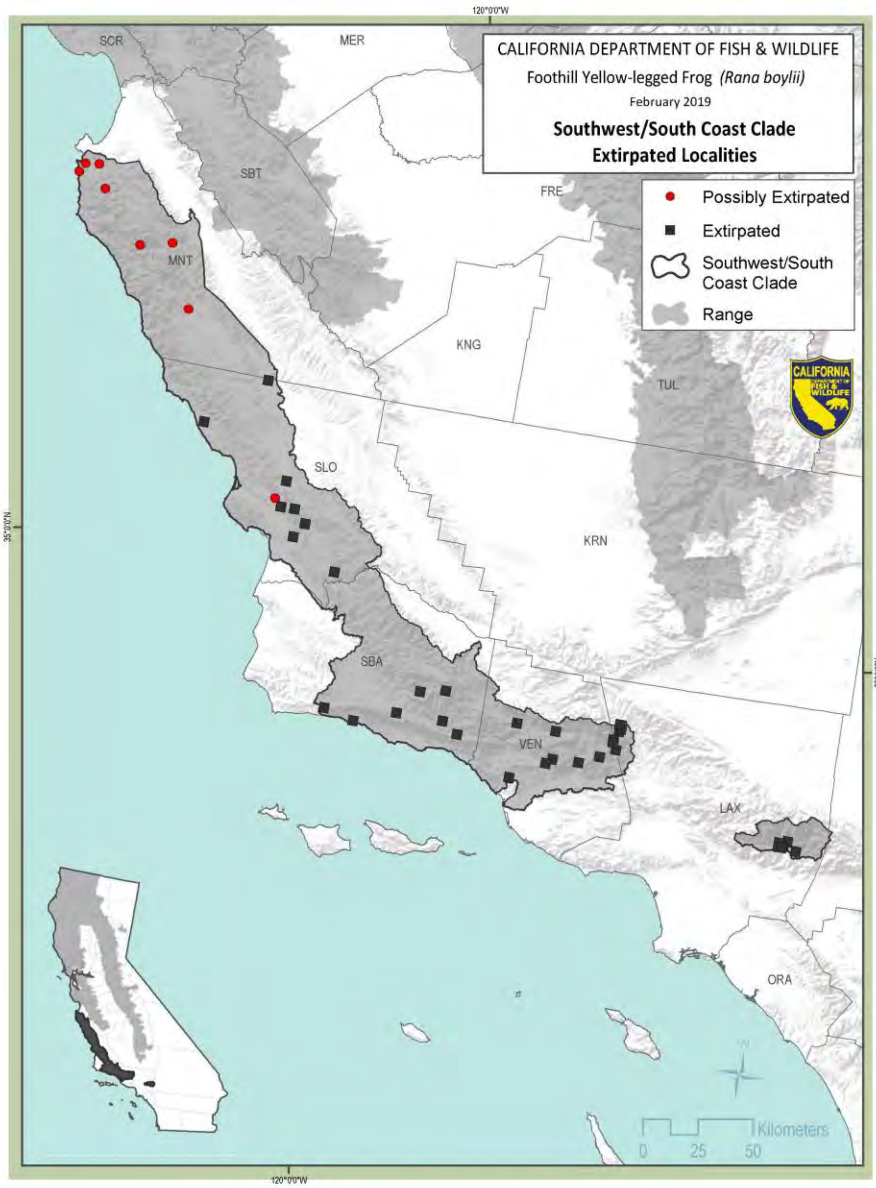

Figure 11. Possibly extirpated and extirpated Southwest/South Coast Foothill Yellow-legged Frog clade sites (CNDDB)

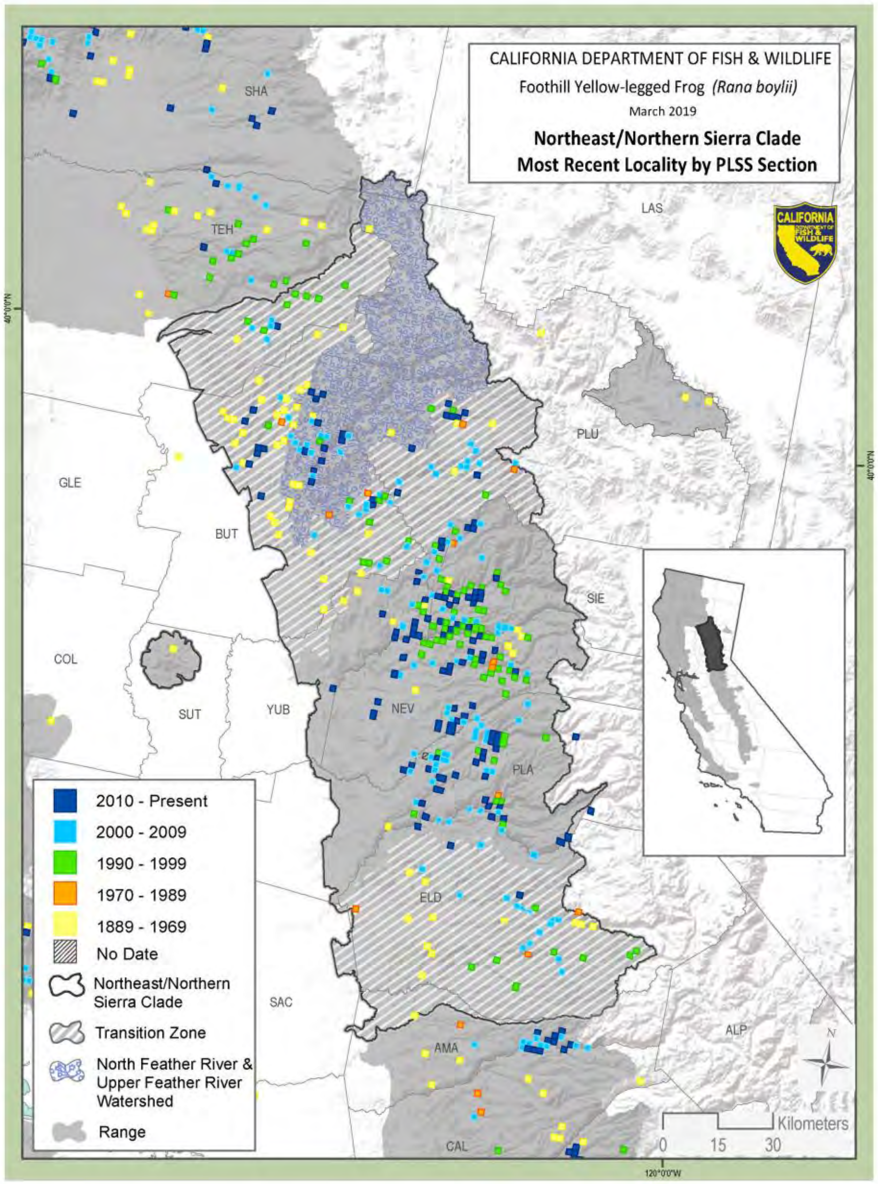

Figure 12. Close-up of Northeast/Feather River and Northern Sierra clades observations from 1889-2019 (ARSSC, BIOS, CNDDB)

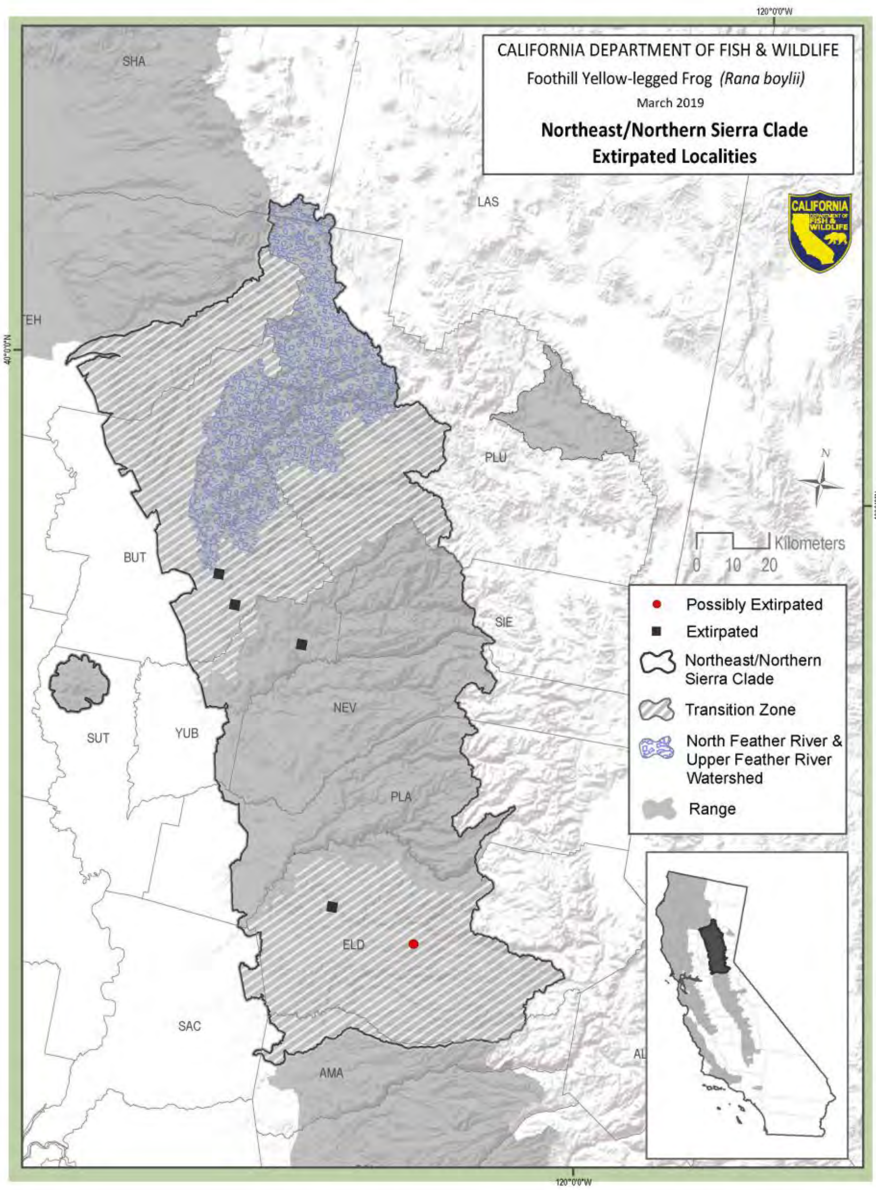

Figure 13. Possibly extirpated and extirpated Northeast/Feather River and Northern Sierra Foothill Yellow-legged Frog clades sites (CNDDB)

Foothill Yellow-legged Frogs have been observed in at least 71 areas in the past 5 years in the presumptive Northeast/Northern Sierra clade. The general pattern in this clade, and across the range for that matter, is that unregulated rivers or reaches have more areas that are occupied more consistently and in larger numbers than regulated rivers or reaches (CNDDB 2019, S. Kupferberg pers. comm. 2019). Foothill Yellow-legged Frogs were rarely observed in the hydropeaking reach of the Middle Fork American River and were observed in low numbers in the bypass reach, but they were present and breeding in small tributary populations (PCWA 2008). Relatively robust populations appear to inhabit the North Fork American River and Lower Rubicon River (Gaos and Bogan 2001, PCWA 2008, Hogan and Zuber 2012, K. Kundargi pers. comm. 2014, S. Kupferberg pers. comm. 2019). Additional apparently sufficiently large and relatively stable populations occur on Clear Creek, South Fork Greenhorn Creek, and Shady Creek (Nevada County) and the North and Middle Yuba River (Sierra County), but the remaining observations are of small numbers in tributaries with minimal connectivity among them (CNDDB 2019, S. Kupferberg pers. comm. 2019).

East/Southern Sierra

The East/Southern Sierra clade is presumed to range from the South Fork American River watershed, the northernmost site where individuals from this clade were collected, south to where the Sierra Nevada meets the Tehachapi Mountains. It likely includes El Dorado, Amador, Calaveras, Tuolumne, Mariposa, Madera, Fresno, Tulare, and Kern counties (Figure 14; Peek 2018). The proportion of extirpated sites in this clade is second only to the Southwest/South Coast and follows the pattern of greater losses in the south (Figure 15). Like the southern coastal clade, the southern Sierra clade has low genetic variability and a trajectory of continued loss of diversity (Ibid.).

Historical collections of small numbers of Foothill Yellow-legged Frogs occurred in every major river system within this clade beginning as early as the turn of the 20th century, indicating widespread distribution but little information on abundance (Hayes et al. 2016). By the early 1970s, declines in Foothill Yellow-legged Frog populations from this area were already apparent; Moyle (1973) found them at 30 of 95 sites surveyed in 1970. Notably bullfrogs inhabited the other 65 sites formerly occupied by Foothill Yellow-legged Frogs, and they co-occurred at only 3 sites (Ibid.). In 1992, Drost and Fellers (1996) revisited the sites around Yosemite National Park (Tuolumne and Mariposa counties) that Grinnell and Storer (1924) surveyed in 1915 and 1919. Foothill Yellow-legged Frogs had disappeared from all seven historically occupied sites and were not found at any new sites surveyed surrounding the park (Ibid.). Resurveys of previously occupied sites on the Stanislaus (Tuolumne County), Sierra (Fresno County), and Sequoia (Tulare County) National Forests were also undertaken (Lind et al. 2003b). Foothill Yellow-legged Frogs were absent from the sites in Sierra and Sequoia National Forests, six at each forest; however, a new population was discovered in the Sierra and two in the Sequoia forests (Ibid.). These populations remain extant but are small and isolated (CNDDB 2019). Two of the six sites on the Stanislaus were still occupied, and 19 new populations were found with evidence of breeding at seven of them (Lind et al. 2003b). Twenty of the 24 populations extant at the time inhabited unregulated waterways (Ibid.). Most of the CNDDB (2019) records of Foothill Yellow-legged Frogs on the Stanislaus are at least a decade old and are represented by low numbers.

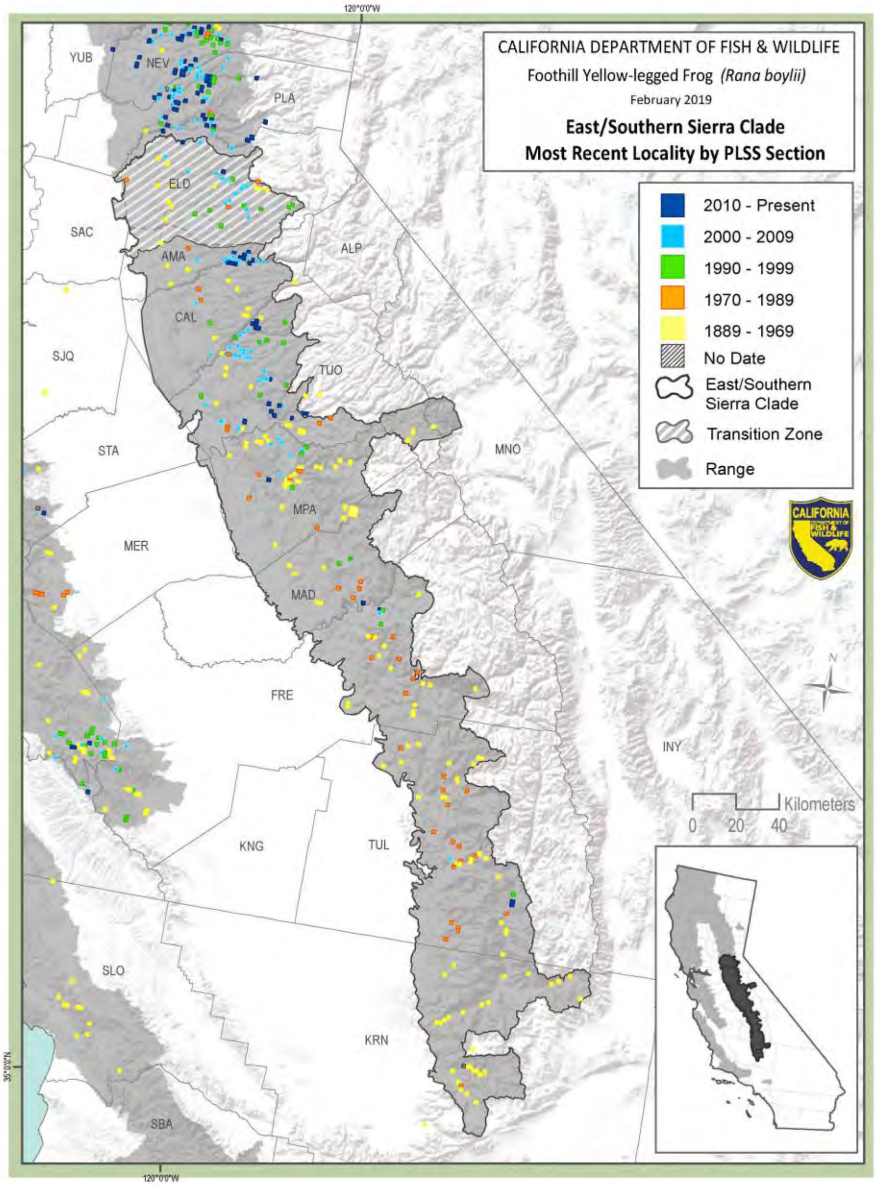

Figure 14. Close-up of East/Southern Sierra clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

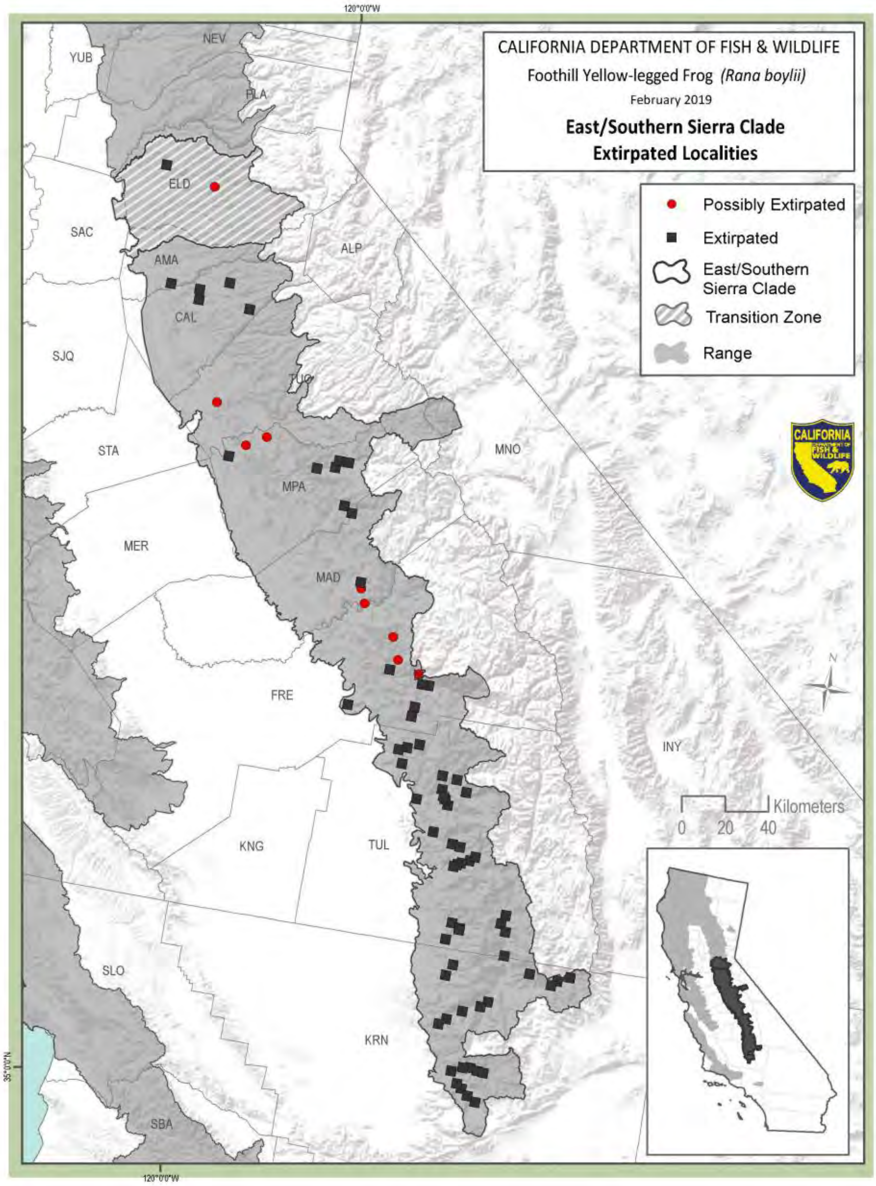

Figure 15. Possibly extirpated and extirpated East/Southern Sierra Foothill Yellow-legged Frog clade sites (CNDDB)

More recently, surveys for Foothill Yellow-legged Frogs were conducted along the South Fork American River as part of the El Dorado Hydroelectric Project's FERC license amphibian monitoring requirements (GANDA 2017). Between 2002 and 2016 counts of different life stages varied significantly by year but the trend for every life stage was a decline over that period (Ibid.). There appears to be a small population persisting along the North Fork Mokelumne River (Amador and Calaveras counties), but it was only productive during the 2012-2014 drought years (Ibid.). Small numbers have also been observed recently in several locations on private timberlands in Tuolumne County (CNDDB 2019).

FACTORS AFFECTING ABILITY TO SURVIVE AND REPRODUCE

"The fortunes of the boylii *population fluctuate with those of the stream"* - Tracy I. Storer, 1925

Several past and ongoing activities have changed the watersheds upon which Foothill Yellow-legged Frogs depend, and many interact with each other exacerbating their adverse impacts. With such an expansive range in California, the degree and severity of these impacts on the species often vary by location. To the extent feasible based on the best scientific information available, those differences are discussed below.

Dams, Diversions, and Water Operations

Foothill Yellow-legged Frogs evolved in a Mediterranean climate with predictable cool, wet winters and hot, dry summers~~,~~; ~~with~~ their life cycle is adapted to these conditions. In California and other areas with a Mediterranean climate, human demands for water are at the highest when runoff and precipitation are lowest, and annual water supply varies significantly but always follows the general pattern of peak discharge declining to baseflow in the late spring or summer (Grantham et al. 2010). The Foothill Yellow-legged Frog's life cycle depends on this discharge pattern and the specific habitat conditions it produces (see the Breeding and Rearing Habitat section). Dams are ubiquitous, but not evenly distributed, in California. Figure 16 depicts the locations of dams under the jurisdiction of the Army Corps of Engineers (ACOE) and the California Department of Water Resources (DWR). Figure 17 depicts the number of surface diversions per PLSS section within the Foothill Yellow-legged Frog's range (eWRIMS 2019).

Dam operations frequently change the amount and timing of water availability; its temperature, depth, and velocity; and its capacity to transport sediment ~~transport~~ and alter channel morphology ~~altering functions~~, all of which can result in dramatic consequences on the Foothill Yellow-legged Frog's ability to survive and successfully reproduce. Several studies comparing Foothill Yellow-legged Frog populations in regulated and unregulated reaches within the same watershed investigate potential dam-effects. These studies demonstrated that dams and their operations can result in several factors that contribute to population declines and possible extirpation. These factors include confusing breeding cues, scouring and stranding of egg masses and tadpoles, reduced quality and quantity of breeding and rearing habitat, reduced tadpole growth rate, barriers to gene flow, and establishment and spread of non-native species (Hayes et al. 2016). In addition, as previously discussed in the Population Structure and Genetic Diversity section, subpopulations of Foothill Yellow-legged Frogs on regulated rivers are more isolated, and the

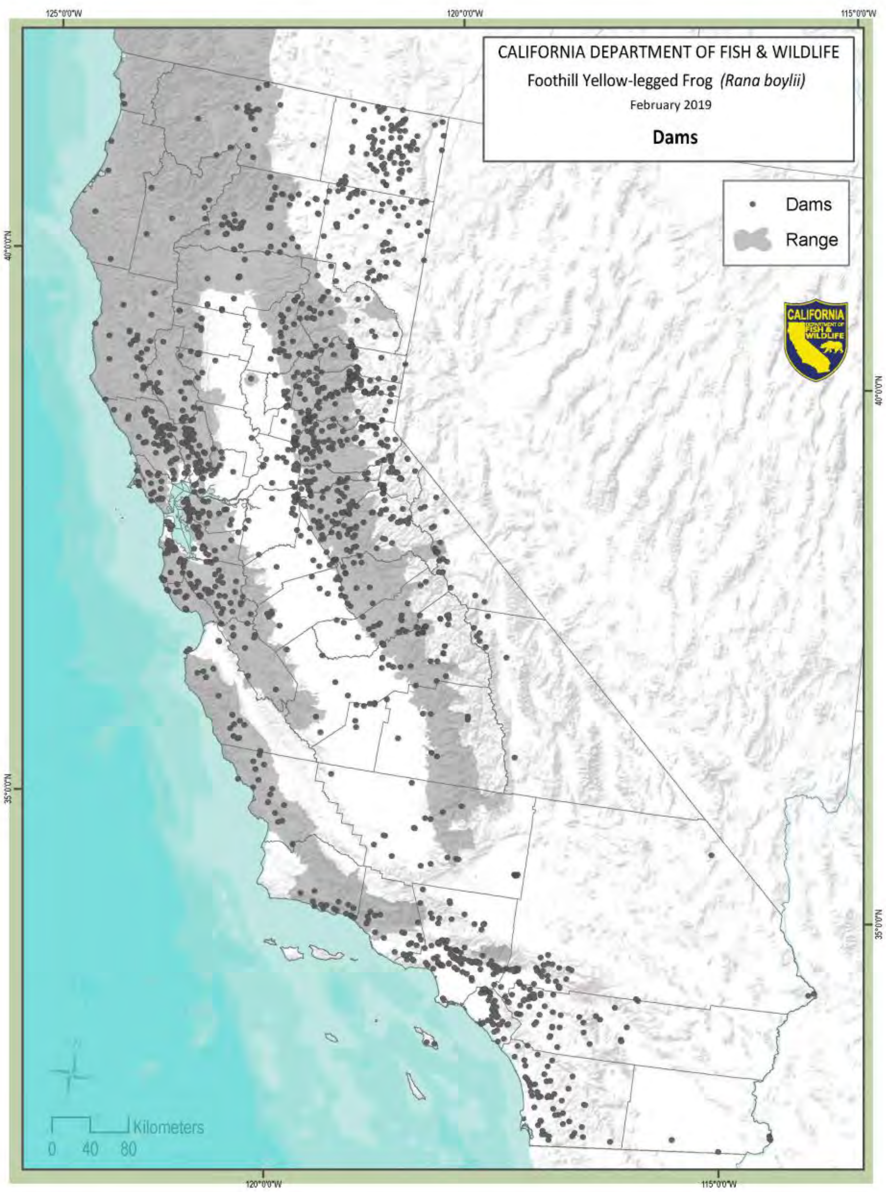

Figure 16. Locations of ACOE and DWR jurisdictional dams (DWR, FRS)

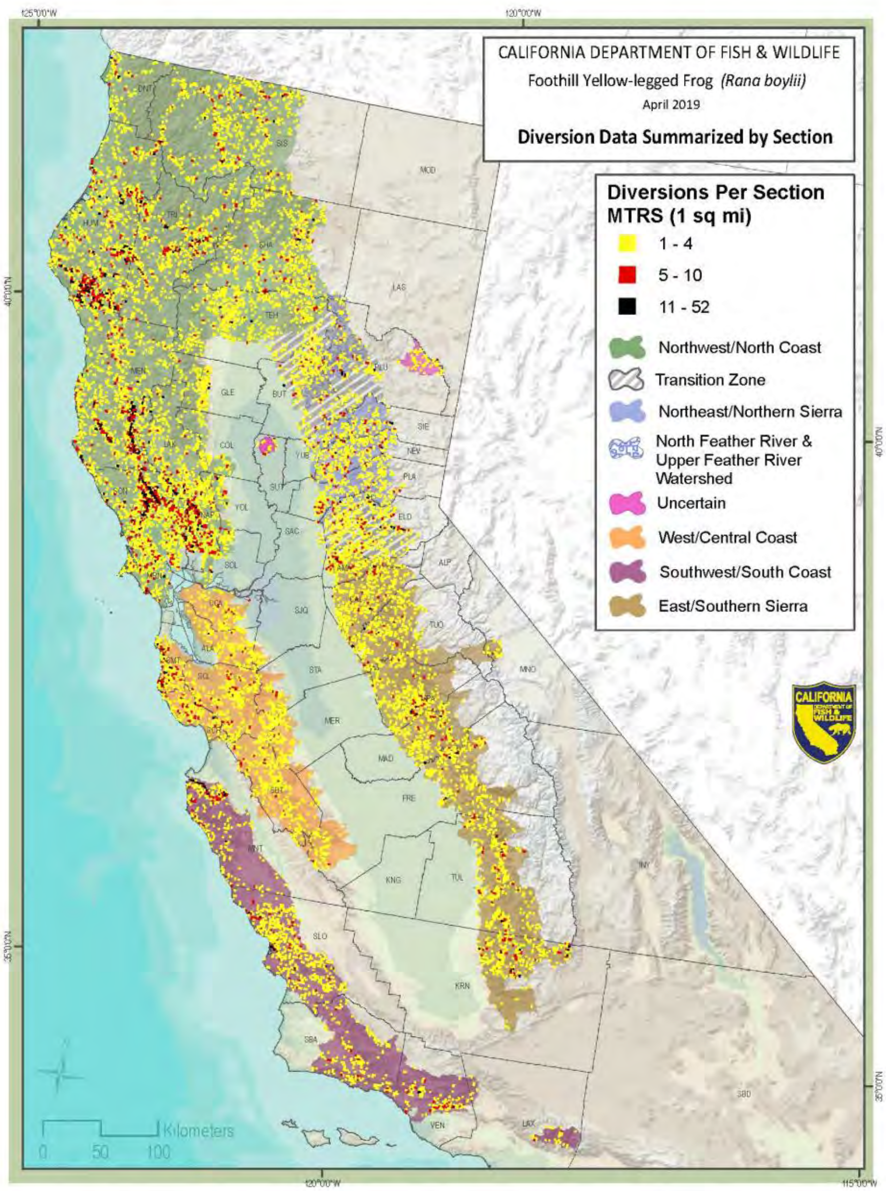

Figure 17. Number of surface water diversions per Public Lands Survey System section within the Foothill Yellow-legged Frog's range in California (eWRIMs)

type of water operations (hydropeaking vs. bypass flows) significantly affects the degree of gene flow loss among them (Peek 2011, 2018). Figure 18 depicts the locations of hydroelectric power plants.

As discussed in the Seasonal Activity and Movements section, cues for Foothill Yellow-legged Frogs to start breeding appear to involve water temperature and velocity, two features altered by dams. Dam operations typically result in reduced flows that are more stable over the course of a year than unimpaired conditions, and dam managers are frequently required to maintain thermally appropriate water temperatures and flows for cold-water-adapted salmonids (USFWS and Hoopa Valley Tribe 1999, Wheeler et al. 2014). For example, late-spring and summer water temperatures on the mainstem Trinity River below Lewiston Dam have been reported to be up to 10°C (20°F) cooler than average pre-dam temperatures, while average winter temperatures are slightly warmer (USFWS and Hoopa Valley Tribe 1999). As a result, Foothill Yellow-legged Frogs breed later on the mainstem Trinity River compared to six nearby tributaries, and some mainstem reaches may never attain the minimum required temperature for breeding (Wheeler et al. 2014, Snover and Adams 2016). In addition, annual discharges past Lewiston Dam have been 10-30% of pre-dam flows and do not mimic the natural hydrograph (Lind et al. 1996).

Aseasonal discharges from dams occur for several reasons including increased flow in late-spring and early summer to facilitate outmigration of salmonids, channel maintenance pulse flows, short-duration releases for recreational whitewater boating, rapid reductions after a spill (uncontrolled flows released down a spillway when reservoir capacity is exceeded) to retain water for power generation or water supply later in the year, peaking flows for hydroelectric power generation, and sustained releases to maintain the seismic integrity of the dam (Lind et al. 1996, Jackman et al. 2004, Kupferberg et al. 2011b, Kupferberg et al. 2012, Snover and Adams 2016). The results of a Foothill Yellow-legged Frog population viability analysis (PVA) suggest that the likelihood a population will persist is very sensitive to early life stage mortality; the 30-year probability of extinction increases significantly with high levels of egg or tadpole scouring or stranding (Kupferberg et al. 2009c). For instance, in 1991 and 1992, all egg masses laid before high flow releases to encourage outmigration of salmonids on the Trinity River were scoured away (Lind et al. 1996). According to the PVA, even a single annual pulse flow such as this or for recreational boating, can result in a three- to five-fold increase in the 30-year extinction risk based on amount of tadpole mortality experienced (Kupferberg et al. 2009c). Management after natural spills can also lead to substantial mortality. For example, in 2006, Foothill Yellow-legged Frogs on the North Fork Feather River bred during a prolonged spill, and the rapid recession below Cresta Dam that followed stranded and desiccated all the eggs laid (Kupferberg et al. 2009b). Rapid flows can also increase predation risk if tadpoles are forced to seek shelter under rocks where crayfish and other invertebrate predators are more common or if they are displaced into the water column where their risk of predation by fish is greater (Ibid.).

The overall reduction of flows and frequency of large winter floods below dams can produce extensive changes to Foothill Yellow-legged Frog habitat quality. They reduce the formation of river bars that are regularly used as breeding habitat, and they create deeper and steeper channels with less complexity and fewer warm, calm, shallow edgewater habitats for tadpole rearing (Lind et al. 1996, Wheeler and Welsh 2008, Kupferberg et al. 2011b, Wheeler et al. 2014). For example, 26 years after construction of

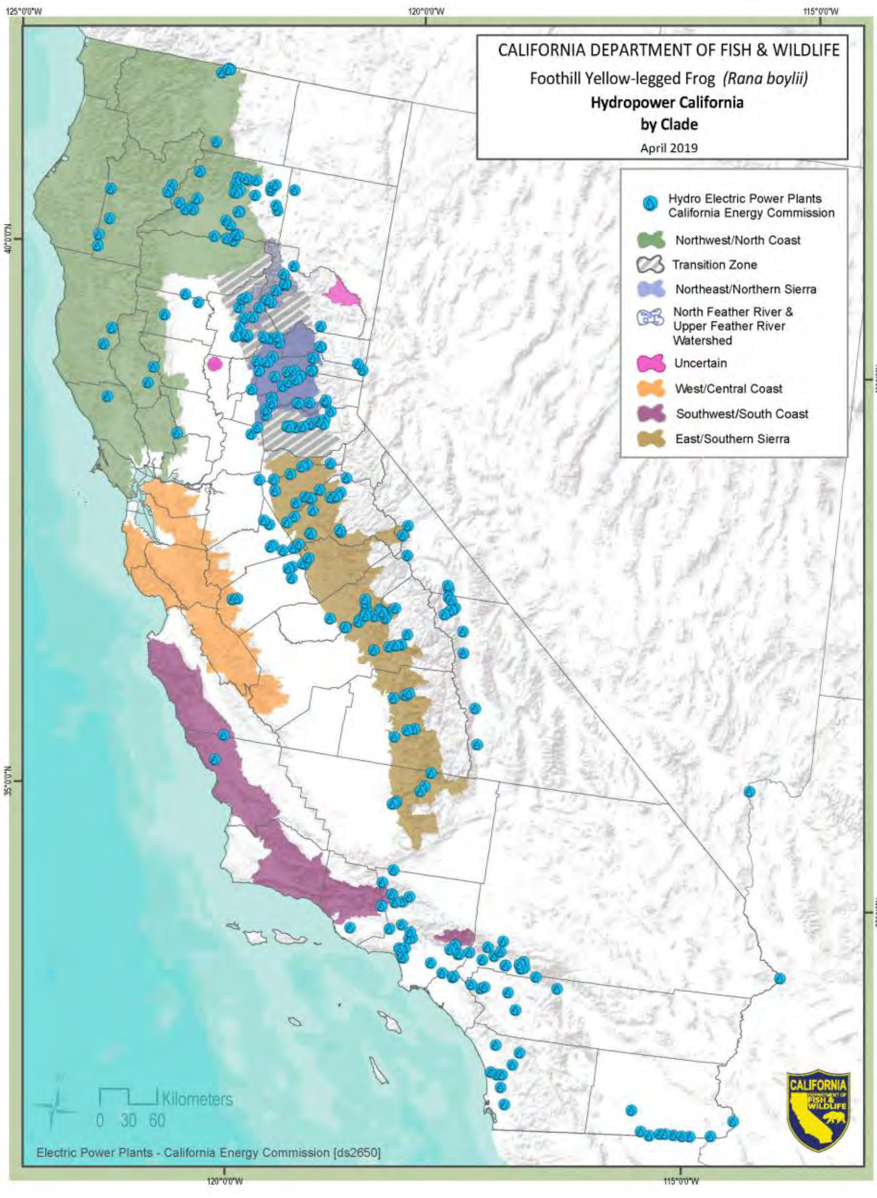

Figure 18. Locations of hydroelectric power generating dams (BIOS)

the Lewiston Dam on the Trinity River, habitat changes in a 63 km (39 mi) stretch from the dam downstream were evaluated (Lind et al. 1996). Riparian vegetation went from covering 30% of the riparian area pre-dam to 95% (Ibid.). Additionally, river bars made up 70% of the pre-dam riparian area compared to 4% post-dam, amounting to a 94% decrease in available Foothill Yellow-legged Frog breeding habitat (Ibid.).

Several features of riverine habitat below dams can decrease tadpole growth rate and other measures of fitness. As ectotherms, Foothill Yellow-legged Frogs require temperatures that support their metabolism, food conversion efficiency, growth, and development, and these temperatures may not be reached until late in the season, or not at all, when the water released is colder than their lower thermal limit (Kupferberg et al. 2011a, Catenazzi and Kupferberg 2013, Wheeler et al. 2014). Colder temperatures and higher flows reduce time spent feeding and efficiency at food assimilation, resulting in slower growth and development (Kupferberg et al. 2011a,b; Catenazzi and Kupferberg 2018). Large bed-scouring winter floods promote greater *Cladophora glomerate* blooms, the filamentous green alga that dominates primary producer biomass during the tadpole rearing season (Power et al. 2008, Kupferberg et al. 2011a). The period of most rapid tadpole growth often coincides with blooms of highly nutritious and more easily assimilated epiphytic diatoms, so reduced flows can have food-web impacts on tadpole growth and survival (Power et al. 2008, Kupferberg et al. 2011a, Catenazzi and Kupferberg 2018). In addition, colder temperatures and fluctuating summer flows, such as those released for hydroelectric power generation, can reduce the amount of algae available for grazing and can change the algal assemblage to one dominated by mucilaginous stalked diatoms like *Didymosphenia* ~~*geminate*~~ *geminata* that have low nutritional value (Spring Rivers Ecological Sciences 2003, Kupferberg et al 2011a, Furey et al. 2014). Altered temperatures, flows, and food quality can contribute to slower growth and development, longer time to metamorphosis, smaller size at metamorphosis, and reduced body condition, which adversely impact fitness (Kupferberg et al. 2011b, Catenazzi and Kupferberg 2018).

As discussed in more detail in the Population Structure and Genetic Diversity section, both are strongly affected by river regulation (Peek 2011, 2018; Stillwater Sciences 2012). Foothill Yellow-legged Frogs primarily use watercourses as movement corridors, so the reservoirs created behind dams are often uninhabitable and represent barriers to gene flow (Bourque 2008; Peek 2011, 2018). This decreased connectivity can lead to loss of genetic diversity, inducing a species' ability to adapt to changing conditions (Palstra and Ruzzante 2008).

Decreased winter discharge below dams facilitates establishment and expansion of invasive bullfrogs, whose tadpoles require overwintering and are not well-adapted to flooding events (Lind et al. 1996, Doubledee et al. 2003). Where they occur, bullfrogs tend to dominate areas more altered by dam operations than less impaired areas that support a higher proportion of native species (Moyle 1973, Fuller et al. 2011). In addition to downstream effects, the reservoirs created behind dams directly destroy lotic (flowing) Foothill Yellow-legged Frog habitat, typically do not retain natural riparian communities due to fluctuating water levels, are often managed for human activities not compatible with the species' needs, and act as a source of introduced species upstream and downstream (Brode and Bury 1984, PG&E 2018). Moyle and Randall (1998) identified characteristics of sites with low native biodiversity in the Sierra Nevada foothills; they were often drainages that had been dammed and

diverted in lower- to middle-elevations and dominated by introduced fishes and bullfrogs. Even small-scale operations can have significant effects. Some farming operations divert water during periods of high flows and store it in small impoundments for use during low flow-high need times; these ponds can serve as sources for introduced species like bullfrogs to spread into areas where the habitat would otherwise be unsuitable (Kupferberg 1996b).

The mechanisms described above result in the widespread pattern of greater Foothill Yellow-legged Frog density in unregulated rivers and in reaches far enough downstream of a dam to experience minimal effects from it (Lind et al. 1996, Kupferberg 1996a, Bobzien and DiDonato 2007, Peek 2011). Abundance in unregulated rivers averages five times greater than population abundance downstream of large dams (Kupferberg et al. 2012). Figure 19 depicts a comprehensive collection of egg mass density data where at least four years of surveys have been undertaken, showing much lower abundance in regulated (S. Kupferberg pers. comm. 2019). In California, Foothill Yellow-legged Frog presence is associated with an absence of dams or with only small dams far upstream (Lind 2005, Kupferberg et al. 2012). Hydroelectric power generation from Sierra Nevada rivers accounts for nearly half its statewide production and about 9% of all electrical power used in California (Dettinger et al. 2018). Every major stream below 600 m (1968 ft) in the Sierra Nevada has at least one large reservoir (≥ 0.12 km^3 [100,000 ac-ft]), and many have multiple medium and small ones (Hayes et al. 2016). Because of this, Catenazzi and Kupferberg (2017) posit that the dam-effect on Foothill Yellow-legged Frog populations is likely greater in the Sierra Nevada than the Coast Range because dams are more often constructed in a series along a river in the former and spaced close enough together such that suitable breeding temperatures may never occur in the intervening reaches.

Pathogens and Parasites

Perhaps the most widely recognized amphibian disease is chytridiomycosis, which is caused by the fungal pathogen *Batrachochytrium dendroabatidis* (Bd). Implicated in the decline of over 500 amphibian species, including 90 presumed extinctions, it represents the greatest recorded loss of biodiversity attributable to a disease (Scheele et al. 2019). The global trade in American Bullfrogs (primarily for food) is connected to the disease's spread because the species can persist with low-level Bd infections without developing chytridiomycosis (Yap et al. 2018). Previous studies suggested Foothill Yellow-legged Frogs may not be susceptible to Bd-associated mass mortality; skin peptides strongly inhibited growth of the fungus in the lab, and the only detectable difference between Bd+ and Bd- juvenile Foothill Yellow-legged Frogs was slower growth (Davidson et al. 2007). At Pinnacles National Park in 2006, 18% of post-metamorphic Foothill Yellow-legged Frogs tested positive for Bd; all were asymptomatic and at least one Bd+ Foothill Yellow-legged Frog subsequently tested negative, demonstrating an ability to shed the fungus (Lowe 2009). However, recent studies have found historical evidence of Bd contributing to the extirpation of Foothill Yellow-legged Frogs in southern California, an acute die-off in 2013 in the Alameda Creek watershed, and another in 2018 in Coyote Creek (Adams et al. 2017a,b; Kupferberg and Catenazzi 2019). Evaluation of museum specimens indicates lower Bd prevalence (proportion of individuals infected) in Foothill Yellow-legged Frogs than most other co-occurring amphibians in southern California in the first part of the 20th century, but it spiked in the 1970s just prior to the last observation of an individual in 1977 (Adams et al. 2017b). Two museum specimens collected in 1966,

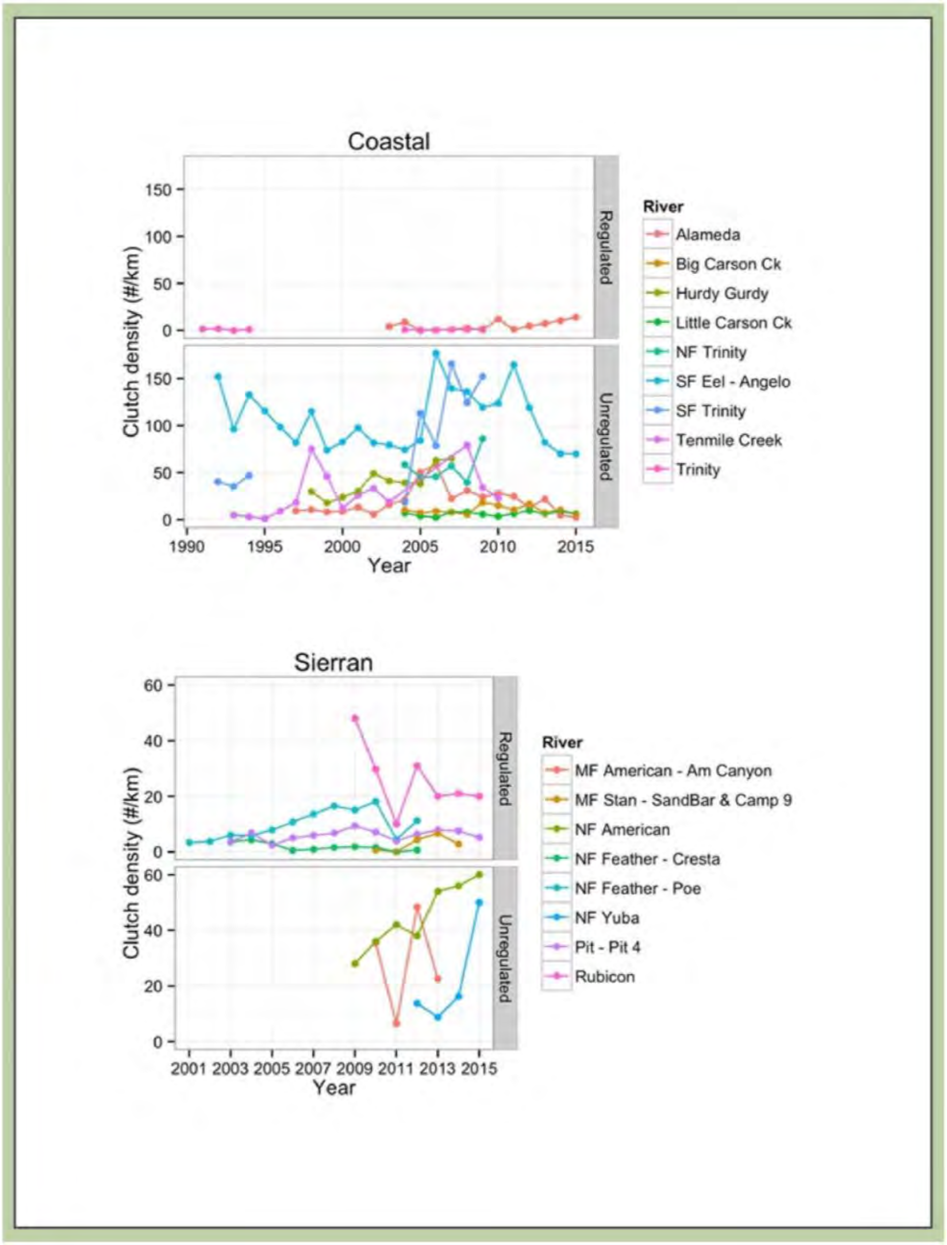

Figure 19. Foothill Yellow-legged Frog Egg mass density estimates along the coast from 1990-2015 and the Sierra Nevada from 2001-2015 from multiple studies compiled by S. Kupferberg (2019)

one from Santa Cruz County and the other from Alameda County, provide the earliest evidence of Bd in Foothill Yellow-legged Frogs in central California (Padgett-Flohr and Hopkins 2009). In contrast to the southern California results, Foothill Yellow-legged Frogs possessed the highest Bd prevalence among all amphibians tested in coastal Humboldt County in 2013 and 2014; however, zoospore (the aquatic dispersal agent) loads were well below the presumed lethal density threshold (Ecoclub Amphibian Group et al. 2016).

In addition to bullfrogs, the native Pacific Treefrog (*Pseudacris regilla*) seems immune to the lethal effects of chytridiomycosis, and owing to its broad ecological tolerances, more terrestrial lifestyle, and relatively large home range size and dispersal ability, the species is ubiquitous across California (Padgett-Flohr and Hopkins 2009). In a laboratory experiment, Bd-infected Pacific Treefrogs shed an average of 68 zoospores per minute, making them the prime candidate for spreading and maintaining Bd in areas where bullfrogs do not occur (Padgett-Flohr and Hopkins 2009, Reeder et al. 2012). In the wild, Pacific Treefrog populations persisted at 100% of sites in the Sierra Nevada (above 1500 m [4920 ft]) where a sympatric ranid species had been extirpated from 72% of its formerly occupied sites due to a Bd outbreak (Reeder et al. 2012). This is consistent with the results of a model that incorporated Bd habitat suitability, host availability, and invasion history in North America, which concluded west coast mountain ranges were at the greatest risk from the disease (Yap et al. 2018).

Several other pathogens and parasites have been encountered with Foothill Yellow-legged Frogs, but none have been ascribed to large-scale mortality events. Another fungus, a water mold (*Saprolegnia* sp.) carried by fish, is an important factor in amphibian embryo mortality in the Pacific Northwest (Blaustein et al. 1994, Kiesecker and Blaustein 1997). Fungal infections of Foothill Yellow-legged Frog egg masses, potentially from *Saprolegnia*, have been observed in the mainstem Trinity River (Ashton et al. 1997). *Saprolegnia* infection is more likely to occur in ponds and lakes, particularly if stocked by hatchery-raised fish into previously fishless areas and when frogs use communal oviposition sites, so it likely does not represent a major source of mortality in Foothill Yellow-legged Frogs (Blaustein et al. 1994, Kiesecker and Blaustein 1997). However, they may be more susceptible to *Saprolegnia* infection when exposed to other environmental stressors that compromise their immune defenses (Blaustein et al. 1994, Kiesecker and Blaustein 1997).

The trematode parasite *Ribeiroia ondatrae* is responsible for limb malformations in ranids (Stopper et al. 2002). *Ribeiroia ondatrae* was detected on a single Foothill Yellow-legged Frog during a study on malformations, but its morphology was normal (Kupferberg et al. 2009a). The results of the study instead linked malformations in Foothill Yellow-legged Frog tadpoles and young-of-year to the Anchor Worm (*Lernaea cyprinacea*), a parasitic copepod from Eurasia (Ibid.). Prevalence of malformations was low, under 4% of the population in both years of study, but there was a pattern of infected individuals metamorphosing at a smaller size, which as previously mentioned can have implications on fitness (Ibid.). Three other species of helminths (parasitic worms) were encountered during the study (*Echinostoma* sp., *Manodistomum* sp., and *Gyrodactylus* sp.); their relative impact on their hosts is unknown, but at least one Foothill Yellow-legged Frog had 700 echinostome cysts in its kidney (Ibid.). Bursey et al. (2010) discovered 13 species of helminths in and on Foothill Yellow-legged Frogs from

Humboldt County. Most are common in anurans, and some are generalists with multiple possible hosts, but studies on their impact on Foothill Yellow-legged Frogs are lacking (Ibid.).

Introduced Species

Species not native to an area, but introduced, can alter food webs and ecosystem processes through predation, competition, hybridization, disease transmission, and habitat modification. Native species lack evolutionary history with introduced species, and early life stages of native anurans are particularly susceptible to predation by aquatic non-native species (Kats and Ferrer 2003). Because introduced species often establish in highly modified habitats, it can be difficult to differentiate between impacts from habitat degradation and the introduced species (Fisher and Shaffer 1996). However, native amphibians have been frequently found successfully reproducing in heavily altered habitats when introduced species were absent, suggesting introduced species themselves can impose an appreciable adverse effect (Ibid.). Numerous introduced species have been documented to adversely impact Foothill Yellow-legged Frogs or are suspected of doing so.

American Bullfrogs were introduced to California from the eastern U.S. around the turn of the 20th century, likely in response to overharvest of native ranids by the frog-leg industry that accompanied the Gold Rush (Jennings and Hayes 1985). Nearly 50 years ago, Moyle (1973) reported that distributions of Foothill Yellow-legged Frogs and bullfrogs in the Sierra Nevada foothills were nearly mutually exclusive. He speculated that bullfrog predation and competition may be causal factors in their disparate distributions in addition to the habitat degradation from dams and diversions that facilitated the bullfrog invasion in the first place. In a study along the South Fork Eel River and one of its tributaries, Foothill Yellow-legged Frog abundance was nearly an order of magnitude lower in reaches where bullfrogs were well established (Kupferberg 1997a). At a site in Napa Valley, after bullfrogs were eradicated, Foothill Yellow-legged Frogs, among other native species, recolonized the area (J. Alvarez pers. comm. 2018). In a mesocosm experiment, Foothill Yellow-legged Frog survival in control enclosures measured half that of enclosures containing bullfrog and Foothill Yellow-legged Frog tadpoles, and they weighed approximately one-quarter lighter at metamorphosis (Kupferberg 1997a). The mechanism for these declines appeared to be the reduction of high quality algae by bullfrog tadpole grazing, as opposed to any behavioral or chemical interference (Ibid.). Adult bullfrogs, which can get very large (9.0-15.2 cm [3.5-6.0 in]), also directly consume Foothill Yellow-legged Frogs, including adults (Moyle 1973, Crayon 1998, Powell et al. 2016). Silver (2017) noted that she never heard Foothill Yellow-legged Frogs calling in areas with bullfrogs, which has implications for breeding success; she speculated the lack of vocalizations may have been a predator avoidance strategy.

Commented [SK1]: This is terrific!

As discussed briefly in the Pathogens and Parasites section, American Bullfrogs act as reservoirs and vectors of the lethal chytrid fungus. In museum specimens from both southern and central California, Bd was detected in bullfrogs before it was detected in Foothill Yellow-legged Frogs in the same area (Padgett-Flohr and Hopkins 2009, Adams et al. 2017b). During a die-off from chytridiomycosis that commenced in 2013, Bd prevalence and load in Foothill Yellow-legged Frogs was positively predicted by bullfrog presence (Adams et al. 2017a). A similar die-off in 2018 from a nearby county appears to be related to transmission by bullfrogs as well (Kupferberg and Catenazzi 2019). In addition, male Foothill

Yellow-legged Frogs have been observed amplexing female bullfrogs, which may not only constitute wasted reproductive effort but could serve to increase their likelihood of contracting Bd (Lind et al. 2003a). In fact, adult males were more likely to be infected with Bd than females or juveniles during the recent die-off in Alameda Creek (Adams et al. 2017a). African Clawed Frogs (*Xenopus laevis*) have also been implicated in the spread of Bd in California because like bullfrogs, they are asymptomatic carriers (Padgett-Flohr and Hopkins 2009). However, African Clawed-Frog distribution only minimally overlaps with the Foothill Yellow-legged Frog's range unlike the widespread bullfrog (Stebbins and McGuinness 2012).

Hayes and Jennings (1986) observed a negative association between the abundance of introduced fish and Foothill Yellow-legged Frogs. Rainbow trout (*Onchorynchus mykiss*) and green sunfish (*Lepomis cyanellus*) are suspected of destroying egg masses (Van Wagner 1996). Bluegill sunfishes (*L. macrochirus*) are likely predators; in captivity when offered eggs and tadpoles of two ranid species, they consumed both life stages but a significantly greater number of tadpoles (Werschkul and Christensen 1977). Common hatchery-stocked fish like brook (*Salvelinus fontinalis*) and rainbow trout commonly carry ~~of~~ *Saprolegnia* (Blaustein et al. 1994). In addition, presence of non-native fish can facilitate bullfrog invasions by reducing the density of macroinvertebrates that prey on their tadpoles (Adams et al. 2003). Foothill Yellow-legged Frog tadpoles raised from eggs from sites with and without smallmouth bass (*Micropterus dolomieu*) did not differ in their responses to exposure to the non-native, predatory bass and a native, non-predatory fish (Paoletti et al. 2011). This result suggests that Foothill Yellow-legged Frogs have not yet evolved a recognition of bass as a threat, which makes them more vulnerable to predation (Ibid.).

Introduced into several areas within the Coast Range and Sierra Nevada, signal crayfish have been recorded preying on Foothill Yellow-legged Frog egg masses and are suspected of preying on their tadpoles based on observations of tail injuries that looked like scissor snips (Riegel 1959, Wiseman et al. 2005). The introduced red swamp crayfish (*Procambarus clarkii*) likely also preys on Foothill Yellow-legged Frogs. Because Foothill Yellow-legged Frogs evolved with native crayfish in northern California, individuals from those areas may more effectively avoid crayfish predation than in other parts of the state where they are not native (Riegel 1959, USFWS 1998, Kats and Ferrer 2003). The Foothill Yellow-legged Frog's naiveté ~~naivety~~ to crayfish was demonstrated in a study that showed they did not change behavior when exposed to signal crayfish chemical cues, but once the crayfish was released and consuming Foothill Yellow-legged Frog tadpoles, the survivors, likely reacting to chemical cues from dead tadpoles, did respond (Kerby and Sih 2015).

Sedimentation

Several anthropogenic activities, some of which are described in greater detail below, can artificially increase sedimentation into waterways occupied by Foothill Yellow-legged Frogs and adversely impact biodiversity (Moyle and Randall 1998). These activities include but are not limited to mining, agriculture, overgrazing, timber harvest, and poorly constructed roads (Ibid.). Increased fine sediments can substantially degrade Foothill Yellow-legged Frog habitat quality. Heightened turbidity decreases light penetration that phytoplankton and other aquatic plants require for photosynthesis (Cordone and Kelley

1961). When silt particles fall out of the water column, they can destroy algae by covering the bottom of the stream (Ibid.). Algae are not only important for Foothill Yellow-legged Frog tadpoles as forage but also oxygen production (Ibid.). Sedimentation may impede attachment of egg masses to substrate (Ashton et al. 1997). The effect of silt accumulation on embryonic development is unknown, but it does make them less visible, which could decrease predation risk (Fellers 2005). Fine sediments can fill interstitial spaces between rocks that tadpoles use for shelter from high velocity flows and cover from predators and that serve as sources for aquatic invertebrate prey for post-metamorphic Foothill Yellow-legged Frogs (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b).

Mining

Current mining practices, as well as legacy effects from historical mining operations, may adversely impact Foothill Yellow-legged Frogs through contaminants, direct mortality, habitat destruction and degradation, and behavioral disruption. While mercury in streams can result from atmospheric deposition, storm-induced runoff of naturally occurring mercury, agricultural runoff, and geothermal springs, runoff from historical mine sites mobilizes a significant amount of mercury (Foe and Croyle 1998, Alpers et al. 2005, Hothem et al. 2010). Beginning in the mid-1800s, extensive mining occurred in the Coast Range to supply mercury for gold mining in the Sierra Nevada, causing widespread contamination of both mountain ranges and the rivers in the Central Valley (Foe and Croyle 1998). Studies on Foothill Yellow-legged Frog tissues collected from the Cache Creek (Coast Ranges) and Greenhorn Creek (Sierra Nevada) watersheds revealed mercury bioaccumulation concentrations as high as 1.7 and 0.3 µg/g (ppm), respectively (Alpers et al. 2005, Hothem et al. 2010). For context, the U.S. Environmental Protection Agency's mercury criterion for issuance of health advisories for fish consumption is 0.3 µg/g; concentrations exceeded this threshold in Foothill Yellow-legged Frog tissues at 62% of sampling sites in the Cache Creek watershed (Hothem et al. 2010). Bioaccumulation of this powerful neurotoxin can cause deleterious impacts on amphibians including inhibited growth, decreased survival to metamorphosis, increased malformations, impaired reproduction, and other sublethal effects (Zillioux et al. 1993, Unrine et al. 2004). In a study measuring Sierra Nevada watershed health, Moyle and Randall (1998) reportedly found very low biodiversity in streams that were heavily polluted by acidic water leaching from historical mines. Acidic drainage measured as low as 3.4 pH from some mined areas in the northern Sierra Nevada (Alpers et al. 2005).

Widespread suction dredging for gold occurred in the Foothill Yellow-legged Frog's California range until enactment of a moratorium on issuing permits in 2009 (Hayes et al. 2016). Suction dredging vacuums up the contents of the streambed, passes them through a sluice box to separate the gold, and then deposits the tailings on the other side of the box (Harvey and Lisle 1998). While most habitat disturbance is localized and minor, it can be especially detrimental if it degrades or destroys breeding and rearing habitat through direct disturbance or sedimentation (Ibid.). In addition, this activity can lead to direct mortality of early life stages through entrainment, and those eggs and tadpoles that do survive passing through the suction dredge may experience greater mortality due to subsequent unfavorable physiochemical conditions and possible increased predation risk (Ibid.). Suction dredging can also reduce the availability of invertebrate prey, although this impact is typically short-lived (Ibid.). Suction dredging alters stream morphology, and relict tailing ponds can serve as breeding habitat for bullfrogs in areas

that would not normally support them (Fuller et al. 2011). However, in some areas these mining holes have reportedly benefited Foothill Yellow-legged Frogs by creating cool persistent pools that adult females appeared to prefer at one Sierra Nevada site (Van Wagner 1996). Senate Bill 637 (2015) directs the Department to work with the State Water Resources Control Board (SWRCB) to develop a statewide water quality permit that would authorize the use of vacuum or suction dredge equipment in California under conditions set forth by the two agencies. SWRCB staff, in coordination with Department staff, are in the process of collecting additional information to inform the next steps that will be taken by the SWRCB (SWRCB 2019).

Instream aggregate (gravel) mining continues today and can have similar impacts to suction dredge mining by removing, processing, and relocating stream substrates (Olson and Davis 2009). This type of mining typically removes bars used as Foothill Yellow-legged Frog breeding habitat and reduces habitat heterogeneity by creating flat wide channels (Kupferberg 1996a). Typically, when listed salmonids are present, mining must be conducted above the wetted edge, but this practice can create perennial off-channel bullfrog breeding ponds (M. van Hattem pers. comm. 2018).

Agriculture

Direct loss of Foothill Yellow-legged Frog habitat from wildland conversion to agriculture is rare because the typically rocky riparian areas they inhabit are usually not conducive to farming, but removal of riparian vegetation directly adjacent to streams for agriculture is more common and widespread. The U.S. Department of Agriculture classifies 3.9 million ha (9.6 million ac) in California as cropland, which amounts to less than 10% of the state's land area, and 70% of this occurs in the Central Valley between Redding and Bakersfield (Martin et al. 2018). In addition, several indirect impacts can adversely affect Foothill Yellow-legged Frogs at substantial distances from agricultural operations such as effects from runoff (sediments and agrochemicals), drift and deposition of airborne pollutants, water diversions, and creation of novel habitats like impoundments that facilitate spread of detrimental non-native species. As sedimentation and introduced species impacts were previously discussed, this section instead focuses on the other possible adverse impacts.

Agrochemicals

Many species of amphibians, particularly ranids, have experienced declines throughout California, but the most dramatic declines have occurred in the Sierra Nevada east of the San Joaquin Valley where 60% of the total pesticide usage in the state was sprayed (Sparling et al. 2001). Agrochemicals applied to crops in the Central Valley can volatilize and travel in the atmosphere and deposit in higher elevations (LeNoir et al. 1999). Pesticide concentrations diminish as elevations increase in the lower foothills but change little from 533 to 1,920 m (1,750-6,300 ft), which coincides with the Foothill Yellow-legged Frog's elevational range (Ibid). Foothill Yellow-legged Frog absence at historically occupied sites in California significantly correlated with agricultural land use within 5 km (3 mi), and a positive relationship exists between Foothill Yellow-legged Frog declines and the amount of upwind agriculture, suggesting airborne agrochemicals may be a contributing factor (Figure 20; Davidson et al. 2002). Cholinesterase-inhibitors (most organophosphates and carbamates), which disrupt nerve impulse transmission, were

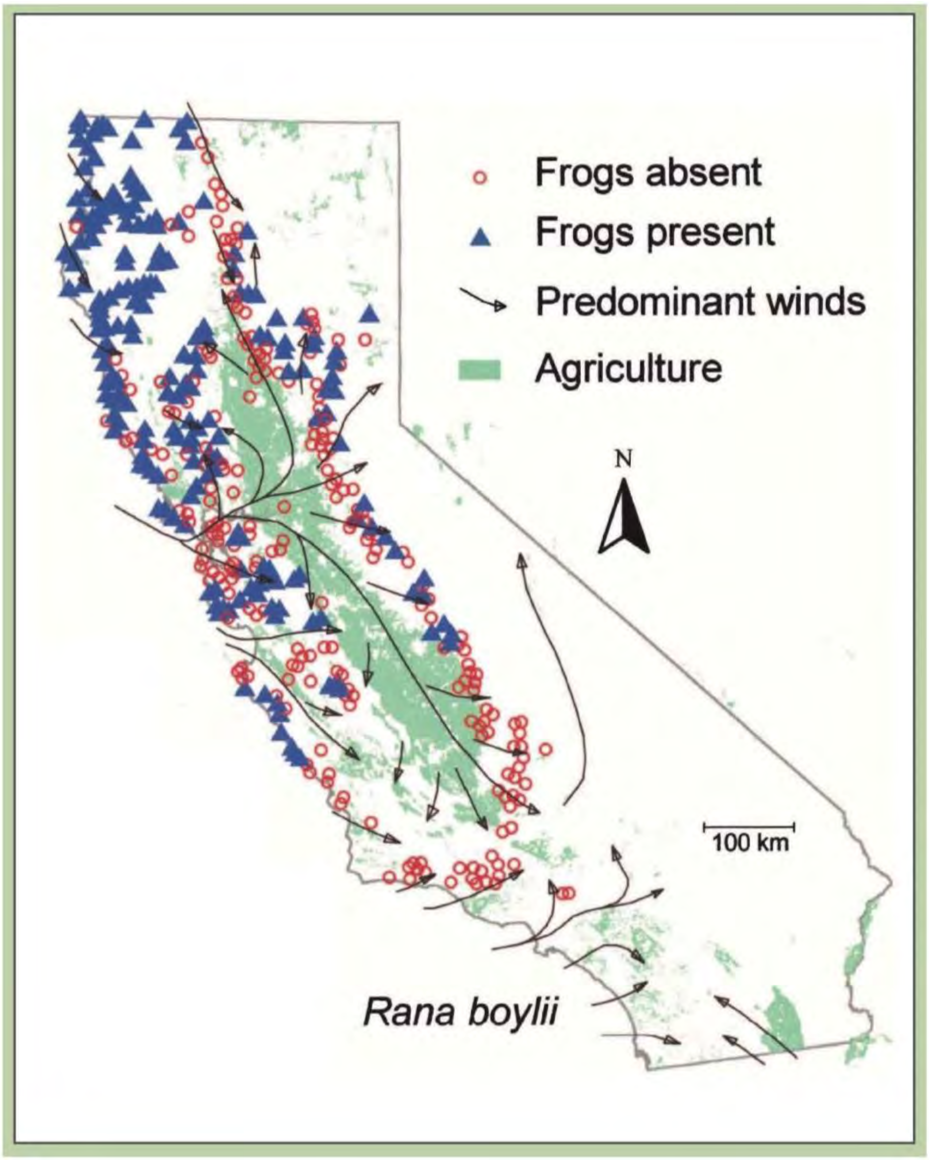

Figure 20. Relationship of Foothill Yellow-legged Frog occupancy to agriculture from Davidson et al. (2002)

more strongly associated with population declines than other pesticide types (Davidson 2004). Olson and Davis (2009) and Lind (2005) also reported a negative correlation between Foothill Yellow-legged Frog presence and proximity and quantity of nearby agriculture in Oregon and across the species' entire range, respectively.

Lethal and sublethal effects of agrochemicals on amphibians can take two general forms: direct toxicity and food-web effects. Sublethal doses of agrochemicals can interact with other environmental stressors to reduce fitness. Foothill Yellow-legged Frog tadpoles showed significantly greater vulnerability to the lethal and sublethal effects of carbaryl than Pacific Treefrogs (Kerby and Sih 2015). An inverse relationship exists between carbaryl concentration and Foothill Yellow-legged Frog activity, and their 72-h LC_{50} (concentration at which 50% die) measured one-fifth that of Pacific Treefrogs (Ibid.). Carbaryl slightly decreased Foothill Yellow-legged Frog development rate, but it significantly increased susceptibility to predation by signal crayfish despite nearly no mortality in the pesticide- and predator-only treatments (Ibid.). Sparling and Fellers (2009) also found Foothill Yellow-legged Frogs were significantly more sensitive to pesticides (chlorpyrifos and endosulfan in this study) than Pacific Treefrogs; their 96-hr LC_{50} was nearly five-times less than for treefrogs. Endosulfan was nearly 121 times more toxic to Foothill Yellow-legged Frogs than chlorpyrifos, and water samples from the Sierra Nevada have contained endosulfan concentrations within their lethal range and sometimes greater than the LC_{50} for the species (Ibid.). Sublethal effects included smaller body size, slower development rate, and increased time to metamorphosis (Ibid.). Sparling and Fellers (2007) determined the organophospates chlorpyrifos, malathion, and diazinon can harm Foothill Yellow-legged Frog populations, and their oxon derivatives (the resultant compounds once they begin breaking down in the body) were 10 to 100 times more toxic than their respective parental forms.

Extrapolating the results of studies on other ranids to Foothill Yellow-legged Frogs should be undertaken with caution; however, those studies can demonstrate additional potential adverse impacts of exposure to agrochemicals. Relyea (2005) discovered that Roundup®, a common herbicide, could cause rapid and widespread mortality in amphibian tadpoles via direct toxicity, and overspray at the manufacturer's recommended application concentrations would be highly lethal. Atrazine, another common herbicide, has been implicated in disrupting reproductive processes in male Northern Leopard Frogs (*Rana pipiens*) by slowing gonadal development, inducing hermaphroditism, and even oocyte (egg) growth (Hayes et al. 2003). However, recent research on sex reversal in wild populations of Green Frogs (*R. clamitans*) suggests it may be a relatively common natural process unrelated to environmental contaminants, requiring more research (Lambert et al. 2019). Malathion, a common organophosphate insecticide, that rapidly breaks down in the environment, applied at low concentrations caused a trophic cascade that resulted in reduced growth and survival of two species of ranid tadpoles (Relyea and Diecks 2008). Malathion caused a reduction in the amount of zooplankton, which resulted in a bloom of phytoplankton and an eventual decline in periphyton, an important food source for tadpoles (Ibid.). In contrast, Relyea (2005) found that some insecticides increased amphibian tadpole survival by reducing their invertebrate predators. Runoff from agricultural areas can contain fertilizers that input nutrients into streams and increase productivity, but they can also result in harmful algal blooms (Cordone and

Kelley 1961). In addition, exposure to pesticides can result in immunosuppression and reduce resistance to the parasites that cause limb malformations (Kiesecker 2002, Hayes et al. 2006).

Cannabis

An estimated 60-70% of the cannabis (*Cannabis indica* and *C. sativa*) used in the U.S. from legal and illegal sources is grown in California, and most comes from the Emerald Triangle, an area comprised of Humboldt, Mendocino, and Trinity counties (Ferguson 2019). Small-scale illegal cannabis farms have operated in this area since at least the 1960s but have expanded rapidly, particularly trespass grows on public land primarily by Mexican cartels, since the passage of the Compassionate Use Act in 1996 (Mallery 2010, Bauer et al. 2015). Like other forms of agriculture, it involves clearing the land, diverting water, and using herbicides and pesticides; however, in addition, many of these illicit operations use large quantities of fertilizers and highly toxic banned pesticides to kill anything that may threaten the crop, and they leave substantial amounts of non-biodegradable trash and human excrement (Mallery 2010, Thompson et al. 2014, Carah et al. 2015).

Measurements of environmental impacts of illegal cannabis grows have been hindered by the difficult and dangerous nature of accessing many of these sites; however, some analyses have been conducted, often using aerial images and geographic information systems (GIS). An evaluation of 54% of watersheds within and bordering Humboldt County revealed that while cannabis grow sites are generally small (< 0.5 ha [1.2 ac]) and comprised a tiny fraction of the study area (122 ha [301 ac]), they were widespread (present in 83% of watersheds) but unevenly distributed, indicating impacts are concentrated in certain watersheds (Butsic and Brenner 2016, Wang et al. 2017). The results also showed that 68% of grows were > 500 m (0.3 mi) from developed roads, 23% were located on slopes steeper than 30%, and 5% were within 100 m (328 ft) of critical habitat for threatened salmonids (Butsic and Brenner 2016). These characteristics suggest wildlands adjacent to cannabis cultivations are at heightened risk of habitat fragmentation, erosion, sedimentation, landslides, and impacts to waterways critical to imperiled species (Ibid.).

A separate analysis in the same general area estimated potentially significant impacts from water diversions alone. Cannabis requires a substantial amount of water during the growing season, so it is often cultivated near sources of perennial surface water for irrigation, commonly diverting from springs and headwater streams (Bauer et al. 2015). In the least impacted of the study watersheds, Bauer et al. (2015) calculated that diversions for cannabis cultivation could reduce the annual seven-day low flow by up to 23%, and in some of the heavily impacted watersheds, water demands for cannabis could exceed surface water availability. If not regulated carefully, cannabis cultivation could have substantial impacts on sensitive aquatic species like Foothill Yellow-legged Frogs in watersheds in which it is concentrated.

For context, cannabis cultivation was responsible for approximately 1.1% of forest cover lost within study watersheds in Humboldt County from 2000 to 2013, while timber harvest accounted for 53.3% (Wang et al. 2017). Cannabis requires approximately two times as much water per day as wine grapes, the other major irrigated crop in the region (Bauer et al. 2015). Impacts from cannabis cultivation have been observed by Foothill Yellow-legged Frog researchers working on the Trinity River and South Fork

Eel River in the form of lower flows in summer, increased egg stranding, and more algae earlier in the season in recent years (S. Kupferberg and M. Power pers. comm. 2015; D. Ashton pers. comm. 2017; S. Kupferberg, M. van Hattem, and W. Stokes pers. comm. 2017). In addition, Gonsolin (2010) reported illegal cannabis cultivations on four headwater streams that drained into his study area along Coyote Creek, three of which were occupied by Foothill Yellow-legged Frogs. The cultivators had removed vegetation adjacent to the creeks, terraced the slopes, diverted water, constructed small water impoundments, poured fertilizers directly into the impoundments, and applied herbicides and pesticides, as evidenced by leftover empty containers littering the site.

Commercial sale of cannabis for recreational use became legal in California on January 1, 2018, through passage of the Control, Regulate and Tax Adult Use of Marijuana Act (2016), and with it an environmental permitting system and habitat restoration fund was established. The number of applications for temporary licenses per watershed is depicted in Figure 21. Two of the expected outcomes of passage of this law were that the profit-margin on growing cannabis would fall to the point that it would discourage illegal trespass grows and move the bulk of the cultivation out of remote forested areas into existing agricultural areas like the Central Valley (CSOS 2016). However, until cannabis is legalized at the federal level, these results may not occur since banks are reluctant to work with growers due to federal prohibitions subjecting them to prosecution for money laundering (ABA 2019). Additional details on cannabis permitting at the state level can be found under the Existing Management section.

Vineyards

Vineyard operators historically built on-stream dams and removed almost all the riparian vegetation to make room for vines and for ease of irrigation (M. van Hattem pers. comm. 2019). They still divert a substantial amount of water for irrigation, and they build on- and off-stream impoundments that support bullfrogs (Ibid.). The acreage of land planted in wine grapes in California began rising dramatically in the 1970s and now accounts for 90% of wine produced in the U.S. (Geisseler and Horwath 2016, Alston et al. 2018). The number of wineries in California rose from approximately 330 to nearly 2,500 between 1975 and 2006; however, expansion slowed and has reversed slightly recently with 24,300 ha (60,000 ac), or 6.5% of total area planted, removed between 2015 and 2017 (Volpe et al. 2010, CDFA 2018). In 2015, 347,000 ha (857,000 ac) were planted in grapes with 70% located in the San Joaquin Valley; 66%, 21%, and 13% were planted in wine, raisin, and table grapes, respectively (Alston et al. 2018).

Expansion of wineries in the coastal counties converted natural areas such as oak woodlands and forests to vineyards (Merenlender 2000, Napa County 2010). The area of Sonoma County covered in grapes increased by 32% from 1990 to 1997, and 42% of these new vineyards were planted above 100 m (328 ft) with 25% on slopes greater than 18% (Merelender 2000). For context, only 18% of vineyards planted before 1990 occurred above 100 m (328 ft) and less than 6% on slopes greater than 18% (Ibid.). This conversion took place on approximately 773 ha (1,909 ac) of conifer and dense hardwood forest, 149 ha (367 ac) of shrubland, and 2,925 ha (7,229 ac) of oak grassland savanna (Ibid.).

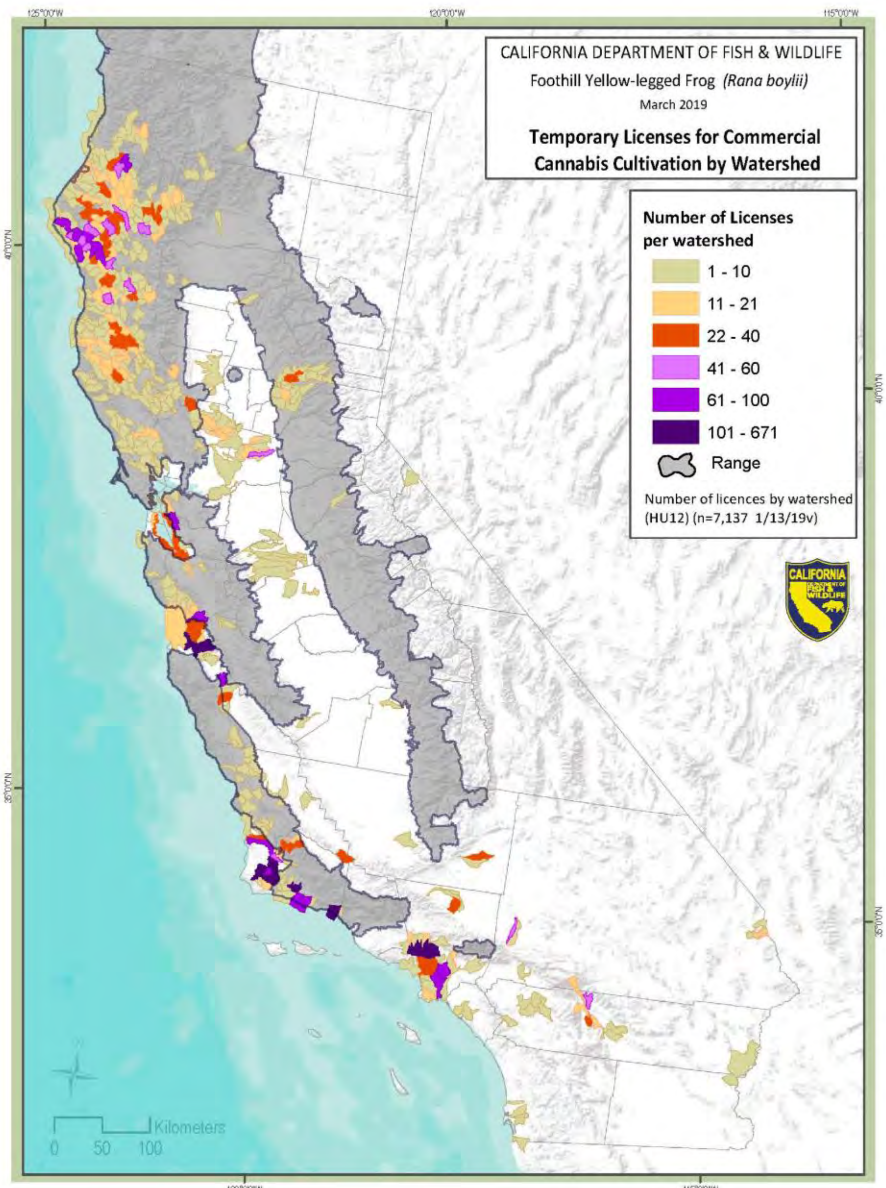

Figure 21. Cannabis cultivation temporary licenses by watershed in California (CDFA, NHD)

Recent expansion of oak woodland conversion to vineyards in Napa County was highest in its eastern hillsides (Napa County 2010). The County estimates that 1,085 and 1,240 ha (2,682-3,065 ac) of woodlands will be converted to vineyards between 2005 and 2030 (Ibid.). For context, 297 ha (733 ac) were converted from 1992 to 2003 (Ibid.). In addition, wine grapes were second only to almonds in terms of overall quantity of pesticides applied in California in 2016, but the quantity per unit area (2.9 kg/ha [2.6 lb/ac]) was 160% greater for the wine grapes (CDPR 2018). Vineyard expansion into hillsides has continued into sensitive headwater areas, and like cannabis cultivation, even small vineyards can have substantial impacts on Foothill Yellow-legged Frog habitat through sedimentation, water diversions, spread of harmful non-native species, and pesticide contamination (Merelender 2000, K. Weiss pers. comm. 2018).

Livestock Grazing

Livestock grazing can be an effective habitat management tool, including control of riparian vegetation encroachment, but overgrazing can significantly degrade the environment (Siekert et al. 1985). Cattle display a strong preference for riparian areas and have been implicated as a major source of habitat damage in the western U.S. where the adverse impacts of overgrazing on riparian vegetation are intensified by arid and semi-arid climates (Behnke and Raleigh 1978, Kauffman and Krueger 1984, Belsky et al. 1999). The severity of grazing impacts on riparian systems can be influenced by the number of animals, duration and time of year, substrate composition, and soil moisture (Benhke and Raleigh 1978, Kauffman et al. 1983, Marlow and Pogacnik 1985, Siekert et al. 1985). In addition to habitat damage, cattle can directly trample any life stage of Foothill Yellow-legged Frog.

Signs of overgrazing include impacts to the streambanks such as increased slough-offs and cave-ins that collapse undercuts used as refuge (Kauffman et al. 1983). Overgrazing reduces riparian cover, increases erosion and sedimentation, which as described above can result in silt degradation of breeding, rearing, and invertebrate food-producing areas (Cordone and Kelley 1961, Behnke and Raleigh 1978, Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). Loss of streamside and instream vegetative cover and changes to channel morphology can increase water temperatures and velocities (Behnke and Raleigh 1978). Water quality can be affected by increased turbidity and nutrient input from excrement, and seasonal water quantity can be impacted through changes to channel morphology (Belsky et al. 1999). In addition, increased nutrients and temperatures can promote blooms of harmful cyanobacteria like *Microcystis aeruginosa*, which releases a toxin when it expires that can cause liver damage to amphibians as well as other animals including humans (Bobzien and DiDonato 2007, Zhang et al. 2013).

While some recent studies indicate livestock grazing continues to damage stream and riparian ecosystems, its impact on Foothill Yellow-legged Frogs in California is unknown (Belsky et al. 1999, Hayes et al. 2016). In Oregon, the species' presence was correlated with significantly less grazing than where they were absent according to Borisenko and Hayes's 1999 report (as cited in Olson and Davis 2009). However, Fellers (2005) reported that apparently some Coast Range foothill populations occupying streams draining east into the San Joaquin Valley were doing well at the time of publication despite being heavily grazed.

Urbanization and Road Effects

Habitat conversion and fragmentation combined with modified environmental disturbance regimes can substantially jeopardize biological diversity (Tracey et al. 2018). This threat is most severe in areas like California with Mediterranean-type ecosystems that are biodiversity hot spots, fire-prone, and heavily altered by human land use (Ibid.). From 1990 to 2010, the fastest-growing land use type in the conterminous U.S. was new housing construction, which rapidly expanded the wildland-urban interface (WUI) where houses and natural vegetation meet or intermix on the landscape (Radeloff et al. 2018).

Of several variables tested, proportion of urban land use within a 5 km (3.1 mi) radius of a site was associated with Foothill Yellow-legged Frog declines (Davidson et al. 2002). Lind (2005) also found significantly less urban development nearby and upwind of sites occupied by Foothill Yellow-legged Frogs, suggesting pollutant drift may be a contributing factor. Changes in wildfires may also contribute to the species' declines; 95% of California's fires are human-caused, and wildfire issues are greatest at the WUI (Syphard et al. 2009, Radeloff et al. 2018). Population density, intermix WUI (where wildland and development intermingle as opposed to an abrupt interface), and distance to WUI explained the most variability in fire frequency (Syphard et al. 2007). In addition to wildfires, habitat loss, and fragmentation, urbanization can impact adjacent ecosystems through non-native species introduction, native predator subsidization, and disease transmission (Bar-Massada et al. 2014).

Projections show growth in California's population to 51 million people by 2060 from approximately 40 million currently (PPIC 2019). This will increase urbanization, the WUI, and habitat fragmentation. The Department of Finance projects the Inland Empire, the San Joaquin Valley, and the Sacramento metropolitan area will be the fastest-growing regions of the state over the next several decades (Ibid.). This puts the greatest pressure in areas outside of the Foothill Yellow-legged Frog's range; however, because the environmental stressors associated with urbanization can span far beyond its physical footprint, they may still adversely affect the species.

Highways are frequently recognized as barriers to dispersal that fragment habitats and populations; however, single-lane roads can pose significant risks to wildlife as well (Cook et al. 2012, Brehme et al. 2018). Foothill Yellow-legged Frogs are at risk of being killed by vehicles when roads are located near their habitat (Cook et al. 2012, Brehme et al. 2018). Fifty-six juvenile Foothill Yellow-legged Frogs were found on a road adjacent to Sulphur Creek (Mendocino County), seven of which had been struck and killed (Cook et al. 2012). When fords (naturally shallow areas) are used as vehicle crossings, they can create sedimentation and poor water quality, and in some cases, the fords are gravel or cobble bars used by Foothill Yellow-legged Frogs for breeding that could result in direct mortality (K. Blanchard pers. comm. 2018, R. Bourque pers. comm. 2018). Construction of culverts under roads to keep vehicles out of the streambed can result in varying impacts. In some cases, they can impede dispersal and create deep scoured pools that support predatory fish and frogs, but when properly constructed, they can facilitate frog movement up and down the channel with reduced road mortality (Van Wagner 1996, GANDA 2008). In areas where non-native species are not a threat, but premature drying is, pools created by culverts can provide habitat in otherwise unsuitable areas (M. Grefsrud pers. comm. 2019). An evaluation of the impact of roads on 166 native California amphibians and reptiles through direct

morality and barriers to movement concluded that Foothill Yellow-legged Frogs, at individual and population levels, were at moderate risk of road impacts in aquatic habitat but very low risk of impacts in terrestrial habitat (Brehme et al. 2018). For context, all chelonids (turtles and tortoises), 72% of snakes, 50% of anurans, 18% of lizards, and 17% of salamander species in California were ranked as having a high or very high risk of negative road impacts in the same evaluation (Ibid.).

Poorly constructed roadways near rivers and streams can result in substantial erosion and sedimentation, leading to reduced amphibian densities (Welsh and Ollivier 1998). Proximity of roads to Foothill Yellow-legged Frog habitat contributes to petrochemical runoff and poses the threat of spills (Ashton et al. 1997). A diesel spill on Hayfork Creek (Trinity County) resulted in mass mortality of Foothill Yellow-legged Frog tadpoles and partial metamorphs (Bury 1972). Roads have also been implicated in the spread of disease and may have aided in the spread of Bd in California (Adams et al. 2017b).

Frogs use auditory and visual cues to defend territories and attract mates, and some studies reveal that realistic levels of traffic noise can impede transmission and reception of these signals (Bee and Swanson 2007). Some male frogs have been observed changing the frequency of their calls to increase the distance they can be heard over traffic noise, but if females have evolved to recognize lower pitched calls as signs of superior fitness, this potential trade-off between audibility and attractiveness could have implications for reproductive success (Parris et al. 2009). In a separate study, traffic noise caused a change in male vocal sac coloration and an increase in stress hormones, which changed sexual selection processes and suppressed immunity (Troïanowski et al. 2017). Because Foothill Yellow-legged Frogs mostly call underwater and are not known to use color displays, communication cues may not be adversely affected by traffic noise, but their stress response is unknown.

Timber Harvest

Because Foothill Yellow-legged Frogs tend to remain close to the water channel (i.e., within the riparian corridor) and current timber harvest practices minimize disturbance in riparian areas for the most part, adverse effects from timber harvest are expected to be relatively low (Hayes et al. 2016, CDFW 2018b). However, some activities have a potential to negatively impact Foothill Yellow-legged Frogs or their habitat, including direct mortality and increased sedimentation during construction and decommissioning of watercourse crossings and infiltration galleries, tree felling, log hauling, and entrainment by water intakes or desiccation of eggs and tadpoles through stranding from dewatering during drafting operations (CDFW 2018b,c). In addition to impacts previously described under the Sedimentation and Road Effects section, when silt runoff into streams is accompanied by organic materials, such as logging debris, impaired water quality can result, including reduced dissolved oxygen, which is important in embryonic and tadpole development (Cordone and Kelley 1961).

Because Foothill Yellow-legged Frogs are heliotherms (i.e, they bask in the sun to raise their body temperature) and sensitive to thermal extremes, some moderate timber harvest may benefit the species (Zweifel 1955, Fellers 2005). Ashton (2002) reported 85% of his Foothill Yellow-legged Frog observations occurred in second-growth forests (37-60 years post-harvest) as opposed to late-seral forests and postulated that the availability of some open canopy areas played a major part in this

disparity. Foothill Yellow-legged Frogs are typically absent in areas with closed canopy (Welsh and Hodgson 2011). Reduced canopy also raises stream temperatures, which could improve tadpole development and promote algal and invertebrate productivity in otherwise cold streams (Olson and Davis 2009; Catenazzi and Kupferberg 2013,2017).

Recreation

Several types of recreation can adversely impact Foothill Yellow-legged Frogs, and some are more severe and widespread than others. One of the main potential factors identified by herpetologists as contributing to disappearance of Foothill Yellow-legged Frogs in southern California was increased and intensified recreation in streams (Adams et al. 2017b). The greater number of people traveling into the backcountry may have facilitated the spread Bd to these areas, and while no evidence shows stress from disturbance or other environmental pressures increases susceptibility to Bd, the stress hormone corticosterone has been implicated in immunosuppression (Hayes et al. 2003, Adams et al. 2017b).

The amount of Foothill Yellow-legged Frog habitat disturbed by off-highway motor vehicles (OHV) throughout its range in California is unknown, but its impacts can be significant, particularly in areas with small isolated populations (Kupferberg et al. 2009c, Kupferberg and Furey 2015). An example is the Carnegie State Vehicular Recreation Area (CVSRA), located in the hills southwest of Tracy in the Corral Hollow Creek watershed (Alameda and San Joaquin counties). The above-described road effects apply: sedimentation, crushing along trail crossings, and potential noise effects (Ibid.). In addition, dust suppression activities employed by CSVRA use magnesium chloride ($MgCl_2$), which has the potential to harm developing embryos and tadpoles (Karraker et al. 2008, Hopkins et al. 2013, OHMVRC 2017). Based on museum records, Foothill Yellow-legged Frogs were apparently abundant in Corral Hollow Creek, but they are extremely rare now and are already extirpated or at risk of extirpation (Kupferberg et al. 2009c, Kupferberg and Furey 2015).

Motorized and non-motorized recreational boating can also impact Foothill Yellow-legged Frogs. The impacts of jet boat traffic were investigated in Oregon; in areas with frequent use and high wakes breaking on shore, Foothill Yellow-legged Frogs were absent (Borisenko and Hayes 1999 as cited in Olson and Davis 2009). This wake action had the potential to dislodge egg masses, strand tadpoles, disrupt adult basking behavior, and erode shorelines (Ibid.). Jet boat tours and races on the Klamath River (Del Norte and Humboldt counties) may have an impact on Foothill Yellow-legged Frog use of the mainstem (M. van Hattem pers. comm. 2019). In addition, using gravel bars as launch and haul out sites for boat trailers, kayaks, or river rafts can result in direct loss of egg masses and tadpoles or damage to breeding and rearing habitat and can disrupt post-metamorphic frog behavior (Ibid.). As described above, pulse flows released for whitewater boating in the late spring and summer can result in scouring and stranding of egg masses and tadpoles (Borisenko and Hayes 1999 as cited in Olson and Davis 2009, Kupferberg et al. 2009b). In addition, the velocities that resulted in stunted growth and increased vulnerability to predation in Foothill Yellow-legged Frog tadpoles were less than the increased velocities experienced in nearshore habitats during intentional release of recreational flows for whitewater boating, as well as hydropeaking for power generation (Kupferberg et al. 2011b).

Hiking, horse-riding, camping, fishing, and swimming, particularly in sensitive breeding and rearing habitat can also adversely impact Foothill Yellow-legged Frog populations (Borisenko and Hayes 1999 in Olson and Davis 2009). Because Foothill Yellow-legged Frog breeding activity was being disturbed and egg masses were being trampled by people and dogs using Carson Falls (Marin County), the land manager established an educational program, including employing docents on weekends that remind people to stay on trails and tread lightly to try to reduce the loss of Foothill Yellow-legged Frog reproductive effort (Prado 2005). In addition, within his study site, Van Wagner (1996) reported that a property owner moved rocks that were being used as breeding habitat to create a swimming hole. The extent to which this is more than a small, local problem is unknown, but as the population of California increases, recreational pressures in Foothill Yellow-legged Frog habitat are likely to increase commensurately.

Drought

Drought is a common phenomenon in California and is characterized by lower than average precipitation. Lower precipitation in general results in less surface water, and water availability is critical for obligate stream-breeding species. Even in the absence of drought, a positive relationship exists between precipitation and latitude within the Foothill Yellow-legged Frog's range in California, and mean annual precipitation has a strong influence on Foothill Yellow-legged Frog presence at historically occupied sites (Davidson et al. 2002, Lind 2005). Figure 22 depicts the recent historical annual average precipitation across the state as well as during the most recent drought and how they differ. Southern California is normally drier than northern California, but the severity of the drought was even greater in the south.

Reduced precipitation can result in deleterious effects to Foothill Yellow-legged Frogs beyond the obvious premature drying of aquatic habitat. When stream flows recede during the summer and fall, sometimes the isolated pools that stay perennially wet are the only remaining habitat. This phenomenon concentrates aquatic species, resulting in several potentially significant adverse impacts. Stream flow volume was negatively correlated with Bd load during a recent chytridiomycosis outbreak in the Alameda Creek watershed (Adams et al. 2017a). The absence of high peak flows in winter coupled with wet years allowed bullfrogs to expand their distribution upstream, and the drought-induced low flows in the fall concentrated them with Foothill Yellow-legged Frogs in the remaining drying pools (Ibid.). This mass mortality event appeared to have been the result of a combination of drought, disease, and dam effects (Ibid.). This die-off occurred in a regulated reach that experiences heavy recreational use and presence of crayfish and bass (Ibid.). Despite these threats, the density of breeding females in this reach was greater in 2014 and 2015 than ~~the~~ in the unregulated reach upstream because the latter dried completely before tadpoles could metamorphose during the preceding drought years (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015).

In addition to increasing the spread of pathogens, drought-induced stream drying can increase predation and competition by introduced fish and frogs in the pools they are forced to share (Moyle 1973, Hayes and Jennings 1988, Drost and Fellers 1996). This concentration in isolated pools can also result in increased native predation as well as facilitate spread of Bd. An aggregation of six adult Foothill

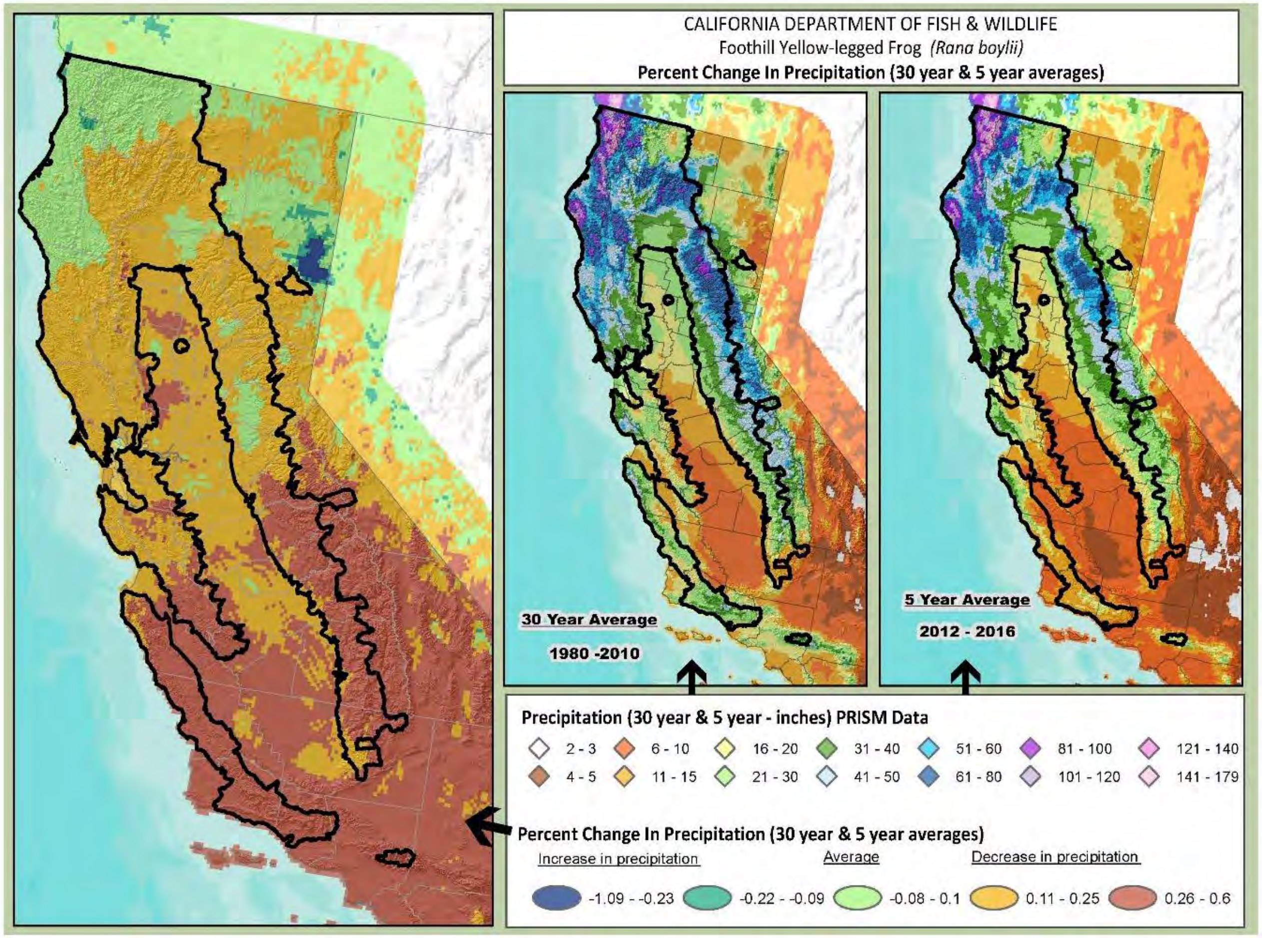

Figure 22. Change in precipitation from 30-year average and during the recent drought (PRISM)

Yellow-legged Frogs was observed perched on a rock above an isolated pool where a gartersnake was foraging on tadpoles during the summer; this close contact may reduce evaporative water loss when they are forced out of the water during high temperatures, but it can also increase disease transmission risk (Leidy et al. 2009.). Gonsolin (2010) also documented a late summer aggregation of juvenile Foothill Yellow-legged Frogs out of water during extremely high temperatures. In addition, drought-induced low flow, high water temperatures, and high densities of tadpoles were associated with outbreaks of malformation-inducing parasitic copepods (Kupferberg et al. 2009a).

Rapidly receding spring flows can result in stranding egg masses and tadpoles. However, this risk is likely less significant when it is drought-induced on an unregulated stream vs. a result of dam operations since Foothill Yellow-legged Frogs have evolved to initiate breeding earlier and shorten the breeding period in drought years (Kupferberg 1996a). If pools stay wet long enough to support metamorphosis, complete drying at the end of the season may benefit Foothill Yellow-legged Frogs if it eliminates introduced species like warm water fish and bullfrogs. Moyle (1973) noted that the only intermittent streams occupied by Foothill Yellow-legged Frogs in the Sierra Nevada foothills had no bullfrogs. At a long-term study site in upper Coyote Creek in 2015, Foothill Yellow-legged Frogs had persisted in reaches that had at least some summer water through the three preceding years of the most severe drought in over a millennium, albeit at much lower abundance than a decade before (Gonsolin 2010, Griffin and Anchokaitis 2014, J. Smith pers. comm. 2015). The population's abundance appeared to have never recovered from the 2007-2009 drought before the 2012-2016 drought began (J. Smith pers. comm. 2015). In 2016, after a relatively wet winter, Foothill Yellow-legged Frogs bred en masse, and only a single adult bullfrog was detected, an unusually low number for that area (CDWR 2016, J. Smith pers. comm. 2016). It appeared the population may rebound; however, in 2018, it experienced lethal chytridiomycosis outbreak, and like the Alameda Creek die-off probably resulted from crowding during drought, presence of bullfrogs as Bd-reservoirs and predators and competitors, and the stress associated with the combination of the two (Kupferberg and Catenazzi 2019).

Drought effects can also exacerbate the effects of other environmental stressors. During the most recent severe drought, tree mortality increased dramatically from 2014 to 2017 and reached approximately 129 million dead trees (OEHHA 2018). Multiple years of high temperatures and low precipitation left them weakened and more susceptible to pathogens and parasites (Ibid.). Vast areas of dead and dying trees are more prone to severe wildfires, and they lose their carbon sequestration function while also emitting methane, which is an extremely damaging greenhouse gas (CNRA 2016). Post-wildfire storms can result in erosion of fine sediments from denuded hillsides into the stream channel (Florsheim et al. 2017). If the storms are short duration and ~~low precipitation~~peak discharges are low in magnitude, as happens during droughts, ~~their magnitude may not~~streamflow may be insufficient to transport the material downstream, ~~resulting in a longer temporal loss or~~extending the duration of ~~degradation of~~ stream habitat degradation (Ibid.). Reduced rainfall may also infiltrate the debris leading to subsurface flows rather than the surface water Foothill Yellow-legged Frogs require (Ibid.). Extended droughts increase risk of the stream being uninhabitable or inadequate for breeding for multiple years, which would result in population-level impacts and possible extirpation (Ibid.).

Wildland Fire and Fire Management

Fire is an important element for shaping and maintaining the species composition and integrity of many California ecosystems (Syphard et al. 2007, SBFFP 2018). Prior to European settlement, an estimated 1.8 to 4.9 million ha (4.5-12 million ac) burned annually (4-11% of total area of the state), ignited both deliberately by Native Americans and through lightning strikes (Keeley 2005, SBFFP 2018). The impacts of wildland fires on Foothill Yellow-legged Frogs are poorly understood and likely vary significantly across the species' range with differences in climate, vegetation, soils, stream-order, slope, frequency, and severity (Olson and Davis 2009). Mortality from direct scorching is unlikely because Foothill Yellow-legged Frogs are highly aquatic, and most wildfires occur during the dry period of the year when the frogs are most likely to be in or near the water (Pilliod et al. 2003, Bourque 2008). Field observations support this presumption; sightings of post-metamorphic Foothill Yellow-legged Frogs immediately after fires in the northern Sierra Nevada and North Coast indicate they are not very vulnerable to the direct effects of fire (S. Kupferberg and R. Peek pers. comm. 2018). Similarly, Foothill Yellow-legged Frogs were observed two months, and again one year, after a low- to moderate-intensity fire burned an area in the southern Sierra Nevada in 2002, and the populations were extant and breeding as recently as 2017 (Lind et al. 2003b, CNDDB 2019). While water may provide a refuge during the fire, it is also possible for temperatures during a fire, or afterward due to increased solar exposure, to near or exceed a threshold resulting lethal or sublethal harm; this would likely impact embryos and tadpoles with limited dispersal abilities (Pilliod et al. 2003).

Intense fires remove overstory canopy, which provides insulation from extreme heat and cold, and woody debris that increases habitat heterogeneity (Pilliod et al. 2003, Olson and Davis 2009). If this happens frequently enough, it can permanently change the landscape. For example, frequent high-severity burning of crown fire-adapted ecosystems can prevent forest regeneration since seeds require sufficient time between fires to mature, and repeated fires can deplete the seed bank (Stephens et al. 2014). Smoke and ash change water chemistry through increased nutrient and heavy metal inputs that can reach concentrations harmful to aquatic species during the fire and for days, weeks, or years after (Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Erosion rates on granitic soils, which make up a large portion of the Foothill Yellow-legged Frog's range, can be over 60 times greater in burned vs. unburned areas and can increase sedimentation for over 10 years (Megahan et al. 1995, Hayes et al. 2016). Post-fire nutrient inputs into streams could benefit Foothill Yellow-legged Frogs through increased productivity and more rapid growth and development (Pilliod et al. 2003). While the loss of leaf litter that accompanies fire alters the food web, insects are expected to recolonize rapidly, and the lack of cover could increase their vulnerability to predation by Foothill Yellow-legged Frogs (Ibid.).

Low-intensity fires likely have no adverse effect on Foothill Yellow-legged Frogs (Olson and Davis 2009). If they occur in areas with dense canopy, wildfires can improve habitat quality for Foothill Yellow-legged Frogs by reducing riparian cover, providing areas to bask, and increasing habitat heterogeneity, which is likely to outweigh any adverse effects from some fire-induced mortality (Russell et al. 1999, Olson and Davis 2009). In a preliminary analysis of threats to Foothill Yellow-legged Frogs in Oregon, proximity to stand-replacing fires was not associated with absence (Olson and Davis 2009).

Euro-American colonization of California significantly altered the pattern of periodic fires with which California's native flora and fauna evolved through fire exclusion, land use practices, and development (OEHHA 2018). Fire suppression can lead to canopy closure, which reduces habitat quality by limiting thermoregulatory opportunities (Olson and Davis 2009). In addition, fire suppression and its subsequent increase in fuel loads combined with expanding urbanization and rising temperatures have resulted in a greater likelihood of catastrophic stand-replacing fires that can significantly alter riparian systems for decades (Pilliod et al. 2003). Firebreaks, in which vegetation is cleared from a swath of land, can result in similar impacts to roads and road construction (Ibid.). Fire suppression can also include bulldozing within streams to create temporary reservoirs for pumping water, which can cause more damage than the fire itself to Foothill Yellow-legged Frogs in some cases (S. Kupferberg and R. Peek pers. comm. 2018). In addition, fire suppression practices can involve applying hundreds of tons of ammonia-based fire retardants and surfactant-based fire suppressant foams from air tankers and fire engines (Pilliod et al. 2003). Some of these chemicals are highly toxic to some anurans (Little and Calfee 2000).

Fire suppression has evolved into fire management with a greater understanding of its importance in ecosystem health (Keeley and Syphard 2016). Several strategies are employed including prescribed burns, mechanical fuels reduction, and allowing some fires to burn instead of necessarily extinguishing them (Pilliod et al. 2003). Like wildfires themselves, fire management strategies have the potential to benefit or harm Foothill Yellow-legged Frogs. Prescribed fires and mechanical fuels removal lessen the likelihood of catastrophic wildfires, but they can also result in loss of riparian vegetation, excessive sedimentation, and increased water temperatures (Ibid.). Salvage logging after a fire may result in similar impacts to timber harvest but with higher rates of erosion and sedimentation (Ibid.). A balanced approach to wildland fires is likely to have the greatest beneficial impact on species and ecosystem health (Stephens et al. 2012).

Floods and Landslides

As previously described, Foothill Yellow-legged Frog persistence is highly sensitive to early life stage mortality (Kupferberg et al. 2009c). While aseasonal dam releases are a major source of egg mass and tadpole scouring, storm-driven floods are also capable of it (Ashton et al. 1997). Van Wagner (1996) concluded that the high discharge associated with heavy rainfall could account for a significant source of mortality in post-metamorphic Foothill Yellow-legged Frogs as well as eggs and tadpoles; he observed two adult females and several juveniles swept downstream with fatal injuries post-flooding. Severe flooding, specifically two 500-year flood events in early 1969 in Evey Canyon (Los Angeles County), resulted in massive riparian habitat destruction (Sweet 1983). Prior to the floods, Foothill Yellow-legged Frogs were widespread and common, but only four subsequent sightings were documented between 1970 and 1974 and none since (Sweet 1983, Adams 2017b). Sweet (1983) speculates that because Foothill Yellow-legged Frogs overwinter in the streambed in that area, the floods may have reduced the population's abundance below an extinction threshold. Four other herpetologists interviewed about Foothill Yellow-legged Frog extirpations in southern California listed severe flooding as a likely cause (Adams et al. 2017b).

As mentioned above, landslides are a frequent consequence of post-fire rainstorms and can result in lasting impacts to stream morphology, water quality, and Foothill Yellow-legged Frog populations. On the other hand, Olson and Davis (2009) suggest that periodic landslides can have beneficial effects by transporting woody debris into the stream that can increase habitat complexity and by replacing sediments that are typically washed downstream over time. Whether a landslide is detrimental or beneficial is likely heavily influenced by amount of precipitation and the underlying system. As previously described, too little precipitation could lead to prolonged loss of habitat through failure to transport material downstream, and too much precipitation can result in large-scale habitat destruction and direct mortality.

Climate Change

Global climate change threatens biodiversity and may lead to increased frequency and severity of drought, wildfires, flooding, and landslides (Williams et al. 2008, Keely and Syphard 2016). Data show a consistent trend of warming temperatures in California and globally; 2014 was the warmest year on record, followed by 2015, 2017, and 2016 (OEHHA 2018). Climate model projections for annual temperature in California in the 21st century range from 1.5 to 4.5°C (2.7-8.1°F) greater than the 1961-1990 mean (Cayan et al. 2008). Precipitation change projections are less consistent than those for temperature, but recent studies indicate increasing variability in precipitation, and increasingly dry conditions in California resulting from increased evaporative water loss primarily due to rising temperatures (Cayan et al. 2005, Williams et al. 2015, OEHHA 2018). Precipitation variability and proportion of dry years were negatively associated with Foothill Yellow-legged Frog presence in a range-wide analysis (Lind 2005). In addition, low precipitation intensified the adverse effects of dams on the species (Ibid.).

California recently experienced the longest drought since the U.S. Drought Monitor began reporting in 2000 (NIDIS 2019). Until March 5, 2019, California experienced drought effects in at least a portion of the state for 376 consecutive weeks; the most intense period occurred during the week of October 28, 2014 when D4 (the most severe drought category) affected 58.4% of California's land area (Figure 23; NIDIS 2019). A recent modeling effort using data on historical droughts, including the Medieval megadrought between 1100 and 1300 CE, indicates the mean state of drought from 2050 to 2099 in California will likely exceed the Medieval-era drought, under both high and moderate greenhouse gas emissions models (Cook et al. 2015). The probability of a multidecadal (35 yr) drought occurring during the late 21st century is greater than 80% in all models used by Cook et al. (2015). If correct, this would represent a climatic shift that not only falls outside of contemporary variability in aridity but would also be unprecedented in the past millennium (Ibid.).

As a result of increasing temperatures, a decreasing proportion of precipitation falls as snow, resulting in more runoff from rainfall during the winter and a shallower snowpack that melts more rapidly (Stewart 2009). A combination of reduced seasonal snow accumulation and earlier streamflow timing significantly reduces surface water storage capacity and increases the risk for winter and spring floods, which may require additional and taller dams and result in alterations to hydroelectric power generation flow regimes (Cayan et al. 2005, Knowles et al. 2006, Stewart 2009). The reduction in snowmelt volume

is expected to impact the northern Sierra (Feather, Yuba, and American River watersheds) to a greater extent than the southern portion (Young et al. 2009). The earlier shift in peak snowmelt timing is predicted to exceed four to six weeks across the entire Sierra Nevada depending on the amount of warming that occurs this century (Ibid.). In addition, the snow water equivalent is predicted to significantly decline by 2070-2099 over the 1961-1990 average in the Trinity, Sacramento, and San Joaquin drainages from -32% to -79%, and effectively no snow is expected to fall below 1000 m (3280 ft) in the high emissions/sensitive model (Cayan et al. 2008).

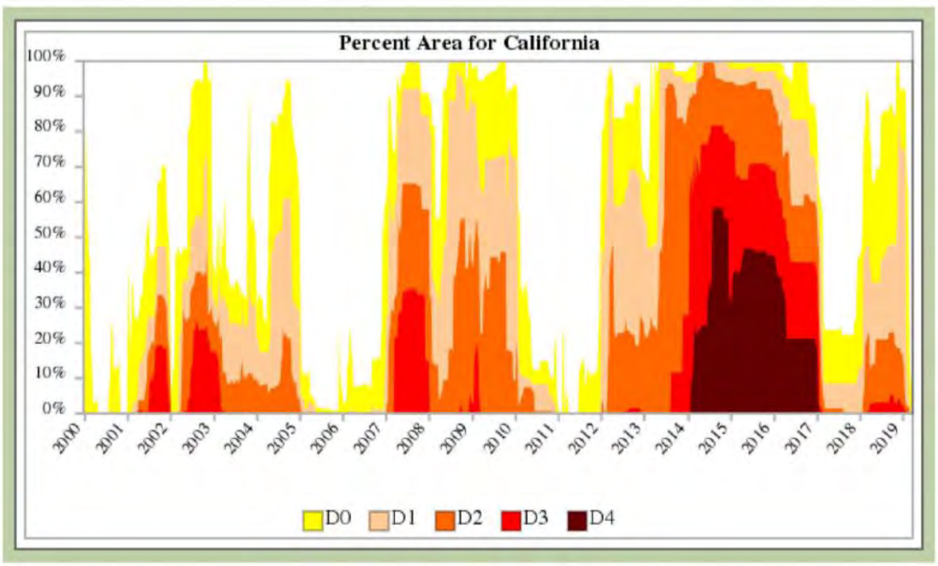

Figure 23. Palmer Hydrological Drought Indices 2000-present (NIDIS)

The earlier shift of snowmelt and lower water content will result in lower summer flows, which will intensify the competition for water among residential, agricultural, industrial, and environmental needs (Field et al. 1999, Cook et al. 2015). In unregulated systems, as long as water is present through late summer, an earlier hydrograph recession that triggers Foothill Yellow-legged Frog breeding could result in a longer time to grow larger prior to metamorphosis, which improves probability of survival (Yarnell et al. 2010, Kupferberg 2011b). However, if duration from peak to base flow shortens, it can result in increased sedimentation and reduced habitat complexity in addition to stranding (Yarnell et al. 2010).

Fire frequency relates to temperature, fuel loads, and fuel moisture (CCSP 2008). Therefore, increasing periods of drought combined with extreme heat and low humidity that stress or kill trees and other vegetation create ideal conditions for wildland fires (Ibid). Not surprisingly, the area burned by wildland fires over the western U.S. increased since 1950 but rose rapidly in the mid-1980s (Westerling et al. 2006, OEHHA 2018). As temperatures warmed and snow melted earlier, large-wildfire frequency and duration increased, and wildfire seasons lengthened (Westerling et al. 2006, OEHHA 2018).

In California, latitude inversely correlates with temperature and annual area burned, but the climate-fire relationship is substantially different across the state, and future wildfire regimes are difficult to predict (Keeley and Syphard 2016). For example, the relationship between spring and summer temperature and area burned in the Sierra Nevada is highly significant but not in southern California (Ibid.). Climate has a greater influence on fire regimes in mesic than arid environments, and the most influential climatological factor (e.g., precipitation, temperature, season, or their interactions) shifts over time (Ibid.). Nine of the 10 largest fires in California since 1932 have occurred in the past 20 years, 4 within the past 2 years (Figure 24; CAL FIRE 2019). However, it is possible this trend will not continue; climate- and wildfire-induced changes in vegetation could reduce wildfire severity in the future (Parks et al. 2016).

Wildfires themselves can accelerate the effects of climate change. Wildfires emit short-lived climate pollutants like black carbon (soot) and methane that are tens to thousands of times greater than carbon dioxide (the main focus of greenhouse gas reduction) in terms of warming effect and are responsible for 40% or more of global warming to date (CNRA 2016). Healthy forests can sequester large amounts of carbon from the atmosphere, but recently carbon emissions from wildfires have exceeded their uptake by vegetation in California (Ackerly et al. 2018).

With increased variability and changes in precipitation type, magnitude, and timing comes more variable and extreme stream flows (Mallakpour et al. 2018). Models for stream flow in California project higher high flows, lower low flows, wetter rainy seasons, and drier dry seasons (Ibid.). The projected water cycle extremes are related to strengthening El Niño and La Niña events, and both severe flooding and intense drought are predicted to increase by at least 50% by the end of the century (Yoon et al. 2015). These changes increase the likelihood of Foothill Yellow-legged Frog egg mass and tadpole scouring and stranding, even in unregulated rivers.

A species' vulnerability to climate change is a function of its sensitivity to climate change effects, its exposure to them, and its ability to adapt its behaviors to survive with them (Dawson et al. 2011). Myriad examples exist of species shifting their geographical distribution toward the poles and to higher elevations and changing their growth and reproduction with increases in temperature over time (Parmesan and Yohe 2003). However, in many places, fragmentation of suitable habitat by anthropogenic barriers (e.g., urbanization, agriculture, and reservoirs) limits a species' ability to shift its range (Pounds et al. 2007). The proportion of sites historically occupied by Foothill Yellow-legged Frogs that are now extirpated increases significantly on a north-to-south latitudinal gradient and at drier sites within California, suggesting climate change may contribute to the spatial pattern of the species' declines (Davidson et al. 2002).

An analysis of the climate change sensitivity of 195 species of plants and animals in northwestern North America revealed that, as a group, amphibians and reptiles were estimated to be the most sensitive (Case et al. 2015). Nevertheless, examples exist of amphibians adjusting their breeding behaviors (e.g., calling and migrating to breeding sites) to occur earlier in the year as global warming increases (Beebee 1995, Gibbs and Breisch 2001). Because of the rapid change in temperature, Beebee (1995) posits these are examples of behavioral and physiological plasticity rather than natural selection. However, for

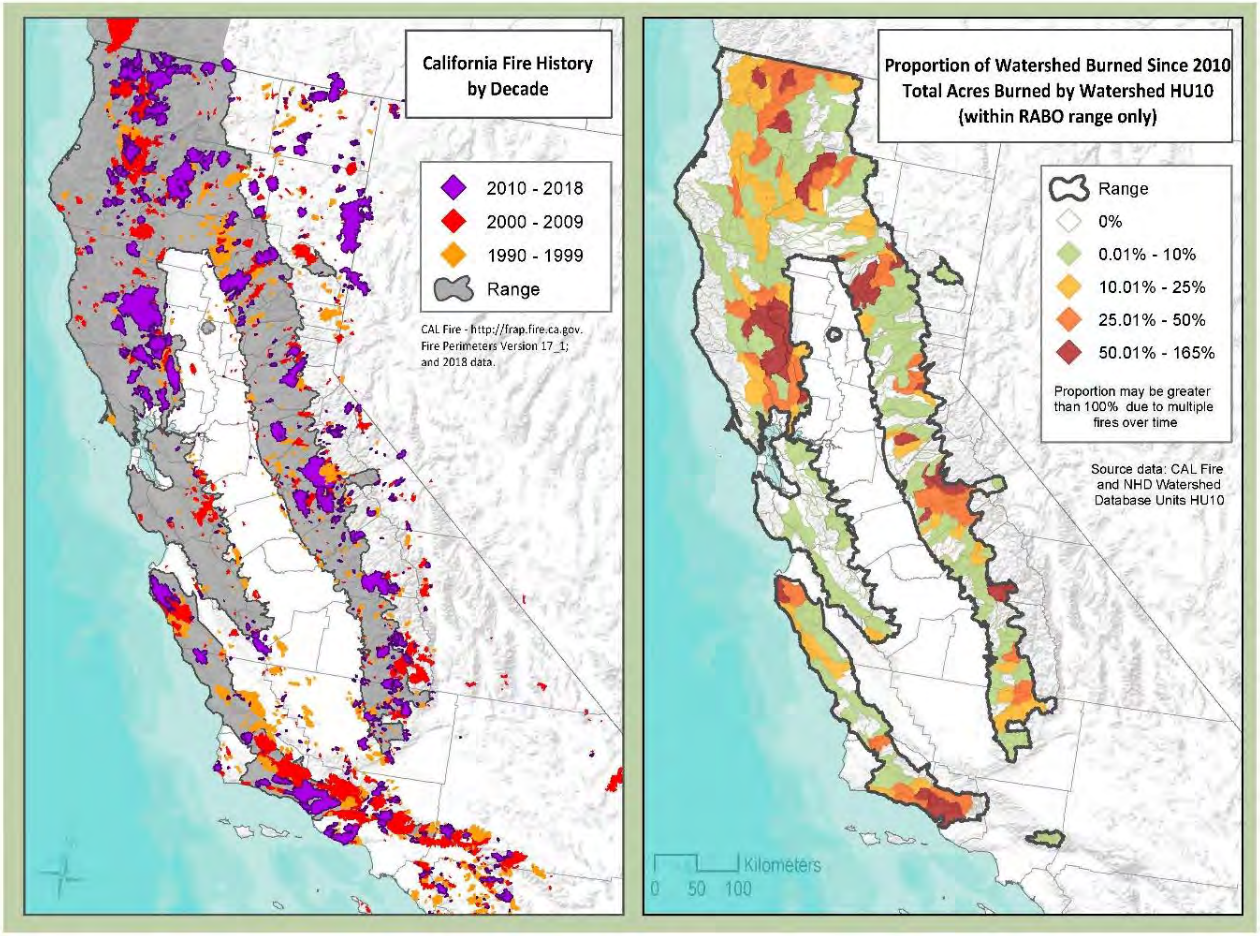

Figure 24. Fire history (1990-2018) and proportion of watershed burned (2010-2018) in California (CAL FIRE, NHD)

species with short generation times or in areas less affected by climate change, populations may be able to undergo evolutionary adaptation to the changing local environmental conditions (Hoffman and Sgrò 2011).

As previously described in the Seasonal Activity and Movements section, Foothill Yellow-legged Frog breeding is closely tied to water temperature, flow, and stage, and the species already adjusts its timing of oviposition by as much as a month in the same location during different water years, so the species may have enough inherent flexibility to reduce their vulnerability. The species appears fairly resilient to drought, fire, and flooding, at least in some circumstances. For example, after the 2012-2016 drought, the Loma Fire in late 2016, and severe winter flooding and landslides in 2016 and 2017, Foothill Yellow-legged Frog adults and metamorphs, as well as aquatic insects and rainbow trout, were abundant throughout Upper Llagas Creek in fall of 2017, and the substrate consisted of generally clean gravels and cobbles with only a slight silt coating in some pools (J. Smith pers. comm. 2017). The frogs and fish likely took refuge in a spring-fed pool, and the heavy rains scoured the fine sediments that eroded downstream (Ibid.). These refugia from the effects of climate change reduce the species' exposure, thereby reducing their vulnerability (Case et al. 2015).

Climate change models that evaluate the Foothill Yellow-legged Frog's susceptibility from a species and habitat perspective yield mixed results. An investigation into the possible effects of climate on California's native amphibians and reptiles used ecological niche models, future climate scenarios, and general circulation models to predict species-specific climatic suitability in 2050 (Wright et al. 2013). The results suggested approximately 90-100% of localities currently occupied by Foothill Yellow-legged Frogs are expected to remain climatically suitable in that time, and the proportion of currently suitable localities predicted to change ranges from -20% to 20% (Ibid.). However, a second study using a subset of these models found that 66.4% of currently occupied cells will experience reduced environmental suitability in 2050 (Warren et al. 2014). This analysis included 90 species of native California mammals, birds, reptiles, and amphibians. For context, over half of the taxa were predicted to experience > 80% reductions, a consistent pattern reflected across taxonomic groups (Ibid.).

A third analysis investigated the long-term risk of climate change by modeling the relative environmental stress a vegetative community would undergo in 2099 given different climate and greenhouse gas emission scenarios (Thorne et al. 2016). This model does not incorporate any Foothill Yellow-legged Frog-specific data; it strictly projects climatic stress levels vegetative communities will experience within the species' range boundaries (Ibid.). Unsurprisingly, higher emissions scenarios resulted in a greater proportion of habitat undergoing climatic stress (Figure 25). Perhaps counterintuitively, the warm and wet scenario resulted in a greater amount of stress than the hot and dry scenario. When high emissions and warm and wet changes are combined, a much greater proportion of the vegetation communities will experience "non-analog" conditions, those outside of the range of conditions currently known in California (Ibid.).

Habitat Restoration and Species Surveys

Potential conflicts between managing riverine habitat below dams for both cold-water adapted salmonids and Foothill Yellow-legged Frogs was discussed previously. In addition to problems with temperatures and pulse flows, some stream restoration projects aimed at physically creating or improving salmonid habitat can also adversely affect the species. For example, boulder deflectors were placed in Hurdygurdy Creek (Del Norte County) to create juvenile steelhead rearing habitat; deflectors change broad, shallow, low-velocity reaches into narrower, deeper, faster reaches preferred by the fish (Fuller and Lind 1992). Foothill Yellow-legged Frogs were documented using the restoration reach as breeding habitat annually prior to placement of the boulders, but no breeding was detected in the following three years, suggesting this project eliminated the conditions the frogs require (Ibid.). In addition, a fish ~~ladder~~ passage structure to facilitate salmonid migration above the Alameda Creek Diversion Dam was recently constructed on a Foothill Yellow-legged Frog lek site~~,~~; the structure blocks a migratory pathway between overwintering habitat in springs and seeps on a hillside and the creek; and creates a potential trap ~~the~~ for frogs ~~may become trapped~~that fall ~~in~~into the ~~ladder~~ structure (M. Grefsrud pers. comm. 2019). Use of rotenone to eradicate non-native fish as part of a habitat restoration project is rare, but if it is applied in streams occupied by Foothill Yellow-legged Frogs, it can kill tadpoles but is unlikely to impact post-metamorphic frogs (Fontenot et al. 1994). Metamorphosing tadpoles may be able to stay close enough to the surface to breathe air and survive but may display lethargy and experience increased susceptibility to predation (Ibid.).

Commented [SK2]: I think ladder is a misnomer for this massive concrete structure – I think it has 37 rectangular pools, it's huge

Commonly when riparian vegetation is removed, regulatory agencies require a greater amount to be planted as mitigation to offset the temporal loss of habitat. This practice can have adverse impacts on habitat suitability Foothill Yellow-legged Frogs, especially where flood suppression by dams has resulted in the active channel being encroached by riparian trees whose roots bind sediment and steepen the slope of the banks. ~~by reducing habitat suitability~~. Foothill Yellow-legged Frogs have been observed moving into areas where trees were recently removed, and they are known to avoid heavily shaded areas (Lind et al. 1996, Welsh and Hodgson 2011, M. Grefsrud pers. comm. 2019).

Biologists and other stream researchers can inadvertently harm Foothill Yellow-legged Frogs. When ~~conducting surveys~~working in Foothill Yellow-legged Frog habitat, in-stream surveyors can trample egg masses or larvae if they are not careful, and those rock-hopping on shore can unknowingly crush post-metamorphic life stages that often take cover under stream-side rocks. One method for sampling fish is electroshocking, which runs a current through the water that stuns the fish temporarily allowing them to be captured. Post-metamorphic frogs are unlikely to be killed by electroshocking; however, at high frequencies (60 Hz), they may experience some difficulty with muscle coordination for a few days (Allen and Riley 2012). This could increase their risk of predation. At 30 Hz, there were no differences between frogs that were shocked and controls (Ibid.). Tadpoles are more similar to fish in tail muscle and spinal structure and are at higher risk of injuries; however, researchers who reported observing stunned tadpoles noted they appeared to recover completely within several seconds (Ibid.). Adverse effects to Foothill Yellow-legged Frogs from electrofishing may only happen at frequencies higher than those typically used for fish sampling (Ibid.)

Small Population Sizes

Small populations are at greater risk of extirpation, primarily throughbecause the effects of demographic, environmental, and genetic stochasticity are disproportionately greater impact of demographic, environmental, and genetic stochasticity on them compared tothan effects on large populations, . so Thus, any of the threats previously discussed will likely have an even greater adverse impact on small populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). This risk of extinction from genetic stochasticity is amplified when connectivity between the small populations, and thus gene flow, is impeded (Fahrig and Merriam 1985, Taylor et al. 1993, Lande and Shannon 1996, Palstra and Ruzzante 2008). Genetic diversity provides capacity to evolve in response to environmental changes, and the "rescue effect" of gene flow is important in minimizing probability of local extinction (Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). However, the rescue effect is diminished in conditions of high local environmental stochasticity of recruitment or survival (Eriksson et al. 2014). In addition, populations living near their physiological limits and lacking adaptive capacity may not be able to evolve in response to rapid changes (Hoffmann and Sgrò 2011). Furthermore, while pathogens or parasites rarely result in host extinction, they can increase its likelihood in small populations by driving the host populations below a critically low threshold beneath which demographic stochasticity can lead to extinction, even if they possess the requisite genetic diversity to adapt to a changed environment (Gomulkiewicz and Holt 1995, Adams et al. 2017b).

A Foothill Yellow-legged Frog PVA revealed that, even with no dam effects considered (e.g., slower growth and increased egg and tadpole mortality), populations with the starting average density of adult females in regulated rivers (4.6/km [2.9/mi]) were four times more likely to go extinct within 30 years than those with the starting average density of adult females from unregulated rivers (32/km [120/mi]) (Kupferberg et al. 2009c). When the density of females in sparse populations was used (2.1/km [1.3/mi], the 30-year risk of extinction increased 13-fold (Ibid.). With dam effects, a number of the risk factors above contribute to the additional probability of local extinction such as living near their lower thermal tolerance and reduced recruitment and survival from scouring and stranding flows, poor food quality, and increased predation and competition (Kupferberg 1997a; Hoffmann and Sgrò 2011; Kupferberg et al. 2011a,b; Kupferberg et al. 2012; Eriksson et al. 2014). These factors act synergistically, contributing in part to the small size, high divergence, and low genetic diversity exhibited by many Foothill Yellow-legged Frog populations located in highly regulated watersheds (Kupferberg et al. 2012, Peek 2018).

EXISTING MANAGEMENT

Land Ownership within the California Range

Using the Department's Foothill Yellow-legged Frog range boundary and the California Protected Areas Database (CPAD), a GIS dataset of lands that are owned in fee title and protected for open space purposes by over 1,000 public agencies or non-profit organizations, the total area of the species' range in California comprises 13,620,447 ha (33,656,857 ac) (CPAD 2019, CWHR 2019). Approximately 37% is owned by federal agencies, 80% of which (4,071,178 ha [10,060,100 ac]) is managed by the Forest Service (Figure 26). Department of Fish and Wildlife-managed lands, State Parks, and other State agency-managed lands constitute around 2.6% of the range. The remainder of the range includes < 1% Tribal lands, 2.3% other conserved lands (e.g., local and regional parks), and 57% private and government-managed lands that are not protected for open space purposes. It is important to note that even if included in the CPAD, a property's management does not necessarily benefit Foothill Yellow-legged Frogs, but in some cases changes in management to conserve the species may be easier to undertake than on private lands or public lands not classified as conserved.

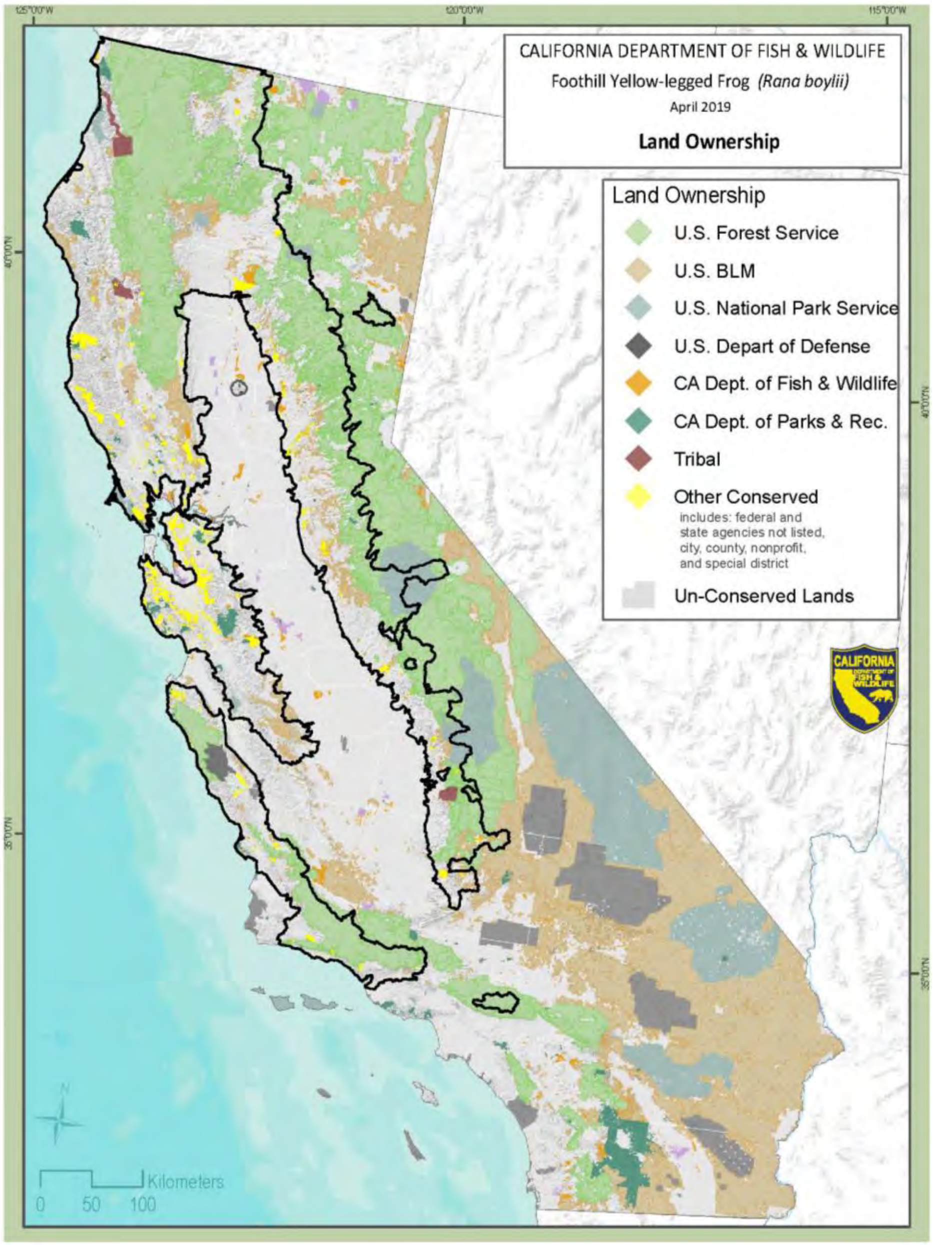

Figure 26. Conserved, Tribal, and other lands (BLM, CMD, CPAD, CWHR, DOD)

Statewide Laws

The laws and regulations governing land management within the Foothill Yellow-legged Frog's range vary by ownership. Several state and federal environmental laws apply to activities undertaken in California that may provide some level of protection for Foothill Yellow-legged Frogs and their habitat. The following is not an exhaustive list.

National Environmental Policy Act and California Environmental Quality Act

Most federal land management actions must undergo National Environmental Policy Act of 1969 (NEPA; 42 U.S.C. § 4321, et seq.) analysis. NEPA requires federal agencies to document, consider alternatives, and disclose to the public the impacts of major federal actions and decisions that may significantly impact the environment. As a BLM and Forest Service Sensitive Species, impacts to Foothill Yellow-legged Legged Frogs are considered during NEPA analysis; however, the law has no requirement to minimize or mitigate adverse effects.

The California Environmental Quality Act (CEQA) is similar to NEPA; it requires state and local agencies to identify, analyze, and consider alternatives, and to publicly disclose environmental impacts from projects over which they have discretionary authority (Pub. Resources Code § 21000 et seq.). CEQA differs substantially from NEPA in requiring mitigation for significant adverse effects to a less than significant level unless overriding considerations are documented. CEQA requires an agency find projects may have a significant effect on the environment if they have the potential to substantially reduce the habitat, decrease the number, or restrict the range of any rare, threatened, or endangered species (Cal. Code Regs., tit. 14, §§ 15065(a)(1), 15380.). CEQA establishes a duty for public agencies to avoid or minimize such significant effects where feasible (Cal. Code regs., tit. 14, § 15021). Impacts to Foothill Yellow-legged Frogs, as an SSC, should be identified, evaluated, disclosed, and mitigated or justified under the Biological Resources section of an environmental document prepared pursuant to CEQA. However, a lead agency is not required to make a mandatory finding of significance conclusion unless it determines on a project-specific basis that the species meets the CEQA criteria for rare, threatened, or endangered.

Clean Water Act and Porter-Cologne Water Quality Control Act

The Clean Water Act originated in 1948 as the Federal Water Pollution Control Act of 1948. It was heavily amended in 1972 and became known as the Clean Water Act (CWA). The purpose of the CWA was to establish regulations for the discharge of pollutants into waters of the United States and establish quality standards for surface waters. Section 404 of the CWA forbids the discharge of dredged or fill material into waters and wetlands without a permit from the ACOE. The CWA also requires an alternatives analysis, and the ACOE is directed to issue their permit for the least environmentally damaging practicable alternative. The definition of waters of the United States has changed substantially over time based on Supreme Court decisions and agency rule changes.

The Porter-Cologne Water Quality Act was established by the State in 1969 and is similar to the CWA in that it establishes water quality standards and regulates discharge of pollutants into state waters, but it

also administers water rights which regulate water diversions and extractions. The SWRCB and nine Regional Water Boards share responsibility for implementation and enforcement of Porter-Cologne as well as the CWA's National Pollutant Discharge Elimination System permitting.

Federal and California Wild and Scenic Rivers Acts

In 1968, the U.S. Congress passed the federal Wild and Scenic Rivers Act (WSRA) (16 U.S.C. § 1271, et seq.) which created the National Wild and Scenic River System. The WSRA requires the federal government to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The WSRA prohibits the federal government from building, licensing, funding or otherwise aiding in the building of dams or other project works on rivers or segments of designated rivers. The WSRA does not give the federal government control of private property including development along protected rivers.

California's Wild and Scenic Rivers Act was enacted in 1972 so rivers that "possess extraordinary scenic, recreational, fishery, or wildlife values shall be preserved in their free-flowing state, together with their immediate environments, for the benefit and enjoyment of the people of the state." (Pub. Res. Code, § 5093.50). Designated waterways are codified in Public Resources Code sections 5093.50-5093.70. In 1981, most of California's designated Wild and Scenic Rivers were adopted into the federal system. Currently in California, 3,218 km (1,999.6 mi) of 23 rivers are protected by the WSRA, most of which are located in the northwest. Foothill Yellow-legged Frogs have been observed in 11 of the 17 designated rivers within their range (CNDDB 2019).

Lake and Streambed Alteration Agreements

Fish and Game Code Section 1602 requires entities to notify the Department of activities that "divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake." If the activity may substantially adversely affect an existing fish and wildlife resource, the Department may enter into a lake or streambed alteration agreement with the entity that includes reasonable measures necessary to protect the fish or wildlife resource (Fish & G. Code, §1602, subd. (a)(4)(B)). A lake or stream alteration agreement does not authorize take of species listed as candidates, threatened, or endangered under CESA (see Protection Afforded by Listing for CESA compliance requirements).

Medicinal and Adult-Use Cannabis Regulation and Safety Act

The commercial cannabis cultivation industry is unique in that any entity applying for an annual cannabis cultivation license from California Department of Food and Agriculture (CDFA) must include "a copy of any final lake or streambed alteration agreement…or written verification from the California Department of Fish and Wildlife that a lake or streambed alteration agreement is not required" with their license application (Cal. Code Regs., tit. 3, § 8102, subd. (v)). The SWRCB also enforces the laws related to waste discharge and water diversions associated with cannabis cultivation (Cal. Code Regs., tit. 3, § 8102, subd. (p)).

Forest Practice Act

The Forest Practice Act was originally enacted in 1973 to ensure that logging in California is undertaken in a manner that will also preserve and protect the State's fish, wildlife, forests, and streams. This law and the regulations adopted by the California Board of Forestry and Fire Protection (BOF) pursuant to it are collectively referred to as the Forest Practice Rules. The Forest Practice Rules implement the provisions of the Forest Practice Act in a manner consistent with other laws, including CEQA, Porter-Cologne, CESA, and the Timberland Productivity Act of 1982. The California Department of Forestry and Fire Protection (CAL FIRE) enforces these laws and regulations governing logging on private land.

Federal Power Act

The Federal Power Act and its major amendments are implemented and enforced by FERC and require licenses for dams operated to generate hydroelectric power. One of the major amendments required that these licenses "shall include conditions for the protection, mitigation and enhancement of fish and wildlife including related spawning grounds and habitat" (ECPA 1986). Hydropower licenses granted by FERC are usually valid for 30-50 years. If a licensee wants to renew their license, it must file a Notice of Intent and a pre-application document five years before the license expires to provide time for public scoping, any potentially new studies necessary to analyze project impacts and alternatives, and preparation of environmental documents. The applicant must officially apply for the new license at least two years before the current license expires.

As a federal agency, FERC must comply with federal environmental laws prior to issuing a new license or relicensing an existing hydropower project, which includes NEPA and ESA. As a result of environmental compliance or settlement agreements formed during the relicensing process, some operations have been modified and habitat restored to protect fish and wildlife. For example, the Lewiston Dam relicensing resulted in establishment of the Trinity River Restoration Program, which takes an ecosystem-approach to studying dam effects and protecting and restoring fish and wildlife populations downstream of the dam (Snover and Adams 2016). Similarly, relicensing of the Rock Creek-Cresta Project on the North Fork Feather River resulted in establishment of a multi-stakeholder Ecological Resources Committee (ERC). As a result of the ERC's studies and recommendations, pulse flows for whitewater boating were suspended for several years following declines of Foothill Yellow-legged Frogs, and the ERC is currently working toward augmenting the population in an attempt to increase abundance to a viable level.

Administrative and Regional Plans

Forest Plans

NORTHWEST FOREST PLAN

In 1994, BLM and the Forest Service adopted the Northwest Forest Plan to guide the management of over 97,000 km^2 (37,500 mi^2) of federal lands in portions of northwestern California, Oregon, and Washington. The Northwest Forest Plan created an extensive network of forest reserves including

Riparian Reserves. Riparian Reserves apply to all land designations to protect riparian dependent resources. With the exception of silvicultural activities consistent with Aquatic Conservation Strategy objectives, timber harvest is not permitted within Riparian Reserves, which can vary in width from 30 to 91 m (100-300 ft) on either side of streams, depending on the classification of the stream or waterbody (USFS and BLM 1994). Fuel treatment and fire suppression strategies and practices implemented within these areas are designed to minimize disturbance.

Sierra Nevada Forest Plan

Land and Resource Management Plans for forests in the Sierra Nevada were changed in 2001 by the Sierra Nevada Forest Plan Amendment and subsequently adjusted via a supplemental Environmental Impact Statement and Record of Decision in 2004, referred to as the Sierra Nevada Framework (USFS 2004). This established an Aquatic Management Strategy with Goals including maintenance and restoration of habitat to support viable populations of riparian-dependent species; spatial and temporal connectivity for aquatic and riparian species within and between watersheds to provide physically, chemically, and biologically unobstructed movement for their survival, migration, and reproduction; instream flows sufficient to sustain desired conditions of riparian, aquatic, wetland, and meadow habitats; the physical structure and condition of streambanks and shorelines to minimize erosion and sustain desired habitat diversity; and prevention of new introductions of invasive species and reduction of invasive species impacts that adversely affect the viability of native species. The Sierra Nevada Framework also includes Riparian Conservation Objectives and associated standards and guidelines specific to aquatic-dependent species, including the Foothill Yellow-legged Frog.

Resource Management Plans

Sequoia, Kings Canyon, and Yosemite National Parks fall within the historical range of the Foothill Yellow-legged Frog, but the species has been extirpated from these areas. The guiding principles for managing biological resources on National Park Service lands include maintenance of animal populations native to park ecosystems (Hayes et al. 2016). They also commit the agency to work with other land managers on regional scientific and planning efforts and maintenance or reintroduction of native species to the parks including conserving Foothill Yellow-legged Frogs in the Sierra Nevada (USDI NPS 1999 as cited in Hayes et al. 2016). A Sequoia and Kings Canyon National Parks Resource Management Plan does not include specific management goals for Foothill Yellow-legged Frogs, but it does include a discussion of the factors leading to the species' decline and measures to restore the integrity of aquatic ecosystems (Ibid.). The Yosemite National Park Resource Management Plan includes a goal of restoring Foothill Yellow-legged Frogs to the Upper Tuolumne River below Hetch Hetchy Reservoir (USDI NPS 2003 as cited in Hayes et al. 2016).

FERC Licenses

Dozens of hydropower dams have been relicensed in California since 1999, and several are in the process of relicensing (FERC 2019). In addition to following the Federal Power Act and other applicable federal laws, Porter-Cologne Water Quality Act requires non-federal dam operators to obtain a Water Quality Certification (WQC) from the SWRCB. Before it can issue the WQC, the SWRCB must consult with

the Department regarding the needs of fish and wildlife. Consequently, SWRCB includes conditions in the WQC that seek to minimize adverse effects to native species, and Foothill Yellow-legged Frogs have received some special considerations due to their sensitivity to dam operations during these licensing processes. As discussed above, the typical outcome is formation of an ERC-type group to implement the environmental compliance requirements and recommend changes to flow management to reduce impacts. Foothill Yellow-legged Frog-specific requirements fall into three general categories: data collection, modified flow regimes, and standard best management practices.

Data Collection

When little is known about the impacts of different flows and temperatures on Foothill Yellow-legged Frog occupancy and breeding success, data are collected and analyzed to inform recommendations for future modifications to operations such as temperature trigger thresholds. These surveys include locating egg masses and tadpoles, monitoring temperatures and flows, and recording their fate (e.g., successful development and metamorphosis, displacement, desiccation) during different flow operations and different water years. Examples of licenses with these conditions include the Lassen Lodge Project (FERC 2018), Rock Creek-Cresta Project (FERC 2009a), and El Dorado Project (EID 2007).

Modified Flow Regimes

When enough data exist to understand the effect of different operations on Foothill Yellow-legged Frog occupancy and success, license conditions may include required minimum seasonal instream flows, specific thermal regimes, gradual ramping rates to reduce the likelihood of early life stage scour or stranding, or freshet releases (winter/spring flooding simulation) to maintain riparian processes, and cancellation or prohibition of recreational pulse flows during the breeding season. Examples of licenses with these conditions include the Poe Hydroelectric Project (SWRCB 2017), Upper American Project (FERC 2014), and Pit 3, 4, 5 Project (FERC 2007b).

Best Management Practices

Efforts to reduce the impacts from maintenance activities and indirect operations include selective herbicide and pesticide application, aquatic invasive species monitoring and control, erosion control, and riparian buffers. Examples of licenses with these conditions include the South Feather Project (SWRCB 2018), Spring Gap-Stanislaus Project (FERC 2009b), and Chili Bar Project (FERC 2007a).

Habitat Conservation Plans and Natural Community Conservation Plans

Non-federal entities can obtain authorization for take of federally threatened and endangered species incidental to otherwise lawful activities through development and implementation of a Habitat Conservation Plan (HCP) pursuant to Section 10 of the ESA. The take authorization can extend to species not currently listed under ESA but which may become listed as threatened or endangered over the term of the HCP, which is often 25-75 years. California's companion law, the Natural Community Conservation Planning Act of 1991, takes a broader approach than either CESA or ESA. A Natural Community Conservation Plan (NCCP) identifies and provides for the protection of plants, animals, and their

habitats, while allowing compatible and appropriate economic activity. There are currently four HCPs that include Foothill Yellow-legged Frogs as a covered species, two of which are also NCCPs.

Humboldt Redwood (formerly Pacific Lumber) Company

The Humboldt Redwood Company (HRC) HCP covers 85,672 ha (211,700 ac) of private Coast Redwood and Douglas-fir forest in Humboldt County (HRC 2015). It is a 50-year HCP/incidental take permit (ITP) that was executed in 1999, revised in 2015 as part of its adaptive management strategy, and expires on March 1, 2049. The HCP includes an Amphibian and Reptile Conservation Plan and an Aquatics Conservation Plan with measures designed to sustain viable populations of Foothill Yellow-legged Frogs and other covered aquatic herpetofauna. These conservation measures include prohibiting or limiting tree harvest within Riparian Management Zones (RMZ), controlling sediment by maintaining roads and hillsides, restricting controlled burns to spring and fall in areas outside of the RMZ, conducting effectiveness monitoring throughout the life of the HCP, and use the data collected to adapt monitoring and management plans accordingly.

Watershed assessment surveys include observations of Foothill Yellow-legged Frogs and have documented their widespread distribution on HRC lands with a pattern of fewer near the coast in the fog belt and more inland (S. Chinnici pers. comm. 2017). The watersheds within the property are largely unaffected by dam-altered flow regimes or non-native species, so aside from the operations described under Timber Harvest above that are minimized to the extent feasible, the focus on suitable temperatures and denser canopy cover for salmonids may reduce habitat suitability for Foothill Yellow-legged Frogs over time (Ibid.).

San Joaquin County Multi-Species Habitat Conservation and Open Space Plan

The San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) is a 50-year HCP/ITP that was signed by the USFWS on November 14, 2000 (San Joaquin County 2000). The SJMSCP covers almost all of San Joaquin County except federal lands, a few select projects, and some properties with certain land uses, roughly 364,000 ha (900,000 ac). At the time of execution, approximately 70 ha (172 ac) of habitat within the SJMSCP area in the southwest portion of the county were considered occupied by Foothill Yellow-legged Frogs with another 1,815 ha (4,484 ac) classified as potential habitat, but it appears the species had been considered extirpated before then (Jennings and Hayes 1994, San Joaquin County 2000, Lind 2005). The HCP estimates around 8% of the combined modeled habitat would be converted to other uses over the permit term, but the establishment of riparian preserves with buffers around Corral Hollow Creek, where the species occurred historically, was expected to offset those impacts (San Joaquin County 2000, SJCOG 2018). However, the HCP did not require surveys to determine if Foothill Yellow-legged Frogs are benefiting (M. Grefsrud pers. comm. 2019).

East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan

The East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan (ECCC HCP/NCCP) is a multi-jurisdictional 30-year plan adopted in 2007 that covers over 70,423 ha (174,018 ac) in eastern Contra Costa County (Jones & Stokes 2006). The Foothill Yellow-legged Frog appears to be

extirpated from the ECCC HCP/NCCP area (CNDDB 2019). Nevertheless, suitable habitat was mapped, and impacts were estimated at well under 1% of both breeding and migratory habitat (Jones & Stokes 2006). One of the HCP/NCCP's objectives is acquiring high-quality Foothill Yellow-legged Frog habitat that has been identified along Marsh Creek (Ibid.). In 2017, the Viera North Peak 65 ha (160 ac) property was acquired that possesses suitable habitat for Foothill Yellow-legged Frogs (ECCCHC 2018).

Santa Clara Valley Habitat Plan

The Santa Clara Valley Habitat Plan (SCVHP) is a 50-year HCP/NCCP covering over 210,237 ha (519,506 ac) in Santa Clara County (ICF 2012). As previously mentioned, Foothill Yellow-legged Frogs appear to have been extirpated from lower elevation sites, particularly below reservoirs in this area. Approximately 17% of modeled Foothill Yellow-legged Frog habitat, measured linearly along streams, was already permanently preserved, and the SCVHP seeks to increase that to 32%. The maximum allowable habitat loss is 11 km (7 mi) permanent loss and 3 km (2 mi) temporary loss, while 167 km (104 mi) of modeled habitat is slated for protection. By mid-2018, 8% of impact area had been accrued and 3% of habitat protected (SCVHA 2019).

Green Diamond Aquatic Habitat Conservation Plan

Green Diamond Resources Company has an Aquatic Habitat Conservation Plan (AHCP) covering 161,875 ha (400,000 ac) of their land that is focused on cold-water adapted species, but many of the conservation measures are expected to benefit Foothill Yellow-legged Frogs as well (K. Hamm pers. comm. 2017). Examples include slope stability and road management measures to reduce stream sedimentation from erosion and landslides, and limiting water drafting during low flow periods with screens over the pumps to avoid entraining animals (Ibid.). Although creating more open canopy areas and warmer water temperatures is not the goal of the AHCP, the areas that are suitable for Foothill Yellow-legged Frog breeding are likely to remain that way because they are wide channels that receive sufficient sunlight (Ibid.).

SUMMARY OF LISTING FACTORS

Commented [sjk3]: I wholeheartedly agree with the assessments in this section. All the summaries are consistent with my knowledge of the species and the literature. My own work is correctly and accurately represented.

CESA's implementing regulations identify key factors relevant to the Department's analyses and the Fish and Game Commission's decision on whether to list a species as threatened or endangered. A species will be listed as endangered or threatened if the Commission determines that the species' continued existence is in serious danger or is threatened by any one or any combination of the following factors: (1) present or threatened modification or destruction of its habitat; (2) overexploitation; (3) predation; (4) competition; (5) disease; or (6) other natural occurrences or human-related activities (Cal. Code Regs., tit. 14, § 670.1, subd. (i).

This section provides summaries of information from the foregoing sections of this status review, arranged under each of the factors to be considered by the Commission in determining whether listing is warranted.

Present or Threatened Modification or Destruction of Habitat

Most of the factors affecting ability to survive and reproduce listed above involve destruction or degradation of Foothill Yellow-legged Frog habitat. The most widespread, and potentially most significant, threats are associated with dams and their flow regimes, particularly in areas where they are concentrated and occur in a series along a river. Dams and the way they are operated can have up- and downstream impacts to Foothill Yellow-legged Frogs. They can result in confusing natural breeding cues, scouring and stranding of egg masses and tadpoles, reducing quality and quantity of breeding and rearing habitat, reducing tadpole growth rate, impeding gene flow among populations, and establishing and spreading non-native species (Hayes et al. 2016). These impacts appear to be most severe when the dam is operated for the generation of hydropower utilizing hydropeaking and pulse flows (Kupferberg et al. 2009c, Peek 2018). Foothill Yellow-legged Frog abundance below dams is an average of five times lower than in unregulated rivers (Kupferberg et al. 2012). The number, height, and distance upstream of dams in a watershed influenced whether Foothill Yellow-legged Frogs still occurred at sites where they had been present in 1975 in California (Ibid.). Water diversions for agricultural, industrial, and municipal uses also reduce the availability and quality of Foothill Yellow-legged Frog habitat. Dams are concentrated in the Bay Area, Sierra Nevada, and southern California (Figure 17), while hydropower plants are densest in the northern and central Sierra Nevada (Figure 18).

With predicted increases in the human population, ambitious renewable energy targets, higher temperatures, and more extreme and variable precipitation falling increasingly more as rain rather than snow, the need for more and taller dams and water diversions for hydroelectric power generation, flood control, and water storage and delivery is not expected to abate in the future. California voters approved Proposition 1, the Water Quality, Supply and Infrastructure Improvement Act of 2014, which dedicated $2.7 billion to water storage projects (PPIC 2018). In 2018, the California Water Commission approved funding for four new dams in California: expansion of Pacheco Reservoir (Santa Clara County), expansion of Los Vaqueros Reservoir (Contra Costa County), Temperance Flat Dam (new construction) on the San Joaquin River (Fresno County), and the off-stream Sites Reservoir (new construction) diverting the Sacramento River (Colusa County) (CWC 2019). No historical records of Foothill Yellow-legged Frogs from the Los Vaqueros or Sites Reservoir areas exist in the CNDDB, and one historical (1950) collection is documented from the Pacheco Reservoir area (CNDDB 2019). However, the proposed Temperance Flat Dam site is downstream of one of the only known extant populations of Foothill Yellow-legged Frogs in the East/Southern Sierra clade (Ibid.).

The other widespread threat to Foothill Yellow-legged Frog habitat is climate change, although the severity of its impacts is somewhat uncertain. While drought, wildland fires, floods, and landslides are natural and ostensibly necessary disturbance events for preservation of native biodiversity, climate change is expected to result in increased frequency and severity of these events in ways that may exceed species' abilities to adapt (Williams et al. 2008, Hoffmann and Sgrò 2011, Keely and Syphard 2016). These disturbance events which can lead to local extirpations will occur across a landscape of fragmented and small populations and thus the likelihood of natural recolonization will be highly impaired. Climatic~~These c~~hanges in flow regime can lead to increased competition, predation, and disease transmission as species become concentrated in areas that remain wet into the late summer

(Adams et al. 2017a, Kupferberg and Catenazzi 2019). Loss of riparian vegetation from wildland fires can result in increased stream temperatures or concentrations of nutrients and trace heavy metals that inhibit growth and survival (Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Stream sedimentation from landslides following fire or excessive precipitation can destroy or degrade breeding and rearing habitat (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). At least some models predict unprecedented dryness in the latter half of the century (Cook et al. 2015). The effects of climate change will be realized across the Foothill Yellow-legged Frog's range, and their severity will likely differ in ways that are difficult to predict. However, the impacts from extended droughts will likely be greatest in the areas that are naturally more arid, the lower elevations and latitudes of southern California and the foothills surrounding the Central Valley (Figure 21).

While most future urbanization is predicted to occur in areas outside of the Foothill Yellow-legged Frog's range, it has already contributed to the loss and fragmentation of Foothill Yellow-legged Frog habitat in California. In addition, the increased predation, wildland fires, introduced species, road mortality, disease transmission, air and water pollution, and disturbance from recreation that can accompany urbanization expand its impact far beyond its physical footprint (Davidson et al. 2002, Syphard et al. 2007, Cook et al. 2012, Bar-Massada et al. 2014). Within the Foothill Yellow-legged Frog's historical range, these effects appear most significant and extensive in terms of population extirpations in southern California and the San Francisco Bay Area.

Several other activities have the potential to destroy or degrade Foothill Yellow-legged Frog habitat, but they are less common across the range. They also tend to have relatively small areas of impact, although they can be significant in those areas, particularly if populations are already small and declining. These include impacts from mining, cannabis cultivation, vineyard expansion, overgrazing, timber harvest, recreation, and some stream habitat restoration projects (Harvey and Lisle 1998, Belsky et al. 1999, Merelender 2000, Pilliod et al. 2003, Bauer et al. 2015, Kupferberg and Furey 2015).

Overexploitation

Foothill Yellow-legged Frogs are not threatened by overexploitation. There is no known pet trade for Foothill Yellow-legged Frogs (Lind 2005). During the massive frog harvest that accompanied the Gold Rush, some Foothill Yellow-legged Frogs were collected, but because they are relatively small and have irritating skin secretions, there was much less of a market for them (Jennings and Hayes 1985). Within these secretions is a peptide with antimicrobial activity that is particularly potent against *Candida albicans*, a human pathogen that has been developing resistance to traditional antifungal agents (Conlon et al. 2003). However, the peptide's therapeutic potential is limited by its strong hemolytic activity, so further studies will focus on synthesizing analogs that can be used as antifungals, and collection of Foothill Yellow-legged Frogs for lab cultures is unlikely (Ibid.).

Like all native California amphibians, collection of Foothill Yellow-legged Frogs is unlawful without a permit from the Department. They may only be collected for scientific, educational, or propagation reasons through a Scientific Collecting Permit (Fish & G. Code § 1002 et seq.). The Department has the discretion to limit or condition the number of individuals collected or handled to ensure no significant adverse effects. Incidental harm from authorized activities on other aquatic species can be avoided or minimized by the inclusion of special terms and conditions in permits.

Predation

Predation is a likely contributor to Foothill Yellow-legged Frog population declines where the habitat is degraded by one or many other risk factors (Hayes and Jennings 1986). Predation by native gartersnakes can be locally substantial; however, it may only have an appreciable population-level impact if the availability of escape refugia is diminished. For example, when streams dry and only pools remain, Foothill Yellow-legged Frogs are more vulnerable to predation by native and non-native species because they are concentrated in a small area with little cover.

Several studies have demonstrated the synergistic impacts of predators and other stressors. Foothill Yellow-legged Frogs, primarily as demonstrated through studies on tadpoles, are more susceptible to predation when exposed to some agrochemicals, cold water, high velocities, excess sedimentation, and even the presence of other species of predators (Harvey and Lisle 1998, Adams et al. 2003, Olson and Davis 2009, Kupferberg et al. 2011b, Kerby and Sih 2015, Catenazzi and Kupferberg 2018). Foothill Yellow-legged Frog tadpoles appear to be naïve to chemical cues from some non-native predators; they have not evolved those species-specific predator avoidance behaviors (Paoletti et al. 2011). Furthermore, early life stages are often more sensitive to environmental stressors, making them more vulnerable to predation, and Foothill Yellow-legged Frog population dynamics are highly sensitive to egg and tadpole mortality (Kats and Ferrer, 2003, Kupferberg et al. 2009c). Predation pressure is likely positively associated with proximity to anthropogenic changes in the environment, so in more remote or pristine places, it probably does not have a serious population-level impact.

Competition

Intra- and interspecific competition in Foothill Yellow-legged Frogs has been documented. Intraspecific male-to-male competition for females has been reported (Rombough and Hayes 2007). Observations include physical aggression and a non-random mating pattern in which larger males were more often engaged in breeding (Rombough and Hayes 2007, Wheeler and Welsh 2008). A behavior resembling clutch-piracy, where a satellite male attempts to fertilize already laid eggs, has also been documented (Rombough and Hayes 2007). These acts of competition play a role in population genetics, but they likely do not result in serious physical injury or mortality. Intraspecific competition among Foothill Yellow-legged Frog tadpoles was negligible (Kupferberg 1997a).

Interspecific competition appears to have a greater possibility of resulting in adverse impacts. Kupferberg (1997a) did not observe a significant change in tadpole mortality for Foothill Yellow-legged Frogs raised with Pacific Treefrogs compared to single-species controls. However, when reared together, Foothill Yellow-legged Frog tadpoles lost mass, while Pacific Treefrog tadpoles increased mass (Kerby and Sih 2015). As described previously under Introduced Species, Foothill Yellow-legged Frog tadpoles experienced significantly higher mortality and smaller size at metamorphosis when raised with bullfrog tadpoles (Kupferberg 1997a). The mechanism of these declines appeared to be exploitative competition, as opposed to interference, through the reduction of available algal resources from bullfrog tadpole grazing in the shared enclosures (Ibid.).

The degree to which competition threatens Foothill Yellow-legged Frogs likely depends on the number and density of non-native species in the area rather than intraspecific competition, and co-occurrence of Foothill Yellow-legged Frog and bullfrog tadpoles may be somewhat rare since the latter tends to breed in lentic (still water) environments (M. van Hattem pers. comm. 2019). Interspecific competition with other native species may have some minor adverse consequences on fitness.

Disease

Currently, the only disease known to pose a serious risk to Foothill Yellow-legged Frogs is Bd. Until 2017, the only published studies on the impact of Bd on Foothill Yellow-legged Frog suggested it could reduce growth and body condition but was not lethal (Davidson et al. 2007, Lowe 2009, Adams et al. 2017b). However, two recent mass mortality events caused by chytridiomycosis proved they are susceptible to lethal effects, at least under certain conditions like drought-related concentration and presence of bullfrogs (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Some evidence indicates disease may have played a principal role in the disappearance of the species from southern California (Adams et al. 2017b). Bd is likely present in the environment~~al~~ throughout the Foothill Yellow-legged Frog's range, and with bullfrogs and treefrogs acting as carriers, it will remain a threat to the species; however, given the dynamics of the two recent die-offs in the San Francisco Bay area, the probability of future outbreaks may be greater in areas where the species is under additional stressors like drought and introduced species (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Therefore, as with predation, Foothill Yellow-legged Frogs are less likely to experience the adverse impacts of diseases in more remote areas with fewer anthropogenic changes to the environment.

Other Natural Events or Human-Related Activities

Agrochemicals, particularly organophosphates that act as endocrine disruptors, can travel substantial distances from the area of application through atmospheric drift and have been implicated in the disappearance and declines of many species of amphibians in California including Foothill Yellow-legged Frogs (LeNoir et al. 1999, Davidson 2004, Lind 2005, Olson and Davis 2009). Foothill Yellow-legged Frogs appear to be significantly more sensitive to the adverse impacts of some pesticides than other native species (Sparling and Fellers 2009, Kerby and Sih 2015). These include smaller body size, slower development rate, increased time to metamorphosis, immunosuppression, and greater vulnerability to predation and malformations (Kiesecker 2002, Hayes et al. 2006, Sparling and Fellers 2009, Kerby and Sih 2015). Some of the most dramatic declines experienced by ranids in California occurred in the Sierra Nevada east of the San Joaquin Valley where over half of the state's total pesticide usage occurs (Sparling et al. 2001).

Many Foothill Yellow-legged Frog populations are small, isolated from other populations, and possess low genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). Genetic diversity is important in providing a population the capacity to evolve in response to environmental changes, and connectivity among populations is important for gene exchange and in minimizing probability of local extinction

(Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). Small populations are at much greater risk of extirpation primarily through the disproportionate impact of demographic, environmental, and genetic stochasticity than robust populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). Based on a Foothill Yellow-legged Frog PVA, populations in regulated rivers face a 4- to 13-fold greater extinction risk in 30 years than populations in unregulated rivers due to smaller population sizes (Kupferberg et al. 2009c). The threat posed by small population sizes is significant and the general pattern shows increases in severity from north to south; however, many sites, primarily in the northern Sierra Nevada, in watersheds with large hydropower projects are also at high risk.

PROTECTION AFFORDED BY LISTING

It is the policy of the State to conserve, protect, restore and enhance any endangered or threatened species and its habitat (Fish & G. Code, § 2052). The conservation, protection, and enhancement of listed species and their habitat is of statewide concern (Fish & G. Code, § 2051(c)). CESA defines "take" as hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill (Fish & G. Code, § 86). The Fish and Game Code provides the Department with related authority to authorize "take" of species listed as threatened or endangered under certain circumstances (see, e.g., Fish & G. Code, §§ 2081, 2081.1, 2086, & 2835).

If the Foothill Yellow-legged Frog is listed under CESA, impacts of take caused by activities authorized through incidental take permits must be minimized and fully mitigated according to state standards (Fish & G. Code, § 2081, subd. (b)). These standards typically include protection of land in perpetuity with an easement, development and implementation of a species-specific adaptive management plan, and funding through an endowment to pay for long-term monitoring and maintenance to ensure the mitigation land meets performance criteria. Obtaining an incidental take permit is voluntary. The Department cannot force compliance; however, any person violating the take prohibition may be criminally and civilly liable under state law.

Additional protection of Foothill Yellow-legged Frogs following listing would be expected to occur through state and local agency environmental review under CEQA. CEQA requires affected public agencies to analyze and disclose project-related environmental effects, including potentially significant impacts on rare, threatened, and endangered species. In common practice, potential impacts to listed species are examined more closely in CEQA documents than potential impacts to unlisted species. Where significant impacts are identified under CEQA, the Department expects project-specific avoidance, minimization, and mitigation measures to benefit the species. State listing, in this respect, and consultation with the Department during state and local agency environmental review under CEQA, would be expected to benefit the Foothill Yellow-legged Frog in terms of reducing impacts from individual projects, which might otherwise occur absent listing.

For some species, CESA listing may prompt increased interagency coordination and the likelihood that state and federal land and resource management agencies will allocate funds toward protection and recovery actions. In the case of the Foothill Yellow-legged Frog, some multi-agency efforts exist, often associated with FERC license requirements, to improve habitat conditions and augment declining populations. The USFWS is leading an effort to develop regional Foothill Yellow-legged Frog conservation strategies, and CESA listing may result in increased priority for limited conservation funds.

LISTING RECOMMENDATION

CESA directs the Department to prepare this report regarding the status of the Foothill Yellow-legged Frog in California based upon the best scientific information available (Fish & G. Code, § 2074.6). CESA also directs the Department based on its analysis to indicate in the status report whether the petitioned action (i.e., listing as threatened) is warranted (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

Under CESA, an endangered species is defined as "a native species or subspecies…which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish & G. Code, § 2062). A threatened species is defined as "a native species or subspecies…that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]" (Fish and G. Code, § 2067).

The Department includes and makes its recommendation in its status report as submitted to the Commission in an advisory capacity based on the best available science. In consideration of the scientific information contained herein, the Department has determined that listing the Foothill Yellow-legged Frog under CESA by genetic clade is the prudent approach due to the disparate degrees of imperilment among them. In areas of uncertainty, the Department recommends the higher protection status until clade boundaries can be better defined.

NORTHWEST/NORTH COAST: Not warranted at this time.

Clade-level Summary: This is the largest clade with the most robust populations (highest densities) and the greatest genetic diversity. This area is the least densely populated by humans; contains relatively few hydroelectric dams, particularly further north; and has the highest precipitation in the species' California range. The species is still known to occur in most, if not all, historically occupied watersheds; presumed extirpations are mainly concentrated in the southern portion of the clade around the heavily urbanized San Francisco Bay area. The proliferation of cannabis cultivation, particularly illicit grows in and around the Emerald Triangle, the apparent increase in severe wildland fires in the area, and potential climate change effects are cause for concern, so the species should remain a Priority 1 SSC here with continued monitoring for any change in its status.

WEST/CENTRAL COAST: Endangered.

Clade-level Summary: Foothill Yellow-legged Frogs appear to be extirpated from a relatively large proportion of historically occupied sites within this clade, particularly in the heavily urbanized northern portion around the San Francisco Bay. In the northern portion of the clade, nearly all the remaining populations (which may be fewer than a dozen) are located above dams, which line the mountains surrounding the Bay Area, and two are known to have undergone recent disease-associated die-offs. These higher elevation sites are more often intermittent or ephemeral streams than the lower in the watersheds. As a result, the more frequent and extreme droughts that have dried up large areas seem to have contributed to recent declines. Illegal cannabis cultivation, historical mining effects, overgrazing, and recreation likely contributed to declines and may continue to threaten remaining populations.

SOUTHWEST/SOUTH COAST: Endangered.

Clade-level Summary: The most extensive extirpations have occurred in this clade, and only two known extant populations remain. Both are small with apparently low genetic diversity, making them especially vulnerable to extirpation. This is also an area with a large human population, many dams, and naturally arid, fire-prone environments, particularly in the southern portion of the clade. Introduced species are widespread, and cannabis cultivation is rivaling the Emerald Triangle in some areas (e.g., Santa Barbara County). Introduced species, expanded recreation, disease, and flooding appear to have contributed to the widespread extirpations in southern California over 40 years ago.

FEATHER RIVER: Threatened.

Clade-level Summary: This is the smallest clade and has a high density of hydroelectric dams. It also recently experienced one of the largest, most catastrophic wildfires in California history. Despite these threats, Foothill Yellow-legged Frogs appear to continue to be relatively broadly distributed within the clade, although with all the dams in the area, most populations are likely disconnected. The area is more mesic and experienced less of a change in precipitation in the most recent drought than the clades south of it. The clade is remarkable genetically and morphologically as it is the only area where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs overlap and can hybridize. The genetic variation within the clade is greater than the other clades except for the Northwest/North Coast. Most of the area within the clade's boundaries is Forest Service-managed, and little urbanization pressure or known extirpations exist in this area. Recent FERC licenses in this area require Foothill Yellow-legged Frog specific conservation, which to date has included cancelling pulse flows, removing encroaching vegetation, and translocating egg masses and in situ head-starting to augment a population that had recently declined.

NORTHEAST/NORTHERN SIERRA: Threatened.

Clade-level Summary: The Northeast/Northern Sierra clade shares many of the same threats as the Feather River clade (e.g., relatively small area with many hydroelectric dams). The area is also more mesic and experienced less of a change in precipitation during the recent drought than more southern clades. However, this pattern may not continue as some models suggest loss of snowmelt will be greater in the northern Sierra Nevada, and one of the climate change exposure models suggests a comparatively large proportion of the lower elevations will experience climatic conditions not currently known from the area (i.e., non-analog) by the end of the century. Recent surveys suggest the area continues to support several populations of the species, some of which seem to remain robust, with a fairly widespread distribution. However, genetic analyses from several watersheds suggest many of these populations are isolated and diverging, particularly in regulated reaches with hydropeaking flows.

EAST/SOUTHERN SIERRA: Endangered.

Clade-level Summary: Like the Southwest/South Coast clade, widespread extirpations in this area were observed as early as the 1970s. Dams and introduced species were credited as causal factors in these declines in distribution and abundance, and mining and disease may also have contributed. This area is relatively arid, and drought effects appear greater here than in northern areas that exhibit both more precipitation and a smaller difference between drought years and the historical average. There is a relatively high number of hydroelectric power generating dams in series along the major rivers in this clade and at least one new proposed dam near one of the remaining populations. This area is also the most heavily impacted by agrochemicals from the San Joaquin Valley.

MANAGEMENT RECOMMENDATIONS

The Department has evaluated existing management recommendations and available literature applicable to the management and conservation of the Foothill Yellow-legged Frog to arrive at the following recommendations. These recommendations, which represent the best available scientific information, are largely derived the from the Foothill Yellow-legged Frog Conservation Assessment, the California Energy Commission's Public Interest Energy Research Reports, the Recovery Plans of West Coast Salmon and Steelhead, and the California Amphibian and Reptile Species of Special Concern (Kupferberg et al. 2009b,c; 2011a; NMFS 2012, 2013, 2014, 2016; Hayes et al. 2016, Thomson et al. 2016).

Conservation Strategies

Maintain current distribution and genetic diversity by protecting existing Foothill Yellow-legged Frog populations and their habitats and providing opportunities for genetic exchange. Increase abundance to viable levels in populations at risk of extirpation due to small sizes, when appropriate, through in situ or ex situ captive rearing and/or translocations. Use habitat suitability and hydrodynamic habitat models to identify historically occupied sites that may currently support Foothill Yellow-legged Frogs, or they could with minor habitat improvements or modified management. Re-establish extirpated populations in suitable habitat through captive propagation, rearing, and/or translocations. Prioritize areas in the southern portions of the species' range where extirpations and loss of diversity have been the most severe.

If establishing reserves, prioritize areas containing high genetic variation in Foothill Yellow-legged Frogs (and among various native species) and climatic gradients where selection varies over small geographical area because environmental heterogeneity can provide a means of maintaining phenotypic variability which increases the adaptive capacity of populations as conditions change. These reserves should provide connectivity to other occupied areas to facilitate gene flow and allow for ongoing selection to fire, drought, thermal stresses, and changing species interactions.

Research and Monitoring

Attempt to rediscover potentially remnant populations in areas where they are considered extirpated, prioritizing the southern portions of the species' range. Collect environmental DNA in addition to conducting visual encounter surveys to improve detectability. Concurrently assess presence of threats and habitat suitability to determine if future reintroductions may be possible. Collect genetic samples from any Foothill Yellow-legged Frogs captured for use in landscape genomics analyses and possible future translocation or captive propagation efforts. Attempt to better clarify clade boundaries where there is uncertainty. Study whether small populations are at risk of inbreeding depression, whether genetic rescue should be attempted, and if so, whether that results in hybrid vigor or outbreeding depression.

Continue to evaluate how water operations affect Foothill Yellow-legged Frog population demographics. Support, and coordinate existing monitoring and ~~Establish~~ establish more long-term monitoring programs in regulated and unregulated (reference) rivers across the species' range but particularly in areas like the Sierra Nevada where most large hydropower dams in the species' range are concentrated. Assess whether the timing of pulse flows influences population dynamics, particularly whether early releases have a disproportionately large adverse effect by eliminating the reproductive success of the largest, most fecund females, who appear to breed earlier in the season. Investigate survival rates in poorly-understood life stages, such as tadpoles, young of the year, and juveniles. Determine the extent to which pulse flows contribute to displacement and mortality of post-metamorphic life stages.

Collect habitat variables that correlate with healthy populations to develop more site-specific habitat suitability and hydrodynamic models. Study the potential synergistic effect of increased flow velocity and decreased temperature on tadpole fitness. Examine the relationship between changes in flow, breeding and rearing habitat connectivity, and scouring and stranding to develop site-specific benign ramping rates. Incorporate these data and demographic data into future PVAs for use in establishing frog-friendly flow regimes in future FERC relicensing or license amendment efforts and habitat restoration projects. Ensure long-term funding for post-license or restoration monitoring to evaluate attainment of expected results and for use in adapting management strategies accordingly.

Evaluate the distribution of other threats such as cannabis cultivation, vineyard expansion, livestock grazing, mining, timber harvest, and urbanization and roads in the Foothill Yellow-legged Frog's range. Study the short- and long-term effects of wildland fires and fire management strategies. Assess the extent to which these potential threats pose a risk to Foothill Yellow-legged Frog persistence in both regulated and unregulated systems.

Investigate how reach-level or short-distance habitat suitability and hydrodynamic models can be extrapolated to a watershed level. Study habitat connectivity needs such as the proximity of breeding sites and other suitable habitats along a waterway necessary to maintain gene flow and functioning meta-population dynamics.

Habitat Restoration and Watershed Management

Remove or update physical barriers like dams and poorly constructed culverts and bridges to improve connectivity and natural stream processes. Remove anthropogenic features that support introduced predators and competitors such as abandoned mine tailing ponds that support bullfrog breeding. Conduct active eradication and management efforts to decrease the abundance of bullfrogs, non-native fish, and crayfish (where they are non-native). In managed rivers, manipulate stream flows to negatively affect non-native species not adapted to a winter flood/summer drought flow regime.

Adopt a multi-species approach to channel restoration projects and managed flow regimes (thermal, velocity, timing) and mimic the natural hydrograph to the greatest extent possible. When this is impractical or infeasible, focus on minimizing adverse impacts by gradually ramping discharge up and down, creating and maintaining gently sloping and sun-lit gravel bars and warm calm edgewater habitats for tadpole rearing, and mixing hypolimnetic water (from the lower colder stratum in a reservoir) with warmer surface water before release if necessary to ensure appropriate thermal conditions for successful metamorphosis. Promote restoration and maintenance of habitat heterogeneity (different depths, velocities, substrates, etc.) and connectivity to support all life stages and gene flow. Avoid damaging Foothill Yellow-legged Frog breeding habitat when restoring habitat for other focal species like anadromous salmonids.

Regulatory Considerations and Best Management Practices

Develop range-wide minimum summer baseflow requirements that protect Foothill Yellow-legged Frogs and their habitat with appropriate provisions to address regional differences using new more ecologically-meaningful approaches such as modified percent-of-flow strategies for watersheds (e.g., Mierau et al. 2018). Limit water diversions during the dry season and construction of new dams by focusing on off-stream water storage strategies.

Ensure and improve protection of riparian systems. Require maintenance of appropriate riparian buffers and canopy coverage (i.e., partly shaded) around occupied habitat or habitat that has been identified for potential future reintroductions. Restrict instream work to dry periods where possible. Prohibit fording in and around breeding habitat. Avoid working near streams after the first major rains in the fall when Foothill Yellow-legged Frogs may be moving upslope toward tributaries and overwintering sites. Use a 3 mm (0.125 in) mesh screen on water diversion pumps and limit the rate and amount of water diverted such that depth and flow remain sufficient to support Foothill Yellow-legged Frogs of all life stages occupying the immediate area and downstream. Install exclusion fencing where appropriate (being mindful of predators, such as river otters, that may take advantage of fencing to catch frogs). I~~, and i~~f Foothill Yellow-legged Frog relocation is required, conduct it early in the season because moving egg masses is easier than moving tadpoles.

Reduce habitat degradation from sedimentation, pesticides, herbicides, and other non-point source waste discharges from adjacent land uses including along tributaries of rivers and streams. Limit mining to parts of rivers not used for oviposition, such as deeper pools or reaches with few tributaries, and at times of year when frogs are more common in tributaries (i.e., fall and winter). Manage recreational activities in or adjacent to Foothill Yellow-legged Frog habitat (e.g., OHV and hiking trails, camp sites, boating ingress/egress, flows, and speeds) in a way that minimizes adverse impacts. Siting cannabis grows in areas with better access to roads, gentler slopes, and ample water resources could significantly reduce threats to the environment. Determine which, when, and where agrochemicals should be restricted to reduce harm to Foothill Yellow-legged Frogs and other species. Ensure all new road crossings and upgrades to existing crossings (bridges, culverts, fills, and other crossings) accommodate at least 100-year flood flows and associated bedload and debris.

Partnerships and Coordination

Establish collaborative partnerships with agencies, universities, and non-governmental organizations working on salmon and steelhead recovery and stream restoration. Anadromous salmonids share many of the same threats as Foothill Yellow-legged Frogs, and recovery actions such as barrier removal, restoration of natural sediment transport processes, reduction in pollution, and eradication of non-native predators ~~would~~ should be planned so as to benefit frogs as well. Ensure Integrated Regional Water Management Plans and fisheries restoration programs take Foothill Yellow-legged Frog conservation into consideration during design, implementation, and maintenance.

Encourage local governments to place conditions on new developments to minimize negative impacts on riparian systems. Promote and implement initiatives and programs that improve water conservation use efficiency, reduce greenhouse gas emissions, promote sustainable agriculture and smart urban growth, and protect and restore riparian ecosystems. Shift reliance from on-stream storage to off-stream storage, resolve frost protection issues (water withdrawals), and ensure necessary flows for all life stages in all water years.

Establish a Department-coordinated staff and citizen scientist program to systematically monitor occupied stream reaches across the species' range.

Education and Enforcement

Support programs to provide educational outreach and local involvement in restoration and watershed stewardship, such as Project Wild, Adopt a Watershed, school district environmental camps, and other programs teaching the effects of human land and water use on Foothill Yellow-legged Frog survival.

Provide additional funding for increased law enforcement to reduce ecologically harmful stream alterations and water pollution and to ensure adequate protection for Foothill Yellow-legged Frogs at pumps and diversions. Identify and address illegal water diverters and out-of-compliance diverters, seasons of diversion, off-stream reservoirs, well pumping, and bypass flows to protect Foothill Yellow-legged Frogs. Prosecute violators accordingly.

ECONOMIC CONSIDERATIONS

The Department is charged in an advisory capacity in the present context to provide a written report and a related recommendation to the Commission based on the best scientific information available regarding the status of Foothill Yellow-legged Frog in California. The Department is not required to prepare an analysis of economic impacts (See Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

To: Patterson, Laura@Wildlife
Subject: RE: Peer Review Request: Foothill Yellow-legged Frog Status Review
Attachments: DRAFT FYLF Status Review-2019.05.21_Lind.docx

Laura – I have gotten through a bit of the document and am now out of the office until July 1. I have included my comments as 'track changes' text edits, or margin notes, through page 35, in the attached WORD document. I was unable to just pick and choose sections to read (lost the thread too much), so I did start at the beginning and work forward.

If you would like my comments on the remainder of the document, I may be to work on it again in early July. Let me know.

Overall, I found this to be a comprehensive document on the status of the foothill yellow-legged frog (*Rana boylii*) in California. It is well written with clear logic. The incorporation of new genetic data is a big positive!

A couple of "housekeeping" items:

- Recommend number the Sections/Subsections for ease of referencing and so the reader can better follow the different heading levels (e.g., 1.0, 1.1, 1.1.1, 1.1.2, etc.)
- Check the use of present and past tense throughout the document – I noted a few places where things seems off.
- Figures:
  - For figures taken from other sources, remove the original figure number and legend, describe the figure in your own words in this document's caption, and cite appropriately (e.g., your Figures 2 and 4)
  - Also, some figures are in the figure list, and included in the text, but never referenced in the text.
  - Consider adding more references to figures (you can point to them more than once if they are relevant) – as they say "a picture is worth 1000 words" ☺

I apologize that I was unable to complete the full review on your requested timeline. My upcoming time off has been planned for months.
Best Regards,
Amy

Subject: RE: Peer Review Request: Foothill Yellow-legged Frog Status Review

Okay, thanks. The letter gives some instruction on what to focus on, but here's how I'd prioritize your review by the major headings in the TOC:

1. Factors Affecting Ability to Survive and Reproduce
2. Status and Trends in California
3. Existing Management
4. Management Recommendations
5. Biology and Ecology
6. Protection Afforded by Listing
7. Summary of Listing Factors
8. Listing Recommendation

If you have very limited time, please try to get through 1, 2, 7 and 8. You can completely ignore the Regulatory Setting and Economic Considerations.

Thanks so much!

Good afternoon, Dr. Lind,

Thanks for your patience. We had a couple of loose ends to tie up. Please see the attached letter and draft status review. If you have any questions or concerns with the timeline, please let me know.

Will you please respond to this email to confirm you received it?

Thanks again,
Laura

Subject: RE: Peer Review Request: Foothill Yellow-legged Frog Status Review

Laura – Sorry for the delayed reply. I am happy to respond positively to your request for a peer review of the California status review for the foothill yellow-legged frog and I look forward to seeing the draft document.

My only constraint is timing. I will be out of town during a portion of the proposed review period. I will do my best to respond by mid-June (as described in your email) and I will certainly update you if I need a few more days.

Thank you for including me in this process,
Amy

Subject: Peer Review Request: Foothill Yellow-legged Frog Status Review

Dear Dr. Lind,

The Fish and Game Commission (Commission) was petitioned to list the Foothill Yellow-legged Frog as threatened under the California Endangered Species Act (CESA) by the Center for Biological Diversity in December 2016. The California Department of Fish and Wildlife (Department) is tasked with writing a status review and providing a recommendation to the Commission on whether or not the best scientific information available supports the petitioner's position that listing is warranted. Part of the status review process is external peer review of the draft status review.

I am contacting you as a Foothill Yellow-legged Frog subject matter expert to request your participation in the peer review process. The Department expects the draft will be ready on for distribution to peer reviewers on or around May 17th. We would ask that you focus your review on the scientific information available regarding the status of Foothill Yellow-legged Frogs in California. Your peer review of the science and analysis regarding each of the listing factors prescribed in CESA (i.e., present or threatened habitat modification, overexploitation, predation, competition, disease, and other natural occurrences or human-related activities that could affect the species) is particularly valuable. We request that comments be submitted on or before one month from the date of receipt (on or around June 17th).

In addition, per the Department's Peer Review Policy (Department Bulletin 2017-03), I must ensure that you have no financial or other conflict of interest with the outcome or implications of the peer reviewed product.

Please respond to whether you are willing and able to participate in this important part of the listing determination process by Thursday April 11th.

Thank you for your consideration,
Laura

ACKNOWLEDGMENTS

Laura Patterson prepared this report. Stephanie Hogan, Madeleine Wieland, and Margaret Mantor assisted with portions of the report, including the sections on Status and Trends in California and Existing Management. Kristi Cripe provided GIS analysis and figures. Review of a draft document was provided by the following California Department of Fish and Wildlife (Department) staff: Ryan Bourque, Marcia Grefsrud, and Mike van Hattem.

The Department is extremely grateful for the valuable comments provided on this report by the following peer reviewers: Dr. Sarah Kupferberg, Dr. Amy Lind, Dr. Jimmy McGuire, and Dr. Ryan Peek. The conclusions in this report are those of the Department and do not necessarily reflect those of the reviewers.

EXECUTIVE SUMMARY

[To be completed after external peer review]

REGULATORY SETTING

Petition Evaluation Process

A petition to list the Foothill Yellow-legged Frog (*Rana boylii*) as threatened under the California Endangered Species Act (CESA) was submitted to the Fish and Game Commission (Commission) on December 14, 2016 by the Center for Biological Diversity. Commission staff transmitted the petition to the Department of Fish and Wildlife (Department) pursuant to Fish and Game Code section 2073 on December 22, 2016 and published a formal notice of receipt of the petition on January 20, 2017 (Cal. Reg. Notice Register 2017, No. 3-Z, p. 46). A petition to list or delist a species under CESA must include "information regarding the population trend, range, distribution, abundance, and life history of a species, the factors affecting the ability of the population to survive and reproduce, the degree and immediacy of the threat, the impact of existing management efforts, suggestions for future management, and the availability and sources of information. The petition shall also include information regarding the kind of habitat necessary for species survival, a detailed distribution map, and any other factors that the petitioner deems relevant" (Fish & G. Code, § 2072.3).

On April 17, 2017, the Department provided the Commission with its evaluation of the petition, "Evaluation of the Petition from the Center For Biological Diversity to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened under the California Endangered Species Act," to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5 & 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & (e)). Focusing on the information available to the Department relating to each of the relevant categories, the Department recommended to the Commission that the petition be accepted.

At its scheduled public meeting on June 21, 2017, in Smith River, California, the Commission considered the petition, the Department's petition evaluation and recommendation, and comments received. The Commission found that sufficient information existed to indicate the petitioned action may be warranted and accepted the petition for consideration. Upon publication of the Commission's notice of its findings, the Foothill Yellow-legged Frog was designated a candidate species on July 7, 2017 (Cal. Reg. Notice Register 2017, No. 27-Z, p. 986).

Status Review Overview

The Commission's action designating the Foothill Yellow-legged Frog as a candidate species triggered the Department's process for conducting a status review to inform the Commission's decision on whether listing the species is warranted. At its scheduled public meeting on June 21, 2018, in Sacramento, California, the Commission granted the Department a six-month extension to complete the status review and facilitate external peer review.

This status review report is not intended to be an exhaustive review of all published scientific literature relevant to the Foothill Yellow-legged Frog; rather, it is intended to summarize the key points from the best scientific information available relevant to the status of the species. This final report, based upon the best scientific information available to the Department, is informed by independent peer review of a draft report by scientists with expertise relevant to the Foothill Yellow-legged Frog. This review is intended to provide the Commission with the most current information on the Foothill Yellow-legged Frog and to serve as the basis for the Department's recommendation to the Commission on whether the petitioned action is warranted. The status review report also identifies habitat that may be essential to continued existence of the species and provides management recommendations for recovery of the species (Fish & G. Code, § 2074.6). Receipt of this report is to be placed on the agenda for the next available meeting of the Commission after delivery. At that time, the report will be made available to the public for a 30-day public comment period prior to the Commission taking any action on the petition.

Federal Endangered Species Act Review

The Foothill Yellow-legged Frog is currently under review for possible listing as threatened or endangered under the federal Endangered Species Act (ESA) in response to a July 11, 2012 petition submitted by the Center for Biological Diversity. On July 1, 2015, the U.S. Fish and Wildlife Service (USFWS) published its 90-day finding that the petition presented substantial scientific or commercial information indicating that the petitioned action may be warranted and initiated a status review of the species (USFWS 2015). On March 16, 2016, the Center for Biological Diversity sued the USFWS to compel issuance of a 12-month finding on whether listing under the ESA is warranted. On August 30, 2016, the parties reached a stipulated settlement agreement that the USFWS shall publish its 12-month finding in the Federal Register on or before September 30, 2020 (*Center for Biological Diversity v. S.M.R. Jewell* (D.D.C. Aug. 30, 2016, No. 16-CV-00503)).

BIOLOGY AND ECOLOGY

Species Description and Life History

> *"In its life-history* boylii *exhibits several striking specializations which are in all probability related to the requirements of life of a stream-dwelling species"* – Tracy I. Storer, 1925

The Foothill Yellow-legged Frog is a small- to medium-sized frog; adults range from 38 to 81 mm (1.5-3.2 in) snout to urostyle length (SUL) with females attaining a larger size than males and males possessing paired internal vocal sacs (Zweifel 1955, Nussbaum et al. 1983, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs are typically gray, brown, olive, or reddish with brown-black flecking and mottling, which generally matches the substrate of the stream in which they reside (Nussbaum et al. 1983, Stebbins and McGinnis 2012). They often have a pale triangle between the eyes and snout and broad dark bars on the hind legs (Zweifel 1955, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs have a relatively squat body and granular skin, giving them a rough appearance similar to a toad, and fully webbed feet with slightly expanded toe tips (Nussbaum et al. 1983). The tympanum is also rough

and relatively small compared to congeners at around one-half the diameter of the eye (Zweifel 1955). The dorsolateral folds (glandular ridges extending from the eye area to the rump) in Foothill Yellow-legged Frogs are indistinct compared to other western North American ranids (Stebbins and McGinnis 2012). Ventrally, the abdomen is white with variable amounts of dark mottling on the chest and throat, which are unique enough to be used to identify individuals (Marlow et al. 2016). As their name suggests, the underside of their hind limbs and lower abdomen are often yellow; however, individuals with orange and red have been observed within the range of the California Red-legged Frog (*Rana draytonii*), making hindlimb coloration a poor diagnostic characteristic for this species (Jennings and Hayes 2005).

Adult females likely lay one clutch of eggs per year and may breed every year (Storer 1925, Wheeler et al. 2006). Foothill Yellow-legged Frog egg masses resemble a compact cluster of grapes approximately 45 to 90 mm (1.8-3.5 in) in diameter length-wise and contain anywhere from around 100 to over 3,000 eggs (Kupferberg et al. 2009c, Hayes et al. 2016). The individual embryos are dark brown to black with a lighter area at the vegetative pole and surrounded by three jelly envelopes that range in diameter from approximately 3.9 to 6.0 mm (0.15-0.25 in) (Storer 1925, Zweifel 1955, Hayes et al. 2016).

Foothill Yellow-legged Frog tadpoles hatch out around 7.5 mm (0.3 in) long and are a dark brown or black (Storer 1925, Zweifel 1955). They grow rapidly to 37 to 56 mm (1.5-2.2 in) and turn olive with a coarse brown mottling above and an opaque silvery color below (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012). Their eyes are positioned dorsally when viewed from above (i.e., within the outline of the head), and their mouths are large, downward-oriented, and suction-like with several tooth rows (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012, Hayes et al. 2016). Foothill Yellow-legged Frogs metamorphose at around 14-17 mm (0.55-0.67 in) SUL (Fellers 2005). Sexual maturity is attained at around 30-40 mm (1.2-1.6 in) SUL and 1 year for males and around 40-50 mm (1.6-2.0 in) SUL and 3 years for females, although in some populations this has been accelerated by a year (Zweifel 1955, Kupferberg et al. 2009c, Breedveld and Ellis 2018). During the breeding season, males can be distinguished from females by the presence of nuptial pads (swollen darkened thumb bases that aid in holding females during amplexus) and calling, which frequently occurs underwater but sometimes from the surface (MacTague and Northen 1993, Stebbins 2003, Silver 2017).

The reported lifespan of Foothill Yellow-legged Frogs varies widely by study. Storer (1925) and Van Wagner (1996) estimated a maximum age of 2 years for both sexes and the vast majority of the population. Breedveld and Ellis (2018) calculated the typical lifespan of males at 3-4 years and 5-6 years for females. Bourque (2008), using skeletochronology, found an individual over 7 years old and a mean age of 4.7 and 3.6 years for males and females, respectively. Drennan et al. (2015) estimated maximum age at 13 years for both sexes in a Sierra Nevada population and 12 for males and 11 for females in a Coast Range population.

Commented [USFS_AJL1]: Check this reference again. Is this correct? It is hard to imagine anyone thinking they only lived two years.

Range and Distribution

Foothill Yellow-legged Frogs historically ranged from the Willamette River drainage in Oregon west of the Sierra-Cascade crest to at least the San Gabriel River drainage in Los Angeles County, California (Figure 1; Zweifel 1955, Stebbins 2003). In addition, a disjunct population was reported from 2,040 m

Figure 1. Foothill Yellow-legged Frog historical range (adapted from CWHR, Loomis [1965], Nussbaum et al. [1983])

(6,700 ft) in the Sierra San Pedro Mártir, Baja California Norte, México (Loomis 1965). In California, the species occupies foothill and mountain streams in the Klamath, Cascade, Sutter Buttes, Coast, Sierra Nevada, and Transverse ranges from sea level to 1,940 m (6,400 ft), but generally below 1,525 m (5,000 ft) (Hemphill 1952, Nussbaum et al. 1983, Stebbins 2003, Olson et al. 2016). Zweifel (1955) considered Foothill Yellow-legged Frogs to be present and abundant throughout their range where streams possessed suitable habitat.

Taxonomy and Phylogeny

Foothill Yellow-legged Frogs belong to the family Ranidae (true frogs), which inhabits every continent except Antarctica and contains more than 700 species (Stebbins 2003). The species was first described by Baird (1854) as *Rana boylii*. After substantial taxonomic uncertainty with respect to its relationship to other ranids (frogs in the family Ranidae) and several name changes over the next century, the Foothill Yellow-legged Frog (*R. boylii* with no subspecific epithet) was eventually recognized as a distinct species again by Zweifel (1955, 1968). The phylogenetic relationships among the western North American *Rana* spp. have been revised several times and are still not entirely resolved (Thomson et al. 2016). The Foothill Yellow-legged Frog was previously thought to be most closely related to the higher elevation Mountain Yellow-legged Frog (*R. muscosa*) (Zweifel 1955; Green 1986a,b). However, genetic analyses undertaken by Macey et al. (2001) and Hillis and Wilcox (2005) suggest they are more closely related to Oregon Spotted Frogs (*R. pretiosa*) and Columbia Spotted Frogs (*R. luteiventris*), respectively.

Population Structure and Genetic Diversity

Foothill Yellow-legged Frog populations exhibit varying levels of partitioning and genetic diversity at different spatial scales. At the coarse landscape level across the species' extant range, McCartney-Melstad et al. (2018) recovered five deeply divergent, geographically cohesive, genetic clades (Figure 2), while Peek (2018) recovered six (Figure 3). Genetic divergence is the process of speciation; it is a measure of the number of mutations accumulated by populations over time from a shared ancestor that differentiate them from the other populations in a species. When genetic divergence among clades is large enough, it can be used as a tool to define new species or subspecies.

The geographic breaks among the five clades were similar between the studies, but Peek (2018) identified a separate deeply divergent genetic clade in the Feather River watershed that is distinct from the rest of the northern Sierra Nevada clade. The five clades the two studies shared include the following [Note: naming conventions follow McCartney-Melstad et al. (2018) and Peek (2018)]:

(1) Northwest/North Coast: north of San Francisco Bay in the Coast Ranges and east into Tehama County;
(2) Northeast/Northern Sierra: northern El Dorado County (North Fork American River watershed, includes Middle Fork) and north in the Sierra Nevada to southern Plumas County (Upper Yuba River watershed);

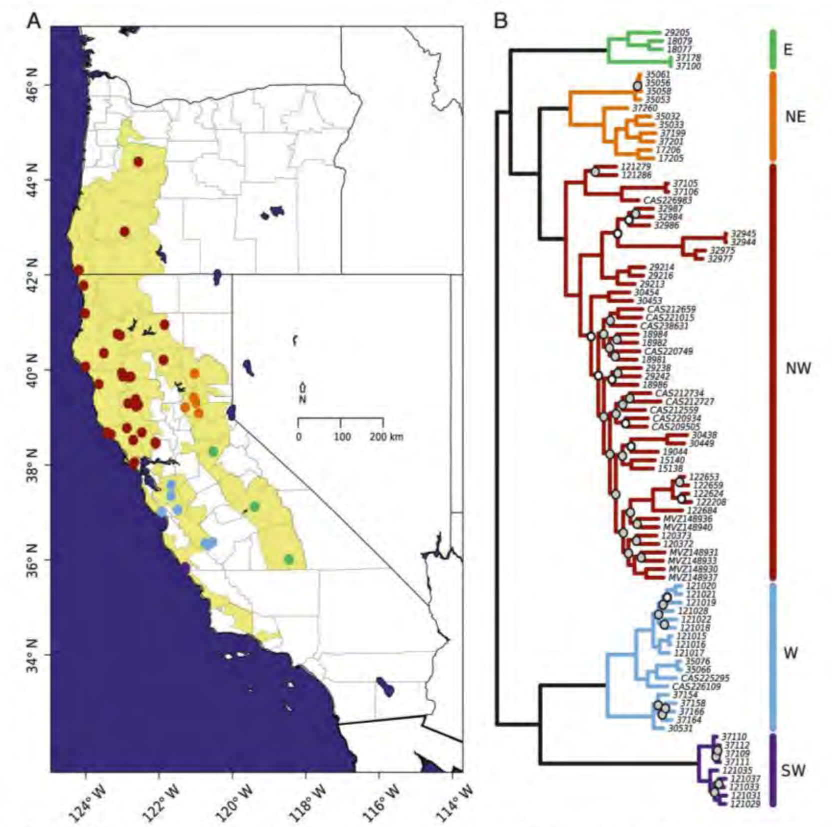

Fig. 1 **a** Map of *Rana boylii* sample localities. County outlines are shown within California and Oregon. Light yellow indicates the IUCN range map of *R. boylii*, excluding a small disjunct population at Sierra San Pedro Martir, Baja California, Mexico. Dots are colored by major grouping as determined in the **b** RAxML phylogeny, with midpoint rooting. Nodes without dots received >95% bootstrap support, those with white dots received <95% but greater than or equal to 75% bootstrap support, while nodes with gray dots received <75% bootstrap support

Figure 2. Foothill Yellow-legged Frog clades by McCartney-Melstad et al. (2018)

(3) East/Southern Sierra: El Dorado County (South Fork American River watershed) and south in the Sierra Nevada [no samples from Amador County were tested, but they would most likely fall within this clade because it is located between two other populations that occur within this clade];

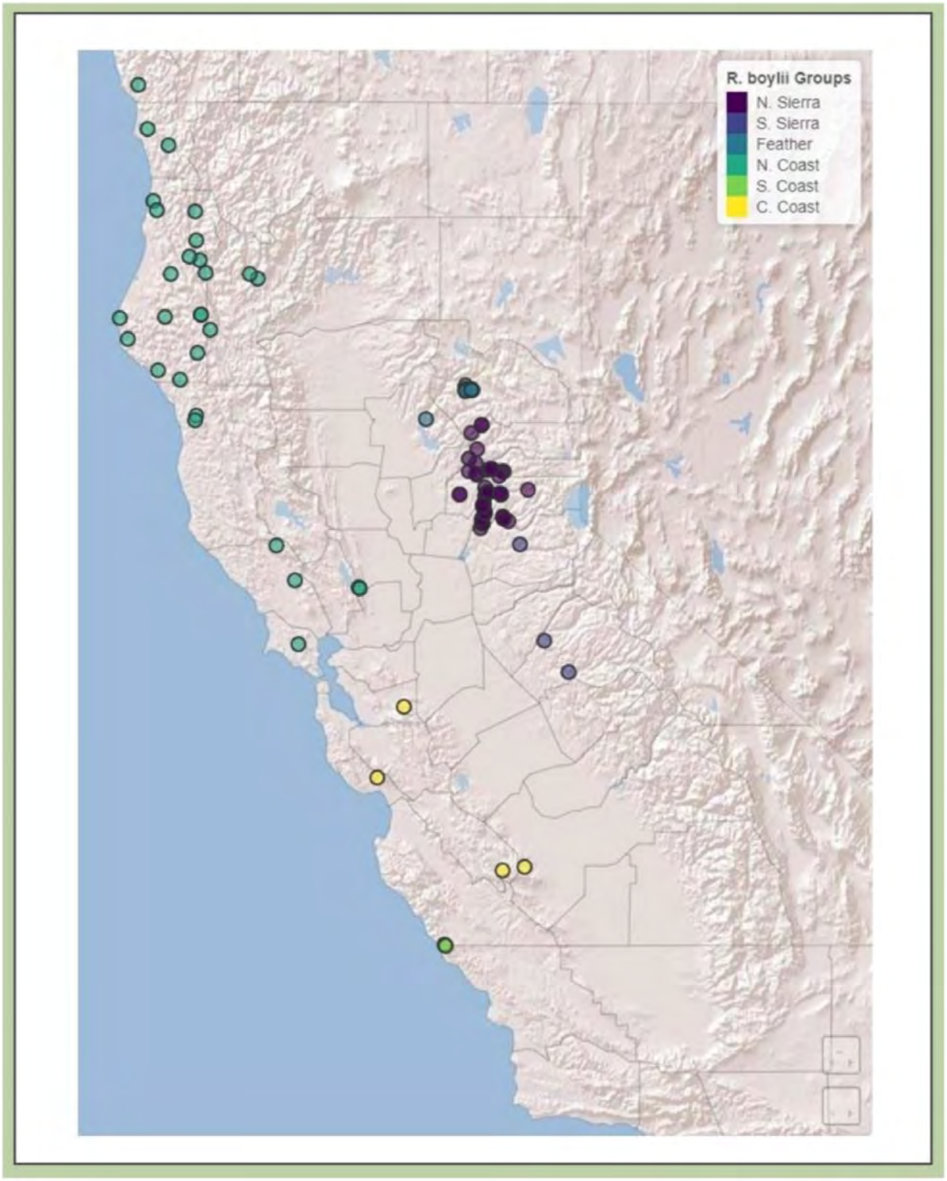

Figure 3. Foothill Yellow-legged Frog clades by Peek (2018)

(4) West/Central Coast: south of San Francisco Bay in the Coast Ranges to San Benito and Monterey counties, presumably east of the San Andreas Fault/Salinas Valley;

(5) Southwest/South Coast presumably west of the San Andreas Fault/Salinas Valley in Monterey County and south in the Coast Ranges.

The Feather River clade is found primarily in Plumas and Butte counties (Peek 2018). Peek's analysis found that this clade is as distinct as the rest of the Sierra Nevada as a cohesive group and all the coastal populations as one group, meaning it was found to be deeply divergent from the rest of the clades. McCartney-Melstad et al. (2018) also recognized the Feather River watershed as distinct from the rest of the northern Sierra but not as deeply divergent from the other clades as Peek. The Feather River watershed is also the only known location where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs (*R. sierrae*) co-occur and where two F1 hybrids (50% ancestry from each species) were found (Peek 2018). In addition, Peek's modeling results only weakly supported dividing the West/Central Coast and Southwest/South Coast groups into separate clades.

Previous work conducted by Lind et al. (2011) found a somewhat similar pattern, that populations on the periphery of the species' range are considerably genetically divergent from the rest of the range. Their results suggested that hydrologic regions and river basins were important landscape features that influenced the genetic structure of Foothill Yellow-legged Frog populations. However, using more modern genomic techniques, McCartney-Melstad et al. (2018) found nearly twice the variation among the five phylogenetic clades than among drainage basins, indicating other factors contributed to current population structure. They report that the depth of genetic divergence among Foothill Yellow-legged Frog clades exceeds that of any anuran (frog or toad) for which similar data are available and recommend using them as management units instead of the previously suggested watershed boundaries.

Levels of genetic diversity within the clades differed significantly. Genetic diversity gives species the ability to adapt to changing conditions (i.e., evolve), and its loss often signals extreme population and range reductions as well as potential inbreeding depression that can reduce survival and reproductive success (Lande and Shannon 1996, Hoffmann and Sgrò 2011, McCartney-Melstad et al. 2018). Loss of genetic diversity in Foothill Yellow-legged Frogs largely follows a north-to-south pattern with the southern clades (Southwest/South Coast and East/Southern Sierra) possessing the least amount (McCartney-Melstad et al. 2018, Peek 2018). In addition, these study results demonstrate that Foothill Yellow-legged Frogs have lost genetic diversity over time across their entire range except for the large Northwest/North Coast clade, which appears to have undergone a relatively recent population expansion (McCartney-Melstad et al. 2018, Peek 2018).

Commented [USFS_AJL2]: This is a key paragraph!

At a watershed scale, Dever (2007) found that tributaries to rivers and streams are important for preserving genetic diversity, and populations separated by more than 10 km (6.2 mi) show signs of genetic isolation. In other words, even in the absence of anthropogenic barriers to dispersal (e.g., dams and reservoirs), individuals located more than 10 km (6.2 mi) are not typically considered part of a single interbreeding population (Olson and Davis 2009). Peek (2011, 2018) reported that at this finer-scale, population structure and genetic diversity appear to be more strongly influenced by river regulation type (i.e., dammed or undammed) than to geographic distance or watershed boundaries. In general, regulated (dammed) rivers had limited gene flow and higher genetic divergence among subpopulations compared with unregulated (undammed) rivers (Peek 2011, 2018). In addition, differences in water flow regimes within regulated rivers affected connectivity (Peek 2011, 2018). Subpopulations in hydropeaking reaches, in which pulsed flows are used for electricity generation or whitewater boating, exhibited significantly lower gene flow than those in bypass reaches where water is diverted from upstream in the basin down to power generating facilities (Figure 4; Peek 2018). River regulation had a greater influence on genetic differentiation among sites than geographic distance in the Alameda Creek watershed as well (Stillwater Sciences 2012). Reduced connectivity among sites leads to lower gene flow and a loss of genetic diversity through genetic drift, which can diminish adaptability to changing environmental conditions (Palstra and Ruzzante 2008). Peek (2011) posits that given the *R. boylii* species group is estimated to be 8 million years old (Macey et al. 2001), the significant reductions in connectivity and genetic diversity over short evolutionary time periods in regulated rivers (often less than 50 years from the time of dam construction) is cause for concern, particularly when combined with small population sizes.

Commented [USFS_AJL3]: This one too!

Habitat Associations and Use

> *"These frogs are so closely restricted to streams that it is unusual to find one at a greater distance from the water than it could cover in one or two leaps."* – Richard G. Zweifel, 1955

Foothill Yellow-legged Frogs inhabit rivers and streams ranging from primarily rain-fed (coastal populations) to primarily snow-influenced (most Sierra Nevada and Klamath-Cascade populations) from headwater streams to large rivers (Bury and Sisk 1997, Wheeler et al. 2014). Occupied rivers and streams flow through a variety of vegetation types including hardwood, conifer, and valley-foothill riparian forests; mixed chaparral; and wet meadows (Hayes et al. 2016). Because the species is so widespread and can be found in so many types of habitats, the vegetation community is likely less important in determining Foothill Yellow-legged Frog occupancy and abundance than the aquatic biotic and abiotic conditions in the specific river, stream, or reach (Zweifel 1955). The species is an obligate stream-breeder, which sets it apart from other western North American ranids (Wheeler et al. 2014). Foothill Yellow-legged Frog habitat is generally characterized as partly-shaded, shallow, perennial rivers and streams with a low gradient and rocky substrate that is at least cobble-sized (Zweifel 1955, Hayes and Jennings 1988). However, the use of intermittent and ephemeral streams by post-metamorphic Foothill Yellow-legged Frogs may not be all that uncommon in some parts of the species' range in California (R. Bourque pers. comm. 2019). The species has been reported from some atypical habitats as well, including ponds, isolated pools in intermittent streams, and meadows along the edge of streams that lack a rocky substrate (Fitch 1938, Zweifel 1955, J. Alvarez pers. comm. 2017, CDFW 2018a).

As stream-breeding poikilotherms (animals whose internal temperature varies with ambient temperature), appropriate flow velocity, temperature, and water availability are critically important to Foothill Yellow-legged Frogs (Kupferberg 1996a, Van Wagner 1996, Wheeler et al. 2006, Lind et al. 2016). Habitat quality is also influenced by hydrologic regime (regulated vs. unregulated), substrate, presence of non-native predators and competitors, water depth, and availability of high-quality food and basking sites (Lind et al. 1996, Yarnell 2005, Wheeler et al. 2006, Catenazzi and Kupferberg 2017). Habitat suitability and use vary by life stage, sex, geographic location, watershed size, and season and

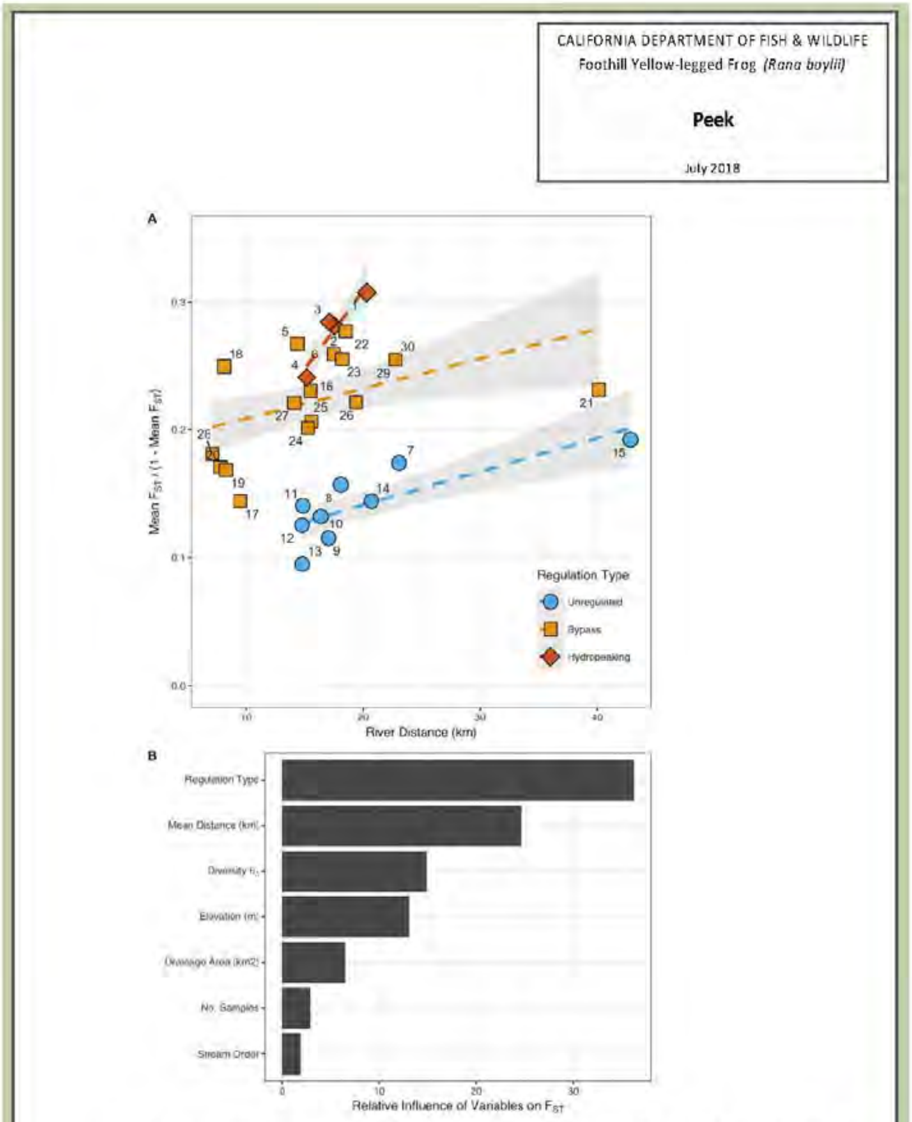

Figure 3. Relationship between river regulation and genetic differentiation in FYLF. A) Mean pairwise F_{ST} vs. mean river distance for each location; B) Relative influence of variables on F_{ST} from boosted regression tree models.

Figure 4. River regulation's relative influence on genetic differentiation from Peek (2018)

can generally be categorized as breeding and rearing habitat, nonbreeding active season habitat, and overwintering habitat (Van Wagner 1996, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011, Hayes et al. 2016, Catenazzi and Kupferberg 2017). Yarnell (2005) located higher densities of Foothill Yellow-legged Frogs in areas with greater habitat heterogeneity and suggested that they were selecting for sites that possessed the diversity of habitats necessary to support each life stage within a relatively short distance.

Breeding and Rearing Habitat

Suitable breeding habitat must be connected to suitable rearing habitat for metamorphosis to be successful. When this connectivity exists, as flows decline through the season, tadpoles can follow the receding shoreline into areas of high productivity and lower predation risk as opposed to becoming trapped in isolated pools with a high risk of overheating, desiccation, and predation (Kupferberg et al. 2009c).

Several studies on Foothill Yellow-legged Frog breeding habitat, carried out across the species' range in California, reported similar findings. Foothill Yellow-legged Frogs select oviposition (egg-laying) sites within a narrow range of depths, velocities, and substrates and exhibit fidelity to breeding sites that consistently possess suitable microhabitat characteristics over time (Kupferberg 1996a, Bondi et al. 2013, Lind et al. 2016). At a coarse-spatial scale, breeding sites in rivers and large streams are often located near the confluence of tributary streams in sunny, wide, shallow reaches (Kupferberg 1996a, Yarnell 2005, GANDA 2008, Peek 2011). These areas are highly productive compared to cooler, deeper, closed-canopy sites (Catenazzi and Kupferberg 2013). At a fine-spatial scale, females prefer to lay eggs in low velocity areas dominated by cobble- and boulder-sized substrates, often associated with sparsely-vegetated point bars (Kupferberg 1996a, Lind et al. 1996, Van Wagner 1996, Bondi et al. 2013, Lind et al. 2016). They tend to select areas with less variable, more stable flows, and in areas with higher flows at the time of oviposition, they place their eggs on the downstream side of large cobblestones and boulders, which protects them from being washed away (Kupferberg 1996a, Wheeler et al. 2006).

Appropriate rearing temperatures are vital for successful metamorphosis. Tadpoles grow faster and larger in warmer water to a point (Zweifel 1955; Catenazzi and Kupferberg 2017, 2018). Zweifel (1955) conducted experiments on embryonic thermal tolerance and determined that the critical low was approximate 6°C (43°F), and the critical high was around 26°C (79°F). Welsh and Hodgson (2011) determined that best the single variable for predicting Foothill Yellow-legged Frog presence was temperature since none were observed below 13°C (55°F), but numbers increased significantly with increasing temperature. Catenazzi and Kupferberg (2013) measured tadpole thermal preference at 16.5-22.2°C (61.7-72.0°F), and the distribution of Foothill Yellow-legged Frog populations across a watershed was consistent within this temperature range. At temperatures below 16°C (61°F), tadpoles were absent under closed canopy and scarce even with an open canopy (Ibid.). Catenazzi and Kupferberg (2017) found regional differences in apparently suitable breeding temperatures. Inland populations from primarily snowmelt-fed systems with relatively cold water were relegated to reaches that are warmer on average during the warmest 30 days of the year than coastal populations in the chiefly rainfall-fed, and thus warmer, systems (17.6-24.2°C [63.7-75.6°F] vs. 15.7-22.0°C [60.3-71.6°F], respectively).

However, experiments on tadpole thermal preference demonstrated that individuals from different source populations selected similar rearing temperatures, which presumably optimized development (Ibid.). In regulated systems, where water released from dams is often colder than normal, suitable rearing temperatures downstream may be limited (Wheeler et al. 2014, Catenazzi and Kupferberg 2017).

Appropriate flow velocities are also critical for survival to metamorphosis. The velocity at which Foothill Yellow-legged Frog egg masses shear away from the substrate they are adhered to varies according to factors such as depth and degree to which the eggs are sheltered (Spring Rivers Ecological Sciences 2003). This critical velocity is expected to decrease as the egg mass ages due to their reduced structural integrity of the protective jelly envelopes (Hayes et al. 2016). Short-duration increases in flow velocity may be tolerated if the egg masses are somewhat sheltered, but sustained high velocities increase the likelihood of detachment (Kupferberg 1996a, Spring Rivers Ecological Sciences 2003). Hatchlings and tadpoles about to undergo metamorphosis are relatively poor swimmers and require especially slow, stable flows during these stages of development (Kupferberg et al. 2011b). Tadpoles respond to increasing flows by swimming against the current to maintain position for a short period of time and eventually swimming to the bottom and seeking refuge in the rocky substrate's interstitial spaces (Ibid.). When tadpoles are exposed to repeated increases in velocities, their growth and development are delayed (Ibid.). Under experimental conditions, the critical velocity at which tadpoles were swept downstream ranged between 20 and 40 cm/s (0.66-1.31 ft/s); however, as they reach metamorphosis it decreases to as low as 10 cm/s (0.33 ft/s) (Ibid.).

Nonbreeding Active Season Habitat

Post-metamorphic Foothill Yellow-legged Frogs utilize a more diverse range of habitats and are much more dispersed during the nonbreeding active season than the breeding season. Microhabitat preferences appear to vary by location and season, but some patterns are common across the species' range. Foothill Yellow-legged Frogs tend to remain close to the water's edge (average < 3 m [10 ft]); select sunny areas with limited canopy cover; and are often associated with riffles and pools (Zweifel 1955, Hayes and Jennings 1988, Van Wagner 1996, Welsh et al. 2005, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011). Adequate water, food resources, cover from predators, ability to thermoregulate (e.g., presence of basking sites and cool refugia), and absence of non-native predators are important components of nonbreeding active season habitat (Hayes and Jennings 1988, Van Wagner 1996, Catenazzi and Kupferberg 2013).

Overwintering Habitat

Overwintering habitat varies depending on local conditions, but as with the rest of the year, Foothill Yellow-legged Frogs are most often found in or near water where they can forage and take cover from predators and high discharge events (Storer 1925, Zweifel 1955). In larger streams and rivers, Foothill Yellow-legged Frogs are often found along tributaries during the winter where the risk of being displaced by heavy flows is reduced (Kupferberg 1996a, Gonsolin 2010). Bourque (2008) found 36.4% of adult females used intermittent and ephemeral tributaries during the overwintering season. Van

Wagner (1996) located most overwintering frogs using pools with cover such as boulders, root wads, and woody debris. During high flow events, they moved to the stream's edge and took cover under vegetation like sedges (*Carex* sp.) or leaf litter (Ibid.). Rombough (2006) found most Foothill Yellow-legged Frogs under woody debris along the high-water line and often using seeps along the stream-edge, which provided them with moisture, a thermally stable environment, and prey.

Exceptions to the pattern of remaining near the stream's edge during winter have been reported. Cook et al. (2012) observed dozens of juvenile Foothill Yellow-legged Frogs traveling over land, as opposed to using riparian corridors. They were found using upland habitats with an average distance of 71.3 m (234 ft) from water (range: 16-331 m [52-1,086 ft]) (Ibid.). In another example, a single subadult that was found adjacent to a large wetland complex 830 m (2,723 ft) straight-line distance from the wetted edge of the Van Duzen River, although it is possible the wetland was connected to the river via a spillway or drainage that may have served as the movement corridor (CDFW 2018a, R. Bourque pers. comm. 2019).

Seasonal Activity and Movements

Because Foothill Yellow-legged Frogs occupy areas with relatively mild winter temperatures, they can be active year-round, although at low temperatures (< 7°C [44 °F], they become lethargic (Storer 1925, Zweifel 1955, Van Wagner 1996, Bourque 2008). They are active both day and night, and during the day adults are often observed basking on warm objects such as sun-heated rocks, although this is also when their detectability is highest (Fellers 2005, Wheeler et al. 2005). By contrast, Gonsolin (2010) tracked radio-telemetered Foothill Yellow-legged Frogs under substrate a third of the time and underwater a quarter of the time, although nearly all his detections of frogs without transmitters were basking.

Adult Foothill Yellow-legged Frogs migrate from their overwintering sites to breeding habitat in the spring, often from a tributary to its confluence with a larger stream or river. In areas where tributaries dry down, juveniles also make this downstream movement (Haggarty 2006). When the tributary itself is perennial and provides suitable breeding habitat, the frogs may not undertake these long-distance movements (Gonsolin 2010). Cues for adults to initiate this migration to breeding sites are somewhat enigmatic and vary by location, elevation, and amount of precipitation (S. Kupferberg and A. Lind pers. comm. 2017). They can also include day length, water temperature, and sex (GANDA 2008, Gonsolin 2010, Yarnell et al. 2010, Wheeler et al. 2018). Males initiate movements to breeding sites where they congregate in leks (areas of aggregation for courtship displays), and females arrive later and over a longer period (Wheeler and Welsh 2008, Gonsolin 2010). Most males utilize breeding sites associated with their overwintering tributaries, but some move substantial distances to other sites and may use more than one breeding site in the same season (Wheeler and Welsh 2006, GANDA 2008).

While the predictable hydrograph in California consists of wet winters with high flows and dry summers with low flows, the timing and quantity of seasonal discharge can vary significantly from year to year. The timing of oviposition can influence offspring growth and survival. Early breeders risk scouring of egg masses from their substrate by late spring storms in wet years or desiccation if waters recede rapidly, but when they successfully hatch, tadpoles benefit from a longer growing season, which can enable them to metamorphose at a larger size and increase their likelihood of survival (Railsback et al. 2016).

Later breeders are less likely to have their eggs scoured away or desiccated because flows are generally more stable, but they have fewer mate choices, and their tadpoles have a shorter growing period before metamorphosis, reducing their chance of survival (Ibid.). Some evidence indicates larger females, who coincidentally lay larger clutches, breed earlier (Kupferberg et al. 2009c, Gonsolin 2010). Consequently, early season scouring or stranding of egg masses or tadpoles can disproportionately impact the population's reproductive output because later breeders produce fewer and smaller eggs per clutch (Kupferberg et al. 2009c, Gonsolin 2010).

Timing of oviposition is often a function of water temperature and flow, but it consistently occurs on the descending limb of the hydrograph which corresponds to high winter discharge gradually receding toward low summer baseflow (Kupferberg 1996a, GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010, Yarnell et al. 2010). Under natural conditions, the timing coincides with intermittent tributaries drying down and increases in algal blooms that provide forage for tadpoles (Haggarty 2006, Power et al. 2008). At lower elevations, breeding can start in late March or early April, and at mid-elevations, breeding typically occurs in mid-May to mid-June (Gonsolin 2010, S. Kupferberg and A. Lind pers. comm. 2017). The time of year a population initiates breeding can vary by a month among water years, occurring later at deeper sites when colder water becomes warmer (Wheeler et al. 2018). In wetter years, delayed breeding into early July can occur in some colder snowmelt systems (S. Kupferberg and A. Lind pers. comm. 2017, GANDA 2018).

Commented [USFS_AJL4]: Define this in a second sentence, footnote, or parenthetically. Non-hydrologists won't necessarily understand this term.

A population's period of oviposition can also vary from two weeks to three months, meaning they could be considered explosive breeders at some sites and prolonged breeders at others (Storer 1925, Zweifel 1955, Van Wagner 1996, Ashton et al. 1997, Wheeler and Welsh 2008). Water temperature typically warms to over 10°C (50°F) before breeding commences (GANDA 2008, Gonsolin 2010, Wheeler et al. 2018). Wheeler and Welsh (2008) observed Foothill Yellow-legged Frogs breeding when flows were below 0.6 m/s (2 ft/s), pausing during increased flows until they receded, and GANDA (2008) reported breeding initiated when flow decreased to less than 55% above baseflow.

Male Foothill Yellow-legged Frogs spend more time at breeding sites during the season than females, many of whom leave immediately after laying their eggs (GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010). Daily movements are usually short (< 0.3 m [1 ft]), but some individuals travel substantial distances: median 70.7 m/d (232 ft/d) in spring and 37.1 m/d (104 ft/day) in fall/winter, nearly always using streams as movement corridors (Van Wagner 1996, Bourque 2008, Gonsolin 2010). The maximum reported movement rate is 1,386 m/d (0.86 mi/d), and the longest seasonal (post-breeding) daily distance reported is 7.04 km (4.37 mi) by a female that traveled up a dry tributary and over a ridge before returning to and moving up the mainstem creek (Bourque 2008). Movements during the non-breeding season are typically in response to drying channels or during rain events (Bourque 2008, Gonsolin 2010, Cook et al. 2012).

Hatchling Foothill Yellow-legged Frogs tend to remain with what is left of the egg mass for several days before dispersing into the interstitial spaces in the substrate (Ashton et al. 1997). They often move downstream in areas of moderate flow and will follow the location of warm water in the channel throughout the day (Brattstrom 1962, Ashton et al. 1997, Kupferberg et al. 2011a). Tadpoles usually

metamorphose in late August or early September (S. Kupferberg and A. Lind pers. comm. 2017). Twitty et al. (1967) reported that newly metamorphosed Foothill Yellow-legged Frogs mostly migrated upstream, which may be an evolutionary mechanism to return to their natal site after being washed downstream (Ashton et al. 1997).

Home Range and Territoriality

Foothill Yellow-legged Frogs exhibit a lek-type mating system in which males aggregate at the breeding site and establish calling territories (Wheeler and Welsh 2008, Bondi et al. 2013). The species has a relatively large calling repertoire for western North American ranids with seven unique vocalizations recorded (Silver 2017). Some of these can be reasonably attributed to territory defense and mate attraction communications (MacTeague and Northen 1993, Silver 2017). Physical aggression among males during the breeding season has been reported (Rombough and Hayes 2007, Wheeler and Welsh 2008). In addition, Wheeler and Welsh (2008) observed a non-random mating pattern in which males engaged in amplexus with females were larger than males never seen in amplexus, suggesting either physical competition or female preference for larger individuals. Very little information has been published on Foothill Yellow-legged Frog home range size. Wheeler and Welsh (2008) studied males during a 17-day period during breeding season and classified some of them "site faithful" based on their movements and calculated their home ranges. Two-thirds of males tracked were site faithful, and their mean home range size was 0.58 m^2 (SE = 0.10 m^2; 6.24 ft^2 [SE = 1.08 ft^2]) (Ibid.). In contrast, perhaps because the study took place over a longer time period, Bourque (2008) reported approximately half of the males he tracked during the spring were mobile, and the other half were sedentary. The median distances traveled along the creek (a proxy for home range size since they rarely leave the riparian corridor) for mobile and sedentary males were 149 m (489 ft) and 5.5 m (18 ft), respectively.

Diet and Predators

Foothill Yellow-legged Frog diet varies by life stage and likely body size. Tadpoles graze on periphyton (algae growing on submerged surfaces) scraped from rocks and vegetation and grow faster, and to a larger size, when it contains a greater proportion of epiphytic diatoms with nitrogen-fixing endosymbionts (*Epithemia* spp.), which are high in protein and fat (Kupferberg 1997b, Fellers 2005, Hayes et al. 2016, Catennazi and Kupferberg 2017). Tadpoles may also forage on necrotic tissue from dead bivalves and other tadpoles, or more likely the algae growing on them (Ashton et al. 1997, Hayes et al. 2016). Post-metamorphic Foothill Yellow-legged Frogs primarily feed on a wide variety of terrestrial arthropods but also some aquatic invertebrates (Fitch 1936, Van Wagner 1996, Haggarty 2006). Most of their diet consists of insects and arachnids (Van Wagner 1996, Haggarty 2006, Hothem et al. 2009). Haggarty (2006) did not identify any preferred taxonomic groups, but she noted larger Foothill Yellow-legged Frogs consumed a greater proportion of large prey items compared to smaller individuals, suggesting the species may be gape-limited generalist predators. Hothem et al. (2009) found mammal hair and bones in a Foothill Yellow-legged Frog. Adult Foothill Yellow-legged Frogs, like many other ranids, also cannibalize conspecifics (Wiseman and Bettaso 2007). In the fall when young-of-year are abundant, they may provide an important source of nutrition for adults prior to overwintering (Ibid.).

Foothill Yellow-legged Frogs are preyed upon by several native and introduced species, including each other as described above. Some predators target specific life stages, while others may consume multiple stages. Several species of gartersnakes (genus *Thamnophis*) are the primary and most widespread group of native predators on Foothill Yellow-legged Frogs tadpoles through adults is (Fitch 1941, Fox 1952, Zweifel 1955, Lind and Welsh 1994, Ashton et al. 1997, Wiseman and Bettaso 2007, Gonsolin 2010). Table 1 lists other known and suspected predators of Foothill Yellow-legged Frogs.

Table 1. Confirmed and potential Foothill Yellow-legged Frog predators in California in addition to gartersnakes (*Thamnophis* spp.)

Common Name	Scientific Name	Classification	Native	Prey Life Stage(s)	Sources

* Introduced to the Eel River, location of documented predation; Foothill Yellow-legged Frogs are extirpated from most areas of historical range overlap

STATUS AND TRENDS IN CALIFORNIA

Administrative Status

Sensitive Species

The Foothill Yellow-legged Frog is listed as a Sensitive Species by the U.S. Bureau of Land Management (BLM) and ~~U.S.~~ USDA Forest Service (Forest Service). These agencies define Sensitive Species as those species that require special management consideration to promote their conservation and reduce the likelihood and need for future listing under the ESA.

California Species of Special Concern

The Department's Species of Special Concern (SSC) designation is similar to the federal Sensitive Species designation. It is administrative, rather than regulatory in nature, and intended to focus attention on animals at conservation risk. The designation is used to stimulate needed research on poorly known species and to target the conservation and recovery of these animals before they meet the CESA criteria for listing as threatened or endangered (Thomson et al. 2016). The Foothill Yellow-legged Frog is listed as a Priority 1 (highest risk) SSC (Ibid.).

Trends in Distribution and Abundance

Range-wide in California

Range is the general geographical area in which an organism occurs. For purposes of CESA and this Status Review, the range is the species' California range (*Cal. Forestry Assn. v. Cal. Fish and Game Com.* (2007) 156 Cal.App.4th 1535, 1551). Systematic, focused, range-wide assessments of Foothill Yellow-legged Frog distribution and abundance are rare, both historically and contemporarily. A detailed account of what has been documented within the National Parks and National Forests in California can be found in Appendix 3 of the *Foothill Yellow-legged Frogs Conservation Assessment in California* (Hayes et al. 2016).

Most Foothill Yellow-legged Frog records are incidental observations made during stream surveys for ESA-listed salmonids and simply document presence at a particular date and location, although some include counts or estimates of abundance by life stage. This makes assessing trends in distribution and abundance difficult despite a relatively large number of observations compared to many other species tracked by the California Natural Diversity Database (CNDDB). The CNDDB contained 2,366 Foothill Yellow-legged Frog occurrences in its March 2019 edition, 500 of which are documented from the past 5 years.

A few wide-ranging survey efforts that included Foothill Yellow-legged Frogs exist. Reports from early naturalists suggest Foothill Yellow-legged Frogs were relatively common in the Coast Ranges as far south as central Monterey County, in eastern Tehama County, and in the foothills in and near Yosemite National Park (Grinnell and Storer 1924, Storer 1925, Grinnell et al. 1930, Martin 1940). In addition to

Commented [USFS_AJL5]: Please replace any references to U.S. Forest Service to USDA Forest Service. I think the others are in the references.

Commented [USFS_AJL6]: Recommend looking at Appendix Table 5 in Lind et al. 2011 for additional "recent" records. These records may not all be in CNDDB. Also, Kern River populations and some central coast populations should reference Lind et al. 2011, as well as unpublished reports referenced.

Commented [USFS_AJL7]: Yet, the remainder of this section describes several such efforts. Suggest rewording this to indicated that several presence (absence) assessments have been done, but that estimates of relative abundance or population trends at local or rangewide scales are less common.

Commented [USFS_AJL8]: In what Db. This is not true for Forest Service data and also not for data collected during hydropower relicensing studies, much of which I believe has contributed to CNDDB.

these areas, relatively large numbers of Foothill Yellow-legged Frogs (17-35 individuals) were collected at sites in the central and southern Sierra Nevada and the San Gabriel Mountains between 1911 and 1950 (Hayes et al. 2016). Widespread disappearances of Foothill Yellow-legged Frog populations were documented as early as the 1970s and 80s in southern California, the southern Coast Range, and the central and southern Sierra Nevada foothills (Moyle 1973, Sweet 1983).

Twenty-five years ago, the Department published the first edition of *Amphibians and Reptile Species of Special Concern in California* (Jennings and Hayes 1994). The authors revisited hundreds of localities that had historically been occupied by Foothill Yellow-legged Frogs between 1988 and 1991 and consulted local experts to determine presumed extant or extirpated status. Based on these survey results and stressors observed on the landscape, they considered Foothill Yellow-legged Frogs endangered in central and southern California south of the Salinas River in Monterey County. They considered the species threatened in the west slope drainages of the Cascade Mountains and Sierra Nevada east of the Central Valley, and they considered the remainder of the range to be of special concern (Ibid.).

Fellers (2005) and his field crews conducted surveys for Foothill Yellow-legged Frogs throughout California. They visited 804 sites across 40 counties with suitable habitat within the species' historical range. They detected at least one individual at 213 sites (26.5% of those surveyed) over 28 counties. They located Foothill Yellow-legged Frogs in approximately 40% of streams in the North Coast, 30% in the Cascade Mountains and south of San Francisco in the Coast Range, and 12% in the Sierra Nevada. Fellers estimated population abundance was 20 or more adults at only 14% of the sites where the species was found and noted the largest and most robust populations occurred along the North Coast. In addition, to determine status of Foothill Yellow-legged Frogs across the species' range and potential causes for declines, between 2000-2002, Lind (2005) used previously published status accounts, species expert and local biologist professional opinions, and field visits to historically occupied sites between 2000-2002. She determined that Foothill Yellow-legged Frogs had disappeared from 201 of 394 of the sites, representing just over 50%. The coarse-scale trend in California is one of greater population declines and extirpations in lower elevations and latitudes (Davidson et al. 2002).

Few site-specific population trend data are available from which to evaluate status. However, long-term monitoring efforts have often used egg mass counts as a proxy to estimate adult breeding females. The results of these studies ~~often~~ revealed extreme interannual variability in number of egg masses laid (Ashton et al. 2010, S. Kupferberg and M. Power pers. comm. 2015, Peek and Kupferberg 2016). In a meta-analysis of egg mass count data collected across the species' range in California over the past 25 years, Peek and Kupferberg (2016) reported declines in two unregulated rivers and an increase in another. Their models did not detect any significant trends in abundance across different locations or regulation type (dammed or undammed); however, high interannual variability can render trend detection difficult. Interannual variability was substantially greater in regulated rivers vs. unregulated; the median coefficient of variation was 66.9% and 41.6%, respectively (Ibid.). The greater variability in regulated rivers decreases the probability of detecting significant declines, and coupled with low abundance, it can lead to populations dropping below a density necessary for persistence without detection, resulting in extirpation.

Regional differences in Foothill Yellow-legged Frog persistence across its range have been recognized for nearly 50 years (i.e., more extirpations documented in the south). Because of these differences and the recent availability of new landscape genomic data, more detailed descriptions of trends in Foothill Yellow-legged Frog population distribution and abundance in California are evaluated by clade below. Figure 5 depicts Foothill Yellow-legged Frog localities across all clades in California by the most recent confirmed sighting in the datasets available to the Department within a Public Lands Survey System (PLSS) section. “Transition Zones” are those areas where the exact clade boundaries are unknown due to a lack of samples. In addition, while not depicted as an area of uncertainty, no genetic samples have been ~~tested~~ evaluated from south of the extant population in northern San Luis Obispo County, in the Sutter Buttes in Sutter County, or northeastern Plumas County. It is possible there were historically more clades than is currently understood.

Caution should be exercised in comparing the following observation data across the species’ range and across time since survey effort and reporting are not standardized. These data can be useful for making some general inferences about distribution, abundance, and trends. For instance, assuming the observation correctly identifies the species, the date on the record is the last time the species was confirmed to have occurred at that location. However, this only works in the affirmative. For example, at a site where the last time the species was seen was 75 years ago, the species may still persist there if no one has surveyed it since the original observation. CNDDB staff use information on land use conversion, follow-up visits, and biological reports to categorize an occurrence location as “extirpated” or “possibly extirpated”.

Northwest/North Coast Clade

This clade extends from north of San Francisco Bay through the Coast Range and Klamath Mountains to the northern limit of the Foothill Yellow-legged Frog’s range and east through the Cascade Range. It includes Del Norte, Siskiyou, Humboldt, Trinity, Shasta, Tehama, Mendocino, Glenn, Colusa, Lake, Sonoma, Napa, Yolo, Solano, and Marin counties. This clade covers the largest geographic area and contains the greatest amount of genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). In addition, it is the only clade with an increasing trend in genetic diversity (Peek 2018).

Early records note the comparatively high abundance of Foothill Yellow-legged Frogs in this area. Storer (1925) described Foothill Yellow-legged Frogs as very common in many of Coast Range streams north of San Francisco Bay, and Cope (1879, 1883 as cited in Hayes et al. 2016) noted they were “rather abundant in the mountainous regions of northern California.” In addition, relatively large collections occurred over short periods of time in this region in the late 1800s and the first half of the 20th century (Hayes et al. 2016). Nineteen were taken over two weeks in 1893 along Orrs Creek, a tributary to the Russian River, and 40 from near Willits (both in Mendocino County) in 1911; 112 were collected over three days at Skaggs Spring (Sonoma County) in 1911; 57 were taken in one day along Lagunitas Creek (Marin County) in 1928; and 50 were collected in one day near Denny (Trinity County) in 1955 (Ibid.).

A few long-term Foothill Yellow-legged Frog egg mass monitoring efforts undertaken within this clade’s boundaries found densities vary significantly, often based on river regulation type, and documented

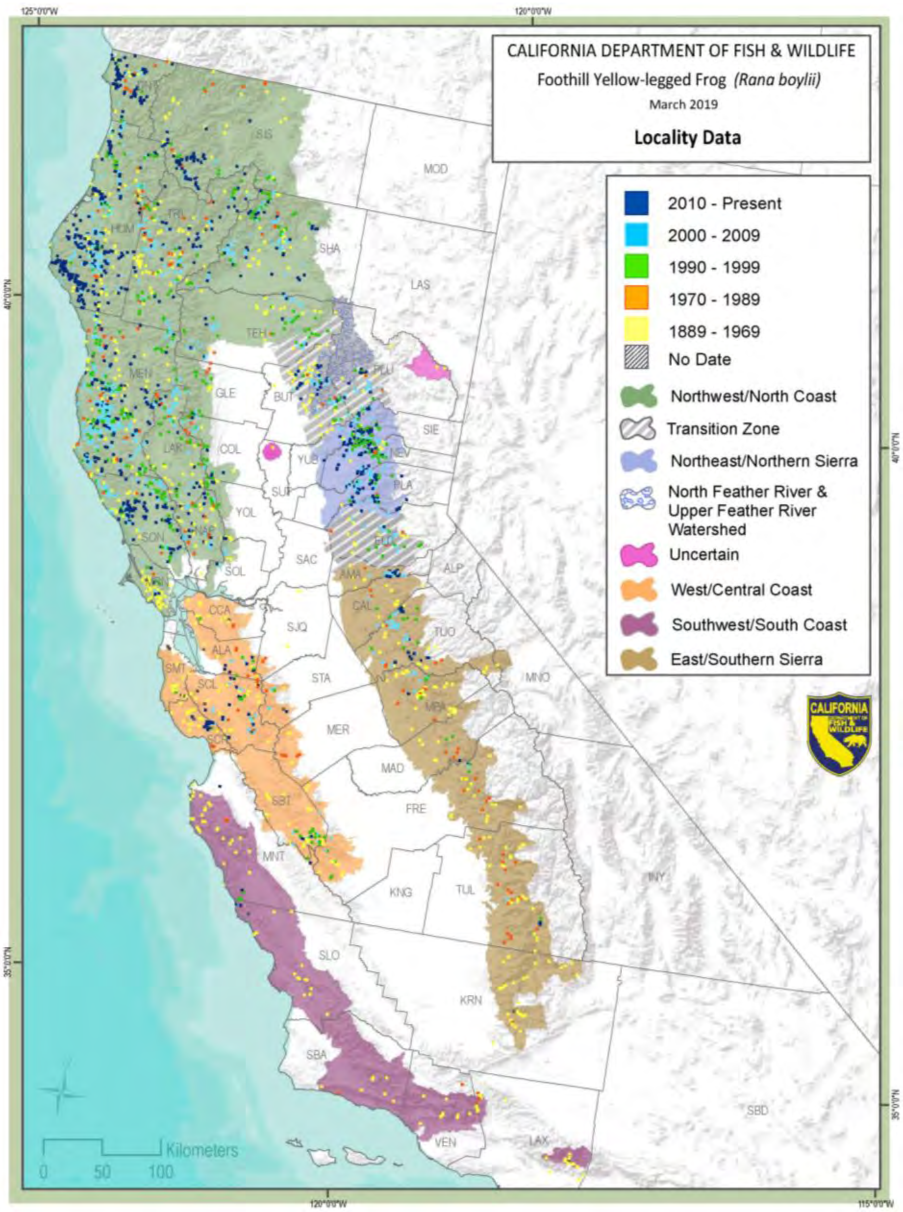

Figure 5. Foothill Yellow-legged Frog occurrence data from 1889-2019 overlaying the six clades by most recent sighting in a Public Lands Survey System section (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

several robust populations. The Green Diamond Resources Company has been monitoring a stretch of the Mad River near Blue Lake (Humboldt County) since 2008 (GDRC 2018). The greatest published density of Foothill Yellow-legged Frog egg masses was documented here in 2009 at 323.6 egg masses/km (520.7/mi) (Bourque and Bettaso 2011). However, in 2017, surveyors counted 625.1 egg masses/km (1,006/mi) along the same reach (GDRC 2018). At its lowest during this period, egg mass density was calculated at 71.54/km (115.1/mi) in 2010, although this count occurred after a flooding even that likely scoured over half of the egg masses laid that season (GDRC 2018, R. Bourque pers. comm. 2019). During a single day survey in 2017 along approximately 2 km (1.3 mi) of Redwood Creek in Redwood National Park (Humboldt County), 2,009 young and 126 adult Foothill Yellow-legged Frogs were found (D. Anderson pers. comm. 2017). Some reaches of the South Fork Eel River (Mendocino County) also support high densities of Foothill Yellow-legged Frogs. Kupferberg (pers. comm. 2018) recorded 206.9 and 106.2 egg masses/km (333 and 171/mi) along two stretches in 2016, and 201.7 and 117.5 egg masses/km (324 and 189/mi) in 2017. However, other reaches yielded counts as low as 6.1 and 8.4 egg masses/km (9.8 and 13.5/mi) (Ibid.). In the Angelo Reserve (an unregulated reach), the 24-year mean density was 109 egg masses/km (175.4/mi) (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015). In contrast, a 10-year mean density of egg masses below Lewiston Dam on the Trinity River (Trinity County) was 0.89/km (1.43/mi) (Ibid.).

Figure 6 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, Biological Information Observation System datasets, and personal communications that are color coded by the most recent date of detection. Within this clade, Foothill Yellow-legged Frogs were observed in at least 343 areas in the past 5 years (CNDDB 2019). The species remains widespread within many watersheds, although most observations only verify presence, or fewer than ten individuals or egg masses are recorded (Ibid.). Documented extirpations are comparatively rare, but also likely undetected or under-reported, and nearly all occurred just north of the high-populated San Francisco Bay area (Figure 7; Ibid.).

West/Central Coast

This clade extends south from the San Francisco Bay through the Diablo Range and down the peninsula through the Santa Cruz and Gabilan Mountains in the Coast Range east of the Salinas Valley. It includes most of Contra Costa, Alameda, San Mateo, Santa Cruz, Santa Clara, and San Benito counties; western San Joaquin, Stanislaus, Merced, and Fresno counties; and a small portion of eastern Monterey County. Records of Foothill Yellow-legged Frogs occurring south of San Francisco Bay did not exist until specimens were collected in 1918 around what is now Pinnacles National Park in San Benito County, and little information exists on historical distribution and abundance within this clade (Storer 1923).

Within this clade, Foothill Yellow-legged Frogs were observed in at least 24 areas in the past five years (Figure 8; CNDDB 2019). Documented and possible extirpations are concentrated around the San Francisco Bay and sites at the southern portion of the clade's range, although these may not have been resurveyed since their original observations in the 1940s through 1960s, except for a site in Pinnacles National Park that was surveyed in 1994 (Figure 9; Ibid.). In addition, although not depicted,

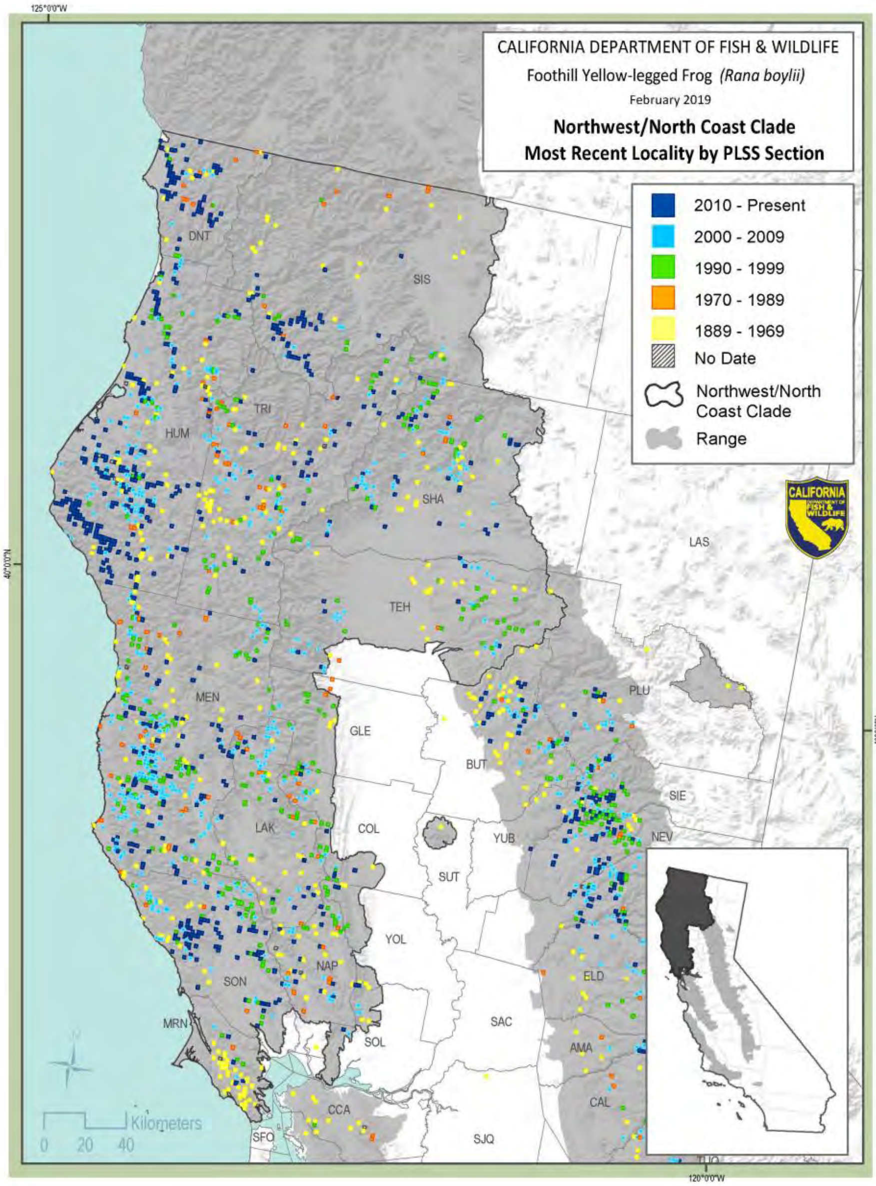

Figure 6. Close-up of Northwest/North Coast Foothill Yellow-legged Frog clade observations from 1889-2019 (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

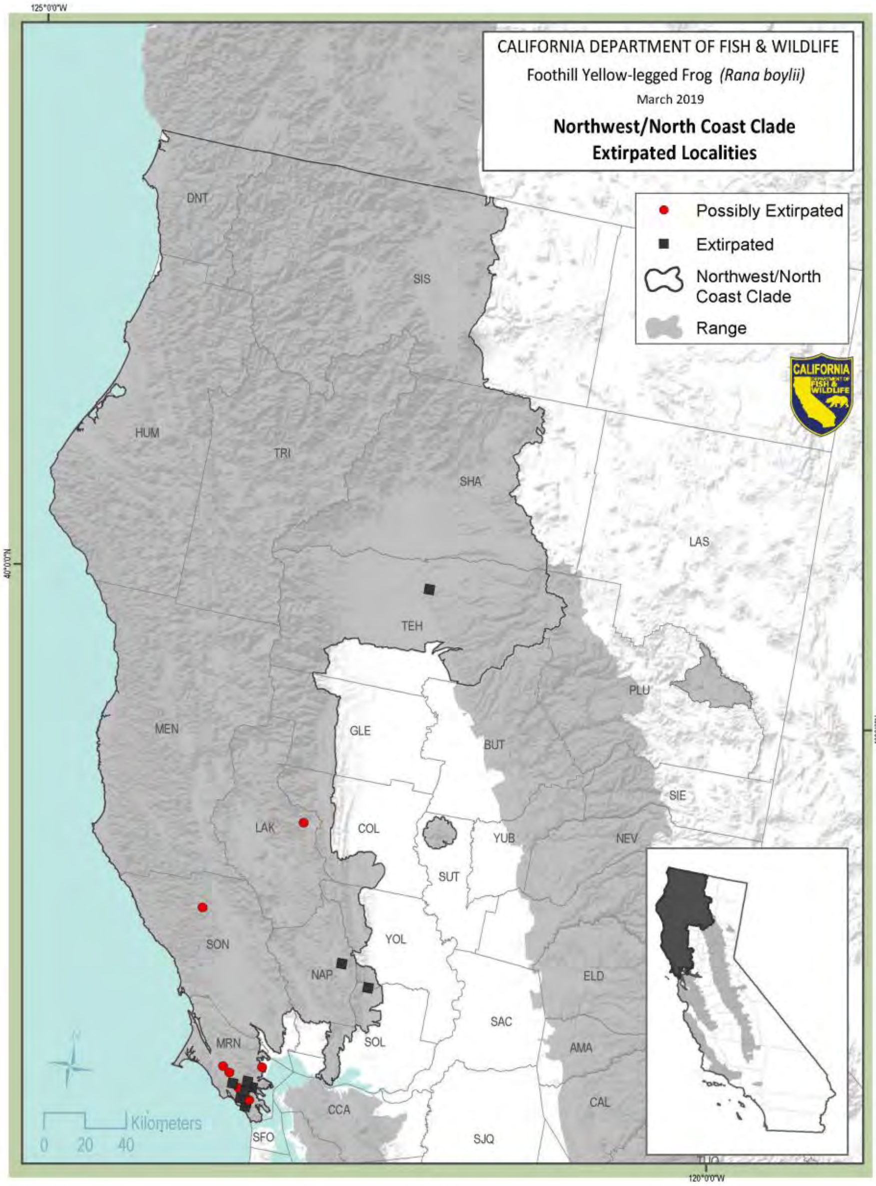

Figure 7. Possibly extirpated and extirpated Northwest/North Coast Foothill Yellow-legged Frog clade sites (CNDDB)

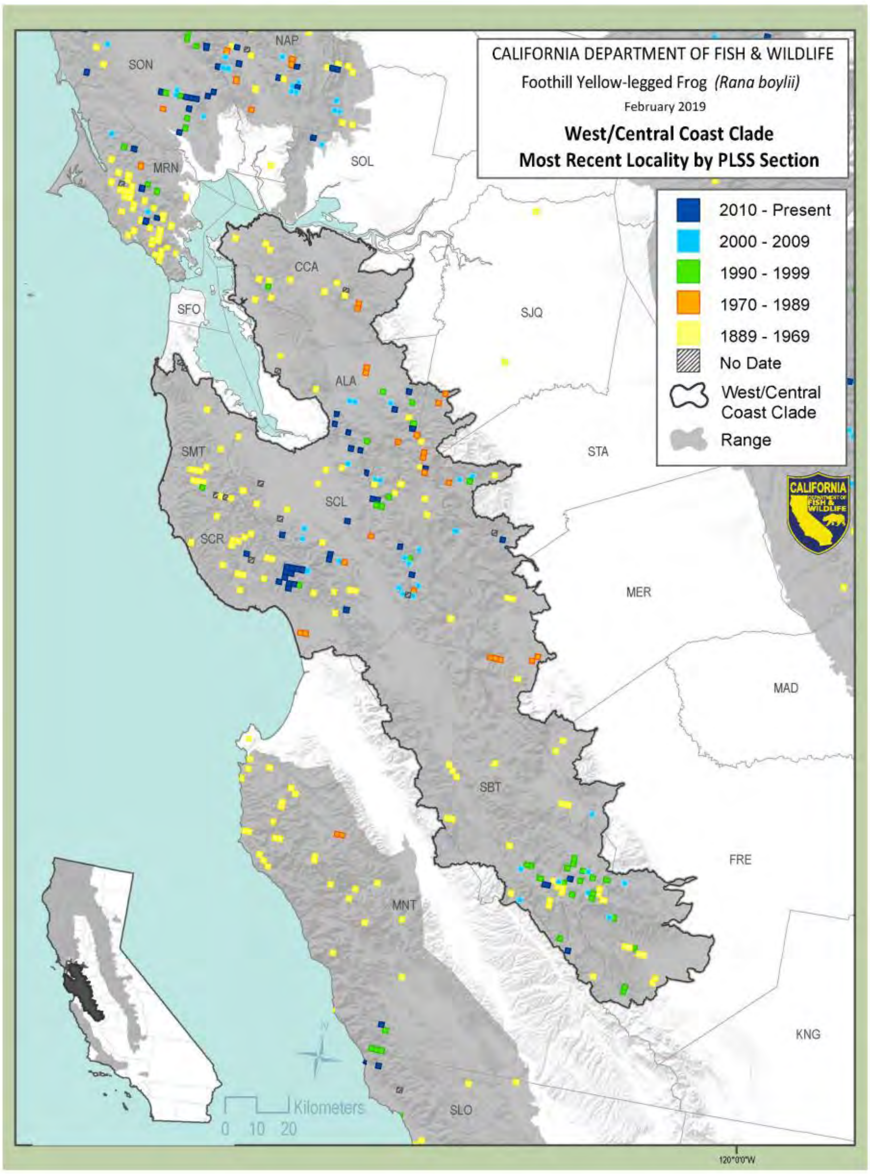

Figure 8. Close-up of West/Central Coast clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

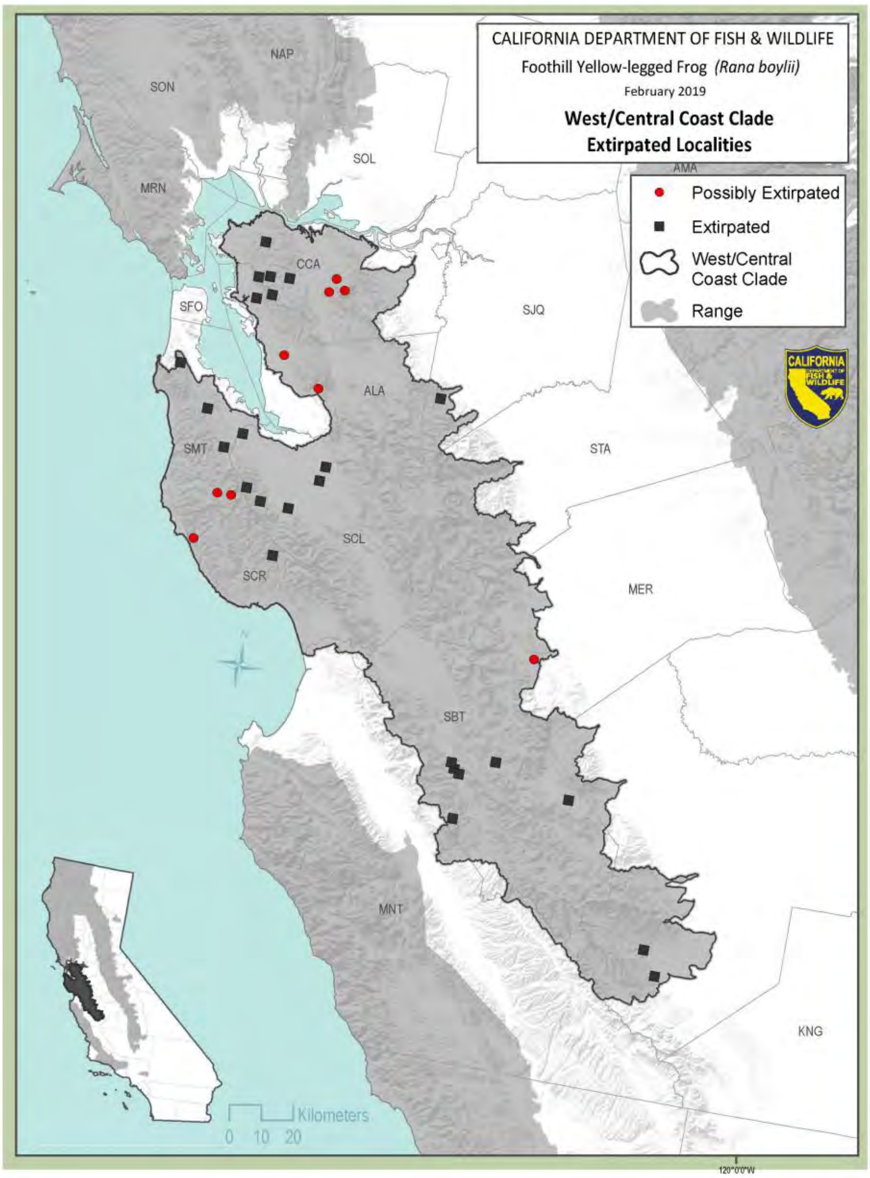

Figure 9. Possibly extirpated and extirpated West/Central Coast Foothill Yellow-legged Frog clade sites (CNDDB)

two populations on Arroyo Mocho and Arroyo Valle south of Livermore (Alameda County) are also likely extirpated (M. Grefsrud pers. comm. 2019).

The San Francisco Bay Area is heavily urbanized. Foothill Yellow-legged Frogs may be gone from Contra Costa County; eight of the nine CNDDB records from the county are museum specimens collected between 1891 and 1953, and the most recent observation was two adults in a plunge pool in an intermittent tributary to Moraga Creek in 1997. No recent (2010 or later) observations exist from San Mateo County (Ibid.). Historically occupied lower-elevation sites surrounding the San Francisco Bay and inland appear to be extirpated, but there are (or were) some moderately abundant breeding populations remaining at higher elevations in Arroyo Hondo (Alameda County), Alameda Creek (Alameda and Santa Clara counties), Coyote and Upper Llagas creeks (Santa Clara County), and Soquel Creek (Santa Cruz County) with some scattered smaller populations also persisting in these counties (J. Smith pers. comm. 2016, 2017; CNDDB 2019). The Alameda Creek and Coyote Creek populations recently underwent large-scale mortality events, so their numbers are likely substantially lower than what is currently reported in the CNDDB (Adams et al. 2017a, Kupferberg and Catenazzi 2019). In addition, the Arroyo Hondo population will lose approximately 1.6 km (1 mi) of prime breeding habitat (i.e., supported the highest density of egg masses on the creek) as the Calaveras Reservoir is refilled following its dam replacement project in 2019 (M. Grefsrud pers. comm. 2019). Foothill Yellow-legged Frogs may be extirpated from Corral Hollow Creek in San Joaquin County, but a single individual was observed five years ago further up the drainage in Alameda County within an Off-Highway Vehicle park (CNDDB 2019). Few recent sightings of Foothill Yellow-legged Frogs in the east-flowing creeks are documented. They may still be extant in the headwaters of Del Puerto Creek (western Stanislaus County), but the records further downstream indicate bullfrogs (known predators and disease reservoirs) are moving up the system (Ibid.). Several locations in southern San Benito, western Fresno, and eastern Monterey counties have relatively recent (2000 and later) detections (Ibid.). However, while many of these sites supported somewhat large populations in the 1990s, the more recent records report fewer than ten individuals (Ibid.). The exception is a Monterey County site where around 25 to 30 were observed in 2012 (Ibid.).

Southwest/South Coast

Widespread extirpations occurred decades ago, primarily in the 1960s and 1970s, in this area (Adams et al. 2017b). As a result, genetic samples were largely unavailable, and the boundaries are speculative. The clade is presumed to include the Coast Range from Monterey Bay south to the Transverse Range across to the San Gabriel Mountains. This clade includes portions of Monterey, San Luis Obispo, Santa Barbara, Ventura, and Los Angeles counties. Storer (1923) reported that Foothill Yellow-legged Frogs were collected for the first time in Monterey County in 1919 and that a specimen collected by Cope in 1889 in Santa Barbara and listed as *Rana temporaria pretiosa* may refer to the Foothill Yellow-legged Frog because as previously mentioned, the taxonomy of this species changed several times over the first century after it was named.

Foothill Yellow-legged Frogs had been widespread and fairly abundant in this area until the late 1960s (Figure 10) but were rapidly extirpated throughout the southern Coast Ranges and western Transverse

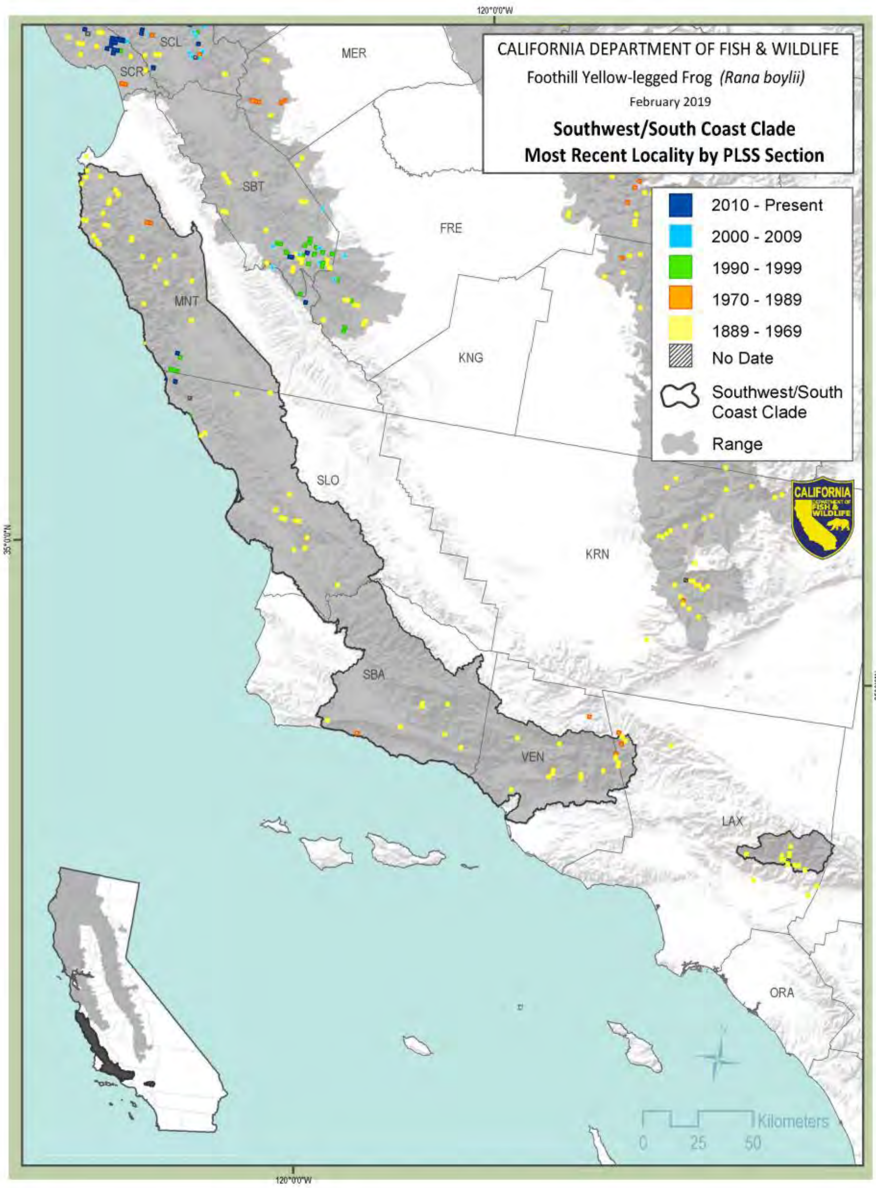

Figure 10. Close-up of Southwest/South Coast clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

Ranges by the mid-1970s (Figure 11; Sweet 1983, Adams et al. 2017b). Only two known extant populations exist from this clade, located near the border of Monterey and San Luis Obispo counties (S. Sweet pers. comm. 2017, McCartney-Melstad et al. 2018, Peek 2018, CNDDB 2019). They appear to be extremely small and rapidly losing genetic diversity, making them at high risk of extirpation (McCartney-Melstad et al. 2018, Peek 2018).

Northeast/Feather River and Northern Sierra

The exact clade boundaries in the Sierra Nevada are unclear and will require additional sampling and testing to define (Figure 12). The Northeast clade presumably encompasses the Feather River and Northern Sierra clades. The Feather River clade is located primarily in Plumas and Butte counties. The Northern Sierra clade roughly extends from the Feather River watershed south to the Middle Fork American River. It includes portions of El Dorado, Placer, Nevada, Sierra, and Plumas counties. It may also include portions of Amador, Butte, and eastern Tehama counties. No genetic samples were available to test in the Sutter Buttes or the disjunct population in northeastern Plumas County to determine which clades they belonged to before they were extirpated (Figure 13; Olson et al. 2016, CNDDB 2019).

In general, there is a paucity of historical Foothill Yellow-legged Frog data for west-slope Sierra Nevada streams, particularly in the lower elevations of the Sacramento Valley, and no quantitative abundance data exist prior to major changes in the landscape (i.e., mining, dams, and diversions) or the introduction of non-native species (Hayes et al. 2016). Foothill Yellow-legged Frogs have been collected frequently from the Plumas National Forest area in small numbers from the turn of the 20th century through the 1970s (Ibid.). Estimates of relative abundance are not clear from the records, but they suggest the species was somewhat widespread in this area.

More recently, Foothill Yellow-legged Frog populations in the Sierra Nevada have been the subject of a substantial number of surveys and focused research associated with recent and ongoing relicensing of hydroelectric power generating dams by the Federal Energy Regulatory Commission (FERC). Consequently, Foothill Yellow-legged Frogs have been observed in at least 30 areas in Plumas and Butte counties (roughly the Feather River clade) over the past five years (CNDDB 2019). As with the rest of the range, most records are observations of only a few individuals; however, many observations occurred over multiple years, and in some cases all life stages were observed over multiple years (Ibid). The populations appear to persist even with the small numbers reported. The only long-term consistent survey effort has been occurring on the North Fork Feather River along the Cresta and Poe reaches (GANDA 2018). The Cresta reach's subpopulation declined significantly in 2006 and never recovered despite modification of the flow regime to reduce egg mass and tadpole scouring and some habitat restoration (Ibid.). A pilot project to augment the Cresta reach's subpopulation through in situ captive rearing was initiated in 2017 (Dillingham et al. 2018). It resulted in the highest number of young-of-year Foothill Yellow-legged Frogs recorded during fall surveys since researchers started keeping count (Ibid.). The number of egg masses laid in the Poe reach varies substantially year-to-year from a low of 26 in 2001 to a high of 154 in 2015 and back down to 36 in 2017 (GANDA 2018).

Commented [USFS_AJL9]: UC Davis folks (Peek and Yarnell) have ongoing monitoring in the Yuba and American Rivers and maybe elsewhere. This info should be include here.

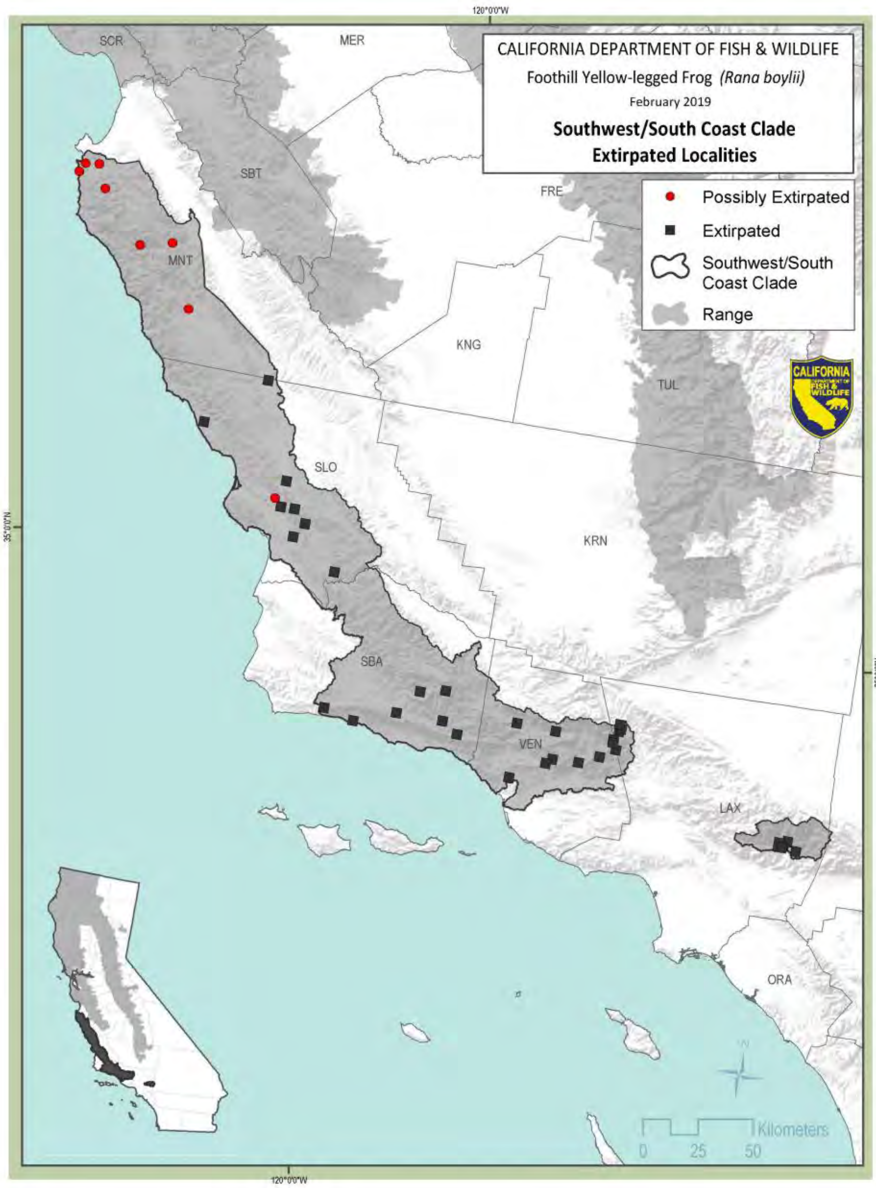

Figure 11. Possibly extirpated and extirpated Southwest/South Coast Foothill Yellow-legged Frog clade sites (CNDDB)

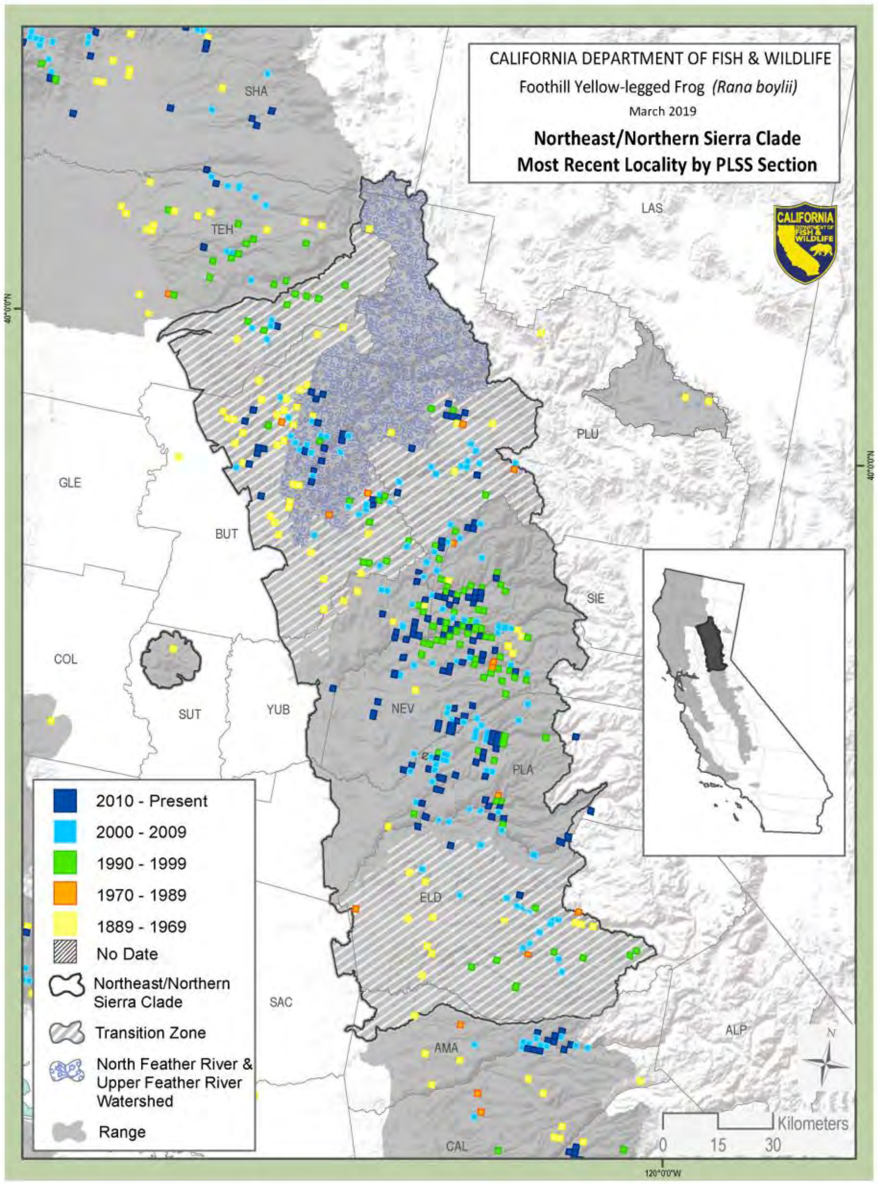

Figure 12. Close-up of Northeast/Feather River and Northern Sierra clades observations from 1889-2019 (ARSSC, BIOS, CNDDB)

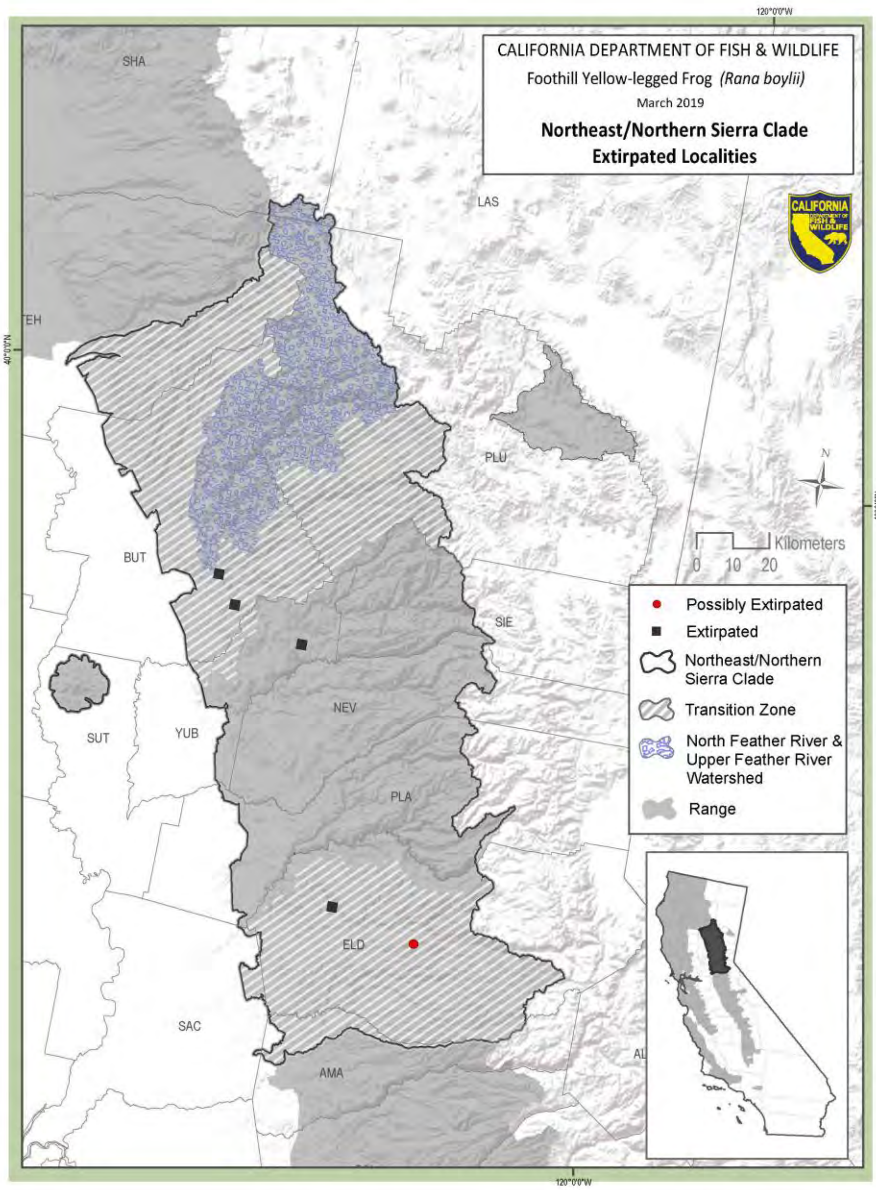

Figure 13. Possibly extirpated and extirpated Northeast/Feather River and Northern Sierra Foothill Yellow-legged Frog clades sites (CNDDB)

Foothill Yellow-legged Frogs have been observed in at least 71 areas in the past 5 years in the presumptive Northeast/Northern Sierra clade. The general pattern in this clade, and across the range for that matter, is that unregulated rivers or reaches have more areas that are occupied more consistently and in larger numbers than regulated rivers or reaches (CNDDB 2019, S. Kupferberg pers. comm. 2019). Foothill Yellow-legged Frogs were rarely observed in the hydropeaking reach of the Middle Fork American River and were observed in low numbers in the bypass reach, but they were present and breeding in small tributary populations (PCWA 2008). Relatively robust populations appear to inhabit the North Fork American River and Lower Rubicon River (Gaos and Bogan 2001, PCWA 2008, Hogan and Zuber 2012, K. Kundargi pers. comm. 2014, S. Kupferberg pers. comm. 2019). Additional apparently sufficiently large and relatively stable populations occur on Clear Creek, South Fork Greenhorn Creek, and Shady Creek (Nevada County) and the North and Middle Yuba River (Sierra County), but the remaining observations are of small numbers in tributaries with minimal connectivity among them (CNDDB 2019, S. Kupferberg pers. comm. 2019).

East/Southern Sierra

The East/Southern Sierra clade is presumed to range from the South Fork American River watershed, the northernmost site where individuals from this clade were collected, south to where the Sierra Nevada meets the Tehachapi Mountains. It likely includes El Dorado, Amador, Calaveras, Tuolumne, Mariposa, Madera, Fresno, Tulare, and Kern counties (Figure 14; Peek 2018). The proportion of extirpated sites in this clade is second only to the Southwest/South Coast and follows the pattern of greater losses in the south (Figure 15). Like the southern coastal clade, the southern Sierra clade has low genetic variability and a trajectory of continued loss of diversity (Ibid.).

Historical collections of small numbers of Foothill Yellow-legged Frogs occurred in every major river system within this clade beginning as early as the turn of the 20th century, indicating widespread distribution but little information on abundance (Hayes et al. 2016). By the early 1970s, declines in Foothill Yellow-legged Frog populations from this area were already apparent; Moyle (1973) found them at 30 of 95 sites surveyed in 1970. Notably bullfrogs inhabited the other 65 sites formerly occupied by Foothill Yellow-legged Frogs, and they co-occurred at only 3 sites (Ibid.). In 1992, Drost and Fellers (1996) revisited the sites around Yosemite National Park (Tuolumne and Mariposa counties) that Grinnell and Storer (1924) surveyed in 1915 and 1919. Foothill Yellow-legged Frogs had disappeared from all seven historically occupied sites and were not found at any new sites surveyed surrounding the park (Ibid.). Resurveys of previously occupied sites on the Stanislaus (Tuolumne County), Sierra (Fresno County), and Sequoia (Tulare County) National Forests were also undertaken (Lind et al. 2003b). Foothill Yellow-legged Frogs were absent from the sites in Sierra and Sequoia National Forests, six at each forest; however, a new population was discovered in the Sierra and two in the Sequoia forests (Ibid.). These populations remain extant but are small and isolated (CNDDB 2019). Two of the six sites on the Stanislaus were still occupied, and 19 new populations were found with evidence of breeding at seven of them (Lind et al. 2003b). Twenty of the 24 populations extant at the time inhabited unregulated waterways (Ibid.). Most of the CNDDB (2019) records of Foothill Yellow-legged Frogs on the Stanislaus are at least a decade old and are represented by low numbers.

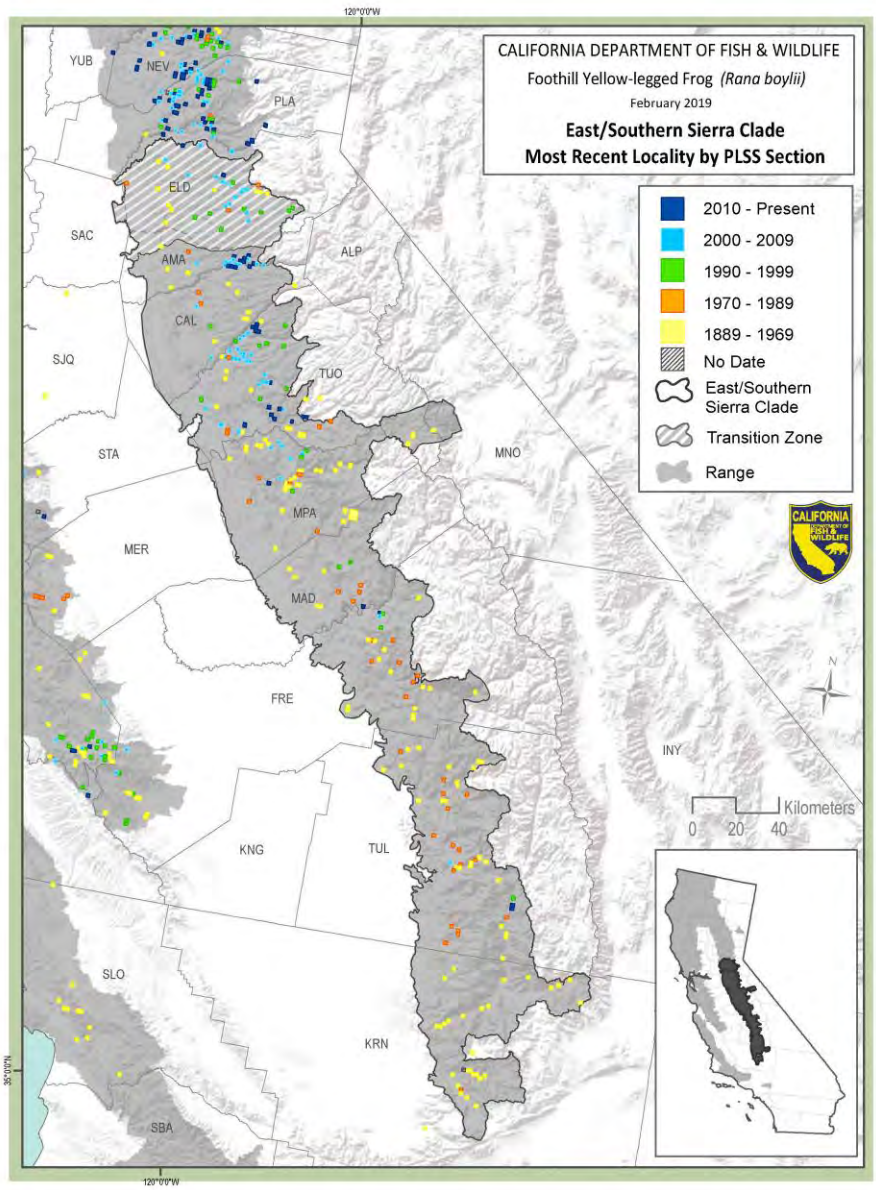

Figure 14. Close-up of East/Southern Sierra clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

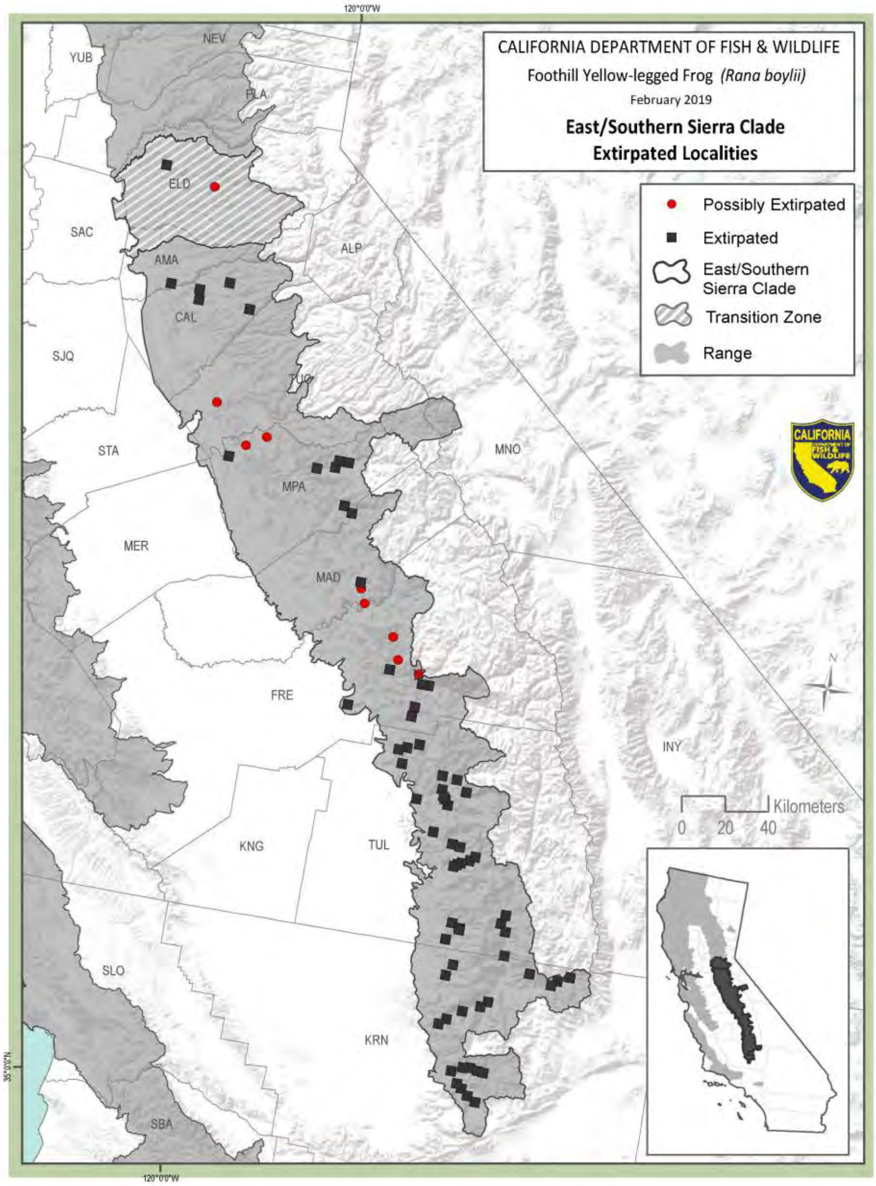

Figure 15. Possibly extirpated and extirpated East/Southern Sierra Foothill Yellow-legged Frog clade sites (CNDDB)

More recently, surveys for Foothill Yellow-legged Frogs were conducted along the South Fork American River as part of the El Dorado Hydroelectric Project's FERC license amphibian monitoring requirements (GANDA 2017). Between 2002 and 2016 counts of different life stages varied significantly by year but the trend for every life stage was a decline over that period (Ibid.). There appears to be a small population persisting along the North Fork Mokelumne River (Amador and Calaveras counties), but it was only productive during the 2012-2014 drought years (Ibid.). Small numbers have also been observed recently in several locations on private timberlands in Tuolumne County (CNDDB 2019).

FACTORS AFFECTING ABILITY TO SURVIVE AND REPRODUCE

"The fortunes of the boylii *population fluctuate with those of the stream"* - Tracy I. Storer, 1925

Several past and ongoing activities have changed the watersheds upon which Foothill Yellow-legged Frogs depend, and many interact with each other exacerbating their adverse impacts. With such an expansive range in California, the degree and severity of these impacts on the species often vary by location. To the extent feasible based on the best scientific information available, those differences are discussed below.

Dams, Diversions, and Water Operations

Foothill Yellow-legged Frogs evolved in a Mediterranean climate with predictable cool, wet winters and hot, dry summers, with their life cycle is adapted to these conditions. In California and other areas with a Mediterranean climate, human demands for water are at the highest when runoff and precipitation are lowest, and annual water supply varies significantly but always follows the general pattern of peak discharge declining to baseflow in the late spring or summer (Grantham et al. 2010). The Foothill Yellow-legged Frog's life cycle depends on this discharge pattern and the specific habitat conditions it produces (see the Breeding and Rearing Habitat section). Dams are ubiquitous, but not evenly distributed, in California. Figure 16 depicts the locations of dams under the jurisdiction of the Army Corps of Engineers (ACOE) and the California Department of Water Resources (DWR). Figure 17 depicts the number of surface diversions per PLSS section within the Foothill Yellow-legged Frog's range (eWRIMS 2019).

Dam operations frequently change the amount and timing of water availability; its temperature, depth, and velocity; and its sediment transport and channel morphology altering functions, which can result in dramatic consequences on the Foothill Yellow-legged Frog's ability to survive and successfully reproduce. Several studies comparing Foothill Yellow-legged Frog populations in regulated and unregulated reaches within the same watershed investigate potential dam-effects. These studies demonstrated that dams and their operations can result in several factors that contribute to population declines and possible extirpation. These factors include confusing breeding cues, scouring and stranding of egg masses and tadpoles, reduced quality and quantity of breeding and rearing habitat, reduced tadpole growth rate, barriers to gene flow, and establishment and spread of non-native species (Hayes et al. 2016). In addition, as previously discussed in the Population Structure and Genetic Diversity section, subpopulations of Foothill Yellow-legged Frogs on regulated rivers are more isolated, and the

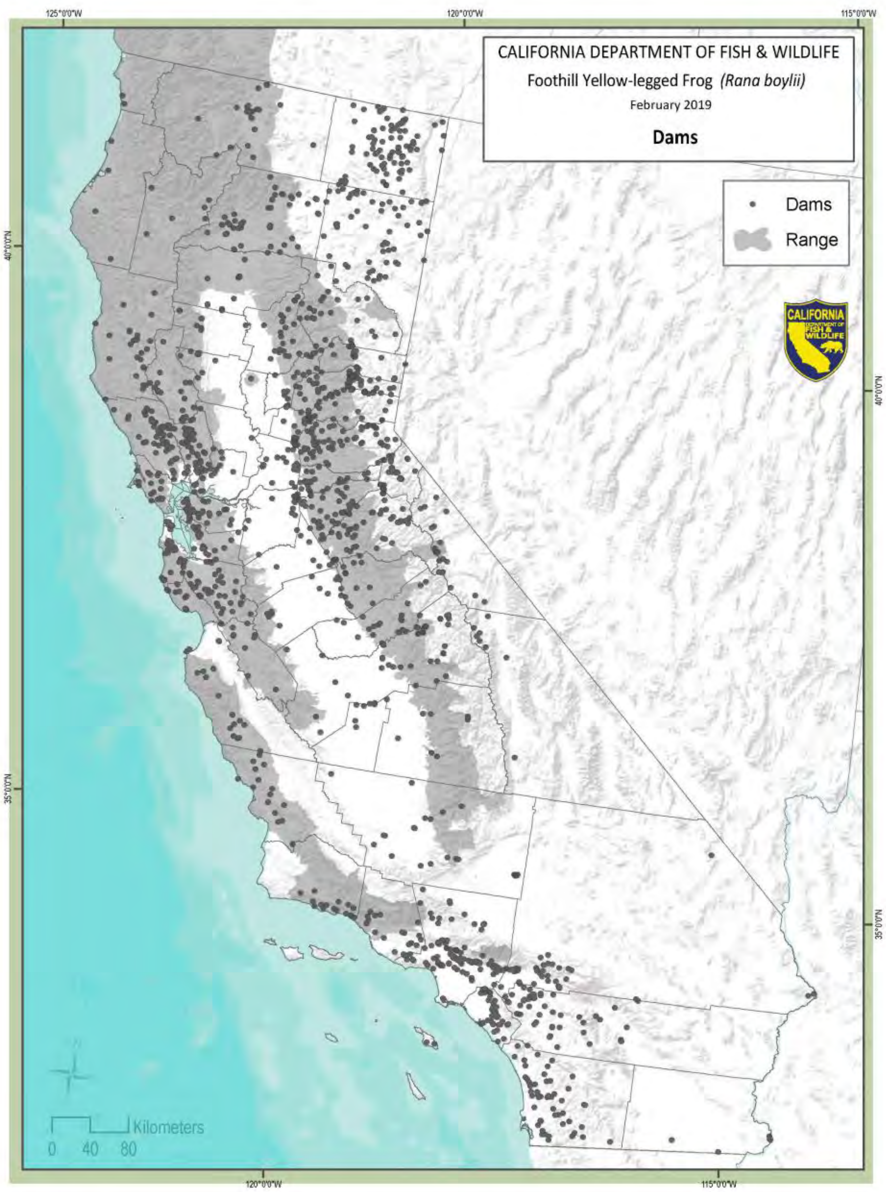

Figure 16. Locations of ACOE and DWR jurisdictional dams (DWR, FRS)

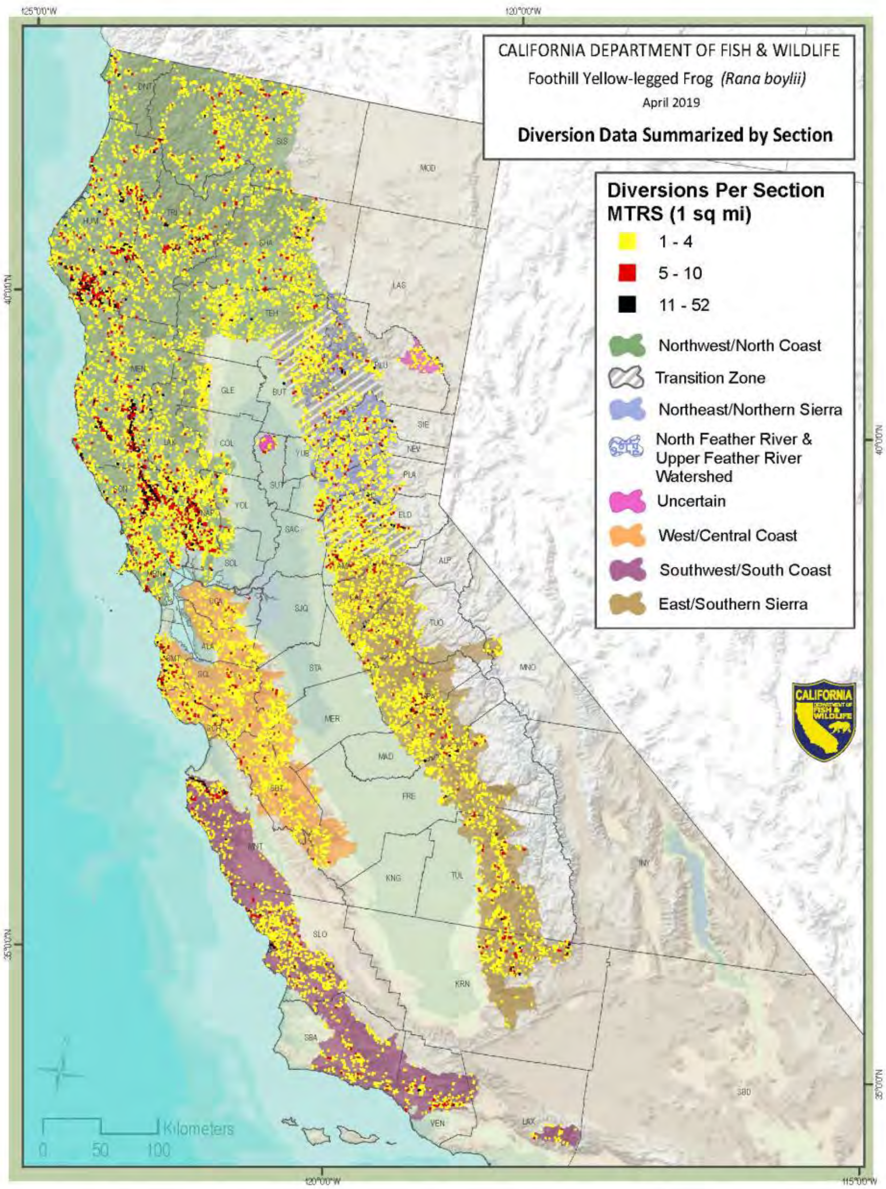

Figure 17. Number of surface water diversions per Public Lands Survey System section within the Foothill Yellow-legged Frog's range in California (eWRIMs)

type of water operations (hydropeaking vs. bypass flows) significantly affects the degree of gene flow loss among them (Peek 2011, 2018). Figure 18 depicts the locations of hydroelectric power plants.

As discussed in the Seasonal Activity and Movements section, cues for Foothill Yellow-legged Frogs to start breeding appear to involve water temperature and velocity, two features altered by dams. Dam operations typically result in reduced flows that are more stable over the course of a year than unimpaired conditions, and dam managers are frequently required to maintain thermally appropriate water temperatures and flows for cold-water-adapted salmonids (USFWS and Hoopa Valley Tribe 1999, Wheeler et al. 2014). For example, late-spring and summer water temperatures on the mainstem Trinity River below Lewiston Dam have been reported to be up to 10°C (20°F) cooler than average pre-dam temperatures, while average winter temperatures are slightly warmer (USFWS and Hoopa Valley Tribe 1999). As a result, Foothill Yellow-legged Frogs breed later on the mainstem Trinity River compared to six nearby tributaries, and some mainstem reaches may never attain the minimum required temperature for breeding (Wheeler et al. 2014, Snover and Adams 2016). In addition, annual discharges past Lewiston Dam have been 10-30% of pre-dam flows and do not mimic the natural hydrograph (Lind et al. 1996).

Aseasonal discharges from dams occur for several reasons including increased flow in late-spring and early summer to facilitate outmigration of salmonids, channel maintenance pulse flows, short-duration releases for recreational whitewater boating, rapid reductions after a spill (uncontrolled flows released down a spillway when reservoir capacity is exceeded) to retain water for power generation or water supply later in the year, peaking flows for hydroelectric power generation, and sustained releases to maintain the seismic integrity of the dam (Lind et al. 1996, Jackman et al. 2004, Kupferberg et al. 2011b, Kupferberg et al. 2012, Snover and Adams 2016). The results of a Foothill Yellow-legged Frog population viability analysis (PVA) suggest that the likelihood a population will persist is very sensitive to early life stage mortality; the 30-year probability of extinction increases significantly with high levels of egg or tadpole scouring or stranding (Kupferberg et al. 2009c). For instance, in 1991 and 1992, all egg masses laid before high flow releases to encourage outmigration of salmonids on the Trinity River were scoured away (Lind et al. 1996). According to the PVA, even a single annual pulse flow such as this or for recreational boating, can result in a three- to five-fold increase in the 30-year extinction risk based on amount of tadpole mortality experienced (Kupferberg et al. 2009c). Management after natural spills can also lead to substantial mortality. For example, in 2006, Foothill Yellow-legged Frogs on the North Fork Feather River bred during a prolonged spill, and the rapid recession below Cresta Dam that followed stranded and desiccated all the eggs laid (Kupferberg et al. 2009b). Rapid flows can also increase predation risk if tadpoles are forced to seek shelter under rocks where crayfish and other invertebrate predators are more common or if they are displaced into the water column where their risk of predation by fish is greater (Ibid.).

The overall reduction of flows and frequency of large winter floods below dams can produce extensive changes to Foothill Yellow-legged Frog habitat quality. They reduce the formation of river bars that are regularly used as breeding habitat, and they create deeper and steeper channels with less complexity and fewer warm, calm, shallow edgewater habitats for tadpole rearing (Lind et al. 1996, Wheeler and Welsh 2008, Kupferberg et al. 2011b, Wheeler et al. 2014). For example, 26 years after construction of

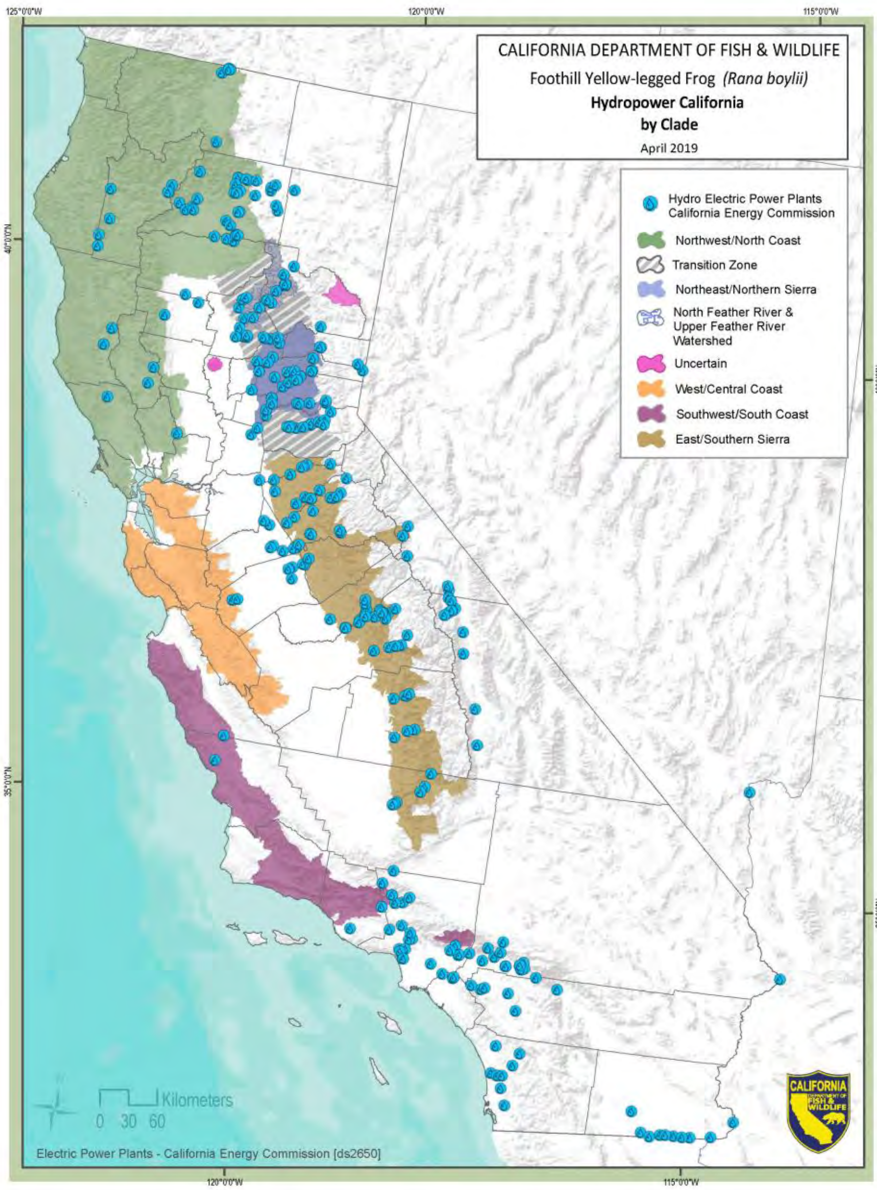

Figure 18. Locations of hydroelectric power generating dams (BIOS)

the Lewiston Dam on the Trinity River, habitat changes in a 63 km (39 mi) stretch from the dam downstream were evaluated (Lind et al. 1996). Riparian vegetation went from covering 30% of the riparian area pre-dam to 95% (Ibid.). Additionally, river bars made up 70% of the pre-dam riparian area compared to 4% post-dam, amounting to a 94% decrease in available Foothill Yellow-legged Frog breeding habitat (Ibid.).

Several features of riverine habitat below dams can decrease tadpole growth rate and other measures of fitness. As ectotherms, Foothill Yellow-legged Frogs require temperatures that support their metabolism, food conversion efficiency, growth, and development, and these temperatures may not be reached until late in the season, or not at all, when the water released is colder than their lower thermal limit (Kupferberg et al. 2011a, Catenazzi and Kupferberg 2013, Wheeler et al. 2014). Colder temperatures and higher flows reduce time spent feeding and efficiency at food assimilation, resulting in slower growth and development (Kupferberg et al. 2011a,b; Catenazzi and Kupferberg 2018). Large bed-scouring winter floods promote greater *Cladophora glomerate* blooms, the filamentous green alga that dominates primary producer biomass during the tadpole rearing season (Power et al. 2008, Kupferberg et al. 2011a). The period of most rapid tadpole growth often coincides with blooms of highly nutritious and more easily assimilated epiphytic diatoms, so reduced flows can have food-web impacts on tadpole growth and survival (Power et al. 2008, Kupferberg et al. 2011a, Catenazzi and Kupferberg 2018). In addition, colder temperatures and fluctuating summer flows, such as those released for hydroelectric power generation, can reduce the amount of algae available for grazing and can change the algal assemblage to one dominated by mucilaginous stalked diatoms like *Didymosphenia geminate* that have low nutritional value (Spring Rivers Ecological Sciences 2003, Kupferberg et al 2011a, Furey et al. 2014). Altered temperatures, flows, and food quality can contribute to slower growth and development, longer time to metamorphosis, smaller size at metamorphosis, and reduced body condition, which adversely impact fitness (Kupferberg et al. 2011b, Catenazzi and Kupferberg 2018).

As discussed in more detail in the Population Structure and Genetic Diversity section, both are strongly affected by river regulation (Peek 2011, 2018; Stillwater Sciences 2012). Foothill Yellow-legged Frogs primarily use watercourses as movement corridors, so the reservoirs created behind dams are often uninhabitable and represent barriers to gene flow (Bourque 2008; Peek 2011, 2018). This decreased connectivity can lead to loss of genetic diversity, inducing a species' ability to adapt to changing conditions (Palstra and Ruzzante 2008).

Decreased winter discharge below dams facilitates establishment and expansion of invasive bullfrogs, whose tadpoles require overwintering and are not well-adapted to flooding events (Lind et al. 1996, Doubledee et al. 2003). Where they occur, bullfrogs tend to dominate areas more altered by dam operations than less impaired areas that support a higher proportion of native species (Moyle 1973, Fuller et al. 2011). In addition to downstream effects, the reservoirs created behind dams directly destroy lotic (flowing) Foothill Yellow-legged Frog habitat, typically do not retain natural riparian communities due to fluctuating water levels, are often managed for human activities not compatible with the species' needs, and act as a source of introduced species upstream and downstream (Brode and Bury 1984, PG&E 2018). Moyle and Randall (1998) identified characteristics of sites with low native biodiversity in the Sierra Nevada foothills; they were often drainages that had been dammed and

diverted in lower- to middle-elevations and dominated by introduced fishes and bullfrogs. Even small-scale operations can have significant effects. Some farming operations divert water during periods of high flows and store it in small impoundments for use during low flow-high need times; these ponds can serve as sources for introduced species like bullfrogs to spread into areas where the habitat would otherwise be unsuitable (Kupferberg 1996b).

The mechanisms described above result in the widespread pattern of greater Foothill Yellow-legged Frog density in unregulated rivers and in reaches far enough downstream of a dam to experience minimal effects from it (Lind et al. 1996, Kupferberg 1996a, Bobzien and DiDonato 2007, Peek 2011). Abundance in unregulated rivers averages five times greater than population abundance downstream of large dams (Kupferberg et al. 2012). Figure 19 depicts a comprehensive collection of egg mass density data where at least four years of surveys have been undertaken, showing much lower abundance in regulated (S. Kupferberg pers. comm. 2019). In California, Foothill Yellow-legged Frog presence is associated with an absence of dams or with only small dams far upstream (Lind 2005, Kupferberg et al. 2012). Hydroelectric power generation from Sierra Nevada rivers accounts for nearly half its statewide production and about 9% of all electrical power used in California (Dettinger et al. 2018). Every major stream below 600 m (1968 ft) in the Sierra Nevada has at least one large reservoir (≥ 0.12 km^3 [100,000 ac-ft]), and many have multiple medium and small ones (Hayes et al. 2016). Because of this, Catenazzi and Kupferberg (2017) posit that the dam-effect on Foothill Yellow-legged Frog populations is likely greater in the Sierra Nevada than the Coast Range because dams are more often constructed in a series along a river in the former and spaced close enough together such that suitable breeding temperatures may never occur in the intervening reaches.

Pathogens and Parasites

Perhaps the most widely recognized amphibian disease is chytridiomycosis, which is caused by the fungal pathogen *Batrachochytrium dendroabatidis* (Bd). Implicated in the decline of over 500 amphibian species, including 90 presumed extinctions, it represents the greatest recorded loss of biodiversity attributable to a disease (Scheele et al. 2019). The global trade in American Bullfrogs (primarily for food) is connected to the disease's spread because the species can persist with low-level Bd infections without developing chytridiomycosis (Yap et al. 2018). Previous studies suggested Foothill Yellow-legged Frogs may not be susceptible to Bd-associated mass mortality; skin peptides strongly inhibited growth of the fungus in the lab, and the only detectable difference between Bd+ and Bd- juvenile Foothill Yellow-legged Frogs was slower growth (Davidson et al. 2007). At Pinnacles National Park in 2006, 18% of post-metamorphic Foothill Yellow-legged Frogs tested positive for Bd; all were asymptomatic and at least one Bd+ Foothill Yellow-legged Frog subsequently tested negative, demonstrating an ability to shed the fungus (Lowe 2009). However, recent studies have found historical evidence of Bd contributing to the extirpation of Foothill Yellow-legged Frogs in southern California, an acute die-off in 2013 in the Alameda Creek watershed, and another in 2018 in Coyote Creek (Adams et al. 2017a,b; Kupferberg and Catenazzi 2019). Evaluation of museum specimens indicates lower Bd prevalence (proportion of individuals infected) in Foothill Yellow-legged Frogs than most other co-occurring amphibians in southern California in the first part of the 20th century, but it spiked in the 1970s just prior to the last observation of an individual in 1977 (Adams et al. 2017b). Two museum specimens collected in 1966,

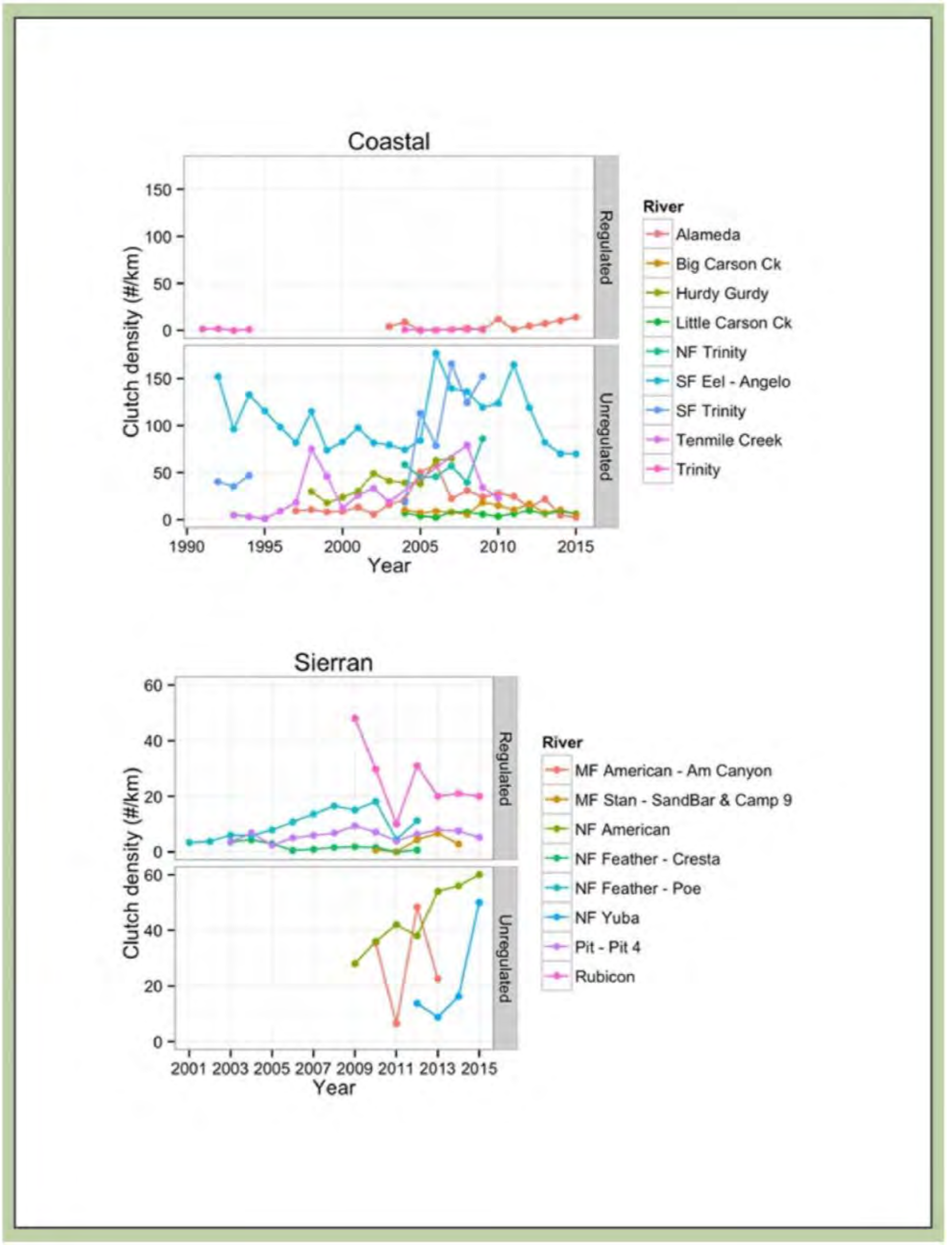

Figure 19. Foothill Yellow-legged Frog Egg mass density estimates along the coast from 1990-2015 and the Sierra Nevada from 2001-2015 from multiple studies compiled by S. Kupferberg (2019)

one from Santa Cruz County and the other from Alameda County, provide the earliest evidence of Bd in Foothill Yellow-legged Frogs in central California (Padgett-Flohr and Hopkins 2009). In contrast to the southern California results, Foothill Yellow-legged Frogs possessed the highest Bd prevalence among all amphibians tested in coastal Humboldt County in 2013 and 2014; however, zoospore (the aquatic dispersal agent) loads were well below the presumed lethal density threshold (Ecoclub Amphibian Group et al. 2016).

In addition to bullfrogs, the native Pacific Treefrog (*Pseudacris regilla*) seems immune to the lethal effects of chytridiomycosis, and owing to its broad ecological tolerances, more terrestrial lifestyle, and relatively large home range size and dispersal ability, the species is ubiquitous across California (Padgett-Flohr and Hopkins 2009). In a laboratory experiment, Bd-infected Pacific Treefrogs shed an average of 68 zoospores per minute, making them the prime candidate for spreading and maintaining Bd in areas where bullfrogs do not occur (Padgett-Flohr and Hopkins 2009, Reeder et al. 2012). In the wild, Pacific Treefrog populations persisted at 100% of sites in the Sierra Nevada (above 1500 m [4920 ft]) where a sympatric ranid species had been extirpated from 72% of its formerly occupied sites due to a Bd outbreak (Reeder et al. 2012). This is consistent with the results of a model that incorporated Bd habitat suitability, host availability, and invasion history in North America, which concluded west coast mountain ranges were at the greatest risk from the disease (Yap et al. 2018).

Several other pathogens and parasites have been encountered with Foothill Yellow-legged Frogs, but none have been ascribed to large-scale mortality events. Another fungus, a water mold (*Saprolegnia* sp.) carried by fish, is an important factor in amphibian embryo mortality in the Pacific Northwest (Blaustein et al. 1994, Kiesecker and Blaustein 1997). Fungal infections of Foothill Yellow-legged Frog egg masses, potentially from *Saprolegnia*, have been observed in the mainstem Trinity River (Ashton et al. 1997). *Saprolegnia* infection is more likely to occur in ponds and lakes, particularly if stocked by hatchery-raised fish into previously fishless areas and when frogs use communal oviposition sites, so it likely does not represent a major source of mortality in Foothill Yellow-legged Frogs (Blaustein et al. 1994, Kiesecker and Blaustein 1997). However, they may be more susceptible to *Saprolegnia* infection when exposed to other environmental stressors that compromise their immune defenses (Blaustein et al. 1994, Kiesecker and Blaustein 1997).

The trematode parasite *Ribeiroia ondatrae* is responsible for limb malformations in ranids (Stopper et al. 2002). *Ribeiroia ondatrae* was detected on a single Foothill Yellow-legged Frog during a study on malformations, but its morphology was normal (Kupferberg et al. 2009a). The results of the study instead linked malformations in Foothill Yellow-legged Frog tadpoles and young-of-year to the Anchor Worm (*Lernae cyprinacea*), a parasitic copepod from Eurasia (Ibid.). Prevalence of malformations was low, under 4% of the population in both years of study, but there was a pattern of infected individuals metamorphosing at a smaller size, which as previously mentioned can have implications on fitness (Ibid.). Three other species of helminths (parasitic worms) were encountered during the study (*Echinostoma* sp., *Manodistomum* sp., and *Gyrodactylus* sp.); their relative impact on their hosts is unknown, but at least one Foothill Yellow-legged Frog had 700 echinstome cysts in its kidney (Ibid.). Bursey et al. (2010) discovered 13 species of helminths in and on Foothill Yellow-legged Frogs from

Humboldt County. Most are common in anurans, and some are generalists with multiple possible hosts, but studies on their impact on Foothill Yellow-legged Frogs are lacking (Ibid.).

Introduced Species

Species not native to an area, but introduced, can alter food webs and ecosystem processes through predation, competition, hybridization, disease transmission, and habitat modification. Native species lack evolutionary history with introduced species, and early life stages of native anurans are particularly susceptible to predation by aquatic non-native species (Kats and Ferrer 2003). Because introduced species often establish in highly modified habitats, it can be difficult to differentiate between impacts from habitat degradation and the introduced species (Fisher and Shaffer 1996). However, native amphibians have been frequently found successfully reproducing in heavily altered habitats when introduced species were absent, suggesting introduced species themselves can impose an appreciable adverse effect (Ibid.). Numerous introduced species have been documented to adversely impact Foothill Yellow-legged Frogs or are suspected of doing so.

American Bullfrogs were introduced to California from the eastern U.S. around the turn of the 20th century, likely in response to overharvest of native ranids by the frog-leg industry that accompanied the Gold Rush (Jennings and Hayes 1985). Nearly 50 years ago, Moyle (1973) reported that distributions of Foothill Yellow-legged Frogs and bullfrogs in the Sierra Nevada foothills were nearly mutually exclusive. He speculated that bullfrog predation and competition may be causal factors in their disparate distributions in addition to the habitat degradation from dams and diversions that facilitated the bullfrog invasion in the first place. In a study along the South Fork Eel River and one of its tributaries, Foothill Yellow-legged Frog abundance was nearly an order of magnitude lower in reaches were bullfrogs were well established (Kupferberg 1997a). At a site in Napa Valley, after bullfrogs were eradicated, Foothill Yellow-legged Frogs, among other native species, recolonized the area (J. Alvarez pers. comm. 2018). In a mesocosm experiment, Foothill Yellow-legged Frog survival in control enclosures measured half that of enclosures containing bullfrog and Foothill Yellow-legged Frog tadpoles, and they weighed approximately one-quarter lighter at metamorphosis (Kupferberg 1997a). The mechanism for these declines appeared to be the reduction of high quality algae by bullfrog tadpole grazing, as opposed to any behavioral or chemical interference (Ibid.). Adult bullfrogs, which can get very large (9.0-15.2 cm [3.5-6.0 in]), also directly consume Foothill Yellow-legged Frogs, including adults (Moyle 1973, Crayon 1998, Powell et al. 2016). Silver (2017) noted that she never heard Foothill Yellow-legged Frogs calling in areas with bullfrogs, which has implications for breeding success; she speculated the lack of vocalizations may have been a predator avoidance strategy.

As discussed briefly in the Pathogens and Parasites section, American Bullfrogs act as reservoirs and vectors of the lethal chytrid fungus. In museum specimens from both southern and central California, Bd was detected in bullfrogs before it was detected in Foothill Yellow-legged Frogs in the same area (Padgett-Flohr and Hopkins 2009, Adams et al. 2017b). During a die-off from chytridiomycosis that commenced in 2013, Bd prevalence and load in Foothill Yellow-legged Frogs was positively predicted by bullfrog presence (Adams et al. 2017a). A similar die-off in 2018 from a nearby county appears to be related to transmission by bullfrogs as well (Kupferberg and Catenazzi 2019). In addition, male Foothill

Yellow-legged Frogs have been observed amplexing female bullfrogs, which may not only constitute wasted reproductive effort but could serve to increase their likelihood of contracting Bd (Lind et al. 2003a). In fact, adult males were more likely to be infected with Bd than females or juveniles during the recent die-off in Alameda Creek (Adams et al. 2017a). African Clawed Frogs (*Xenopus laevis*) have also been implicated in the spread of Bd in California because like bullfrogs, they are asymptomatic carriers (Padgett-Flohr and Hopkins 2009). However, African Clawed-Frog distribution only minimally overlaps with the Foothill Yellow-legged Frog's range unlike the widespread bullfrog (Stebbins and McGuinness 2012).

Hayes and Jennings (1986) observed a negative association between the abundance of introduced fish and Foothill Yellow-legged Frogs. Rainbow trout (*Onchorynchus mykiss*) and green sunfish (*Lepomis cyanellus*) are suspected of destroying egg masses (Van Wagner 1996). Bluegill sunfishes (*L. macrochirus*) are likely predators; in captivity when offered eggs and tadpoles of two ranid species, they consumed both life stages but a significantly greater number of tadpoles (Werschkul and Christensen 1977). Common hatchery-stocked fish like brook (*Salvelinus fontinalis*) and rainbow trout commonly carry of *Saprolegnia* (Blaustein et al. 1994). In addition, presence of non-native fish can facilitate bullfrog invasions by reducing the density of macroinvertebrates that prey on their tadpoles (Adams et al. 2003). Foothill Yellow-legged Frog tadpoles raised from eggs from sites with and without smallmouth bass (*Micropterus dolomieu*) did not differ in their responses to exposure to the non-native, predatory bass and a native, non-predatory fish (Paoletti et al. 2011). This result suggests that Foothill Yellow-legged Frogs have not yet evolved a recognition of bass as a threat, which makes them more vulnerable to predation (Ibid.).

Introduced into several areas within the Coast Range and Sierra Nevada, signal crayfish have been recorded preying on Foothill Yellow-legged Frog egg masses and are suspected of preying on their tadpoles based on observations of tail injuries that looked like scissor snips (Riegel 1959, Wiseman et al. 2005). The introduced red swamp crayfish (*Procambarus clarkii*) likely also preys on Foothill Yellow-legged Frogs. Because Foothill Yellow-legged Frogs evolved with native crayfish in northern California, individuals from those areas may more effectively avoid crayfish predation than in other parts of the state where they are not native (Riegel 1959, USFWS 1998, Kats and Ferrer 2003). The Foothill Yellow-legged Frog's naivety to crayfish was demonstrated in a study that showed they did not change behavior when exposed to signal crayfish chemical cues, but once the crayfish was released and consuming Foothill Yellow-legged Frog tadpoles, the survivors, likely reacting to chemical cues from dead tadpoles, did respond (Kerby and Sih 2015).

Sedimentation

Several anthropogenic activities, some of which are described in greater detail below, can artificially increase sedimentation into waterways occupied by Foothill Yellow-legged Frogs and adversely impact biodiversity (Moyle and Randall 1998). These activities include but are not limited to mining, agriculture, overgrazing, timber harvest, and poorly constructed roads (Ibid.). Increased fine sediments can substantially degrade Foothill Yellow-legged Frog habitat quality. Heightened turbidity decreases light penetration that phytoplankton and other aquatic plants require for photosynthesis (Cordone and Kelley

1961). When silt particles fall out of the water column, they can destroy algae by covering the bottom of the stream (Ibid.). Algae are not only important for Foothill Yellow-legged Frog tadpoles as forage but also oxygen production (Ibid.). Sedimentation may impede attachment of egg masses to substrate (Ashton et al. 1997). The effect of silt accumulation on embryonic development is unknown, but it does make them less visible, which could decrease predation risk (Fellers 2005). Fine sediments can fill interstitial spaces between rocks that tadpoles use for shelter from high velocity flows and cover from predators and that serve as sources for aquatic invertebrate prey for post-metamorphic Foothill Yellow-legged Frogs (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b).

Mining

Current mining practices, as well as legacy effects from historical mining operations, may adversely impact Foothill Yellow-legged Frogs through contaminants, direct mortality, habitat destruction and degradation, and behavioral disruption. While mercury in streams can result from atmospheric deposition, storm-induced runoff of naturally occurring mercury, agricultural runoff, and geothermal springs, runoff from historical mine sites mobilizes a significant amount of mercury (Foe and Croyle 1998, Alpers et al. 2005, Hothem et al. 2010). Beginning in the mid-1800s, extensive mining occurred in the Coast Range to supply mercury for gold mining in the Sierra Nevada, causing widespread contamination of both mountain ranges and the rivers in the Central Valley (Foe and Croyle 1998). Studies on Foothill Yellow-legged Frog tissues collected from the Cache Creek (Coast Ranges) and Greenhorn Creek (Sierra Nevada) watersheds revealed mercury bioaccumulation concentrations as high as 1.7 and 0.3 μg/g (ppm), respectively (Alpers et al. 2005, Hothem et al. 2010). For context, the U.S. Environmental Protection Agency's mercury criterion for issuance of health advisories for fish consumption is 0.3 μg/g; concentrations exceeded this threshold in Foothill Yellow-legged Frog tissues at 62% of sampling sites in the Cache Creek watershed (Hothem et al. 2010). Bioaccumulation of this powerful neurotoxin can cause deleterious impacts on amphibians including inhibited growth, decreased survival to metamorphosis, increased malformations, impaired reproduction, and other sublethal effects (Zillioux et al. 1993, Unrine et al. 2004). In a study measuring Sierra Nevada watershed health, Moyle and Randall (1998) reportedly found very low biodiversity in streams that were heavily polluted by acidic water leaching from historical mines. Acidic drainage measured as low as 3.4 pH from some mined areas in the northern Sierra Nevada (Alpers et al. 2005).

Widespread suction dredging for gold occurred in the Foothill Yellow-legged Frog's California range until enactment of a moratorium on issuing permits in 2009 (Hayes et al. 2016). Suction dredging vacuums up the contents of the streambed, passes them through a sluice box to separate the gold, and then deposits the tailings on the other side of the box (Harvey and Lisle 1998). While most habitat disturbance is localized and minor, it can be especially detrimental if it degrades or destroys breeding and rearing habitat through direct disturbance or sedimentation (Ibid.). In addition, this activity can lead to direct mortality of early life stages through entrainment, and those eggs and tadpoles that do survive passing through the suction dredge may experience greater mortality due to subsequent unfavorable physiochemical conditions and possible increased predation risk (Ibid.). Suction dredging can also reduce the availability of invertebrate prey, although this impact is typically short-lived (Ibid.). Suction dredging alters stream morphology, and relict tailing ponds can serve as breeding habitat for bullfrogs in areas

that would not normally support them (Fuller et al. 2011). However, in some areas these mining holes have reportedly benefited Foothill Yellow-legged Frogs by creating cool persistent pools that adult females appeared to prefer at one Sierra Nevada site (Van Wagner 1996). Senate Bill 637 (2015) directs the Department to work with the State Water Resources Control Board (SWRCB) to develop a statewide water quality permit that would authorize the use of vacuum or suction dredge equipment in California under conditions set forth by the two agencies. SWRCB staff, in coordination with Department staff, are in the process of collecting additional information to inform the next steps that will be taken by the SWRCB (SWRCB 2019).

Instream aggregate (gravel) mining continues today and can have similar impacts to suction dredge mining by removing, processing, and relocating stream substrates (Olson and Davis 2009). This type of mining typically removes bars used as Foothill Yellow-legged Frog breeding habitat and reduces habitat heterogeneity by creating flat wide channels (Kupferberg 1996a). Typically when listed salmonids are present, mining must be conducted above the wetted edge, but this practice can create perennial off-channel bullfrog breeding ponds (M. van Hattem pers. comm. 2018).

Agriculture

Direct loss of Foothill Yellow-legged Frog habitat from wildland conversion to agriculture is rare because the typically rocky riparian areas they inhabit are usually not conducive to farming, but removal of riparian vegetation directly adjacent to streams for agriculture is more common and widespread. The U.S. Department of Agriculture classifies 3.9 million ha (9.6 million ac) in California as cropland, which amounts to less than 10% of the state's land area, and 70% of this occurs in the Central Valley between Redding and Bakersfield (Martin et al. 2018). In addition, several indirect impacts can adversely affect Foothill Yellow-legged Frogs at substantial distances from agricultural operations such as effects from runoff (sediments and agrochemicals), drift and deposition of airborne pollutants, water diversions, and creation of novel habitats like impoundments that facilitate spread of detrimental non-native species. As sedimentation and introduced species impacts were previously discussed, this section instead focuses on the other possible adverse impacts.

Agrochemicals

Many species of amphibians, particularly ranids, have experienced declines throughout California, but the most dramatic declines have occurred in the Sierra Nevada east of the San Joaquin Valley where 60% of the total pesticide usage in the state was sprayed (Sparling et al. 2001). Agrochemicals applied to crops in the Central Valley can volatilize and travel in the atmosphere and deposit in higher elevations (LeNoir et al. 1999). Pesticide concentrations diminish as elevations increase in the lower foothills but change little from 533 to 1,920 m (1,750-6,300 ft), which coincides with the Foothill Yellow-legged Frog's elevational range (Ibid). Foothill Yellow-legged Frog absence at historically occupied sites in California significantly correlated with agricultural land use within 5 km (3 mi), and a positive relationship exists between Foothill Yellow-legged Frog declines and the amount of upwind agriculture, suggesting airborne agrochemicals may be a contributing factor (Figure 20; Davidson et al. 2002). Cholinesterase-inhibitors (most organophosphates and carbamates), which disrupt nerve impulse transmission, were

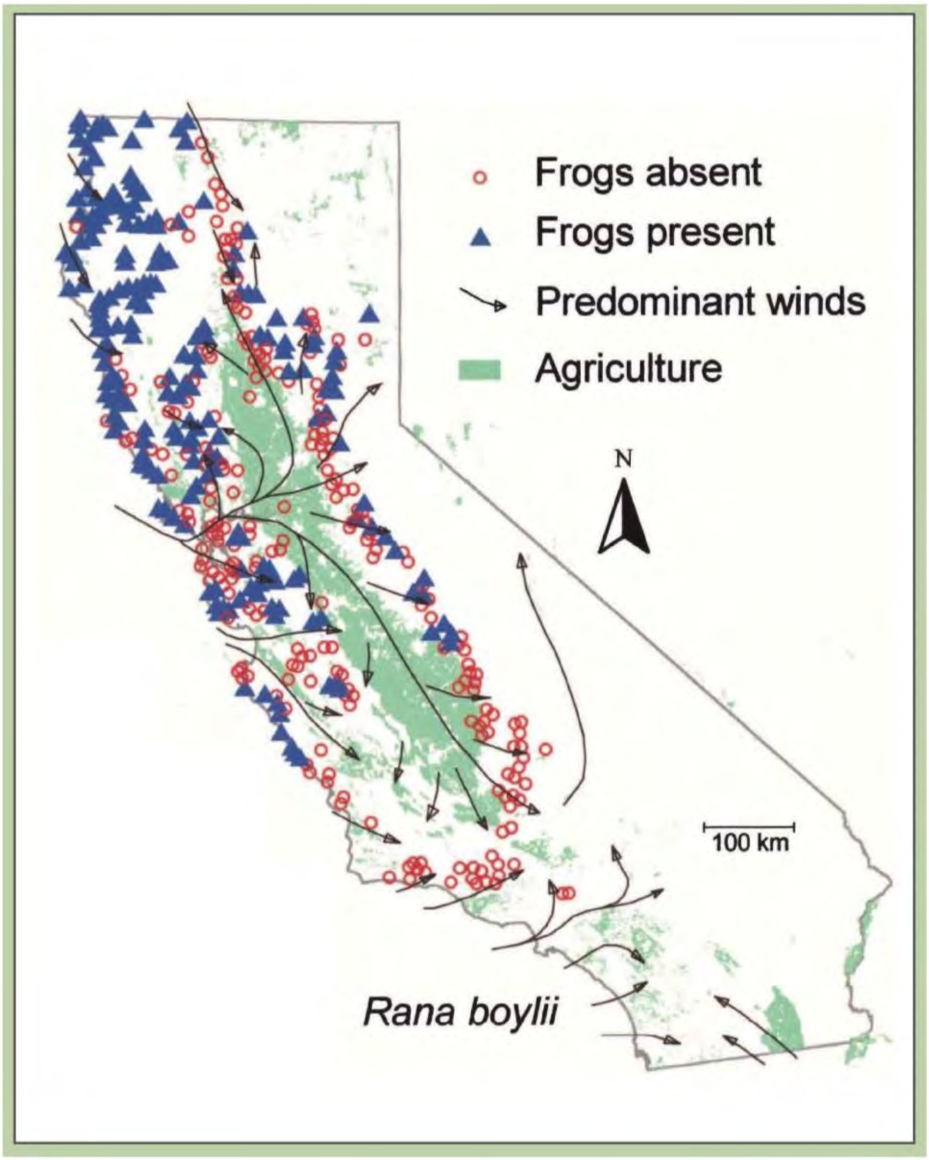

Figure 20. Relationship of Foothill Yellow-legged Frog occupancy to agriculture from Davidson et al. (2002)

more strongly associated with population declines than other pesticide types (Davidson 2004). Olson and Davis (2009) and Lind (2005) also reported a negative correlation between Foothill Yellow-legged Frog presence and proximity and quantity of nearby agriculture in Oregon and across the species' entire range, respectively.

Lethal and sublethal effects of agrochemicals on amphibians can take two general forms: direct toxicity and food-web effects. Sublethal doses of agrochemicals can interact with other environmental stressors to reduce fitness. Foothill Yellow-legged Frog tadpoles showed significantly greater vulnerability to the lethal and sublethal effects of carbaryl than Pacific Treefrogs (Kerby and Sih 2015). An inverse relationship exists between carbaryl concentration and Foothill Yellow-legged Frog activity, and their 72-h LC_{50} (concentration at which 50% die) measured one-fifth that of Pacific Treefrogs (Ibid.). Carbaryl slightly decreased Foothill Yellow-legged Frog development rate, but it significantly increased susceptibility to predation by signal crayfish despite nearly no mortality in the pesticide- and predator-only treatments (Ibid.). Sparling and Fellers (2009) also found Foothill Yellow-legged Frogs were significantly more sensitive to pesticides (chlorpyrifos and endosulfan in this study) than Pacific Treefrogs; their 96-hr LC_{50} was nearly five-times less than for treefrogs. Endosulfan was nearly 121 times more toxic to Foothill Yellow-legged Frogs than chlorpyrifos, and water samples from the Sierra Nevada have contained endosulfan concentrations within their lethal range and sometimes greater than the LC_{50} for the species (Ibid.). Sublethal effects included smaller body size, slower development rate, and increased time to metamorphosis (Ibid.). Sparling and Fellers (2007) determined the organophospates chlorpyrifos, malathion, and diazinon can harm Foothill Yellow-legged Frog populations, and their oxon derivatives (the resultant compounds once they begin breaking down in the body) were 10 to 100 times more toxic than their respective parental forms.

Extrapolating the results of studies on other ranids to Foothill Yellow-legged Frogs should be undertaken with caution; however, those studies can demonstrate additional potential adverse impacts of exposure to agrochemicals. Relyea (2005) discovered that Roundup®, a common herbicide, could cause rapid and widespread mortality in amphibian tadpoles via direct toxicity, and overspray at the manufacturer's recommended application concentrations would be highly lethal. Atrazine, another common herbicide, has been implicated in disrupting reproductive processes in male Northern Leopard Frogs (*Rana pipiens*) by slowing gonadal development, inducing hermaphroditism, and even oocyte (egg) growth (Hayes et al. 2003). However, recent research on sex reversal in wild populations of Green Frogs (*R. clamitans*) suggests it may be a relatively common natural process unrelated to environmental contaminants, requiring more research (Lambert et al. 2019). Malathion, a common organophosphate insecticide, that rapidly breaks down in the environment, applied at low concentrations caused a trophic cascade that resulted in reduced growth and survival of two species of ranid tadpoles (Relyea and Diecks 2008). Malathion caused a reduction in the amount of zooplankton, which resulted in a bloom of phytoplankton and an eventual decline in periphyton, an important food source for tadpoles (Ibid.). In contrast, Relyea (2005) found that some insecticides increased amphibian tadpole survival by reducing their invertebrate predators. Runoff from agricultural areas can contain fertilizers that input nutrients into streams and increase productivity, but they can also result in harmful algal blooms (Cordone and

Kelley 1961). In addition, exposure to pesticides can result in immunosuppression and reduce resistance to the parasites that cause limb malformations (Kiesecker 2002, Hayes et al. 2006).

Cannabis

An estimated 60-70% of the cannabis (*Cannabis indica* and *C. sativa*) used in the U.S. from legal and illegal sources is grown in California, and most comes from the Emerald Triangle, an area comprised of Humboldt, Mendocino, and Trinity counties (Ferguson 2019). Small-scale illegal cannabis farms have operated in this area since at least the 1960s but have expanded rapidly, particularly trespass grows on public land primarily by Mexican cartels, since the passage of the Compassionate Use Act in 1996 (Mallery 2010, Bauer et al. 2015). Like other forms of agriculture, it involves clearing the land, diverting water, and using herbicides and pesticides; however, in addition, many of these illicit operations use large quantities of fertilizers and highly toxic banned pesticides to kill anything that may threaten the crop, and they leave substantial amounts of non-biodegradable trash and human excrement (Mallery 2010, Thompson et al. 2014, Carah et al. 2015).

Measurements of environmental impacts of illegal cannabis grows have been hindered by the difficult and dangerous nature of accessing many of these sites; however, some analyses have been conducted, often using aerial images and geographic information systems (GIS). An evaluation of 54% of watersheds within and bordering Humboldt County revealed that while cannabis grow sites are generally small (< 0.5 ha [1.2 ac]) and comprised a tiny fraction of the study area (122 ha [301 ac]), they were widespread (present in 83% of watersheds) but unevenly distributed, indicating impacts are concentrated in certain watersheds (Butsic and Brenner 2016, Wang et al. 2017). The results also showed that 68% of grows were > 500 m (0.3 mi) from developed roads, 23% were located on slopes steeper than 30%, and 5% were within 100 m (328 ft) of critical habitat for threatened salmonids (Butsic and Brenner 2016). These characteristics suggest wildlands adjacent to cannabis cultivations are at heightened risk of habitat fragmentation, erosion, sedimentation, landslides, and impacts to waterways critical to imperiled species (Ibid.).

A separate analysis in the same general area estimated potentially significant impacts from water diversions alone. Cannabis requires a substantial amount of water during the growing season, so it is often cultivated near sources of perennial surface water for irrigation, commonly diverting from springs and headwater streams (Bauer et al. 2015). In the least impacted of the study watersheds, Bauer et al. (2015) calculated that diversions for cannabis cultivation could reduce the annual seven-day low flow by up to 23%, and in some of the heavily impacted watersheds, water demands for cannabis could exceed surface water availability. If not regulated carefully, cannabis cultivation could have substantial impacts on sensitive aquatic species like Foothill Yellow-legged Frogs in watersheds in which it is concentrated.

For context, cannabis cultivation was responsible for approximately 1.1% of forest cover lost within study watersheds in Humboldt County from 2000 to 2013, while timber harvest accounted for 53.3% (Wang et al. 2017). Cannabis requires approximately two times as much water per day as wine grapes, the other major irrigated crop in the region (Bauer et al. 2015). Impacts from cannabis cultivation have been observed by Foothill Yellow-legged Frog researchers working on the Trinity River and South Fork

Eel River in the form of lower flows in summer, increased egg stranding, and more algae earlier in the season in recent years (S. Kupferberg and M. Power pers. comm. 2015; D. Ashton pers. comm. 2017; S. Kupferberg, M. van Hattem, and W. Stokes pers. comm. 2017). In addition, Gonsolin (2010) reported illegal cannabis cultivations on four headwater streams that drained into his study area along Coyote Creek, three of which were occupied by Foothill Yellow-legged Frogs. The cultivators had removed vegetation adjacent to the creeks, terraced the slopes, diverted water, constructed small water impoundments, poured fertilizers directly into the impoundments, and applied herbicides and pesticides, as evidenced by leftover empty containers littering the site.

Commercial sale of cannabis for recreational use became legal in California on January 1, 2018, through passage of the Control, Regulate and Tax Adult Use of Marijuana Act (2016), and with it an environmental permitting system and habitat restoration fund was established. The number of applications for temporary licenses per watershed is depicted in Figure 21. Two of the expected outcomes of passage of this law were that the profit-margin on growing cannabis would fall to the point that it would discourage illegal trespass grows and move the bulk of the cultivation out of remote forested areas into existing agricultural areas like the Central Valley (CSOS 2016). However, until cannabis is legalized at the federal level, these results may not occur since banks are reluctant to work with growers due to federal prohibitions subjecting them to prosecution for money laundering (ABA 2019). Additional details on cannabis permitting at the state level can be found under the Existing Management section.

Vineyards

Vineyard operators historically built on-stream dams and removed almost all the riparian vegetation to make room for vines and for ease of irrigation (M. van Hattem pers. comm. 2019). They still divert a substantial amount of water for irrigation, and they build on- and off-stream impoundments that support bullfrogs (Ibid.). The acreage of land planted in wine grapes in California began rising dramatically in the 1970s and now accounts for 90% of wine produced in the U.S. (Geisseler and Horwath 2016, Alston et al. 2018). The number of wineries in California rose from approximately 330 to nearly 2,500 between 1975 and 2006; however, expansion slowed and has reversed slightly recently with 24,300 ha (60,000 ac), or 6.5% of total area planted, removed between 2015 and 2017 (Volpe et al. 2010, CDFA 2018). In 2015, 347,000 ha (857,000 ac) were planted in grapes with 70% located in the San Joaquin Valley; 66%, 21%, and 13% were planted in wine, raisin, and table grapes, respectively (Alston et al. 2018).

Expansion of wineries in the coastal counties converted natural areas such as oak woodlands and forests to vineyards (Merenlender 2000, Napa County 2010). The area of Sonoma County covered in grapes increased by 32% from 1990 to 1997, and 42% of these new vineyards were planted above 100 m (328 ft) with 25% on slopes greater than 18% (Merelender 2000). For context, only 18% of vineyards planted before 1990 occurred above 100 m (328 ft) and less than 6% on slopes greater than 18% (Ibid.). This conversion took place on approximately 773 ha (1,909 ac) of conifer and dense hardwood forest, 149 ha (367 ac) of shrubland, and 2,925 ha (7,229 ac) of oak grassland savanna (Ibid.).

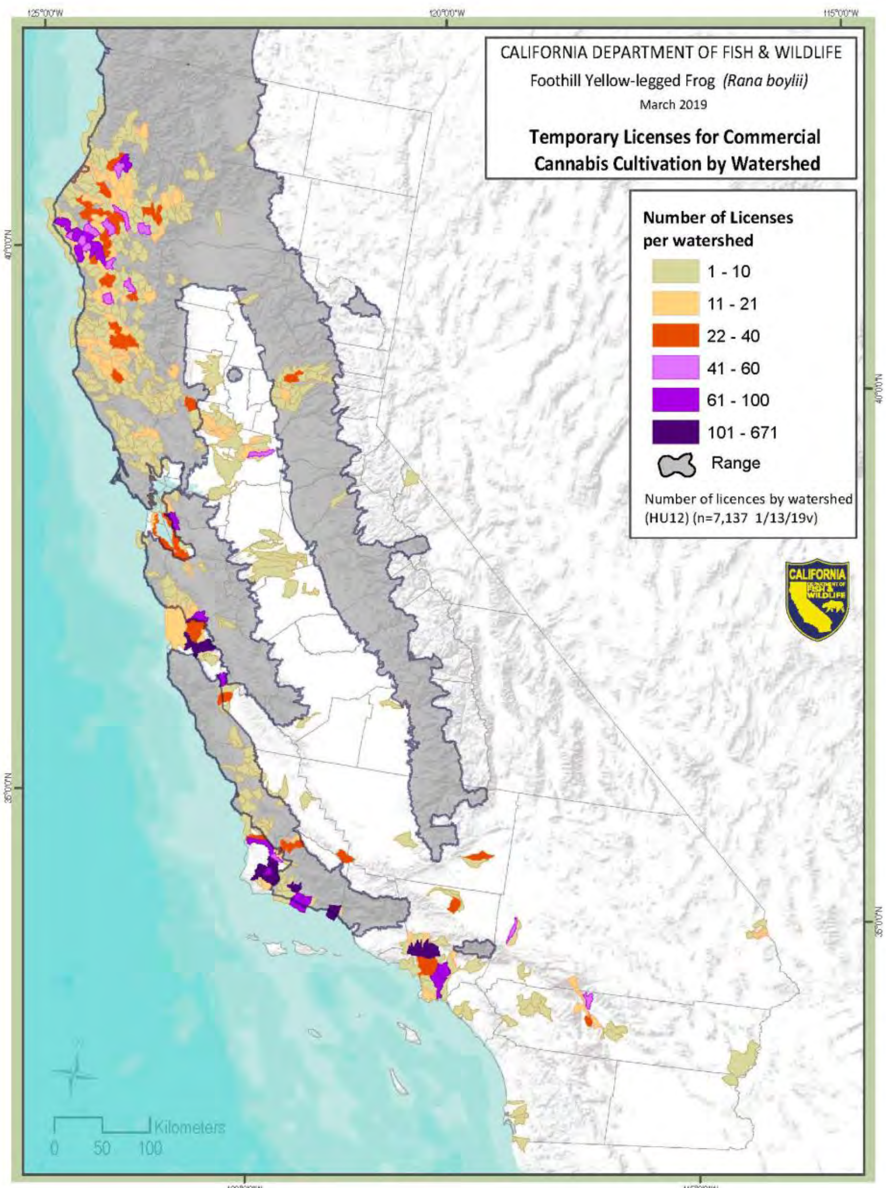

Figure 21. Cannabis cultivation temporary licenses by watershed in California (CDFA, NHD)

Recent expansion of oak woodland conversion to vineyards in Napa County was highest in its eastern hillsides (Napa County 2010). The County estimates that 1,085 and 1,240 ha (2,682-3,065 ac) of woodlands will be converted to vineyards between 2005 and 2030 (Ibid.). For context, 297 ha (733 ac) were converted from 1992 to 2003 (Ibid.). In addition, wine grapes were second only to almonds in terms of overall quantity of pesticides applied in California in 2016, but the quantity per unit area (2.9 kg/ha [2.6 lb/ac]) was 160% greater for the wine grapes (CDPR 2018). Vineyard expansion into hillsides has continued into sensitive headwater areas, and like cannabis cultivation, even small vineyards can have substantial impacts on Foothill Yellow-legged Frog habitat through sedimentation, water diversions, spread of harmful non-native species, and pesticide contamination (Merelender 2000, K. Weiss pers. comm. 2018).

Livestock Grazing

Livestock grazing can be an effective habitat management tool, including control of riparian vegetation encroachment, but overgrazing can significantly degrade the environment (Siekert et al. 1985). Cattle display a strong preference for riparian areas and have been implicated as a major source of habitat damage in the western U.S. where the adverse impacts of overgrazing on riparian vegetation are intensified by arid and semi-arid climates (Behnke and Raleigh 1978, Kauffman and Krueger 1984, Belsky et al. 1999). The severity of grazing impacts on riparian systems can be influenced by the number of animals, duration and time of year, substrate composition, and soil moisture (Benhke and Raleigh 1978, Kauffman et al. 1983, Marlow and Pogacnik 1985, Siekert et al. 1985). In addition to habitat damage, cattle can directly trample any life stage of Foothill Yellow-legged Frog.

Signs of overgrazing include impacts to the streambanks such as increased slough-offs and cave-ins that collapse undercuts used as refuge (Kauffman et al. 1983). Overgrazing reduces riparian cover, increases erosion and sedimentation, which as described above can result in silt degradation of breeding, rearing, and invertebrate food-producing areas (Cordone and Kelley 1961, Behnke and Raleigh 1978, Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). Loss of streamside and instream vegetative cover and changes to channel morphology can increase water temperatures and velocities (Behnke and Raleigh 1978). Water quality can be affected by increased turbidity and nutrient input from excrement, and seasonal water quantity can be impacted through changes to channel morphology (Belsky et al. 1999). In addition, increased nutrients and temperatures can promote blooms of harmful cyanobacteria like *Microcystis aeruginosa*, which releases a toxin when it expires that can cause liver damage to amphibians as well as other animals including humans (Bobzien and DiDonato 2007, Zhang et al. 2013).

While some recent studies indicate livestock grazing continues to damage stream and riparian ecosystems, its impact on Foothill Yellow-legged Frogs in California is unknown (Belsky et al. 1999, Hayes et al. 2016). In Oregon, the species' presence was correlated with significantly less grazing than where they were absent according to Borisenko and Hayes's 1999 report (as cited in Olson and Davis 2009). However, Fellers (2005) reported that apparently some Coast Range foothill populations occupying streams draining east into the San Joaquin Valley were doing well at the time of publication despite being heavily grazed.

Urbanization and Road Effects

Habitat conversion and fragmentation combined with modified environmental disturbance regimes can substantially jeopardize biological diversity (Tracey et al. 2018). This threat is most severe in areas like California with Mediterranean-type ecosystems that are biodiversity hot spots, fire-prone, and heavily altered by human land use (Ibid.). From 1990 to 2010, the fastest-growing land use type in the conterminous U.S. was new housing construction, which rapidly expanded the wildland-urban interface (WUI) where houses and natural vegetation meet or intermix on the landscape (Radeloff et al. 2018).

Of several variables tested, proportion of urban land use within a 5 km (3.1 mi) radius of a site was associated with Foothill Yellow-legged Frog declines (Davidson et al. 2002). Lind (2005) also found significantly less urban development nearby and upwind of sites occupied by Foothill Yellow-legged Frogs, suggesting pollutant drift may be a contributing factor. Changes in wildfires may also contribute to the species' declines; 95% of California's fires are human-caused, and wildfire issues are greatest at the WUI (Syphard et al. 2009, Radeloff et al. 2018). Population density, intermix WUI (where wildland and development intermingle as opposed to an abrupt interface), and distance to WUI explained the most variability in fire frequency (Syphard et al. 2007). In addition to wildfires, habitat loss, and fragmentation, urbanization can impact adjacent ecosystems through non-native species introduction, native predator subsidization, and disease transmission (Bar-Massada et al. 2014).

Projections show growth in California's population to 51 million people by 2060 from approximately 40 million currently (PPIC 2019). This will increase urbanization, the WUI, and habitat fragmentation. The Department of Finance projects the Inland Empire, the San Joaquin Valley, and the Sacramento metropolitan area will be the fastest-growing regions of the state over the next several decades (Ibid.). This puts the greatest pressure in areas outside of the Foothill Yellow-legged Frog's range; however, because the environmental stressors associated with urbanization can span far beyond its physical footprint, they may still adversely affect the species.

Highways are frequently recognized as barriers to dispersal that fragment habitats and populations; however, single-lane roads can pose significant risks to wildlife as well (Cook et al. 2012, Brehme et al. 2018). Foothill Yellow-legged Frogs are at risk of being killed by vehicles when roads are located near their habitat (Cook et al. 2012, Brehme et al. 2018). Fifty-six juvenile Foothill Yellow-legged Frogs were found on a road adjacent to Sulphur Creek (Mendocino County), seven of which had been struck and killed (Cook et al. 2012). When fords (naturally shallow areas) are used as vehicle crossings, they can create sedimentation and poor water quality, and in some cases, the fords are gravel or cobble bars used by Foothill Yellow-legged Frogs for breeding that could result in direct mortality (K. Blanchard pers. comm. 2018, R. Bourque pers. comm. 2018). Construction of culverts under roads to keep vehicles out of the streambed can result in varying impacts. In some cases, they can impede dispersal and create deep scoured pools that support predatory fish and frogs, but when properly constructed, they can facilitate frog movement up and down the channel with reduced road mortality (Van Wagner 1996, GANDA 2008). In areas where non-native species are not a threat, but premature drying is, pools created by culverts can provide habitat in otherwise unsuitable areas (M. Grefsrud pers. comm. 2019). An evaluation of the impact of roads on 166 native California amphibians and reptiles through direct

morality and barriers to movement concluded that Foothill Yellow-legged Frogs, at individual and population levels, were at moderate risk of road impacts in aquatic habitat but very low risk of impacts in terrestrial habitat (Brehme et al. 2018). For context, all chelonids (turtles and tortoises), 72% of snakes, 50% of anurans, 18% of lizards, and 17% of salamander species in California were ranked as having a high or very high risk of negative road impacts in the same evaluation (Ibid.).

Poorly constructed roadways near rivers and streams can result in substantial erosion and sedimentation, leading to reduced amphibian densities (Welsh and Ollivier 1998). Proximity of roads to Foothill Yellow-legged Frog habitat contributes to petrochemical runoff and poses the threat of spills (Ashton et al. 1997). A diesel spill on Hayfork Creek (Trinity County) resulted in mass mortality of Foothill Yellow-legged Frog tadpoles and partial metamorphs (Bury 1972). Roads have also been implicated in the spread of disease and may have aided in the spread of Bd in California (Adams et al. 2017b).

Frogs use auditory and visual cues to defend territories and attract mates, and some studies reveal that realistic levels of traffic noise can impede transmission and reception of these signals (Bee and Swanson 2007). Some male frogs have been observed changing the frequency of their calls to increase the distance they can be heard over traffic noise, but if females have evolved to recognize lower pitched calls as signs of superior fitness, this potential trade-off between audibility and attractiveness could have implications for reproductive success (Parris et al. 2009). In a separate study, traffic noise caused a change in male vocal sac coloration and an increase in stress hormones, which changed sexual selection processes and suppressed immunity (Troïanowski et al. 2017). Because Foothill Yellow-legged Frogs mostly call underwater and are not known to use color displays, communication cues may not be adversely affected by traffic noise, but their stress response is unknown.

Timber Harvest

Because Foothill Yellow-legged Frogs tend to remain close to the water channel (i.e., within the riparian corridor) and current timber harvest practices minimize disturbance in riparian areas for the most part, adverse effects from timber harvest are expected to be relatively low (Hayes et al. 2016, CDFW 2018b). However, some activities have a potential to negatively impact Foothill Yellow-legged Frogs or their habitat, including direct mortality and increased sedimentation during construction and decommissioning of watercourse crossings and infiltration galleries, tree felling, log hauling, and entrainment by water intakes or desiccation of eggs and tadpoles through stranding from dewatering during drafting operations (CDFW 2018b,c). In addition to impacts previously described under the Sedimentation and Road Effects section, when silt runoff into streams is accompanied by organic materials, such as logging debris, impaired water quality can result, including reduced dissolved oxygen, which is important in embryonic and tadpole development (Cordone and Kelley 1961).

Because Foothill Yellow-legged Frogs are heliotherms (i.e, they bask in the sun to raise their body temperature) and sensitive to thermal extremes, some moderate timber harvest may benefit the species (Zweifel 1955, Fellers 2005). Ashton (2002) reported 85% of his Foothill Yellow-legged Frog observations occurred in second-growth forests (37-60 years post-harvest) as opposed to late-seral forests and postulated that the availability of some open canopy areas played a major part in this

disparity. Foothill Yellow-legged Frogs are typically absent in areas with closed canopy (Welsh and Hodgson 2011). Reduced canopy also raises stream temperatures, which could improve tadpole development and promote algal and invertebrate productivity in otherwise cold streams (Olson and Davis 2009; Catenazzi and Kupferberg 2013,2017).

Recreation

Several types of recreation can adversely impact Foothill Yellow-legged Frogs, and some are more severe and widespread than others. One of the main potential factors identified by herpetologists as contributing to disappearance of Foothill Yellow-legged Frogs in southern California was increased and intensified recreation in streams (Adams et al. 2017b). The greater number of people traveling into the backcountry may have facilitated the spread Bd to these areas, and while no evidence shows stress from disturbance or other environmental pressures increases susceptibility to Bd, the stress hormone corticosterone has been implicated in immunosuppression (Hayes et al. 2003, Adams et al. 2017b).

The amount of Foothill Yellow-legged Frog habitat disturbed by off-highway motor vehicles (OHV) throughout its range in California is unknown, but its impacts can be significant, particularly in areas with small isolated populations (Kupferberg et al. 2009c, Kupferberg and Furey 2015). An example is the Carnegie State Vehicular Recreation Area (CVSRA), located in the hills southwest of Tracy in the Corral Hollow Creek watershed (Alameda and San Joaquin counties). The above-described road effects apply: sedimentation, crushing along trail crossings, and potential noise effects (Ibid.). In addition, dust suppression activities employed by CSVRA use magnesium chloride ($MgCl_2$), which has the potential to harm developing embryos and tadpoles (Karraker et al. 2008, Hopkins et al. 2013, OHMVRC 2017). Based on museum records, Foothill Yellow-legged Frogs were apparently abundant in Corral Hollow Creek, but they are extremely rare now and are already extirpated or at risk of extirpation (Kupferberg et al. 2009c, Kupferberg and Furey 2015).

Motorized and non-motorized recreational boating can also impact Foothill Yellow-legged Frogs. The impacts of jet boat traffic were investigated in Oregon; in areas with frequent use and high wakes breaking on shore, Foothill Yellow-legged Frogs were absent (Borisenko and Hayes 1999 as cited in Olson and Davis 2009). This wake action had the potential to dislodge egg masses, strand tadpoles, disrupt adult basking behavior, and erode shorelines (Ibid.). Jet boat tours and races on the Klamath River (Del Norte and Humboldt counties) may have an impact on Foothill Yellow-legged Frog use of the mainstem (M. van Hattem pers. comm. 2019). In addition, using gravel bars as launch and haul out sites for boat trailers, kayaks, or river rafts can result in direct loss of egg masses and tadpoles or damage to breeding and rearing habitat and can disrupt post-metamorphic frog behavior (Ibid.). As described above, pulse flows released for whitewater boating in the late spring and summer can result in scouring and stranding of egg masses and tadpoles (Borisenko and Hayes 1999 as cited in Olson and Davis 2009, Kupferberg et al. 2009b). In addition, the velocities that resulted in stunted growth and increased vulnerability to predation in Foothill Yellow-legged Frog tadpoles were less than the increased velocities experienced in nearshore habitats during intentional release of recreational flows for whitewater boating, as well as hydropeaking for power generation (Kupferberg et al. 2011b).

Hiking, horse-riding, camping, fishing, and swimming, particularly in sensitive breeding and rearing habitat can also adversely impact Foothill Yellow-legged Frog populations (Borisenko and Hayes 1999 in Olson and Davis 2009). Because Foothill Yellow-legged Frog breeding activity was being disturbed and egg masses were being trampled by people and dogs using Carson Falls (Marin County), the land manager established an educational program, including employing docents on weekends that remind people to stay on trails and tread lightly to try to reduce the loss of Foothill Yellow-legged Frog reproductive effort (Prado 2005). In addition, within his study site, Van Wagner (1996) reported that a property owner moved rocks that were being used as breeding habitat to create a swimming hole. The extent to which this is more than a small, local problem is unknown, but as the population of California increases, recreational pressures in Foothill Yellow-legged Frog habitat are likely to increase commensurately.

Drought

Drought is a common phenomenon in California and is characterized by lower than average precipitation. Lower precipitation in general results in less surface water, and water availability is critical for obligate stream-breeding species. Even in the absence of drought, a positive relationship exists between precipitation and latitude within the Foothill Yellow-legged Frog's range in California, and mean annual precipitation has a strong influence on Foothill Yellow-legged Frog presence at historically occupied sites (Davidson et al. 2002, Lind 2005). Figure 22 depicts the recent historical annual average precipitation across the state as well as during the most recent drought and how they differ. Southern California is normally drier than northern California, but the severity of the drought was even greater in the south.

Reduced precipitation can result in deleterious effects to Foothill Yellow-legged Frogs beyond the obvious premature drying of aquatic habitat. When stream flows recede during the summer and fall, sometimes the isolated pools that stay perennially wet are the only remaining habitat. This phenomenon concentrates aquatic species, resulting in several potentially significant adverse impacts. Stream flow volume was negatively correlated with Bd load during a recent chytridiomycosis outbreak in the Alameda Creek watershed (Adams et al. 2017a). The absence of high peak flows in winter coupled with wet years allowed bullfrogs to expand their distribution upstream, and the drought-induced low flows in the fall concentrated them with Foothill Yellow-legged Frogs in the remaining drying pools (Ibid.). This mass mortality event appeared to have been the result of a combination of drought, disease, and dam effects (Ibid.). This die-off occurred in a regulated reach that experiences heavy recreational use and presence of crayfish and bass (Ibid.). Despite these threats, the density of breeding females in this reach was greater in 2014 and 2015 than the in the unregulated reach upstream because the latter dried completely before tadpoles could metamorphose during the preceding drought years (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015).

In addition to increasing the spread of pathogens, drought-induced stream drying can increase predation and competition by introduced fish and frogs in the pools they are forced to share (Moyle 1973, Hayes and Jennings 1988, Drost and Fellers 1996). This concentration in isolated pools can also result in increased native predation as well as facilitate spread of Bd. An aggregation of six adult Foothill

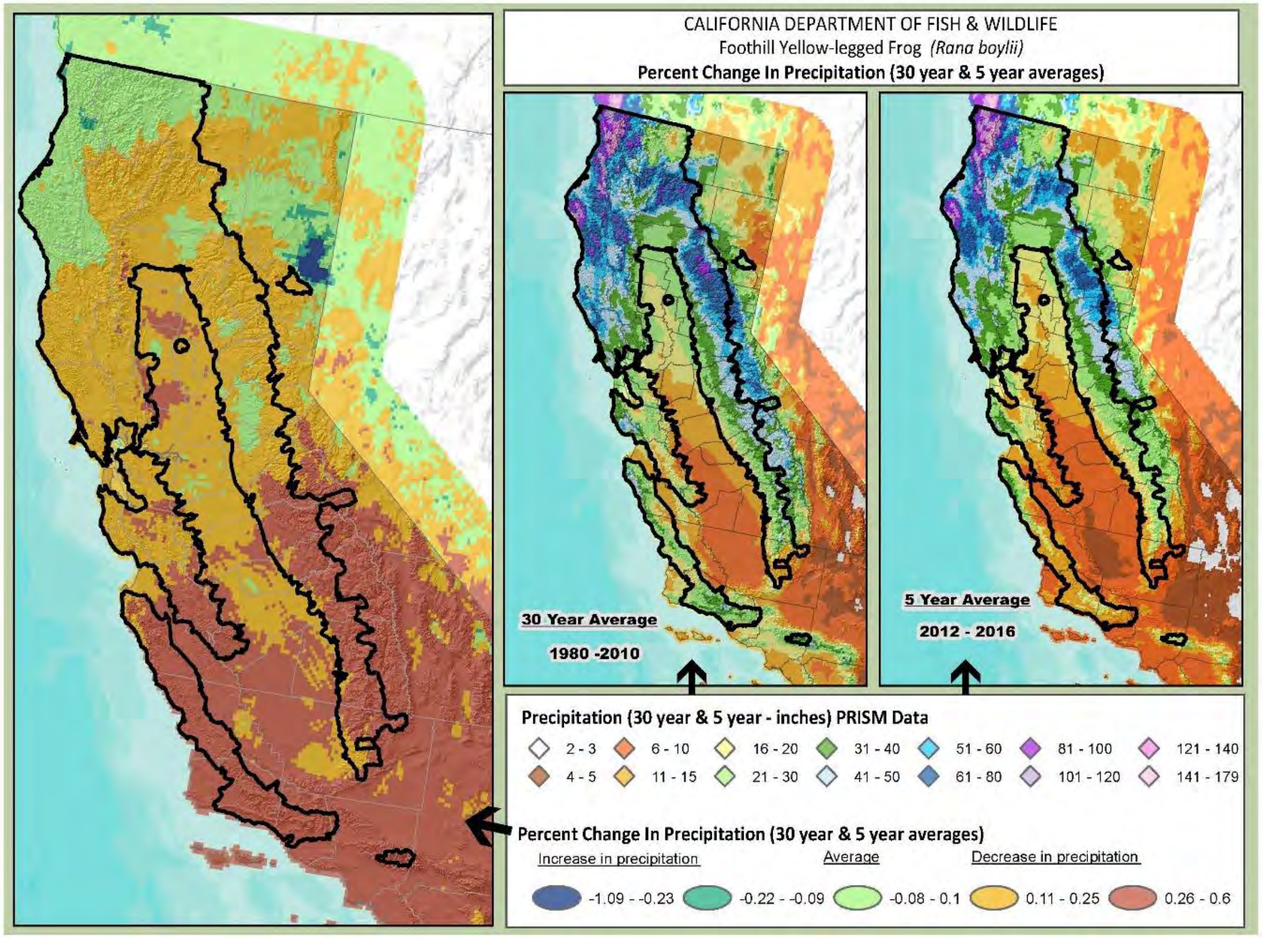

Figure 22. Change in precipitation from 30-year average and during the recent drought (PRISM)

Yellow-legged Frogs was observed perched on a rock above an isolated pool where a gartersnake was foraging on tadpoles during the summer; this close contact may reduce evaporative water loss when they are forced out of the water during high temperatures, but it can also increase disease transmission risk (Leidy et al. 2009.). Gonsolin (2010) also documented a late summer aggregation of juvenile Foothill Yellow-legged Frogs out of water during extremely high temperatures. In addition, drought-induced low flow, high water temperatures, and high densities of tadpoles were associated with outbreaks of malformation-inducing parasitic copepods (Kupferberg et al. 2009a).

Rapidly receding spring flows can result in stranding egg masses and tadpoles. However, this risk is likely less significant when it is drought-induced on an unregulated stream vs. a result of dam operations since Foothill Yellow-legged Frogs have evolved to initiate breeding earlier and shorten the breeding period in drought years (Kupferberg 1996a). If pools stay wet long enough to support metamorphosis, complete drying at the end of the season may benefit Foothill Yellow-legged Frogs if it eliminates introduced species like warm water fish and bullfrogs. Moyle (1973) noted that the only intermittent streams occupied by Foothill Yellow-legged Frogs in the Sierra Nevada foothills had no bullfrogs. At a long-term study site in upper Coyote Creek in 2015, Foothill Yellow-legged Frogs had persisted in reaches that had at least some summer water through the three preceding years of the most severe drought in over a millennium, albeit at much lower abundance than a decade before (Gonsolin 2010, Griffin and Anchokaitis 2014, J. Smith pers. comm. 2015). The population's abundance appeared to have never recovered from the 2007-2009 drought before the 2012-2016 drought began (J. Smith pers. comm. 2015). In 2016, after a relatively wet winter, Foothill Yellow-legged Frogs bred en masse, and only a single adult bullfrog was detected, an unusually low number for that area (CDWR 2016, J. Smith pers. comm. 2016). It appeared the population may rebound; however, in 2018, it experienced lethal chytridiomycosis outbreak, and like the Alameda Creek die-off probably resulted from crowding during drought, presence of bullfrogs as Bd-reservoirs and predators and competitors, and the stress associated with the combination of the two (Kupferberg and Catenazzi 2019).

Drought effects can also exacerbate other environmental stressors. During the most recent severe drought, tree mortality increased dramatically from 2014 to 2017 and reached approximately 129 million dead trees (OEHHA 2018). Multiple years of high temperatures and low precipitation left them weakened and more susceptible to pathogens and parasites (Ibid.). Vast areas of dead and dying trees are more prone to severe wildfires, and they lose their carbon sequestration function while also emitting methane, which is an extremely damaging greenhouse gas (CNRA 2016). Post-wildfire storms can result in erosion of fine sediments from denuded hillsides into the stream channel (Florsheim et al. 2017). If the storms are short duration and low precipitation, as happens during droughts, their magnitude may not be sufficient to transport the material downstream, resulting in a longer temporal loss or degradation of stream habitat (Ibid.). Reduced rainfall may also infiltrate the debris leading to subsurface flows rather than the surface water Foothill Yellow-legged Frogs require (Ibid.). Extended droughts increase risk of the stream being uninhabitable or inadequate for breeding for multiple years, which would result in population-level impacts and possible extirpation (Ibid.).

Wildland Fire and Fire Management

Fire is an important element for shaping and maintaining the species composition and integrity of many California ecosystems (Syphard et al. 2007, SBFFP 2018). Prior to European settlement, an estimated 1.8 to 4.9 million ha (4.5-12 million ac) burned annually (4-11% of total area of the state), ignited both deliberately by Native Americans and through lightning strikes (Keeley 2005, SBFFP 2018). The impacts of wildland fires on Foothill Yellow-legged Frogs are poorly understood and likely vary significantly across the species' range with differences in climate, vegetation, soils, stream-order, slope, frequency, and severity (Olson and Davis 2009). Mortality from direct scorching is unlikely because Foothill Yellow-legged Frogs are highly aquatic, and most wildfires occur during the dry period of the year when the frogs are most likely to be in or near the water (Pilliod et al. 2003, Bourque 2008). Field observations support this presumption; sightings of post-metamorphic Foothill Yellow-legged Frogs immediately after fires in the northern Sierra Nevada and North Coast indicate they are not very vulnerable to the direct effects of fire (S. Kupferberg and R. Peek pers. comm. 2018). Similarly, Foothill Yellow-legged Frogs were observed two months, and again one year, after a low- to moderate-intensity fire burned an area in the southern Sierra Nevada in 2002, and the populations were extant and breeding as recently as 2017 (Lind et al. 2003b, CNDDB 2019). While water may provide a refuge during the fire, it is also possible for temperatures during a fire, or afterward due to increased solar exposure, to near or exceed a threshold resulting lethal or sublethal harm; this would likely impact embryos and tadpoles with limited dispersal abilities (Pilliod et al. 2003).

Intense fires remove overstory canopy, which provides insulation from extreme heat and cold, and woody debris that increases habitat heterogeneity (Pilliod et al. 2003, Olson and Davis 2009). If this happens frequently enough, it can permanently change the landscape. For example, frequent high-severity burning of crown fire-adapted ecosystems can prevent forest regeneration since seeds require sufficient time between fires to mature, and repeated fires can deplete the seed bank (Stephens et al. 2014). Smoke and ash change water chemistry through increased nutrient and heavy metal inputs that can reach concentrations harmful to aquatic species during the fire and for days, weeks, or years after (Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Erosion rates on granitic soils, which make up a large portion of the Foothill Yellow-legged Frog's range, can be over 60 times greater in burned vs. unburned areas and can increase sedimentation for over 10 years (Megahan et al. 1995, Hayes et al. 2016). Post-fire nutrient inputs into streams could benefit Foothill Yellow-legged Frogs through increased productivity and more rapid growth and development (Pilliod et al. 2003). While the loss of leaf litter that accompanies fire alters the food web, insects are expected to recolonize rapidly, and the lack of cover could increase their vulnerability to predation by Foothill Yellow-legged Frogs (Ibid.).

Low-intensity fires likely have no adverse effect on Foothill Yellow-legged Frogs (Olson and Davis 2009). If they occur in areas with dense canopy, wildfires can improve habitat quality for Foothill Yellow-legged Frogs by reducing riparian cover, providing areas to bask, and increasing habitat heterogeneity, which is likely to outweigh any adverse effects from some fire-induced mortality (Russell et al. 1999, Olson and Davis 2009). In a preliminary analysis of threats to Foothill Yellow-legged Frogs in Oregon, proximity to stand-replacing fires was not associated with absence (Olson and Davis 2009).

Euro-American colonization of California significantly altered the pattern of periodic fires with which California's native flora and fauna evolved through fire exclusion, land use practices, and development (OEHHA 2018). Fire suppression can lead to canopy closure, which reduces habitat quality by limiting thermoregulatory opportunities (Olson and Davis 2009). In addition, fire suppression and its subsequent increase in fuel loads combined with expanding urbanization and rising temperatures have resulted in a greater likelihood of catastrophic stand-replacing fires that can significantly alter riparian systems for decades (Pilliod et al. 2003). Firebreaks, in which vegetation is cleared from a swath of land, can result in similar impacts to roads and road construction (Ibid.). Fire suppression can also include bulldozing within streams to create temporary reservoirs for pumping water, which can cause more damage than the fire itself to Foothill Yellow-legged Frogs in some cases (S. Kupferberg and R. Peek pers. comm. 2018). In addition, fire suppression practices can involve applying hundreds of tons of ammonia-based fire retardants and surfactant-based fire suppressant foams from air tankers and fire engines (Pilliod et al. 2003). Some of these chemicals are highly toxic to some anurans (Little and Calfee 2000).

Fire suppression has evolved into fire management with a greater understanding of its importance in ecosystem health (Keeley and Syphard 2016). Several strategies are employed including prescribed burns, mechanical fuels reduction, and allowing some fires to burn instead of necessarily extinguishing them (Pilliod et al. 2003). Like wildfires themselves, fire management strategies have the potential to benefit or harm Foothill Yellow-legged Frogs. Prescribed fires and mechanical fuels removal lessen the likelihood of catastrophic wildfires, but they can also result in loss of riparian vegetation, excessive sedimentation, and increased water temperatures (Ibid.). Salvage logging after a fire may result in similar impacts to timber harvest but with higher rates of erosion and sedimentation (Ibid.). A balanced approach to wildland fires is likely to have the greatest beneficial impact on species and ecosystem health (Stephens et al. 2012).

Floods and Landslides

As previously described, Foothill Yellow-legged Frog persistence is highly sensitive to early life stage mortality (Kupferberg et al. 2009c). While aseasonal dam releases are a major source of egg mass and tadpole scouring, storm-driven floods are also capable of it (Ashton et al. 1997). Van Wagner (1996) concluded that the high discharge associated with heavy rainfall could account for a significant source of mortality in post-metamorphic Foothill Yellow-legged Frogs as well as eggs and tadpoles; he observed two adult females and several juveniles swept downstream with fatal injuries post-flooding. Severe flooding, specifically two 500-year flood events in early 1969 in Evey Canyon (Los Angeles County), resulted in massive riparian habitat destruction (Sweet 1983). Prior to the floods, Foothill Yellow-legged Frogs were widespread and common, but only four subsequent sightings were documented between 1970 and 1974 and none since (Sweet 1983, Adams 2017b). Sweet (1983) speculates that because Foothill Yellow-legged Frogs overwinter in the streambed in that area, the floods may have reduced the population's abundance below an extinction threshold. Four other herpetologists interviewed about Foothill Yellow-legged Frog extirpations in southern California listed severe flooding as a likely cause (Adams et al. 2017b).

As mentioned above, landslides are a frequent consequence of post-fire rainstorms and can result in lasting impacts to stream morphology, water quality, and Foothill Yellow-legged Frog populations. On the other hand, Olson and Davis (2009) suggest that periodic landslides can have beneficial effects by transporting woody debris into the stream that can increase habitat complexity and by replacing sediments that are typically washed downstream over time. Whether a landslide is detrimental or beneficial is likely heavily influenced by amount of precipitation and the underlying system. As previously described, too little precipitation could lead to prolonged loss of habitat through failure to transport material downstream, and too much precipitation can result in large-scale habitat destruction and direct mortality.

Climate Change

Global climate change threatens biodiversity and may lead to increased frequency and severity of drought, wildfires, flooding, and landslides (Williams et al. 2008, Keely and Syphard 2016). Data show a consistent trend of warming temperatures in California and globally; 2014 was the warmest year on record, followed by 2015, 2017, and 2016 (OEHHA 2018). Climate model projections for annual temperature in California in the 21st century range from 1.5 to 4.5°C (2.7-8.1°F) greater than the 1961-1990 mean (Cayan et al. 2008). Precipitation change projections are less consistent than those for temperature, but recent studies indicate increasing variability in precipitation, and increasingly dry conditions in California resulting from increased evaporative water loss primarily due to rising temperatures (Cayan et al. 2005, Williams et al. 2015, OEHHA 2018). Precipitation variability and proportion of dry years were negatively associated with Foothill Yellow-legged Frog presence in a range-wide analysis (Lind 2005). In addition, low precipitation intensified the adverse effects of dams on the species (Ibid.).

California recently experienced the longest drought since the U.S. Drought Monitor began reporting in 2000 (NIDIS 2019). Until March 5, 2019, California experienced drought effects in at least a portion of the state for 376 consecutive weeks; the most intense period occurred during the week of October 28, 2014 when D4 (the most severe drought category) affected 58.4% of California's land area (Figure 23; NIDIS 2019). A recent modeling effort using data on historical droughts, including the Medieval megadrought between 1100 and 1300 CE, indicates the mean state of drought from 2050 to 2099 in California will likely exceed the Medieval-era drought, under both high and moderate greenhouse gas emissions models (Cook et al. 2015). The probability of a multidecadal (35 yr) drought occurring during the late 21st century is greater than 80% in all models used by Cook et al. (2015). If correct, this would represent a climatic shift that not only falls outside of contemporary variability in aridity but would also be unprecedented in the past millennium (Ibid.).

As a result of increasing temperatures, a decreasing proportion of precipitation falls as snow, resulting in more runoff from rainfall during the winter and a shallower snowpack that melts more rapidly (Stewart 2009). A combination of reduced seasonal snow accumulation and earlier streamflow timing significantly reduces surface water storage capacity and increases the risk for winter and spring floods, which may require additional and taller dams and result in alterations to hydroelectric power generation flow regimes (Cayan et al. 2005, Knowles et al. 2006, Stewart 2009). The reduction in snowmelt volume

is expected to impact the northern Sierra (Feather, Yuba, and American River watersheds) to a greater extent than the southern portion (Young et al. 2009). The earlier shift in peak snowmelt timing is predicted to exceed four to six weeks across the entire Sierra Nevada depending on the amount of warming that occurs this century (Ibid.). In addition, the snow water equivalent is predicted to significantly decline by 2070-2099 over the 1961-1990 average in the Trinity, Sacramento, and San Joaquin drainages from -32% to -79%, and effectively no snow is expected to fall below 1000 m (3280 ft) in the high emissions/sensitive model (Cayan et al. 2008).

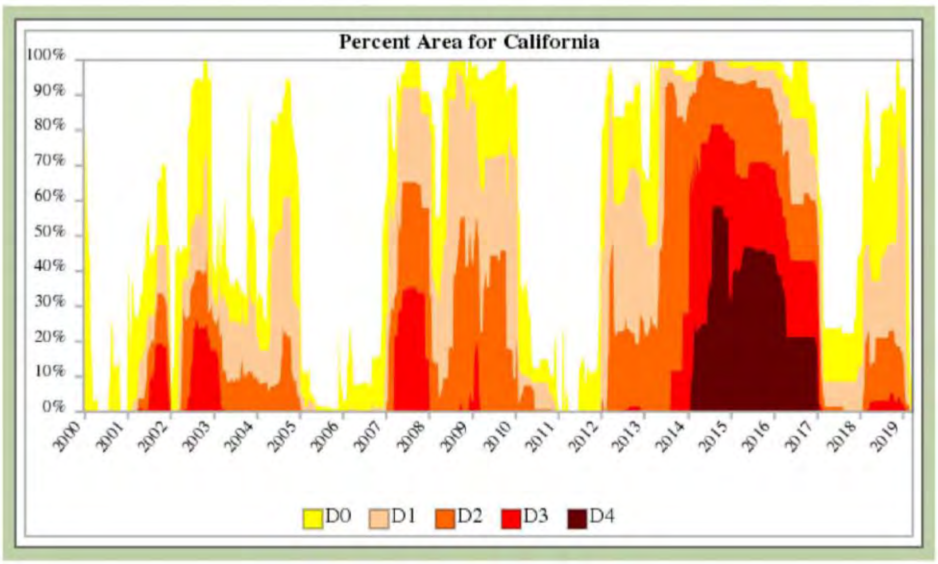

Figure 23. Palmer Hydrological Drought Indices 2000-present (NIDIS)

The earlier shift of snowmelt and lower water content will result in lower summer flows, which will intensify the competition for water among residential, agricultural, industrial, and environmental needs (Field et al. 1999, Cook et al. 2015). In unregulated systems, as long as water is present through late summer, an earlier hydrograph recession that triggers Foothill Yellow-legged Frog breeding could result in a longer time to grow larger prior to metamorphosis, which improves probability of survival (Yarnell et al. 2010, Kupferberg 2011b). However, if duration from peak to base flow shortens, it can result in increased sedimentation and reduced habitat complexity in addition to stranding (Yarnell et al. 2010).

Fire frequency relates to temperature, fuel loads, and fuel moisture (CCSP 2008). Therefore, increasing periods of drought combined with extreme heat and low humidity that stress or kill trees and other vegetation create ideal conditions for wildland fires (Ibid). Not surprisingly, the area burned by wildland fires over the western U.S. increased since 1950 but rose rapidly in the mid-1980s (Westerling et al. 2006, OEHHA 2018). As temperatures warmed and snow melted earlier, large-wildfire frequency and duration increased, and wildfire seasons lengthened (Westerling et al. 2006, OEHHA 2018).

In California, latitude inversely correlates with temperature and annual area burned, but the climate-fire relationship is substantially different across the state, and future wildfire regimes are difficult to predict (Keeley and Syphard 2016). For example, the relationship between spring and summer temperature and area burned in the Sierra Nevada is highly significant but not in southern California (Ibid.). Climate has a greater influence on fire regimes in mesic than arid environments, and the most influential climatological factor (e.g., precipitation, temperature, season, or their interactions) shifts over time (Ibid.). Nine of the 10 largest fires in California since 1932 have occurred in the past 20 years, 4 within the past 2 years (Figure 24; CAL FIRE 2019). However, it is possible this trend will not continue; climate- and wildfire-induced changes in vegetation could reduce wildfire severity in the future (Parks et al. 2016).

Wildfires themselves can accelerate the effects of climate change. Wildfires emit short-lived climate pollutants like black carbon (soot) and methane that are tens to thousands of times greater than carbon dioxide (the main focus of greenhouse gas reduction) in terms of warming effect and are responsible for 40% or more of global warming to date (CNRA 2016). Healthy forests can sequester large amounts of carbon from the atmosphere, but recently carbon emissions from wildfires have exceeded their uptake by vegetation in California (Ackerly et al. 2018).

With increased variability and changes in precipitation type, magnitude, and timing comes more variable and extreme stream flows (Mallakpour et al. 2018). Models for stream flow in California project higher high flows, lower low flows, wetter rainy seasons, and drier dry seasons (Ibid.). The projected water cycle extremes are related to strengthening El Niño and La Niña events, and both severe flooding and intense drought are predicted to increase by at least 50% by the end of the century (Yoon et al. 2015). These changes increase the likelihood of Foothill Yellow-legged Frog egg mass and tadpole scouring and stranding, even in unregulated rivers.

A species' vulnerability to climate change is a function of its sensitivity to climate change effects, its exposure to them, and its ability to adapt its behaviors to survive with them (Dawson et al. 2011). Myriad examples exist of species shifting their geographical distribution toward the poles and to higher elevations and changing their growth and reproduction with increases in temperature over time (Parmesan and Yohe 2003). However, in many places, fragmentation of suitable habitat by anthropogenic barriers (e.g., urbanization, agriculture, and reservoirs) limits a species' ability to shift its range (Pounds et al. 2007). The proportion of sites historically occupied by Foothill Yellow-legged Frogs that are now extirpated increases significantly on a north-to-south latitudinal gradient and at drier sites within California, suggesting climate change may contribute to the spatial pattern of the species' declines (Davidson et al. 2002).

An analysis of the climate change sensitivity of 195 species of plants and animals in northwestern North America revealed that, as a group, amphibians and reptiles were estimated to be the most sensitive (Case et al. 2015). Nevertheless, examples exist of amphibians adjusting their breeding behaviors (e.g., calling and migrating to breeding sites) to occur earlier in the year as global warming increases (Beebee 1995, Gibbs and Breisch 2001). Because of the rapid change in temperature, Beebee (1995) posits these are examples of behavioral and physiological plasticity rather than natural selection. However, for

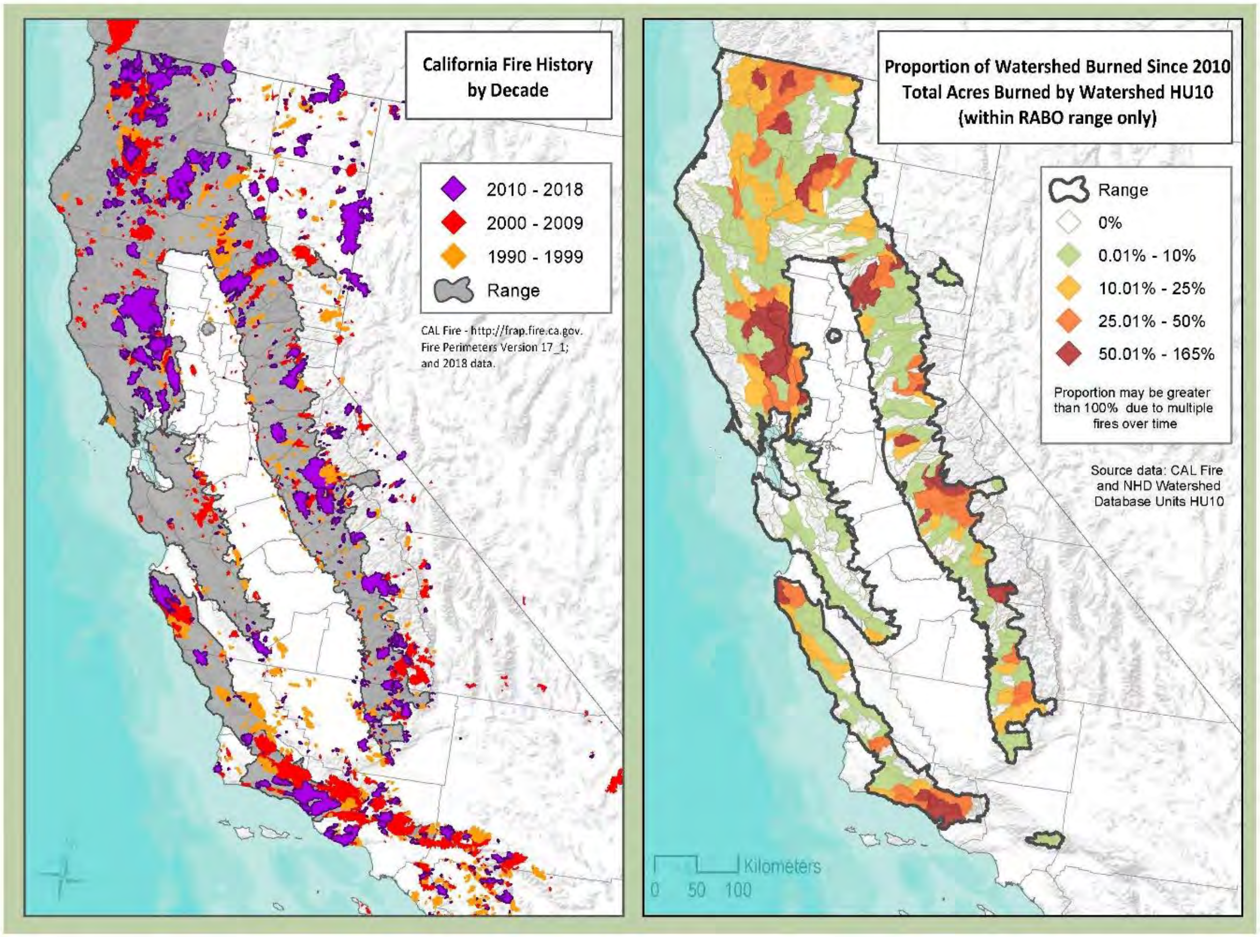

Figure 24. Fire history (1990-2018) and proportion of watershed burned (2010-2018) in California (CAL FIRE, NHD)

species with short generation times or in areas less affected by climate change, populations may be able to undergo evolutionary adaptation to the changing local environmental conditions (Hoffman and Sgrò 2011).

As previously described in the Seasonal Activity and Movements section, Foothill Yellow-legged Frog breeding is closely tied to water temperature, flow, and stage, and the species already adjusts its timing of oviposition by as much as a month in the same location during different water years, so the species may have enough inherent flexibility to reduce their vulnerability. The species appears fairly resilient to drought, fire, and flooding, at least in some circumstances. For example, after the 2012-2016 drought, the Loma Fire in late 2016, and severe winter flooding and landslides in 2016 and 2017, Foothill Yellow-legged Frog adults and metamorphs, as well as aquatic insects and rainbow trout, were abundant throughout Upper Llagas Creek in fall of 2017, and the substrate consisted of generally clean gravels and cobbles with only a slight silt coating in some pools (J. Smith pers. comm. 2017). The frogs and fish likely took refuge in a spring-fed pool, and the heavy rains scoured the fine sediments that eroded downstream (Ibid.). These refugia from the effects of climate change reduce the species' exposure, thereby reducing their vulnerability (Case et al. 2015).

Climate change models that evaluate the Foothill Yellow-legged Frog's susceptibility from a species and habitat perspective yield mixed results. An investigation into the possible effects of climate on California's native amphibians and reptiles used ecological niche models, future climate scenarios, and general circulation models to predict species-specific climatic suitability in 2050 (Wright et al. 2013). The results suggested approximately 90-100% of localities currently occupied by Foothill Yellow-legged Frogs are expected to remain climatically suitable in that time, and the proportion of currently suitable localities predicted to change ranges from -20% to 20% (Ibid.). However, a second study using a subset of these models found that 66.4% of currently occupied cells will experience reduced environmental suitability in 2050 (Warren et al. 2014). This analysis included 90 species of native California mammals, birds, reptiles, and amphibians. For context, over half of the taxa were predicted to experience > 80% reductions, a consistent pattern reflected across taxonomic groups (Ibid.).

A third analysis investigated the long-term risk of climate change by modeling the relative environmental stress a vegetative community would undergo in 2099 given different climate and greenhouse gas emission scenarios (Thorne et al. 2016). This model does not incorporate any Foothill Yellow-legged Frog-specific data; it strictly projects climatic stress levels vegetative communities will experience within the species' range boundaries (Ibid.). Unsurprisingly, higher emissions scenarios resulted in a greater proportion of habitat undergoing climatic stress (Figure 25). Perhaps counterintuitively, the warm and wet scenario resulted in a greater amount of stress than the hot and dry scenario. When high emissions and warm and wet changes are combined, a much greater proportion of the vegetation communities will experience "non-analog" conditions, those outside of the range of conditions currently known in California (Ibid.).

Habitat Restoration and Species Surveys

Potential conflicts between managing riverine habitat below dams for both cold-water adapted salmonids and Foothill Yellow-legged Frogs was discussed previously. In addition to problems with temperatures and pulse flows, some stream restoration projects aimed at physically creating or improving salmonid habitat can also adversely affect the species. For example, boulder deflectors were placed in Hurdygurdy Creek (Del Norte County) to create juvenile steelhead rearing habitat; deflectors change broad, shallow, low-velocity reaches into narrower, deeper, faster reaches preferred by the fish (Fuller and Lind 1992). Foothill Yellow-legged Frogs were documented using the restoration reach as breeding habitat annually prior to placement of the boulders, but no breeding was detected in the following three years, suggesting this project eliminated the conditions the frogs require (Ibid.). In addition, a fish ladder to facilitate salmonid migration above the Alameda Creek Diversion Dam was recently constructed on a Foothill Yellow-legged Frog lek site, and the frogs may become trapped in the ladder (M. Grefsrud pers. comm. 2019). Use of rotenone to eradicate non-native fish as part of a habitat restoration project is rare, but if it is applied in streams occupied by Foothill Yellow-legged Frogs, it can kill tadpoles but is unlikely to impact post-metamorphic frogs (Fontenot et al. 1994). Metamorphosing tadpoles may be able to stay close enough to the surface to breathe air and survive but may display lethargy and experience increased susceptibility to predation (Ibid.).

Commonly when riparian vegetation is removed, regulatory agencies require a greater amount to be planted as mitigation to offset the temporal loss of habitat. This practice can have adverse impacts on Foothill Yellow-legged Frogs by reducing habitat suitability. Foothill Yellow-legged Frogs have been observed moving into areas where trees were recently removed, and they are known to avoid heavily shaded areas (Welsh and Hodgson 2011, M. Grefsrud pers. comm. 2019).

Biologists conducting surveys in Foothill Yellow-legged Frog habitat can trample egg masses or larvae if they are not careful. One method for sampling fish is electroshocking, which runs a current through the water that stuns the fish temporarily allowing them to be captured. Post-metamorphic frogs are unlikely to be killed by electroshocking; however, at high frequencies (60 Hz), they may experience some difficulty with muscle coordination for a few days (Allen and Riley 2012). This could increase their risk of predation. At 30 Hz, there were no differences between frogs that were shocked and controls (Ibid.). Tadpoles are more similar to fish in tail muscle and spinal structure and are at higher risk of injuries; however, researchers who reported observing stunned tadpoles noted they appeared to recover completely within several seconds (Ibid.). Adverse effects to Foothill Yellow-legged Frogs from electrofishing may only happen at frequencies higher than those typically used for fish sampling (Ibid.)

Small Population Sizes

Small populations are at greater risk of extirpation, primarily through the disproportionately greater impact of demographic, environmental, and genetic stochasticity on them compared to large populations, so any of the threats previously discussed will likely have an even greater adverse impact on small populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). This risk of extinction from genetic stochasticity is amplified when connectivity between the small populations, and thus gene flow,

is impeded (Fahrig and Merriam 1985, Taylor et al. 1993, Lande and Shannon 1996, Palstra and Ruzzante 2008). Genetic diversity provides capacity to evolve in response to environmental changes, and the "rescue effect" of gene flow is important in minimizing probability of local extinction (Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). However, the rescue effect is diminished in conditions of high local environmental stochasticity of recruitment or survival (Eriksson et al. 2014). In addition, populations living near their physiological limits and lacking adaptive capacity may not be able to evolve in response to rapid changes (Hoffmann and Sgrò 2011). Furthermore, while pathogens or parasites rarely result in host extinction, they can increase its likelihood in small populations by driving the host populations below a critically low threshold beneath which demographic stochasticity can lead to extinction, even if they possess the requisite genetic diversity to adapt to a changed environment (Gomulkiewicz and Holt 1995, Adams et al. 2017b).

A Foothill Yellow-legged Frog PVA revealed that, even with no dam effects considered (e.g., slower growth and increased egg and tadpole mortality), populations with the starting average density of adult females in regulated rivers (4.6/km [2.9/mi]) were four times more likely to go extinct within 30 years than those with the starting average density of adult females from unregulated rivers (32/km [120/mi]) (Kupferberg et al. 2009c). When the density of females in sparse populations was used (2.1/km [1.3/mi], the 30-year risk of extinction increased 13-fold (Ibid.). With dam effects, a number of the risk factors above contribute to the additional probability of local extinction such as living near their lower thermal tolerance and reduced recruitment and survival from scouring and stranding flows, poor food quality, and increased predation and competition (Kupferberg 1997a; Hoffmann and Sgrò 2011; Kupferberg et al. 2011a,b; Kupferberg et al. 2012; Eriksson et al. 2014). These factors act synergistically, contributing in part to the small size, high divergence, and low genetic diversity exhibited by many Foothill Yellow-legged Frog populations located in highly regulated watersheds (Kupferberg et al. 2012, Peek 2018).

EXISTING MANAGEMENT

Land Ownership within the California Range

Using the Department's Foothill Yellow-legged Frog range boundary and the California Protected Areas Database (CPAD), a GIS dataset of lands that are owned in fee title and protected for open space purposes by over 1,000 public agencies or non-profit organizations, the total area of the species' range in California comprises 13,620,447 ha (33,656,857 ac) (CPAD 2019, CWHR 2019). Approximately 37% is owned by federal agencies, 80% of which (4,071,178 ha [10,060,100 ac]) is managed by the Forest Service (Figure 26). Department of Fish and Wildlife-managed lands, State Parks, and other State agency-managed lands constitute around 2.6% of the range. The remainder of the range includes < 1% Tribal lands, 2.3% other conserved lands (e.g., local and regional parks), and 57% private and government-managed lands that are not protected for open space purposes. It is important to note that even if included in the CPAD, a property's management does not necessarily benefit Foothill Yellow-legged Frogs, but in some cases changes in management to conserve the species may be easier to undertake than on private lands or public lands not classified as conserved.

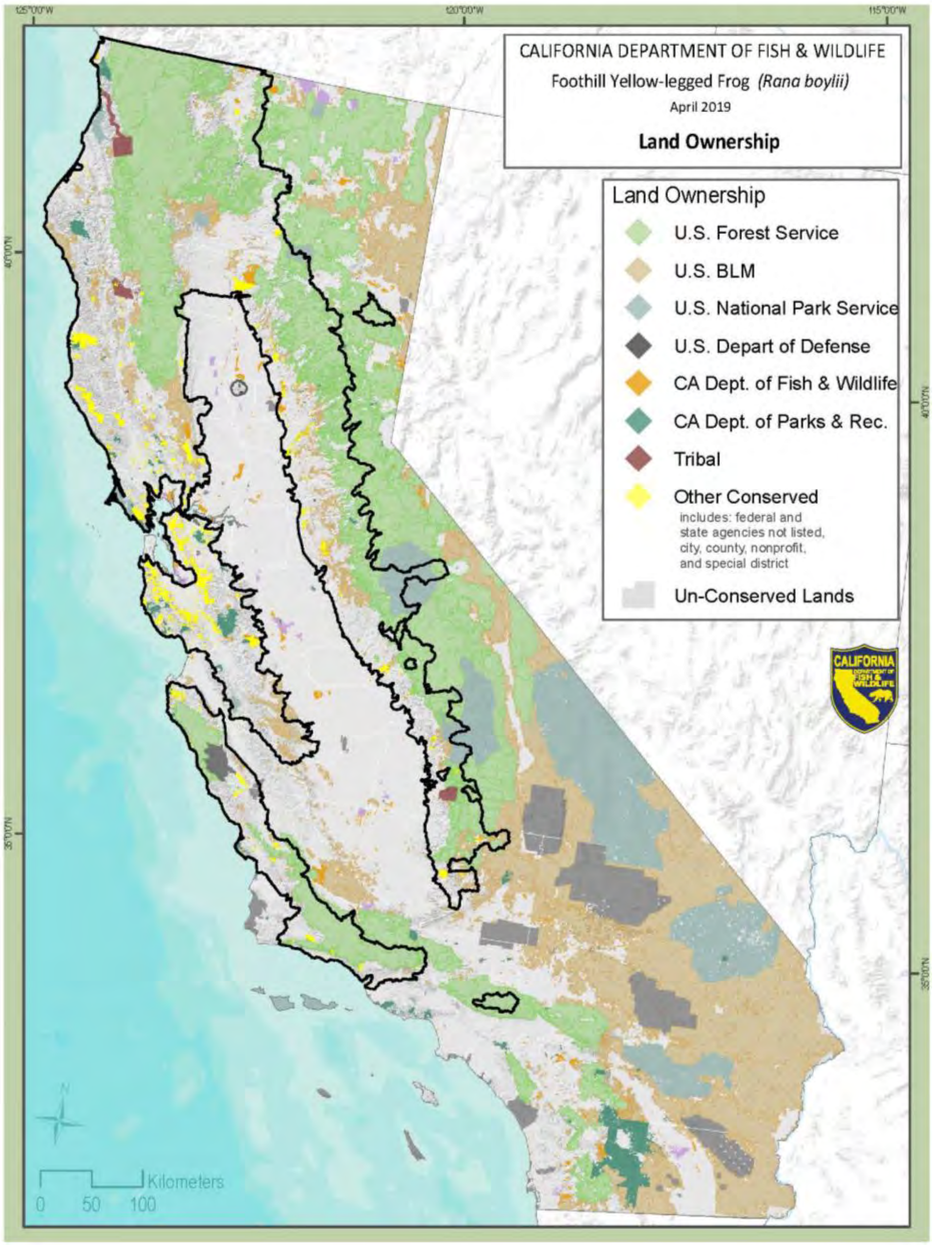

Figure 26. Conserved, Tribal, and other lands (BLM, CMD, CPAD, CWHR, DOD)

Statewide Laws

The laws and regulations governing land management within the Foothill Yellow-legged Frog's range vary by ownership. Several state and federal environmental laws apply to activities undertaken in California that may provide some level of protection for Foothill Yellow-legged Frogs and their habitat. The following is not an exhaustive list.

National Environmental Policy Act and California Environmental Quality Act

Most federal land management actions must undergo National Environmental Policy Act of 1969 (NEPA; 42 U.S.C. § 4321, et seq.) analysis. NEPA requires federal agencies to document, consider alternatives, and disclose to the public the impacts of major federal actions and decisions that may significantly impact the environment. As a BLM and Forest Service Sensitive Species, impacts to Foothill Yellow-legged Legged Frogs are considered during NEPA analysis; however, the law has no requirement to minimize or mitigate adverse effects.

The California Environmental Quality Act (CEQA) is similar to NEPA; it requires state and local agencies to identify, analyze, and consider alternatives, and to publicly disclose environmental impacts from projects over which they have discretionary authority (Pub. Resources Code § 21000 et seq.). CEQA differs substantially from NEPA in requiring mitigation for significant adverse effects to a less than significant level unless overriding considerations are documented. CEQA requires an agency find projects may have a significant effect on the environment if they have the potential to substantially reduce the habitat, decrease the number, or restrict the range of any rare, threatened, or endangered species (Cal. Code Regs., tit. 14, §§ 15065(a)(1), 15380.). CEQA establishes a duty for public agencies to avoid or minimize such significant effects where feasible (Cal. Code regs., tit. 14, § 15021). Impacts to Foothill Yellow-legged Frogs, as an SSC, should be identified, evaluated, disclosed, and mitigated or justified under the Biological Resources section of an environmental document prepared pursuant to CEQA. However, a lead agency is not required to make a mandatory finding of significance conclusion unless it determines on a project-specific basis that the species meets the CEQA criteria for rare, threatened, or endangered.

Clean Water Act and Porter-Cologne Water Quality Control Act

The Clean Water Act originated in 1948 as the Federal Water Pollution Control Act of 1948. It was heavily amended in 1972 and became known as the Clean Water Act (CWA). The purpose of the CWA was to establish regulations for the discharge of pollutants into waters of the United States and establish quality standards for surface waters. Section 404 of the CWA forbids the discharge of dredged or fill material into waters and wetlands without a permit from the ACOE. The CWA also requires an alternatives analysis, and the ACOE is directed to issue their permit for the least environmentally damaging practicable alternative. The definition of waters of the United States has changed substantially over time based on Supreme Court decisions and agency rule changes.

The Porter-Cologne Water Quality Act was established by the State in 1969 and is similar to the CWA in that it establishes water quality standards and regulates discharge of pollutants into state waters, but it

also administers water rights which regulate water diversions and extractions. The SWRCB and nine Regional Water Boards share responsibility for implementation and enforcement of Porter-Cologne as well as the CWA's National Pollutant Discharge Elimination System permitting.

Federal and California Wild and Scenic Rivers Acts

In 1968, the U.S. Congress passed the federal Wild and Scenic Rivers Act (WSRA) (16 U.S.C. § 1271, et seq.) which created the National Wild and Scenic River System. The WSRA requires the federal government to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The WSRA prohibits the federal government from building, licensing, funding or otherwise aiding in the building of dams or other project works on rivers or segments of designated rivers. The WSRA does not give the federal government control of private property including development along protected rivers.

California's Wild and Scenic Rivers Act was enacted in 1972 so rivers that "possess extraordinary scenic, recreational, fishery, or wildlife values shall be preserved in their free-flowing state, together with their immediate environments, for the benefit and enjoyment of the people of the state." (Pub. Res. Code, § 5093.50). Designated waterways are codified in Public Resources Code sections 5093.50-5093.70. In 1981, most of California's designated Wild and Scenic Rivers were adopted into the federal system. Currently in California, 3,218 km (1,999.6 mi) of 23 rivers are protected by the WSRA, most of which are located in the northwest. Foothill Yellow-legged Frogs have been observed in 11 of the 17 designated rivers within their range (CNDDB 2019).

Lake and Streambed Alteration Agreements

Fish and Game Code Section 1602 requires entities to notify the Department of activities that "divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake." If the activity may substantially adversely affect an existing fish and wildlife resource, the Department may enter into a lake or streambed alteration agreement with the entity that includes reasonable measures necessary to protect the fish or wildlife resource (Fish & G. Code, §1602, subd. (a)(4)(B)). A lake or stream alteration agreement does not authorize take of species listed as candidates, threatened, or endangered under CESA (see Protection Afforded by Listing for CESA compliance requirements).

Medicinal and Adult-Use Cannabis Regulation and Safety Act

The commercial cannabis cultivation industry is unique in that any entity applying for an annual cannabis cultivation license from California Department of Food and Agriculture (CDFA) must include "a copy of any final lake or streambed alteration agreement…or written verification from the California Department of Fish and Wildlife that a lake or streambed alteration agreement is not required" with their license application (Cal. Code Regs., tit. 3, § 8102, subd. (v)). The SWRCB also enforces the laws related to waste discharge and water diversions associated with cannabis cultivation (Cal. Code Regs., tit. 3, § 8102, subd. (p)).

Forest Practice Act

The Forest Practice Act was originally enacted in 1973 to ensure that logging in California is undertaken in a manner that will also preserve and protect the State's fish, wildlife, forests, and streams. This law and the regulations adopted by the California Board of Forestry and Fire Protection (BOF) pursuant to it are collectively referred to as the Forest Practice Rules. The Forest Practice Rules implement the provisions of the Forest Practice Act in a manner consistent with other laws, including CEQA, Porter-Cologne, CESA, and the Timberland Productivity Act of 1982. The California Department of Forestry and Fire Protection (CAL FIRE) enforces these laws and regulations governing logging on private land.

Federal Power Act

The Federal Power Act and its major amendments are implemented and enforced by FERC and require licenses for dams operated to generate hydroelectric power. One of the major amendments required that these licenses "shall include conditions for the protection, mitigation and enhancement of fish and wildlife including related spawning grounds and habitat" (ECPA 1986). Hydropower licenses granted by FERC are usually valid for 30-50 years. If a licensee wants to renew their license, it must file a Notice of Intent and a pre-application document five years before the license expires to provide time for public scoping, any potentially new studies necessary to analyze project impacts and alternatives, and preparation of environmental documents. The applicant must officially apply for the new license at least two years before the current license expires.

As a federal agency, FERC must comply with federal environmental laws prior to issuing a new license or relicensing an existing hydropower project, which includes NEPA and ESA. As a result of environmental compliance or settlement agreements formed during the relicensing process, some operations have been modified and habitat restored to protect fish and wildlife. For example, the Lewiston Dam relicensing resulted in establishment of the Trinity River Restoration Program, which takes an ecosystem-approach to studying dam effects and protecting and restoring fish and wildlife populations downstream of the dam (Snover and Adams 2016). Similarly, relicensing of the Rock Creek-Cresta Project on the North Fork Feather River resulted in establishment of a multi-stakeholder Ecological Resources Committee (ERC). As a result of the ERC's studies and recommendations, pulse flows for whitewater boating were suspended for several years following declines of Foothill Yellow-legged Frogs, and the ERC is currently working toward augmenting the population in an attempt to increase abundance to a viable level.

Administrative and Regional Plans

Forest Plans

NORTHWEST FOREST PLAN

In 1994, BLM and the Forest Service adopted the Northwest Forest Plan to guide the management of over 97,000 km^2 (37,500 mi^2) of federal lands in portions of northwestern California, Oregon, and Washington. The Northwest Forest Plan created an extensive network of forest reserves including

Riparian Reserves. Riparian Reserves apply to all land designations to protect riparian dependent resources. With the exception of silvicultural activities consistent with Aquatic Conservation Strategy objectives, timber harvest is not permitted within Riparian Reserves, which can vary in width from 30 to 91 m (100-300 ft) on either side of streams, depending on the classification of the stream or waterbody (USFS and BLM 1994). Fuel treatment and fire suppression strategies and practices implemented within these areas are designed to minimize disturbance.

Sierra Nevada Forest Plan

Land and Resource Management Plans for forests in the Sierra Nevada were changed in 2001 by the Sierra Nevada Forest Plan Amendment and subsequently adjusted via a supplemental Environmental Impact Statement and Record of Decision in 2004, referred to as the Sierra Nevada Framework (USFS 2004). This established an Aquatic Management Strategy with Goals including maintenance and restoration of habitat to support viable populations of riparian-dependent species; spatial and temporal connectivity for aquatic and riparian species within and between watersheds to provide physically, chemically, and biologically unobstructed movement for their survival, migration, and reproduction; instream flows sufficient to sustain desired conditions of riparian, aquatic, wetland, and meadow habitats; the physical structure and condition of streambanks and shorelines to minimize erosion and sustain desired habitat diversity; and prevention of new introductions of invasive species and reduction of invasive species impacts that adversely affect the viability of native species. The Sierra Nevada Framework also includes Riparian Conservation Objectives and associated standards and guidelines specific to aquatic-dependent species, including the Foothill Yellow-legged Frog.

Resource Management Plans

Sequoia, Kings Canyon, and Yosemite National Parks fall within the historical range of the Foothill Yellow-legged Frog, but the species has been extirpated from these areas. The guiding principles for managing biological resources on National Park Service lands include maintenance of animal populations native to park ecosystems (Hayes et al. 2016). They also commit the agency to work with other land managers on regional scientific and planning efforts and maintenance or reintroduction of native species to the parks including conserving Foothill Yellow-legged Frogs in the Sierra Nevada (USDI NPS 1999 as cited in Hayes et al. 2016). A Sequoia and Kings Canyon National Parks Resource Management Plan does not include specific management goals for Foothill Yellow-legged Frogs, but it does include a discussion of the factors leading to the species' decline and measures to restore the integrity of aquatic ecosystems (Ibid.). The Yosemite National Park Resource Management Plan includes a goal of restoring Foothill Yellow-legged Frogs to the Upper Tuolumne River below Hetch Hetchy Reservoir (USDI NPS 2003 as cited in Hayes et al. 2016).

FERC Licenses

Dozens of hydropower dams have been relicensed in California since 1999, and several are in the process of relicensing (FERC 2019). In addition to following the Federal Power Act and other applicable federal laws, Porter-Cologne Water Quality Act requires non-federal dam operators to obtain a Water Quality Certification (WQC) from the SWRCB. Before it can issue the WQC, the SWRCB must consult with

the Department regarding the needs of fish and wildlife. Consequently, SWRCB includes conditions in the WQC that seek to minimize adverse effects to native species, and Foothill Yellow-legged Frogs have received some special considerations due to their sensitivity to dam operations during these licensing processes. As discussed above, the typical outcome is formation of an ERC-type group to implement the environmental compliance requirements and recommend changes to flow management to reduce impacts. Foothill Yellow-legged Frog-specific requirements fall into three general categories: data collection, modified flow regimes, and standard best management practices.

Data Collection

When little is known about the impacts of different flows and temperatures on Foothill Yellow-legged Frog occupancy and breeding success, data are collected and analyzed to inform recommendations for future modifications to operations such as temperature trigger thresholds. These surveys include locating egg masses and tadpoles, monitoring temperatures and flows, and recording their fate (e.g., successful development and metamorphosis, displacement, desiccation) during different flow operations and different water years. Examples of licenses with these conditions include the Lassen Lodge Project (FERC 2018), Rock Creek-Cresta Project (FERC 2009a), and El Dorado Project (EID 2007).

Modified Flow Regimes

When enough data exist to understand the effect of different operations on Foothill Yellow-legged Frog occupancy and success, license conditions may include required minimum seasonal instream flows, specific thermal regimes, gradual ramping rates to reduce the likelihood of early life stage scour or stranding, or freshet releases (winter/spring flooding simulation) to maintain riparian processes, and cancellation or prohibition of recreational pulse flows during the breeding season. Examples of licenses with these conditions include the Poe Hydroelectric Project (SWRCB 2017), Upper American Project (FERC 2014), and Pit 3, 4, 5 Project (FERC 2007b).

Best Management Practices

Efforts to reduce the impacts from maintenance activities and indirect operations include selective herbicide and pesticide application, aquatic invasive species monitoring and control, erosion control, and riparian buffers. Examples of licenses with these conditions include the South Feather Project (SWRCB 2018), Spring Gap-Stanislaus Project (FERC 2009b), and Chili Bar Project (FERC 2007a).

Habitat Conservation Plans and Natural Community Conservation Plans

Non-federal entities can obtain authorization for take of federally threatened and endangered species incidental to otherwise lawful activities through development and implementation of a Habitat Conservation Plan (HCP) pursuant to Section 10 of the ESA. The take authorization can extend to species not currently listed under ESA but which may become listed as threatened or endangered over the term of the HCP, which is often 25-75 years. California's companion law, the Natural Community Conservation Planning Act of 1991, takes a broader approach than either CESA or ESA. A Natural Community Conservation Plan (NCCP) identifies and provides for the protection of plants, animals, and their

habitats, while allowing compatible and appropriate economic activity. There are currently four HCPs that include Foothill Yellow-legged Frogs as a covered species, two of which are also NCCPs.

Humboldt Redwood (formerly Pacific Lumber) Company

The Humboldt Redwood Company (HRC) HCP covers 85,672 ha (211,700 ac) of private Coast Redwood and Douglas-fir forest in Humboldt County (HRC 2015). It is a 50-year HCP/incidental take permit (ITP) that was executed in 1999, revised in 2015 as part of its adaptive management strategy, and expires on March 1, 2049. The HCP includes an Amphibian and Reptile Conservation Plan and an Aquatics Conservation Plan with measures designed to sustain viable populations of Foothill Yellow-legged Frogs and other covered aquatic herpetofauna. These conservation measures include prohibiting or limiting tree harvest within Riparian Management Zones (RMZ), controlling sediment by maintaining roads and hillsides, restricting controlled burns to spring and fall in areas outside of the RMZ, conducting effectiveness monitoring throughout the life of the HCP, and use the data collected to adapt monitoring and management plans accordingly.

Watershed assessment surveys include observations of Foothill Yellow-legged Frogs and have documented their widespread distribution on HRC lands with a pattern of fewer near the coast in the fog belt and more inland (S. Chinnici pers. comm. 2017). The watersheds within the property are largely unaffected by dam-altered flow regimes or non-native species, so aside from the operations described under Timber Harvest above that are minimized to the extent feasible, the focus on suitable temperatures and denser canopy cover for salmonids may reduce habitat suitability for Foothill Yellow-legged Frogs over time (Ibid.).

San Joaquin County Multi-Species Habitat Conservation and Open Space Plan

The San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) is a 50-year HCP/ITP that was signed by the USFWS on November 14, 2000 (San Joaquin County 2000). The SJMSCP covers almost all of San Joaquin County except federal lands, a few select projects, and some properties with certain land uses, roughly 364,000 ha (900,000 ac). At the time of execution, approximately 70 ha (172 ac) of habitat within the SJMSCP area in the southwest portion of the county were considered occupied by Foothill Yellow-legged Frogs with another 1,815 ha (4,484 ac) classified as potential habitat, but it appears the species had been considered extirpated before then (Jennings and Hayes 1994, San Joaquin County 2000, Lind 2005). The HCP estimates around 8% of the combined modeled habitat would be converted to other uses over the permit term, but the establishment of riparian preserves with buffers around Corral Hollow Creek, where the species occurred historically, was expected to offset those impacts (San Joaquin County 2000, SJCOG 2018). However, the HCP did not require surveys to determine if Foothill Yellow-legged Frogs are benefiting (M. Grefsrud pers. comm. 2019).

East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan

The East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan (ECCC HCP/NCCP) is a multi-jurisdictional 30-year plan adopted in 2007 that covers over 70,423 ha (174,018 ac) in eastern Contra Costa County (Jones & Stokes 2006). The Foothill Yellow-legged Frog appears to be

extirpated from the ECCC HCP/NCCP area (CNDDB 2019). Nevertheless, suitable habitat was mapped, and impacts were estimated at well under 1% of both breeding and migratory habitat (Jones & Stokes 2006). One of the HCP/NCCP's objectives is acquiring high-quality Foothill Yellow-legged Frog habitat that has been identified along Marsh Creek (Ibid.). In 2017, the Viera North Peak 65 ha (160 ac) property was acquired that possesses suitable habitat for Foothill Yellow-legged Frogs (ECCCHC 2018).

Santa Clara Valley Habitat Plan

The Santa Clara Valley Habitat Plan (SCVHP) is a 50-year HCP/NCCP covering over 210,237 ha (519,506 ac) in Santa Clara County (ICF 2012). As previously mentioned, Foothill Yellow-legged Frogs appear to have been extirpated from lower elevation sites, particularly below reservoirs in this area. Approximately 17% of modeled Foothill Yellow-legged Frog habitat, measured linearly along streams, was already permanently preserved, and the SCVHP seeks to increase that to 32%. The maximum allowable habitat loss is 11 km (7 mi) permanent loss and 3 km (2 mi) temporary loss, while 167 km (104 mi) of modeled habitat is slated for protection. By mid-2018, 8% of impact area had been accrued and 3% of habitat protected (SCVHA 2019).

Green Diamond Aquatic Habitat Conservation Plan

Green Diamond Resources Company has an Aquatic Habitat Conservation Plan (AHCP) covering 161,875 ha (400,000 ac) of their land that is focused on cold-water adapted species, but many of the conservation measures are expected to benefit Foothill Yellow-legged Frogs as well (K. Hamm pers. comm. 2017). Examples include slope stability and road management measures to reduce stream sedimentation from erosion and landslides, and limiting water drafting during low flow periods with screens over the pumps to avoid entraining animals (Ibid.). Although creating more open canopy areas and warmer water temperatures is not the goal of the AHCP, the areas that are suitable for Foothill Yellow-legged Frog breeding are likely to remain that way because they are wide channels that receive sufficient sunlight (Ibid.).

SUMMARY OF LISTING FACTORS

CESA's implementing regulations identify key factors relevant to the Department's analyses and the Fish and Game Commission's decision on whether to list a species as threatened or endangered. A species will be listed as endangered or threatened if the Commission determines that the species' continued existence is in serious danger or is threatened by any one or any combination of the following factors: (1) present or threatened modification or destruction of its habitat; (2) overexploitation; (3) predation; (4) competition; (5) disease; or (6) other natural occurrences or human-related activities (Cal. Code Regs., tit. 14, § 670.1, subd. (i).

This section provides summaries of information from the foregoing sections of this status review, arranged under each of the factors to be considered by the Commission in determining whether listing is warranted.

Present or Threatened Modification or Destruction of Habitat

Most of the factors affecting ability to survive and reproduce listed above involve destruction or degradation of Foothill Yellow-legged Frog habitat. The most widespread, and potentially most significant, threats are associated with dams and their flow regimes, particularly in areas where they are concentrated and occur in a series along a river. Dams and the way they are operated can have up- and downstream impacts to Foothill Yellow-legged Frogs. They can result in confusing natural breeding cues, scouring and stranding of egg masses and tadpoles, reducing quality and quantity of breeding and rearing habitat, reducing tadpole growth rate, impeding gene flow among populations, and establishing and spreading non-native species (Hayes et al. 2016). These impacts appear to be most severe when the dam is operated for the generation of hydropower utilizing hydropeaking and pulse flows (Kupferberg et al. 2009c, Peek 2018). Foothill Yellow-legged Frog abundance below dams is an average of five times lower than in unregulated rivers (Kupferberg et al. 2012). The number, height, and distance upstream of dams in a watershed influenced whether Foothill Yellow-legged Frogs still occurred at sites where they had been present in 1975 in California (Ibid.). Water diversions for agricultural, industrial, and municipal uses also reduce the availability and quality of Foothill Yellow-legged Frog habitat. Dams are concentrated in the Bay Area, Sierra Nevada, and southern California (Figure 17), while hydropower plants are densest in the northern and central Sierra Nevada (Figure 18).

With predicted increases in the human population, ambitious renewable energy targets, higher temperatures, and more extreme and variable precipitation falling increasingly more as rain rather than snow, the need for more and taller dams and water diversions for hydroelectric power generation, flood control, and water storage and delivery is not expected to abate in the future. California voters approved Proposition 1, the Water Quality, Supply and Infrastructure Improvement Act of 2014, which dedicated $2.7 billion to water storage projects (PPIC 2018). In 2018, the California Water Commission approved funding for four new dams in California: expansion of Pacheco Reservoir (Santa Clara County), expansion of Los Vaqueros Reservoir (Contra Costa County), Temperance Flat Dam (new construction) on the San Joaquin River (Fresno County), and the off-stream Sites Reservoir (new construction) diverting the Sacramento River (Colusa County) (CWC 2019). No historical records of Foothill Yellow-legged Frogs from the Los Vaqueros or Sites Reservoir areas exist in the CNDDB, and one historical (1950) collection is documented from the Pacheco Reservoir area (CNDDB 2019). However, the proposed Temperance Flat Dam site is downstream of one of the only known extant populations of Foothill Yellow-legged Frogs in the East/Southern Sierra clade (Ibid.).

The other widespread threat to Foothill Yellow-legged Frog habitat is climate change, although the severity of its impacts is somewhat uncertain. While drought, wildland fires, floods, and landslides are natural and ostensibly necessary disturbance events for preservation of native biodiversity, climate change is expected to result in increased frequency and severity of these events in ways that may exceed species' abilities to adapt (Williams et al. 2008, Hoffmann and Sgrò 2011, Keely and Syphard 2016). These changes can lead to increased competition, predation, and disease transmission as species become concentrated in areas that remain wet into the late summer (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Loss of riparian vegetation from wildland fires can result in increased stream temperatures or concentrations of nutrients and trace heavy metals that inhibit growth and survival

(Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Stream sedimentation from landslides following fire or excessive precipitation can destroy or degrade breeding and rearing habitat (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). At least some models predict unprecedented dryness in the latter half of the century (Cook et al. 2015). The effects of climate change will be realized across the Foothill Yellow-legged Frog's range, and their severity will likely differ in ways that are difficult to predict. However, the impacts from extended droughts will likely be greatest in the areas that are naturally more arid, the lower elevations and latitudes of southern California and the foothills surrounding the Central Valley (Figure 21).

While most future urbanization is predicted to occur in areas outside of the Foothill Yellow-legged Frog's range, it has already contributed to the loss and fragmentation of Foothill Yellow-legged Frog habitat in California. In addition, the increased predation, wildland fires, introduced species, road mortality, disease transmission, air and water pollution, and disturbance from recreation that can accompany urbanization expand its impact far beyond its physical footprint (Davidson et al. 2002, Syphard et al. 2007, Cook et al. 2012, Bar-Massada et al. 2014). Within the Foothill Yellow-legged Frog's historical range, these effects appear most significant and extensive in terms of population extirpations in southern California and the San Francisco Bay Area.

Several other activities have the potential to destroy or degrade Foothill Yellow-legged Frog habitat, but they are less common across the range. They also tend to have relatively small areas of impact, although they can be significant in those areas, particularly if populations are already small and declining. These include impacts from mining, cannabis cultivation, vineyard expansion, overgrazing, timber harvest, recreation, and some stream habitat restoration projects (Harvey and Lisle 1998, Belsky et al. 1999, Merelender 2000, Pilliod et al. 2003, Bauer et al. 2015, Kupferberg and Furey 2015).

Overexploitation

Foothill Yellow-legged Frogs are not threatened by overexploitation. There is no known pet trade for Foothill Yellow-legged Frogs (Lind 2005). During the massive frog harvest that accompanied the Gold Rush, some Foothill Yellow-legged Frogs were collected, but because they are relatively small and have irritating skin secretions, there was much less of a market for them (Jennings and Hayes 1985). Within these secretions is a peptide with antimicrobial activity that is particularly potent against *Candida albicans*, a human pathogen that has been developing resistance to traditional antifungal agents (Conlon et al. 2003). However, the peptide's therapeutic potential is limited by its strong hemolytic activity, so further studies will focus on synthesizing analogs that can be used as antifungals, and collection of Foothill Yellow-legged Frogs for lab cultures is unlikely (Ibid.).

Like all native California amphibians, collection of Foothill Yellow-legged Frogs is unlawful without a permit from the Department. They may only be collected for scientific, educational, or propagation reasons through a Scientific Collecting Permit (Fish & G. Code § 1002 et seq.). The Department has the discretion to limit or condition the number of individuals collected or handled to ensure no significant adverse effects. Incidental harm from authorized activities on other aquatic species can be avoided or minimized by the inclusion of special terms and conditions in permits.

Predation

Predation is a likely contributor to Foothill Yellow-legged Frog population declines where the habitat is degraded by one or many other risk factors (Hayes and Jennings 1986). Predation by native gartersnakes can be locally substantial; however, it may only have an appreciable population-level impact if the availability of escape refugia is diminished. For example, when streams dry and only pools remain, Foothill Yellow-legged Frogs are more vulnerable to predation by native and non-native species because they are concentrated in a small area with little cover.

Several studies have demonstrated the synergistic impacts of predators and other stressors. Foothill Yellow-legged Frogs, primarily as demonstrated through studies on tadpoles, are more susceptible to predation when exposed to some agrochemicals, cold water, high velocities, excess sedimentation, and even the presence of other species of predators (Harvey and Lisle 1998, Adams et al. 2003, Olson and Davis 2009, Kupferberg et al. 2011b, Kerby and Sih 2015, Catenazzi and Kupferberg 2018). Foothill Yellow-legged Frog tadpoles appear to be naïve to chemical cues from some non-native predators; they have not evolved those species-specific predator avoidance behaviors (Paoletti et al. 2011). Furthermore, early life stages are often more sensitive to environmental stressors, making them more vulnerable to predation, and Foothill Yellow-legged Frog population dynamics are highly sensitive to egg and tadpole mortality (Kats and Ferrer, 2003, Kupferberg et al. 2009c). Predation pressure is likely positively associated with proximity to anthropogenic changes in the environment, so in more remote or pristine places, it probably does not have a serious population-level impact.

Competition

Intra- and interspecific competition in Foothill Yellow-legged Frogs has been documented. Intraspecific male-to-male competition for females has been reported (Rombough and Hayes 2007). Observations include physical aggression and a non-random mating pattern in which larger males were more often engaged in breeding (Rombough and Hayes 2007, Wheeler and Welsh 2008). A behavior resembling clutch-piracy, where a satellite male attempts to fertilize already laid eggs, has also been documented (Rombough and Hayes 2007). These acts of competition play a role in population genetics, but they likely do not result in serious physical injury or mortality. Intraspecific competition among Foothill Yellow-legged Frog tadpoles was negligible (Kupferberg 1997a).

Interspecific competition appears to have a greater possibility of resulting in adverse impacts. Kupferberg (1997a) did not observe a significant change in tadpole mortality for Foothill Yellow-legged Frogs raised with Pacific Treefrogs compared to single-species controls. However, when reared together, Foothill Yellow-legged Frog tadpoles lost mass, while Pacific Treefrog tadpoles increased mass (Kerby and Sih 2015). As described previously under Introduced Species, Foothill Yellow-legged Frog tadpoles experienced significantly higher mortality and smaller size at metamorphosis when raised with bullfrog tadpoles (Kupferberg 1997a). The mechanism of these declines appeared to be exploitative competition, as opposed to interference, through the reduction of available algal resources from bullfrog tadpole grazing in the shared enclosures (Ibid.).

The degree to which competition threatens Foothill Yellow-legged Frogs likely depends on the number and density of non-native species in the area rather than intraspecific competition, and co-occurrence of Foothill Yellow-legged Frog and bullfrog tadpoles may be somewhat rare since the latter tends to breed in lentic (still water) environments (M. van Hattem pers. comm. 2019). Interspecific competition with other native species may have some minor adverse consequences on fitness.

Disease

Currently, the only disease known to pose a serious risk to Foothill Yellow-legged Frogs is Bd. Until 2017, the only published studies on the impact of Bd on Foothill Yellow-legged Frog suggested it could reduce growth and body condition but was not lethal (Davidson et al. 2007, Lowe 2009, Adams et al. 2017b). However, two recent mass mortality events caused by chytridiomycosis proved they are susceptible to lethal effects, at least under certain conditions like drought-related concentration and presence of bullfrogs (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Some evidence indicates disease may have played a principal role in the disappearance of the species from southern California (Adams et al. 2017b). Bd is likely present in the environmental throughout the Foothill Yellow-legged Frog's range, and with bullfrogs and treefrogs acting as carriers, it will remain a threat to the species; however, given the dynamics of the two recent die-offs in the San Francisco Bay area, the probability of future outbreaks may be greater in areas where the species is under additional stressors like drought and introduced species (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Therefore, as with predation, Foothill Yellow-legged Frogs are less likely to experience the adverse impacts of diseases in more remote areas with fewer anthropogenic changes to the environment.

Other Natural Events or Human-Related Activities

Agrochemicals, particularly organophosphates that act as endocrine disruptors, can travel substantial distances from the area of application through atmospheric drift and have been implicated in the disappearance and declines of many species of amphibians in California including Foothill Yellow-legged Frogs (LeNoir et al. 1999, Davidson 2004, Lind 2005, Olson and Davis 2009). Foothill Yellow-legged Frogs appear to be significantly more sensitive to the adverse impacts of some pesticides than other native species (Sparling and Fellers 2009, Kerby and Sih 2015). These include smaller body size, slower development rate, increased time to metamorphosis, immunosuppression, and greater vulnerability to predation and malformations (Kiesecker 2002, Hayes et al. 2006, Sparling and Fellers 2009, Kerby and Sih 2015). Some of the most dramatic declines experienced by ranids in California occurred in the Sierra Nevada east of the San Joaquin Valley where over half of the state's total pesticide usage occurs (Sparling et al. 2001).

Many Foothill Yellow-legged Frog populations are small, isolated from other populations, and possess low genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). Genetic diversity is important in providing a population the capacity to evolve in response to environmental changes, and connectivity among populations is important for gene exchange and in minimizing probability of local extinction (Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). Small populations are at much greater risk of extirpation primarily through the disproportionate impact of demographic, environmental, and genetic stochasticity than robust populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). Based on a Foothill Yellow-legged Frog PVA, populations in regulated rivers face a 4- to 13-fold greater extinction risk in 30 years than populations in unregulated rivers due to smaller population sizes (Kupferberg et al. 2009c). The threat posed by small population sizes is significant and the general pattern shows increases in severity from north to south; however, many sites, primarily in the northern Sierra Nevada, in watersheds with large hydropower projects are also at high risk.

PROTECTION AFFORDED BY LISTING

It is the policy of the State to conserve, protect, restore and enhance any endangered or threatened species and its habitat (Fish & G. Code, § 2052). The conservation, protection, and enhancement of listed species and their habitat is of statewide concern (Fish & G. Code, § 2051(c)). CESA defines "take" as hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill (Fish & G. Code, § 86). The Fish and Game Code provides the Department with related authority to authorize "take" of species listed as threatened or endangered under certain circumstances (see, e.g., Fish & G. Code, §§ 2081, 2081.1, 2086, & 2835).

If the Foothill Yellow-legged Frog is listed under CESA, impacts of take caused by activities authorized through incidental take permits must be minimized and fully mitigated according to state standards (Fish & G. Code, § 2081, subd. (b)). These standards typically include protection of land in perpetuity with an easement, development and implementation of a species-specific adaptive management plan, and funding through an endowment to pay for long-term monitoring and maintenance to ensure the mitigation land meets performance criteria. Obtaining an incidental take permit is voluntary. The Department cannot force compliance; however, any person violating the take prohibition may be criminally and civilly liable under state law.

Additional protection of Foothill Yellow-legged Frogs following listing would be expected to occur through state and local agency environmental review under CEQA. CEQA requires affected public agencies to analyze and disclose project-related environmental effects, including potentially significant impacts on rare, threatened, and endangered species. In common practice, potential impacts to listed species are examined more closely in CEQA documents than potential impacts to unlisted species. Where significant impacts are identified under CEQA, the Department expects project-specific avoidance, minimization, and mitigation measures to benefit the species. State listing, in this respect, and consultation with the Department during state and local agency environmental review under CEQA, would be expected to benefit the Foothill Yellow-legged Frog in terms of reducing impacts from individual projects, which might otherwise occur absent listing.

For some species, CESA listing may prompt increased interagency coordination and the likelihood that state and federal land and resource management agencies will allocate funds toward protection and recovery actions. In the case of the Foothill Yellow-legged Frog, some multi-agency efforts exist, often associated with FERC license requirements, to improve habitat conditions and augment declining populations. The USFWS is leading an effort to develop regional Foothill Yellow-legged Frog conservation strategies, and CESA listing may result in increased priority for limited conservation funds.

LISTING RECOMMENDATION

CESA directs the Department to prepare this report regarding the status of the Foothill Yellow-legged Frog in California based upon the best scientific information available (Fish & G. Code, § 2074.6). CESA also directs the Department based on its analysis to indicate in the status report whether the petitioned action (i.e., listing as threatened) is warranted (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

Under CESA, an endangered species is defined as "a native species or subspecies…which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish & G. Code, § 2062). A threatened species is defined as "a native species or subspecies…that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]" (Fish and G. Code, § 2067).

The Department includes and makes its recommendation in its status report as submitted to the Commission in an advisory capacity based on the best available science. In consideration of the scientific information contained herein, the Department has determined that listing the Foothill Yellow-legged Frog under CESA by genetic clade is the prudent approach due to the disparate degrees of imperilment among them. In areas of uncertainty, the Department recommends the higher protection status until clade boundaries can be better defined.

NORTHWEST/NORTH COAST: Not warranted at this time.

Clade-level Summary: This is the largest clade with the most robust populations (highest densities) and the greatest genetic diversity. This area is the least densely populated by humans; contains relatively few hydroelectric dams, particularly further north; and has the highest precipitation in the species' California range. The species is still known to occur in most, if not all, historically occupied watersheds; presumed extirpations are mainly concentrated in the southern portion of the clade around the heavily urbanized San Francisco Bay area. The proliferation of cannabis cultivation, particularly illicit grows in and around the Emerald Triangle, the apparent increase in severe wildland fires in the area, and potential climate change effects are cause for concern, so the species should remain a Priority 1 SSC here with continued monitoring for any change in its status.

WEST/CENTRAL COAST: Endangered.

Clade-level Summary: Foothill Yellow-legged Frogs appear to be extirpated from a relatively large proportion of historically occupied sites within this clade, particularly in the heavily urbanized northern portion around the San Francisco Bay. In the northern portion of the clade, nearly all the remaining populations (which may be fewer than a dozen) are located above dams, which line the mountains surrounding the Bay Area, and two are known to have undergone recent disease-associated die-offs. These higher elevation sites are more often intermittent or ephemeral streams than the lower in the watersheds. As a result, the more frequent and extreme droughts that have dried up large areas seem to have contributed to recent declines. Illegal cannabis cultivation, historical mining effects, overgrazing, and recreation likely contributed to declines and may continue to threaten remaining populations.

SOUTHWEST/SOUTH COAST: Endangered.

Clade-level Summary: The most extensive extirpations have occurred in this clade, and only two known extant populations remain. Both are small with apparently low genetic diversity, making them especially vulnerable to extirpation. This is also an area with a large human population, many dams, and naturally arid, fire-prone environments, particularly in the southern portion of the clade. Introduced species are widespread, and cannabis cultivation is rivaling the Emerald Triangle in some areas (e.g., Santa Barbara County). Introduced species, expanded recreation, disease, and flooding appear to have contributed to the widespread extirpations in southern California over 40 years ago.

FEATHER RIVER: Threatened.

Clade-level Summary: This is the smallest clade and has a high density of hydroelectric dams. It also recently experienced one of the largest, most catastrophic wildfires in California history. Despite these threats, Foothill Yellow-legged Frogs appear to continue to be relatively broadly distributed within the clade, although with all the dams in the area, most populations are likely disconnected. The area is more mesic and experienced less of a change in precipitation in the most recent drought than the clades south of it. The clade is remarkable genetically and morphologically as it is the only area where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs overlap and can hybridize. The genetic variation within the clade is greater than the other clades except for the Northwest/North Coast. Most of the area within the clade's boundaries is Forest Service-managed, and little urbanization pressure or known extirpations exist in this area. Recent FERC licenses in this area require Foothill Yellow-legged Frog specific conservation, which to date has included cancelling pulse flows, removing encroaching vegetation, and translocating egg masses and in situ head-starting to augment a population that had recently declined.

NORTHEAST/NORTHERN SIERRA: Threatened.

Clade-level Summary: The Northeast/Northern Sierra clade shares many of the same threats as the Feather River clade (e.g., relatively small area with many hydroelectric dams). The area is also more mesic and experienced less of a change in precipitation during the recent drought than more southern clades. However, this pattern may not continue as some models suggest loss of snowmelt will be greater in the northern Sierra Nevada, and one of the climate change exposure models suggests a comparatively large proportion of the lower elevations will experience climatic conditions not currently known from the area (i.e., non-analog) by the end of the century. Recent surveys suggest the area continues to support several populations of the species, some of which seem to remain robust, with a fairly widespread distribution. However, genetic analyses from several watersheds suggest many of these populations are isolated and diverging, particularly in regulated reaches with hydropeaking flows.

EAST/SOUTHERN SIERRA: Endangered.

Clade-level Summary: Like the Southwest/South Coast clade, widespread extirpations in this area were observed as early as the 1970s. Dams and introduced species were credited as causal factors in these declines in distribution and abundance, and mining and disease may also have contributed. This area is relatively arid, and drought effects appear greater here than in northern areas that exhibit both more precipitation and a smaller difference between drought years and the historical average. There is a relatively high number of hydroelectric power generating dams in series along the major rivers in this clade and at least one new proposed dam near one of the remaining populations. This area is also the most heavily impacted by agrochemicals from the San Joaquin Valley.

MANAGEMENT RECOMMENDATIONS

The Department has evaluated existing management recommendations and available literature applicable to the management and conservation of the Foothill Yellow-legged Frog to arrive at the following recommendations. These recommendations, which represent the best available scientific information, are largely derived the from the Foothill Yellow-legged Frog Conservation Assessment, the California Energy Commission's Public Interest Energy Research Reports, the Recovery Plans of West Coast Salmon and Steelhead, and the California Amphibian and Reptile Species of Special Concern (Kupferberg et al. 2009b,c; 2011a; NMFS 2012, 2013, 2014, 2016; Hayes et al. 2016, Thomson et al. 2016).

Conservation Strategies

Maintain current distribution and genetic diversity by protecting existing Foothill Yellow-legged Frog populations and their habitats and providing opportunities for genetic exchange. Increase abundance to viable levels in populations at risk of extirpation due to small sizes, when appropriate, through in situ or ex situ captive rearing and/or translocations. Use habitat suitability and hydrodynamic habitat models to identify historically occupied sites that may currently support Foothill Yellow-legged Frogs, or they could with minor habitat improvements or modified management. Re-establish extirpated populations in suitable habitat through captive propagation, rearing, and/or translocations. Prioritize areas in the southern portions of the species' range where extirpations and loss of diversity have been the most severe.

If establishing reserves, prioritize areas containing high genetic variation in Foothill Yellow-legged Frogs (and among various native species) and climatic gradients where selection varies over small geographical area because environmental heterogeneity can provide a means of maintaining phenotypic variability which increases the adaptive capacity of populations as conditions change. These reserves should provide connectivity to other occupied areas to facilitate gene flow and allow for ongoing selection to fire, drought, thermal stresses, and changing species interactions.

Research and Monitoring

Attempt to rediscover potentially remnant populations in areas where they are considered extirpated, prioritizing the southern portions of the species' range. Collect environmental DNA in addition to conducting visual encounter surveys to improve detectability. Concurrently assess presence of threats and habitat suitability to determine if future reintroductions may be possible. Collect genetic samples from any Foothill Yellow-legged Frogs captured for use in landscape genomics analyses and possible future translocation or captive propagation efforts. Attempt to better clarify clade boundaries where there is uncertainty. Study whether small populations are at risk of inbreeding depression, whether genetic rescue should be attempted, and if so, whether that results in hybrid vigor or outbreeding depression.

Continue to evaluate how water operations affect Foothill Yellow-legged Frog population demographics. Establish more long-term monitoring programs in regulated and unregulated (reference) rivers across the species' range but particularly in areas like the Sierra Nevada where most large hydropower dams in the species' range are concentrated. Assess whether the timing of pulse flows influences population dynamics, particularly whether early releases have a disproportionately large adverse effect by eliminating the reproductive success of the largest, most fecund females, who appear to breed earlier in the season. Investigate survival rates in poorly-understood life stages, such as tadpoles, young of the year, and juveniles. Determine the extent to which pulse flows contribute to displacement and mortality of post-metamorphic life stages.

Collect habitat variables that correlate with healthy populations to develop more site-specific habitat suitability and hydrodynamic models. Study the potential synergistic effect of increased flow velocity and decreased temperature on tadpole fitness. Examine the relationship between changes in flow, breeding and rearing habitat connectivity, and scouring and stranding to develop site-specific benign ramping rates. Incorporate these data and demographic data into future PVAs for use in establishing frog-friendly flow regimes in future FERC relicensing or license amendment efforts and habitat restoration projects. Ensure long-term funding for post-license or restoration monitoring to evaluate attainment of expected results and for use in adapting management strategies accordingly.

Evaluate the distribution of other threats such as cannabis cultivation, vineyard expansion, livestock grazing, mining, timber harvest, and urbanization and roads in the Foothill Yellow-legged Frog's range. Study the short- and long-term effects of wildland fires and fire management strategies. Assess the extent to which these potential threats pose a risk to Foothill Yellow-legged Frog persistence in both regulated and unregulated systems.

Investigate how reach-level or short-distance habitat suitability and hydrodynamic models can be extrapolated to a watershed level. Study habitat connectivity needs such as the proximity of breeding sites and other suitable habitats along a waterway necessary to maintain gene flow and functioning meta-population dynamics.

Habitat Restoration and Watershed Management

Remove or update physical barriers like dams and poorly constructed culverts and bridges to improve connectivity and natural stream processes. Remove anthropogenic features that support introduced predators and competitors such as abandoned mine tailing ponds that support bullfrog breeding. Conduct active eradication and management efforts to decrease the abundance of bullfrogs, non-native fish, and crayfish (where they are non-native). In managed rivers, manipulate stream flows to negatively affect non-native species not adapted to a winter flood/summer drought flow regime.

Adopt a multi-species approach to channel restoration projects and managed flow regimes (thermal, velocity, timing) and mimic the natural hydrograph to the greatest extent possible. When this is impractical or infeasible, focus on minimizing adverse impacts by gradually ramping discharge up and down, creating and maintaining gently sloping and sun-lit gravel bars and warm calm edgewater habitats for tadpole rearing, and mixing hypolimnetic water (from the lower colder stratum in a reservoir) with warmer surface water before release if necessary to ensure appropriate thermal conditions for successful metamorphosis. Promote restoration and maintenance of habitat heterogeneity (different depths, velocities, substrates, etc.) and connectivity to support all life stages and gene flow. Avoid damaging Foothill Yellow-legged Frog breeding habitat when restoring habitat for other focal species like anadromous salmonids.

Regulatory Considerations and Best Management Practices

Develop range-wide minimum summer baseflow requirements that protect Foothill Yellow-legged Frogs and their habitat with appropriate provisions to address regional differences using new more ecologically-meaningful approaches such as modified percent-of-flow strategies for watersheds (e.g., Mierau et al. 2018). Limit water diversions during the dry season and construction of new dams by focusing on off-stream water storage strategies.

Ensure and improve protection of riparian systems. Require maintenance of appropriate riparian buffers and canopy coverage (i.e., partly shaded) around occupied habitat or habitat that has been identified for potential future reintroductions. Restrict instream work to dry periods where possible. Prohibit fording in and around breeding habitat. Avoid working near streams after the first major rains in the fall when Foothill Yellow-legged Frogs may be moving upslope toward tributaries and overwintering sites. Use a 3 mm (0.125 in) mesh screen on water diversion pumps and limit the rate and amount of water diverted such that depth and flow remain sufficient to support Foothill Yellow-legged Frogs of all life stages occupying the immediate area and downstream. Install exclusion fencing where appropriate, and if Foothill Yellow-legged Frog relocation is required, conduct it early in the season because moving egg masses is easier than moving tadpoles.

Reduce habitat degradation from sedimentation, pesticides, herbicides, and other non-point source waste discharges from adjacent land uses including along tributaries of rivers and streams. Limit mining to parts of rivers not used for oviposition, such as deeper pools or reaches with few tributaries, and at times of year when frogs are more common in tributaries (i.e., fall and winter). Manage recreational activities in or adjacent to Foothill Yellow-legged Frog habitat (e.g., OHV and hiking trails, camp sites, boating ingress/egress, flows, and speeds) in a way that minimizes adverse impacts. Siting cannabis grows in areas with better access to roads, gentler slopes, and ample water resources could significantly reduce threats to the environment. Determine which, when, and where agrochemicals should be restricted to reduce harm to Foothill Yellow-legged Frogs and other species. Ensure all new road crossings and upgrades to existing crossings (bridges, culverts, fills, and other crossings) accommodate at least 100-year flood flows and associated bedload and debris.

Partnerships and Coordination

Establish collaborative partnerships with agencies, universities, and non-governmental organizations working on salmon and steelhead recovery and stream restoration. Anadromous salmonids share many of the same threats as Foothill Yellow-legged Frogs, and recovery actions such as barrier removal, restoration of natural sediment transport processes, reduction in pollution, and eradication of non-native predators would benefit frogs as well. Ensure Integrated Regional Water Management Plans and fisheries restoration programs take Foothill Yellow-legged Frog conservation into consideration during design, implementation, and maintenance.

Encourage local governments to place conditions on new developments to minimize negative impacts on riparian systems. Promote and implement initiatives and programs that improve water conservation use efficiency, reduce greenhouse gas emissions, promote sustainable agriculture and smart urban growth, and protect and restore riparian ecosystems. Shift reliance from on-stream storage to off-stream storage, resolve frost protection issues (water withdrawals), and ensure necessary flows for all life stages in all water years.

Establish a Department-coordinated staff and citizen scientist program to systematically monitor occupied stream reaches across the species' range.

Education and Enforcement

Support programs to provide educational outreach and local involvement in restoration and watershed stewardship, such as Project Wild, Adopt a Watershed, school district environmental camps, and other programs teaching the effects of human land and water use on Foothill Yellow-legged Frog survival.

Provide additional funding for increased law enforcement to reduce ecologically harmful stream alterations and water pollution and to ensure adequate protection for Foothill Yellow-legged Frogs at pumps and diversions. Identify and address illegal water diverters and out-of-compliance diverters, seasons of diversion, off-stream reservoirs, well pumping, and bypass flows to protect Foothill Yellow-legged Frogs. Prosecute violators accordingly.

ECONOMIC CONSIDERATIONS

The Department is charged in an advisory capacity in the present context to provide a written report and a related recommendation to the Commission based on the best scientific information available regarding the status of Foothill Yellow-legged Frog in California. The Department is not required to prepare an analysis of economic impacts (See Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

Subject: Re: Peer Review Request: Foothill Yellow-legged Frog Status Review
Attachments: DRAFT FYLF Status Review-2019.05.21.docx; Untitled attachment 00038.html

Hi Laura,

I've attached the Draft report with my comments incorporated directly in the document via Track Changes. I'm extremely impressed by the depth and detail provided in your report! Although I didn't have much in the way of suggested changes to the document, I gave it a careful read and learned a lot myself. I noted a few typos and and suggested a few updates to the ranid taxonomy section, but you and the various folks that were cited extensively in the report (especially Sarah Kupferberg and Amy Lind) obviously know a ton about these animals (far more than I do)..

I agree whole-heartedly with your assessment of the listing needs for the genetic clades. My question for you now - having never reviewed one of these reports and being naive to the process - is what sort of review you need from me. Will my review simply be used by you to improve your document, or do you need formal reviews that accompany the final document and thus need to be detailed assessments? In other words, am I simply helping you fine-tune your document or is this more like an NSF grant proposal and the review will influence whomever will be evaluating your recommendations? Just let me know!

Cheers,

Jim

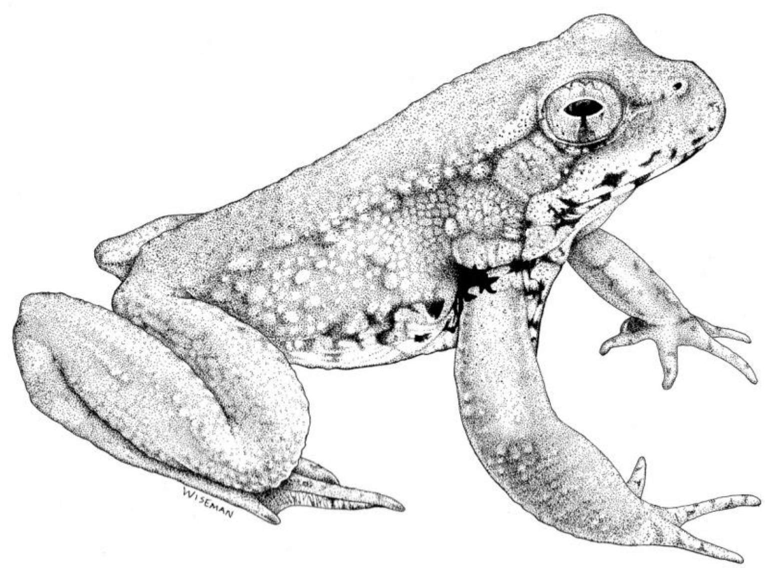
LIST OF TABLES



ACKNOWLEDGMENTS

Laura Patterson prepared this report. Stephanie Hogan, Madeleine Wieland, and Margaret Mantor assisted with portions of the report, including the sections on Status and Trends in California and Existing Management. Kristi Cripe provided GIS analysis and figures. Review of a draft document was provided by the following California Department of Fish and Wildlife (Department) staff: Ryan Bourque, Marcia Grefsrud, and Mike van Hattem.

The Department is extremely grateful for the valuable comments provided on this report by the following peer reviewers: Dr. Sarah Kupferberg, Dr. Amy Lind, Dr. Jimmy McGuire, and Dr. Ryan Peek. The conclusions in this report are those of the Department and do not necessarily reflect those of the reviewers.

EXECUTIVE SUMMARY

[To be completed after external peer review]

REGULATORY SETTING

Petition Evaluation Process

A petition to list the Foothill Yellow-legged Frog (*Rana boylii*) as threatened under the California Endangered Species Act (CESA) was submitted to the Fish and Game Commission (Commission) on December 14, 2016 by the Center for Biological Diversity. Commission staff transmitted the petition to the Department of Fish and Wildlife (Department) pursuant to Fish and Game Code section 2073 on December 22, 2016 and published a formal notice of receipt of the petition on January 20, 2017 (Cal. Reg. Notice Register 2017, No. 3-Z, p. 46). A petition to list or delist a species under CESA must include "information regarding the population trend, range, distribution, abundance, and life history of a species, the factors affecting the ability of the population to survive and reproduce, the degree and immediacy of the threat, the impact of existing management efforts, suggestions for future management, and the availability and sources of information. The petition shall also include information regarding the kind of habitat necessary for species survival, a detailed distribution map, and any other factors that the petitioner deems relevant" (Fish & G. Code, § 2072.3).

On April 17, 2017, the Department provided the Commission with its evaluation of the petition, "Evaluation of the Petition from the Center For Biological Diversity to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened under the California Endangered Species Act," to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5 & 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & (e)). Focusing on the information available to the Department relating to each of the relevant categories, the Department recommended to the Commission that the petition be accepted.

At its scheduled public meeting on June 21, 2017, in Smith River, California, the Commission considered the petition, the Department's petition evaluation and recommendation, and comments received. The Commission found that sufficient information existed to indicate the petitioned action may be warranted and accepted the petition for consideration. Upon publication of the Commission's notice of its findings, the Foothill Yellow-legged Frog was designated a candidate species on July 7, 2017 (Cal. Reg. Notice Register 2017, No. 27-Z, p. 986).

Status Review Overview

The Commission's action designating the Foothill Yellow-legged Frog as a candidate species triggered the Department's process for conducting a status review to inform the Commission's decision on whether listing the species is warranted. At its scheduled public meeting on June 21, 2018, in Sacramento, California, the Commission granted the Department a six-month extension to complete the status review and facilitate external peer review.

This status review report is not intended to be an exhaustive review of all published scientific literature relevant to the Foothill Yellow-legged Frog; rather, it is intended to summarize the key points from the best scientific information available relevant to the status of the species. This final report, based upon the best scientific information available to the Department, is informed by independent peer review of a draft report by scientists with expertise relevant to the Foothill Yellow-legged Frog. This review is intended to provide the Commission with the most current information on the Foothill Yellow-legged Frog and to serve as the basis for the Department's recommendation to the Commission on whether the petitioned action is warranted. The status review report also identifies habitat that may be essential to continued existence of the species and provides management recommendations for recovery of the species (Fish & G. Code, § 2074.6). Receipt of this report is to be placed on the agenda for the next available meeting of the Commission after delivery. At that time, the report will be made available to the public for a 30-day public comment period prior to the Commission taking any action on the petition.

Federal Endangered Species Act Review

The Foothill Yellow-legged Frog is currently under review for possible listing as threatened or endangered under the federal Endangered Species Act (ESA) in response to a July 11, 2012 petition submitted by the Center for Biological Diversity. On July 1, 2015, the U.S. Fish and Wildlife Service (USFWS) published its 90-day finding that the petition presented substantial scientific or commercial information indicating that the petitioned action may be warranted and initiated a status review of the species (USFWS 2015). On March 16, 2016, the Center for Biological Diversity sued the USFWS to compel issuance of a 12-month finding on whether listing under the ESA is warranted. On August 30, 2016, the parties reached a stipulated settlement agreement that the USFWS shall publish its 12-month finding in the Federal Register on or before September 30, 2020 (*Center for Biological Diversity v. S.M.R. Jewell* (D.D.C. Aug. 30, 2016, No. 16-CV-00503)).

BIOLOGY AND ECOLOGY

Species Description and Life History

> *"In its life-history* boylii *exhibits several striking specializations which are in all probability related to the requirements of life of a stream-dwelling species"* – Tracy I. Storer, 1925

The Foothill Yellow-legged Frog is a small- to medium-sized frog; adults range from 38 to 81 mm (1.5-3.2 in) snout to urostyle length (SUL) with females attaining a larger size than males and males possessing paired internal vocal sacs (Zweifel 1955, Nussbaum et al. 1983, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs are typically gray, brown, olive, or reddish with brown-black flecking and mottling, which generally matches the substrate of the stream in which they reside (Nussbaum et al. 1983, Stebbins and McGinnis 2012). They often have a pale triangle between the eyes and snout and broad dark bars on the hind legs (Zweifel 1955, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs have a relatively squat body and granular skin, giving them a rough appearance similar to a toad, and fully webbed feet with slightly expanded toe tips (Nussbaum et al. 1983). The tympanum is also rough

and relatively small compared to congeners at around one-half the diameter of the eye (Zweifel 1955). The dorsolateral folds (glandular ridges extending from the eye area to the rump) in Foothill Yellow-legged Frogs are indistinct compared to other western North American ranids (Stebbins and McGinnis 2012). Ventrally, the abdomen is white with variable amounts of dark mottling on the chest and throat, which are unique enough to be used to identify individuals (Marlow et al. 2016). As their name suggests, the underside of their hind limbs and lower abdomen are often yellow; however, individuals with orange and red have been observed within the range of the California Red-legged Frog (*Rana draytonii*), making hindlimb coloration a poor diagnostic characteristic for this species (Jennings and Hayes 2005).

Adult females likely lay one clutch of eggs per year and may breed every year (Storer 1925, Wheeler et al. 2006). Foothill Yellow-legged Frog egg masses resemble a compact cluster of grapes approximately 45 to 90 mm (1.8-3.5 in) in diameter length-wise and contain anywhere from around 100 to over 3,000 eggs (Kupferberg et al. 2009c, Hayes et al. 2016). The individual embryos are dark brown to black with a lighter area at the vegetative pole and surrounded by three jelly envelopes that range in diameter from approximately 3.9 to 6.0 mm (0.15-0.25 in) (Storer 1925, Zweifel 1955, Hayes et al. 2016).

Foothill Yellow-legged Frog tadpoles hatch out around 7.5 mm (0.3 in) long and are a dark brown or black (Storer 1925, Zweifel 1955). They grow rapidly to 37 to 56 mm (1.5-2.2 in) and turn olive with a coarse brown mottling above and an opaque silvery color below (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012). Their eyes are positioned dorsally when viewed from above (i.e., within the outline of the head), and their mouths are large, downward-oriented, and suction-like with several tooth rows (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012, Hayes et al. 2016). Foothill Yellow-legged Frogs metamorphose at around 14-17 mm (0.55-0.67 in) SUL (Fellers 2005). Sexual maturity is attained at around 30-40 mm (1.2-1.6 in) SUL and 1 year for males and around 40-50 mm (1.6-2.0 in) SUL and 3 years for females, although in some populations this has been accelerated by a year (Zweifel 1955, Kupferberg et al. 2009c, Breedveld and Ellis 2018). During the breeding season, males can be distinguished from females by the presence of nuptial pads (swollen darkened thumb bases that aid in holding females during amplexus) and calling, which frequently occurs underwater but sometimes from the surface (MacTague and Northen 1993, Stebbins 2003, Silver 2017).

The reported lifespan of Foothill Yellow-legged Frogs varies widely by study. Storer (1925) and Van Wagner (1996) estimated a maximum age of 2 years for both sexes and the vast majority of the population. Breedveld and Ellis (2018) calculated the typical lifespan of males at 3-4 years and 5-6 years for females. Bourque (2008), using skeletochronology, found an individual over 7 years old and a mean age of 4.7 and 3.6 years for males and females, respectively. Drennan et al. (2015) estimated maximum age at 13 years for both sexes in a Sierra Nevada population and 12 for males and 11 for females in a Coast Range population.

Range and Distribution

Foothill Yellow-legged Frogs historically ranged from the Willamette River drainage in Oregon west of the Sierra-Cascade crest to at least the San Gabriel River drainage in Los Angeles County, California (Figure 1; Zweifel 1955, Stebbins 2003). In addition, a disjunct population was reported from 2,040 m

Figure 1. Foothill Yellow-legged Frog historical range (adapted from CWHR, Loomis [1965], Nussbaum et al. [1983])

(6,700 ft) in the Sierra San Pedro Mártir, Baja California Norte, México (Loomis 1965). In California, the species occupies foothill and mountain streams in the Klamath, Cascade, Sutter Buttes, Coast, Sierra Nevada, and Transverse ranges from sea level to 1,940 m (6,400 ft), but generally below 1,525 m (5,000 ft) (Hemphill 1952, Nussbaum et al. 1983, Stebbins 2003, Olson et al. 2016). Zweifel (1955) considered Foothill Yellow-legged Frogs to be present and abundant throughout their range where streams possessed suitable habitat.

Taxonomy and Phylogeny

Foothill Yellow-legged Frogs belong to the family Ranidae (true frogs), which inhabits every continent except Antarctica and contains more than 700 species (Stebbins 2003). The species was first described by Baird (1854) as *Rana boylii*. After substantial taxonomic uncertainty with respect to its relationship to other ranids (frogs in the family Ranidae) and several name changes over the next century, the Foothill Yellow-legged Frog (*R. boylii* with no subspecific epithet) was ~~eventually~~ again recognized as a ~~distinct~~ monotypic species ~~again~~ by Zweifel (1955, 1968). The phylogenetic relationships among the western North American *Rana* spp. have been revised several times and are still not entirely resolved (Thomson et al. 2016). The Foothill Yellow-legged Frog was previously thought to be most closely related to the higher elevation Mountain Yellow-legged Frog (*R. muscosa*) (Zweifel 1955; Green 1986a,b). However, genetic analyses undertaken by Macey et al. (2001) and Hillis and Wilcox (2005) suggest they are more closely related to Oregon Spotted Frogs (*R. pretiosa*) and Columbia Spotted Frogs (*R. luteiventris*), respectively.

Commented [MOU1]: The old Ranidae has been partitioned into several families. The distribution is still as you indicated but the number of species is 407 according to AmphibiaWeb (and they stay completely on top of the taxonomic literature).

Formatted: Highlight

Population Structure and Genetic Diversity

Foothill Yellow-legged Frog populations exhibit varying levels of partitioning and genetic diversity at different spatial scales. At the coarse landscape level across the species' extant range, McCartney-Melstad et al. (2018) genomic data set composed of RadSeq data, analysis of which recovered five deeply divergent, geographically cohesive, genetic clades (Figure 2), while Peek (2018) (using ???? data) recovered six (Figure 3). Genetic divergence ~~is~~ occurs during the process of speciation; it is a measure of the number of mutations accumulated by populations over time from a shared ancestor that differentiate them from the other populations in a species. When genetic divergence among clades is large enough, it can be used as a tool to assist in the ~~define~~ identification of new species or subspecies.

Commented [MOU2]: Genetic divergence definitely takes places within species and is not strictly speaking the same as speciation.

The geographic breaks among the five clades were similar between the studies, but Peek (2018) identified a separate deeply divergent genetic clade in the Feather River watershed that is distinct from the rest of the northern Sierra Nevada clade. The five clades the two studies shared include the following [Note: naming conventions follow McCartney-Melstad et al. (2018) and Peek (2018)]:

(1) Northwest/North Coast: north of San Francisco Bay in the Coast Ranges and east into Tehama County;
(2) Northeast/Northern Sierra: northern El Dorado County (North Fork American River watershed, includes Middle Fork) and north in the Sierra Nevada to southern Plumas County (Upper Yuba River watershed);

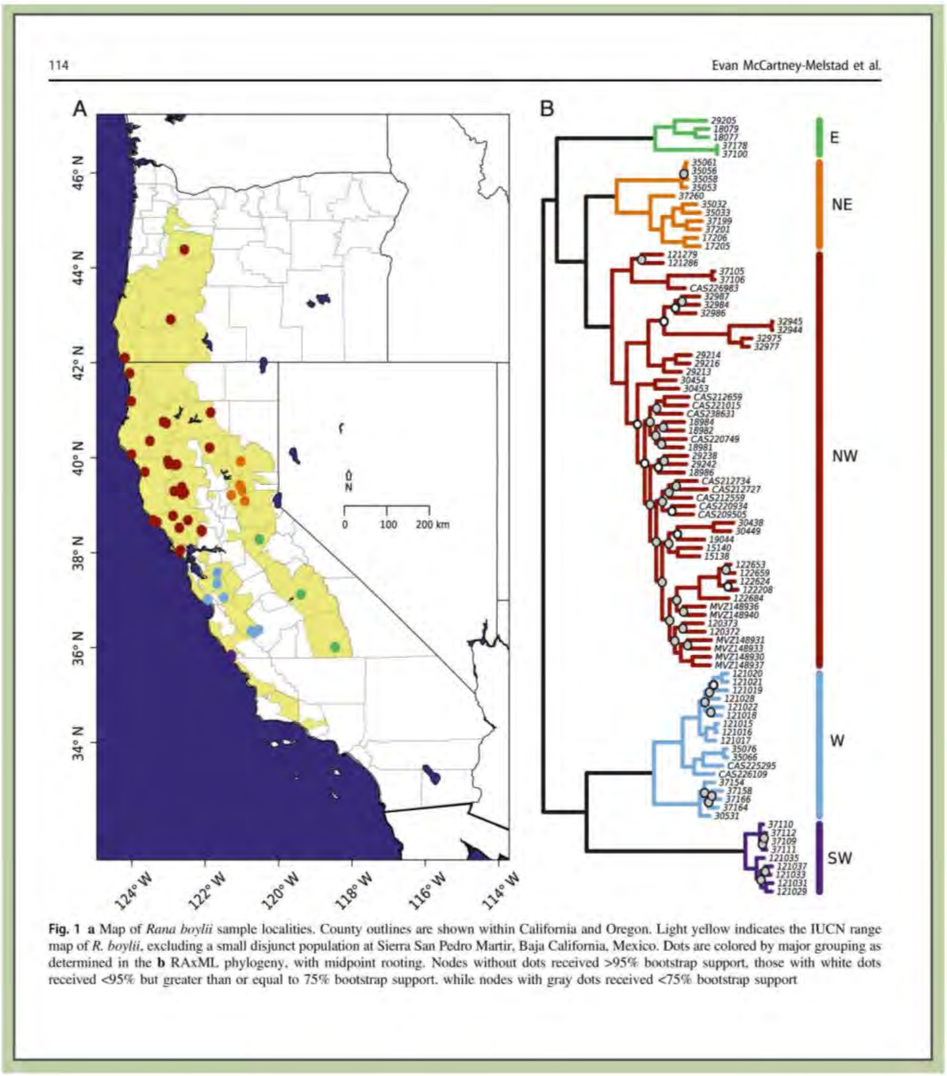

Fig. 1 **a** Map of *Rana boylii* sample localities. County outlines are shown within California and Oregon. Light yellow indicates the IUCN range map of *R. boylii*, excluding a small disjunct population at Sierra San Pedro Martir, Baja California, Mexico. Dots are colored by major grouping as determined in the **b** RAxML phylogeny, with midpoint rooting. Nodes without dots received >95% bootstrap support, those with white dots received <95% but greater than or equal to 75% bootstrap support, while nodes with gray dots received <75% bootstrap support

Figure 2. Foothill Yellow-legged Frog clades by McCartney-Melstad et al. (2018)

(3) East/Southern Sierra: El Dorado County (South Fork American River watershed) and south in the Sierra Nevada [no samples from Amador County were tested, but they would most likely fall within this clade because it is located between two other populations that occur within this clade];

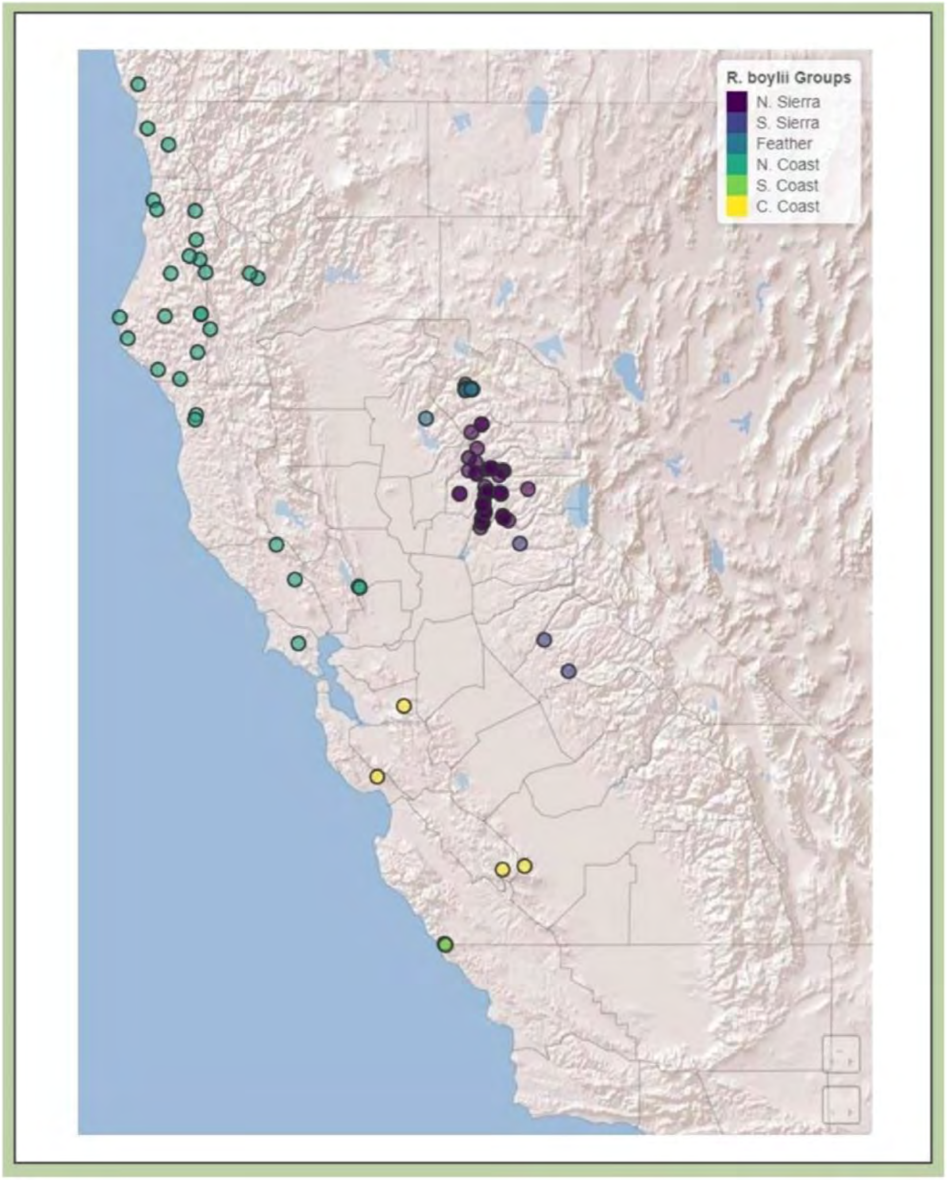

Figure 3. Foothill Yellow-legged Frog clades by Peek (2018)

(4) West/Central Coast: south of San Francisco Bay in the Coast Ranges to San Benito and Monterey counties, presumably east of the San Andreas Fault/Salinas Valley;
(5) Southwest/South Coast presumably west of the San Andreas Fault/Salinas Valley in Monterey County and south in the Coast Ranges.

The Feather River clade is found primarily in Plumas and Butte counties (Peek 2018). Peek's analysis found that this clade is as distinct as the rest of the Sierra Nevada as a cohesive group and all the coastal populations as one group, meaning it was found to be deeply divergent from the rest of the clades. McCartney-Melstad et al. (2018) also recognized the Feather River watershed as distinct from the rest of the northern Sierra but not as deeply divergent from the other clades as Peek. The Feather River watershed is also the only known location where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs (*R. sierrae*) co-occur and where two F1 hybrids (50% ancestry from each species) were found (Peek 2018). In addition, Peek's modeling results only weakly supported dividing the West/Central Coast and Southwest/South Coast groups into separate clades.

Previous work conducted by Lind et al. (2011) based on two mitochondrial genes found a somewhat similar pattern, that populations on the periphery of the species' range are considerably genetically divergent from the rest of the range. Their results suggested that hydrologic regions and river basins were important landscape features that influenced the genetic structure of Foothill Yellow-legged Frog populations. However, using more modern genomic techniques, McCartney-Melstad et al. (2018) found nearly twice the variation among the five phylogenetic clades than among drainage basins, indicating other factors contributed to current population structure. They report that the depth of genetic divergence among Foothill Yellow-legged Frog clades exceeds that of any anuran (frog or toad) for which similar data are available and recommend using them as management units instead of the previously suggested watershed boundaries.

Levels of genetic diversity within the clades differed significantly. Genetic diversity gives species the ability to adapt to changing conditions (i.e., evolve), and its loss often signals extreme population and range reductions as well as potential inbreeding depression that can reduce survival and reproductive success (Lande and Shannon 1996, Hoffmann and Sgrò 2011, McCartney-Melstad et al. 2018). Loss of genetic diversity in Foothill Yellow-legged Frogs largely follows a north-to-south pattern with the southern clades (Southwest/South Coast and East/Southern Sierra) possessing the least amount (McCartney-Melstad et al. 2018, Peek 2018). In addition, these study results demonstrate that Foothill Yellow-legged Frogs have lost genetic diversity over time across their entire range except for the large Northwest/North Coast clade, which appears to have undergone a relatively recent population expansion (McCartney-Melstad et al. 2018, Peek 2018).

At a watershed scale, Dever (2007) found that tributaries to rivers and streams are important for preserving genetic diversity, and populations separated by more than 10 km (6.2 mi) show signs of genetic isolation. In other words, even in the absence of anthropogenic barriers to dispersal (e.g., dams and reservoirs), individuals located more than 10 km (6.2 mi) are not typically considered part of a single interbreeding population (Olson and Davis 2009). Peek (2011, 2018) reported that at this finer-scale, population structure and genetic diversity appear to be more strongly influenced by river regulation type (i.e., dammed or undammed) than to geographic distance or watershed boundaries. In general, regulated (dammed) rivers had limited gene flow and higher genetic divergence among subpopulations compared with unregulated (undammed) rivers (Peek 2011, 2018). In addition, differences in water flow regimes within regulated rivers affected connectivity (Peek 2011, 2018). Subpopulations in hydropeaking reaches, in which pulsed flows are used for electricity generation or whitewater boating, exhibited significantly lower gene flow than those in bypass reaches where water is diverted from upstream in the basin down to power generating facilities (Figure 4; Peek 2018). River regulation had a greater influence on genetic differentiation among sites than geographic distance in the Alameda Creek watershed as well (Stillwater Sciences 2012). Reduced connectivity among sites leads to lower gene flow and a loss of genetic diversity through genetic drift, which can diminish adaptability to changing environmental conditions (Palstra and Ruzzante 2008). Peek (2011) posits that given the *R. boylii* species group is estimated to be 8 million years old (Macey et al. 2001), the significant reductions in connectivity and genetic diversity over short evolutionary time periods in regulated rivers (often less than 50 years from the time of dam construction) is cause for concern, particularly when combined with small population sizes.

Habitat Associations and Use

> *"These frogs are so closely restricted to streams that it is unusual to find one at a greater distance from the water than it could cover in one or two leaps."* – Richard G. Zweifel, 1955

Foothill Yellow-legged Frogs inhabit rivers and streams ranging from primarily rain-fed (coastal populations) to primarily snow-influenced (most Sierra Nevada and Klamath-Cascade populations) from headwater streams to large rivers (Bury and Sisk 1997, Wheeler et al. 2014). Occupied rivers and streams flow through a variety of vegetation types including hardwood, conifer, and valley-foothill riparian forests; mixed chaparral; and wet meadows (Hayes et al. 2016). Because the species is so widespread and can be found in so many types of habitats, the vegetation community is likely less important in determining Foothill Yellow-legged Frog occupancy and abundance than the aquatic biotic and abiotic conditions in the specific river, stream, or reach (Zweifel 1955). The species is an obligate stream-breeder, which sets it apart from other western North American ranids (Wheeler et al. 2014). Foothill Yellow-legged Frog habitat is generally characterized as partly-shaded, shallow, perennial rivers and streams with a low gradient and rocky substrate that is at least cobble-sized (Zweifel 1955, Hayes and Jennings 1988). However, the use of intermittent and ephemeral streams by post-metamorphic Foothill Yellow-legged Frogs may not be all that uncommon in some parts of the species' range in California (R. Bourque pers. comm. 2019). The species has been reported from some atypical habitats as well, including ponds, isolated pools in intermittent streams, and meadows along the edge of streams that lack a rocky substrate (Fitch 1938, Zweifel 1955, J. Alvarez pers. comm. 2017, CDFW 2018a).

As stream-breeding poikilotherms (animals whose internal temperature varies with ambient temperature), appropriate flow velocity, temperature, and water availability are critically important to Foothill Yellow-legged Frogs (Kupferberg 1996a, Van Wagner 1996, Wheeler et al. 2006, Lind et al. 2016). Habitat quality is also influenced by hydrologic regime (regulated vs. unregulated), substrate, presence of non-native predators and competitors, water depth, and availability of high-quality food and basking sites (Lind et al. 1996, Yarnell 2005, Wheeler et al. 2006, Catenazzi and Kupferberg 2017). Habitat suitability and use vary by life stage, sex, geographic location, watershed size, and season and

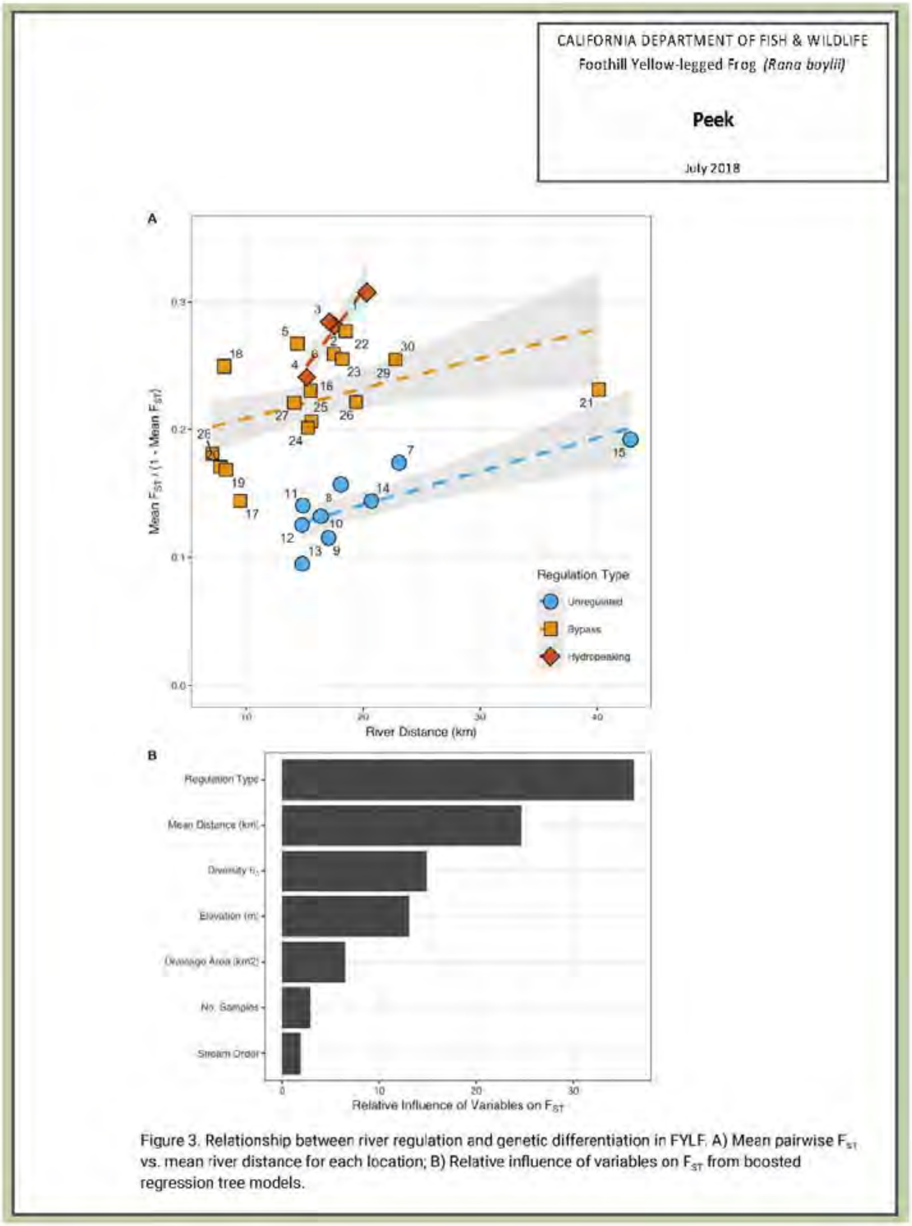

Figure 4. River regulation's relative influence on genetic differentiation from Peek (2018)

can generally be categorized as breeding and rearing habitat, nonbreeding active season habitat, and overwintering habitat (Van Wagner 1996, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011, Hayes et al. 2016, Catenazzi and Kupferberg 2017). Yarnell (2005) located higher densities of Foothill Yellow-legged Frogs in areas with greater habitat heterogeneity and suggested that they were selecting ~~for~~ sites that possessed the diversity of habitats necessary to support each life stage within a relatively short distance.

Breeding and Rearing Habitat

Suitable breeding habitat must be connected to suitable rearing habitat for metamorphosis to be successful. When this connectivity exists, as flows decline through the season, tadpoles can follow the receding shoreline into areas of high productivity and lower predation risk as opposed to becoming trapped in isolated pools with a high risk of overheating, desiccation, and predation (Kupferberg et al. 2009c).

Several studies on Foothill Yellow-legged Frog breeding habitat, carried out across the species' range in California, reported similar findings. Foothill Yellow-legged Frogs select oviposition (egg-laying) sites within a narrow range of depths, velocities, and substrates and exhibit fidelity to breeding sites that consistently possess suitable microhabitat characteristics over time (Kupferberg 1996a, Bondi et al. 2013, Lind et al. 2016). At a coarse-spatial scale, breeding sites in rivers and large streams are often located near the confluence of tributary streams in sunny, wide, shallow reaches (Kupferberg 1996a, Yarnell 2005, GANDA 2008, Peek 2011). These areas are highly productive compared to cooler, deeper, closed-canopy sites (Catenazzi and Kupferberg 2013). At a fine-spatial scale, females prefer to lay eggs in low velocity areas dominated by cobble- and boulder-sized substrates, often associated with sparsely-vegetated point bars (Kupferberg 1996a, Lind et al. 1996, Van Wagner 1996, Bondi et al. 2013, Lind et al. 2016). They tend to select areas with less variable, more stable flows, and in areas with higher flows at the time of oviposition, they place their eggs on the downstream side of large cobblestones and boulders, which protects them from being washed away (Kupferberg 1996a, Wheeler et al. 2006).

Appropriate rearing temperatures are vital for successful metamorphosis. Tadpoles grow faster and larger in warmer water to a point (Zweifel 1955; Catenazzi and Kupferberg 2017, 2018). Zweifel (1955) conducted experiments on embryonic thermal tolerance and determined that the critical low was approximate 6°C (43°F), and the critical high was around 26°C (79°F). Welsh and Hodgson (2011) determined that best the single variable for predicting Foothill Yellow-legged Frog presence was temperature since none were observed below 13°C (55°F), but numbers increased significantly with increasing temperature. Catenazzi and Kupferberg (2013) measured tadpole thermal preference at 16.5-22.2°C (61.7-72.0°F), and the distribution of Foothill Yellow-legged Frog populations across a watershed was consistent within this temperature range. At temperatures below 16°C (61°F), tadpoles were absent under closed canopy and scarce even with an open canopy (Ibid.). Catenazzi and Kupferberg (2017) found regional differences in apparently suitable breeding temperatures. Inland populations from primarily snowmelt-fed systems with relatively cold water were relegated to reaches that are warmer on average during the warmest 30 days of the year than coastal populations in the chiefly rainfall-fed, and thus warmer, systems (17.6-24.2°C [63.7-75.6°F] vs. 15.7-22.0°C [60.3-71.6°F], respectively).

However, experiments on tadpole thermal preference demonstrated that individuals from different source populations selected similar rearing temperatures, which presumably optimized development (Ibid.). In regulated systems, where water released from dams is often colder than normal, suitable rearing temperatures downstream may be limited (Wheeler et al. 2014, Catenazzi and Kupferberg 2017).

Appropriate flow velocities are also critical for survival to metamorphosis. The velocity at which Foothill Yellow-legged Frog egg masses shear away from the substrate they are adhered to varies according to factors such as depth and degree to which the eggs are sheltered (Spring Rivers Ecological Sciences 2003). This critical velocity is expected to decrease as the egg mass ages due to their reduced structural integrity of the protective jelly envelopes (Hayes et al. 2016). Short-duration increases in flow velocity may be tolerated if the egg masses are somewhat sheltered, but sustained high velocities increase the likelihood of detachment (Kupferberg 1996a, Spring Rivers Ecological Sciences 2003). Hatchlings and tadpoles about to undergo metamorphosis are relatively poor swimmers and require especially slow, stable flows during these stages of development (Kupferberg et al. 2011b). Tadpoles respond to increasing flows by swimming against the current to maintain position for a short period of time and eventually swimming to the bottom and seeking refuge in the rocky substrate's interstitial spaces (Ibid.). When tadpoles are exposed to repeated increases in velocities, their growth and development are delayed (Ibid.). Under experimental conditions, the critical velocity at which tadpoles were swept downstream ranged between 20 and 40 cm/s (0.66-1.31 ft/s); however, as they reach metamorphosis it decreases to as low as 10 cm/s (0.33 ft/s) (Ibid.).

Nonbreeding Active Season Habitat

Post-metamorphic Foothill Yellow-legged Frogs utilize a more diverse range of habitats and are much more dispersed during the nonbreeding active season than the breeding season. Microhabitat preferences appear to vary by location and season, but some patterns are common across the species' range. Foothill Yellow-legged Frogs tend to remain close to the water's edge (average < 3 m [10 ft]); select sunny areas with limited canopy cover; and are often associated with riffles and pools (Zweifel 1955, Hayes and Jennings 1988, Van Wagner 1996, Welsh et al. 2005, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011). Adequate water, food resources, cover from predators, ability to thermoregulate (e.g., presence of basking sites and cool refugia), and absence of non-native predators are important components of nonbreeding active season habitat (Hayes and Jennings 1988, Van Wagner 1996, Catenazzi and Kupferberg 2013).

Overwintering Habitat

Overwintering habitat varies depending on local conditions, but as with the rest of the year, Foothill Yellow-legged Frogs are most often found in or near water where they can forage and take cover from predators and high discharge events (Storer 1925, Zweifel 1955). In larger streams and rivers, Foothill Yellow-legged Frogs are often found along tributaries during the winter where the risk of being displaced by heavy flows is reduced (Kupferberg 1996a, Gonsolin 2010). Bourque (2008) found 36.4% of adult females used intermittent and ephemeral tributaries during the overwintering season. Van

Wagner (1996) located most overwintering frogs using pools with cover such as boulders, root wads, and woody debris. During high flow events, they moved to the stream's edge and took cover under vegetation like sedges (*Carex* sp.) or leaf litter (Ibid.). Rombough (2006) found most Foothill Yellow-legged Frogs under woody debris along the high-water line and often using seeps along the stream-edge, which provided them with moisture, a thermally stable environment, and prey.

Exceptions to the pattern of remaining near the stream's edge during winter have been reported. Cook et al. (2012) observed dozens of juvenile Foothill Yellow-legged Frogs traveling over land, as opposed to using riparian corridors. They were found using upland habitats with an average distance of 71.3 m (234 ft) from water (range: 16-331 m [52-1,086 ft]) (Ibid.). In another example, a single subadult that was found adjacent to a large wetland complex 830 m (2,723 ft) straight-line distance from the wetted edge of the Van Duzen River, although it is possible the wetland was connected to the river via a spillway or drainage that may have served as the movement corridor (CDFW 2018a, R. Bourque pers. comm. 2019).

Seasonal Activity and Movements

Because Foothill Yellow-legged Frogs occupy areas with relatively mild winter temperatures, they can be active year-round, although at low temperatures (< 7°C [44 °F], they become lethargic (Storer 1925, Zweifel 1955, Van Wagner 1996, Bourque 2008). They are active both day and night, and during the day adults are often observed basking on warm objects such as sun-heated rocks, although this is also when their detectability is highest (Fellers 2005, Wheeler et al. 2005). By contrast, Gonsolin (2010) tracked radio-telemetered Foothill Yellow-legged Frogs under substrate a third of the time and underwater a quarter of the time, although nearly all his detections of frogs without transmitters were basking.

Adult Foothill Yellow-legged Frogs migrate from their overwintering sites to breeding habitat in the spring, often from a tributary to its confluence with a larger stream or river. In areas where tributaries dry down, juveniles also make this downstream movement (Haggarty 2006). When the tributary itself is perennial and provides suitable breeding habitat, the frogs may not undertake these long-distance movements (Gonsolin 2010). Cues for adults to initiate this migration to breeding sites are somewhat enigmatic and vary by location, elevation, and amount of precipitation (S. Kupferberg and A. Lind pers. comm. 2017). They can also include day length, water temperature, and sex (GANDA 2008, Gonsolin 2010, Yarnell et al. 2010, Wheeler et al. 2018). Males initiate movements to breeding sites where they congregate in leks (areas of aggregation for courtship displays), and females arrive later and over a longer period (Wheeler and Welsh 2008, Gonsolin 2010). Most males utilize breeding sites associated with their overwintering tributaries, but some move substantial distances to other sites and may use more than one breeding site in the same season (Wheeler and Welsh 2006, GANDA 2008).

While the predictable hydrograph in California consists of wet winters with high flows and dry summers with low flows, the timing and quantity of seasonal discharge can vary significantly from year to year. The timing of oviposition can influence offspring growth and survival. Early breeders risk scouring of egg masses from their substrate by late spring storms in wet years or desiccation if waters recede rapidly, but when they successfully hatch, tadpoles benefit from a longer growing season, which can enable them to metamorphose at a larger size and increase their likelihood of survival (Railsback et al. 2016).

Later breeders are less likely to have their eggs scoured away or desiccated because flows are generally more stable, but they have fewer mate choices, and their tadpoles have a shorter growing period before metamorphosis, reducing their chance of survival (Ibid.). Some evidence indicates larger females, who coincidentally lay larger clutches, breed earlier (Kupferberg et al. 2009c, Gonsolin 2010). Consequently, early season scouring or stranding of egg masses or tadpoles can disproportionately impact the population's reproductive output because later breeders produce fewer and smaller eggs per clutch (Kupferberg et al. 2009c, Gonsolin 2010).

Timing of oviposition is often a function of water temperature and flow, but it consistently occurs on the descending limb of the hydrograph which corresponds to high winter discharge gradually receding toward low summer baseflow (Kupferberg 1996a, GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010, Yarnell et al. 2010). Under natural conditions, the timing coincides with intermittent tributaries drying down and increases in algal blooms that provide forage for tadpoles (Haggarty 2006, Power et al. 2008). At lower elevations, breeding can start in late March or early April, and at mid-elevations, breeding typically occurs in mid-May to mid-June (Gonsolin 2010, S. Kupferberg and A. Lind pers. comm. 2017). The time of year a population initiates breeding can vary by a month among water years, occurring later at deeper sites when colder water becomes warmer (Wheeler et al. 2018). In wetter years, delayed breeding into early July can occur in some colder snowmelt systems (S. Kupferberg and A. Lind pers. comm. 2017, GANDA 2018).

A population's period of oviposition can also vary from two weeks to three months, meaning they could be considered explosive breeders at some sites and prolonged breeders at others (Storer 1925, Zweifel 1955, Van Wagner 1996, Ashton et al. 1997, Wheeler and Welsh 2008). Water temperature typically warms to over 10°C (50°F) before breeding commences (GANDA 2008, Gonsolin 2010, Wheeler et al. 2018). Wheeler and Welsh (2008) observed Foothill Yellow-legged Frogs breeding when flows were below 0.6 m/s (2 ft/s), pausing during increased flows until they receded, and GANDA (2008) reported breeding initiated when flow decreased to less than 55% above baseflow.

Male Foothill Yellow-legged Frogs spend more time at breeding sites during the season than females, many of whom leave immediately after laying their eggs (GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010). Daily movements are usually short (< 0.3 m [1 ft]), but some individuals travel substantial distances: median 70.7 m/d (232 ft/d) in spring and 37.1 m/d (104 ft/day) in fall/winter, nearly always using streams as movement corridors (Van Wagner 1996, Bourque 2008, Gonsolin 2010). The maximum reported movement rate is 1,386 m/d (0.86 mi/d), and the longest seasonal (post-breeding) daily distance reported is 7.04 km (4.37 mi) by a female that traveled up a dry tributary and over a ridge before returning to and moving up the mainstem creek (Bourque 2008). Movements during the non-breeding season are typically in response to drying channels or during rain events (Bourque 2008, Gonsolin 2010, Cook et al. 2012).

Hatchling Foothill Yellow-legged Frogs tend to remain with what is left of the egg mass for several days before dispersing into the interstitial spaces in the substrate (Ashton et al. 1997). They often move downstream in areas of moderate flow and will follow the location of warm water in the channel throughout the day (Brattstrom 1962, Ashton et al. 1997, Kupferberg et al. 2011a). Tadpoles usually

metamorphose in late August or early September (S. Kupferberg and A. Lind pers. comm. 2017). Twitty et al. (1967) reported that newly metamorphosed Foothill Yellow-legged Frogs mostly migrated upstream, which may be an evolutionary mechanism to return to their natal site after being washed downstream (Ashton et al. 1997).

Home Range and Territoriality

Foothill Yellow-legged Frogs exhibit a lek-type mating system in which males aggregate at the breeding site and establish calling territories (Wheeler and Welsh 2008, Bondi et al. 2013). The species has a relatively large calling repertoire for western North American ranids with seven unique vocalizations recorded (Silver 2017). Some of these can be reasonably attributed to territory defense and mate attraction communications (MacTeague and Northen 1993, Silver 2017). Physical aggression among males during the breeding season has been reported (Rombough and Hayes 2007, Wheeler and Welsh 2008). In addition, Wheeler and Welsh (2008) observed a non-random mating pattern in which males engaged in amplexus with females were larger than males never seen in amplexus, suggesting either physical competition or female preference for larger individuals. Very little information has been published on Foothill Yellow-legged Frog home range size. Wheeler and Welsh (2008) studied males during a 17-day period during breeding season and classified some of them as "site faithful" based on their movements and calculated their home ranges. Two-thirds of males tracked were site faithful, and their mean home range size was 0.58 m^2 (SE = 0.10 m^2; 6.24 ft^2 [SE = 1.08 ft^2]) (Ibid.). In contrast, perhaps because the study took place over a longer time period, Bourque (2008) reported approximately half of the males he tracked during the spring were mobile, and the other half were sedentary. The median distances traveled along the creek (a proxy for home range size since they rarely leave the riparian corridor) for mobile and sedentary males were 149 m (489 ft) and 5.5 m (18 ft), respectively.

Diet and Predators

Foothill Yellow-legged Frog diet varies by life stage and likely body size. Tadpoles graze on periphyton (algae growing on submerged surfaces) scraped from rocks and vegetation and grow faster, and to a larger size, when it contains a greater proportion of epiphytic diatoms with nitrogen-fixing endosymbionts (*Epithemia* spp.), which are high in protein and fat (Kupferberg 1997b, Fellers 2005, Hayes et al. 2016, Catennazi and Kupferberg 2017). Tadpoles may also forage on necrotic tissue from dead bivalves and other tadpoles, or more likely the algae growing on them (Ashton et al. 1997, Hayes et al. 2016). Post-metamorphic Foothill Yellow-legged Frogs primarily feed on a wide variety of terrestrial arthropods but also some aquatic invertebrates (Fitch 1936, Van Wagner 1996, Haggarty 2006). Most of their diet consists of insects and arachnids (Van Wagner 1996, Haggarty 2006, Hothem et al. 2009). Haggarty (2006) did not identify any preferred taxonomic groups, but she noted larger Foothill Yellow-legged Frogs consumed a greater proportion of large prey items compared to smaller individuals, suggesting the species may be gape-limited generalist predators. Hothem et al. (2009) found mammal hair and bones in a Foothill Yellow-legged Frog. Adult Foothill Yellow-legged Frogs, like many other ranids, also cannibalize conspecifics (Wiseman and Bettaso 2007). In the fall when young-of-year are abundant, they may provide an important source of nutrition for adults prior to overwintering (Ibid.).

Foothill Yellow-legged Frogs are preyed upon by several native and introduced species, including each other as described above. Some predators target specific life stages, while others may consume multiple stages. Several species of garter snakes (genus *Thamnophis*) are the primary and most widespread group of native predators on Foothill Yellow-legged Frogs tadpoles through adults is (Fitch 1941, Fox 1952, Zweifel 1955, Lind and Welsh 1994, Ashton et al. 1997, Wiseman and Bettaso 2007, Gonsolin 2010). Table 1 lists other known and suspected predators of Foothill Yellow-legged Frogs.

Table 1. Confirmed and potential Foothill Yellow-legged Frog predators in California in addition to gartersnakes (*Thamnophis* spp.)

Common Name	Scientific Name	Classification	Native	Prey Life Stage(s)	Sources
Caddisfly (larva)	*Dicosmoecus gilvipes*	Insect	Yes	Embryos (eggs)	Rombough and Hayes 2005
Dragonfly (nymph)	*Aeshna walker*	Insect	Yes	Larvae	Catenazzi and Kupferberg 2018
Waterscorpion	*Ranatra brevicollis*	Insect	Yes	Larvae	Catenaazi and Kupferberg 2018
Signal Crayfish	*Pacifastacus leniusculus*	Crustacean	No	Embryos (eggs) and Larvae	Rombough and Hayes 2005; Wiseman et al. 2005
Speckled Dace	*Rhinichthys osculus*	Fish	Yes	Larvae	Rombough and Hayes 2005
Reticulate Sculpin	*Cottus perplexus*	Fish	Yes	Larvae	Rombough and Hayes 2005
Sacramento Pike Minnow	*Ptychocheilus grandis*	Fish	Yes*	Embryos (eggs) and Adults	Ashton and Nakamoto 2007
Sunfishes	Family Centrachidae	Fish	No	Larvae	Moyle (1973); Hayes and Jennings 1986
Catfishes	Family Ictaluridae	Fish	No	Larvae	Moyle (1973); Hayes and Jennings 1986
Rough-skinned Newt	*Taricha granulosa*	Amphibian	Yes	Embryos (eggs)	Evenden 1948
California Giant Salamander	*Dicamptodon ensatus*	Amphibian	Yes	Larvae	Fidenci 2006
American Bullfrog	*Rana catesbeiana*	Amphibian	No	Larvae to Adults	Crayon 1998; Hothem et al. 2009
California Red-legged Frog	*Rana draytonii*	Amphibian	Yes	Larvae to Adults	Gonsolin 2010
American Robin	*Turdus migratorius*	Bird	Yes	Larvae	Gonsolin 2010
Common Merganser	*Mergus merganser*	Bird	Yes	Larvae	Gonsolin 2010
American Dipper	*Cinclus mexicanus*	Bird	Yes	Larvae	Ashton et al. 1997
Mallard	*Anas platyrhynchos*	Bird	Yes	Adults	Rombough et al. 2005
Raccoon	*Procyon lotor*	Mammal	Yes	Larvae to Adults	Zweifel 1955; Ashton et al. 1997
River Otter	*Lontra canadensis*	Mammal	Yes	Adults	T. Rose pers. comm. 2014

* Introduced to the Eel River, location of documented predation; Foothill Yellow-legged Frogs are extirpated from most areas of historical range overlap

STATUS AND TRENDS IN CALIFORNIA

Administrative Status

Sensitive Species

The Foothill Yellow-legged Frog is listed as a Sensitive Species by the U.S. Bureau of Land Management (BLM) and U.S. Forest Service (Forest Service). These agencies define Sensitive Species as those species that require special management consideration to promote their conservation and reduce the likelihood and need for future listing under the ESA.

California Species of Special Concern

The Department's Species of Special Concern (SSC) designation is similar to the federal Sensitive Species designation. It is administrative, rather than regulatory in nature, and intended to focus attention on animals at conservation risk. The designation is used to stimulate needed research on poorly known species and to target the conservation and recovery of these animals before they meet the CESA criteria for listing as threatened or endangered (Thomson et al. 2016). The Foothill Yellow-legged Frog is listed as a Priority 1 (highest risk) SSC (Ibid.).

Trends in Distribution and Abundance

Range-wide in California

Range is the general geographical area in which an organism occurs. For purposes of CESA and this Status Review, the range is the species' California range (*Cal. Forestry Assn. v. Cal. Fish and Game Com.* (2007) 156 Cal.App.4th 1535, 1551). Systematic, focused, range-wide assessments of Foothill Yellow-legged Frog distribution and abundance are rare, both historically and contemporarily. A detailed account of what has been documented within the National Parks and National Forests in California can be found in Appendix 3 of the *Foothill Yellow-legged Frogs Conservation Assessment in California* (Hayes et al. 2016).

Most Foothill Yellow-legged Frog records are incidental observations made during stream surveys for ESA-listed salmonids and simply document presence at a particular date and location, although some include counts or estimates of abundance by life stage. This makes assessing trends in distribution and abundance difficult despite a relatively large number of observations compared to many other species tracked by the California Natural Diversity Database (CNDDB). The CNDDB contained 2,366 Foothill Yellow-legged Frog occurrences in its March 2019 edition, 500 of which are documented from the past 5 years.

A few wide-ranging survey efforts that included Foothill Yellow-legged Frogs exist. Reports from early naturalists suggest Foothill Yellow-legged Frogs were relatively common in the Coast Ranges as far south as central Monterey County, in eastern Tehama County, and in the foothills in and near Yosemite National Park (Grinnell and Storer 1924, Storer 1925, Grinnell et al. 1930, Martin 1940). In addition to

these areas, relatively large numbers of Foothill Yellow-legged Frogs (17-35 individuals) were collected at sites in the central and southern Sierra Nevada and the San Gabriel Mountains between 1911 and 1950 (Hayes et al. 2016). Widespread disappearances of Foothill Yellow-legged Frog populations were documented as early as the 1970s and 80s in southern California, the southern Coast Range, and the central and southern Sierra Nevada foothills (Moyle 1973, Sweet 1983).

Twenty-five years ago, the Department published the first edition of *Amphibians and Reptile Species of Special Concern in California* (Jennings and Hayes 1994). The authors revisited hundreds of localities between 1988 and 1991 that had historically been occupied by Foothill Yellow-legged Frogs ~~between 1988 and 1991~~ and consulted local experts to determine presumed extant or extirpated status. Based on these survey results and stressors observed on the landscape, they considered Foothill Yellow-legged Frogs endangered in central and southern California south of the Salinas River in Monterey County. They considered the species threatened in the west slope drainages of the Cascade Mountains and Sierra Nevada east of the Central Valley, and they considered the remainder of the range to be of special concern (Ibid.).

Fellers (2005) and his field crews conducted surveys for Foothill Yellow-legged Frogs throughout California. They visited 804 sites across 40 counties with suitable habitat within the species' historical range. They detected at least one individual at 213 sites (26.5% of those surveyed) over 28 counties. They located Foothill Yellow-legged Frogs in approximately 40% of streams in the North Coast, 30% in the Cascade Mountains and south of San Francisco in the Coast Range, and 12% in the Sierra Nevada. Fellers estimated population abundance was 20 or more adults at only 14% of the sites where the species was found and noted the largest and most robust populations occurred along the North Coast. In addition, to determine status of Foothill Yellow-legged Frogs across the species' range and potential causes for declines, Lind (2005) used previously published status accounts, species expert and local biologist professional opinions, and field visits to historically occupied sites between 2000-2002. She determined that Foothill Yellow-legged Frogs had disappeared from 201 of 394 of the sites, representing just over 50%. The coarse-scale trend in California is one of greater population declines and extirpations in lower elevations and latitudes (Davidson et al. 2002).

Few site-specific population trend data are available from which to evaluate status. However, long-term monitoring efforts often use egg mass counts as a proxy to estimate adult breeding females. The results of these studies often reveal extreme interannual variability in number of egg masses laid (Ashton et al. 2010, S. Kupferberg and M. Power pers. comm. 2015, Peek and Kupferberg 2016). In a meta-analysis of egg mass count data collected across the species' range in California over the past 25 years, Peek and Kupferberg (2016) reported declines in two unregulated rivers and an increase in another. Their models did not detect any significant trends in abundance across different locations or regulation type (dammed or undammed); however, high interannual variability can render trend detection difficult. Interannual variability was substantially greater in regulated rivers vs. unregulated; the median coefficient of variation was 66.9% and 41.6%, respectively (Ibid.). The greater variability in regulated rivers decreases the probability of detecting significant declines, and coupled with low abundance, it can lead to populations dropping below a density necessary for persistence without detection, resulting in extirpation.

Regional differences in Foothill Yellow-legged Frog persistence across its range have been recognized for nearly 50 years (i.e., more extirpations documented in the south). Because of these differences and the recent availability of new landscape genomic data, more detailed descriptions of trends in Foothill Yellow-legged Frog population distribution and abundance in California are evaluated by clade below. Figure 5 depicts Foothill Yellow-legged Frog localities across all clades in California by the most recent confirmed sighting in the datasets available to the Department within a Public Lands Survey System (PLSS) section. “Transition Zones” are those areas where the exact clade boundaries are unknown due to a lack of samples. In addition, while not depicted as an area of uncertainty, no genetic samples have been tested south of the extant population in northern San Luis Obispo County, in the Sutter Buttes in Sutter County, or northeastern Plumas County. It is possible there were historically more clades than currently understood.

Caution should be exercised in comparing the following observation data across the species’ range and across time since survey effort and reporting are not standardized. These data can be useful for making some general inferences about distribution, abundance, and trends. For instance, assuming the observation correctly identifies the species, the date on the record is the last time the species was confirmed to have occurred at that location. However, this only works in the affirmative. For example, at a site where the last time the species was seen was 75 years ago, the species may still persist there if no one has surveyed it since the original observation. CNDDB staff use information on land use conversion, follow-up visits, and biological reports to categorize an occurrence location as “extirpated” or “possibly extirpated”.

Northwest/North Coast Clade

This clade extends from north of San Francisco Bay through the Coast Range and Klamath Mountains to the northern limit of the Foothill Yellow-legged Frog’s range and east through the Cascade Range. It includes Del Norte, Siskiyou, Humboldt, Trinity, Shasta, Tehama, Mendocino, Glenn, Colusa, Lake, Sonoma, Napa, Yolo, Solano, and Marin counties. This clade covers the largest geographic area and contains the greatest amount of genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). In addition, it is the only clade with an increasing trend in genetic diversity (Peek 2018).

Early records note the comparatively high abundance of Foothill Yellow-legged Frogs in this area. Storer (1925) described Foothill Yellow-legged Frogs as very common in many of Coast Range streams north of San Francisco Bay, and Cope (1879,1883 as cited in Hayes et al. 2016) noted they were “rather abundant in the mountainous regions of northern California.” In addition, relatively large collections occurred over short periods of time in this region in the late 1800s and the first half of the 20th century (Hayes et al. 2016). Nineteen were taken over two weeks in 1893 along Orrs Creek, a tributary to the Russian River, and 40 from near Willits (both in Mendocino County) in 1911; 112 were collected over three days at Skaggs Spring (Sonoma County) in 1911; 57 were taken in one day along Lagunitas Creek (Marin County) in 1928; and 50 were collected in one day near Denny (Trinity County) in 1955 (Ibid.).

A few long-term Foothill Yellow-legged Frog egg mass monitoring efforts undertaken within this clade’s boundaries found densities vary significantly, often based on river regulation type, and documented

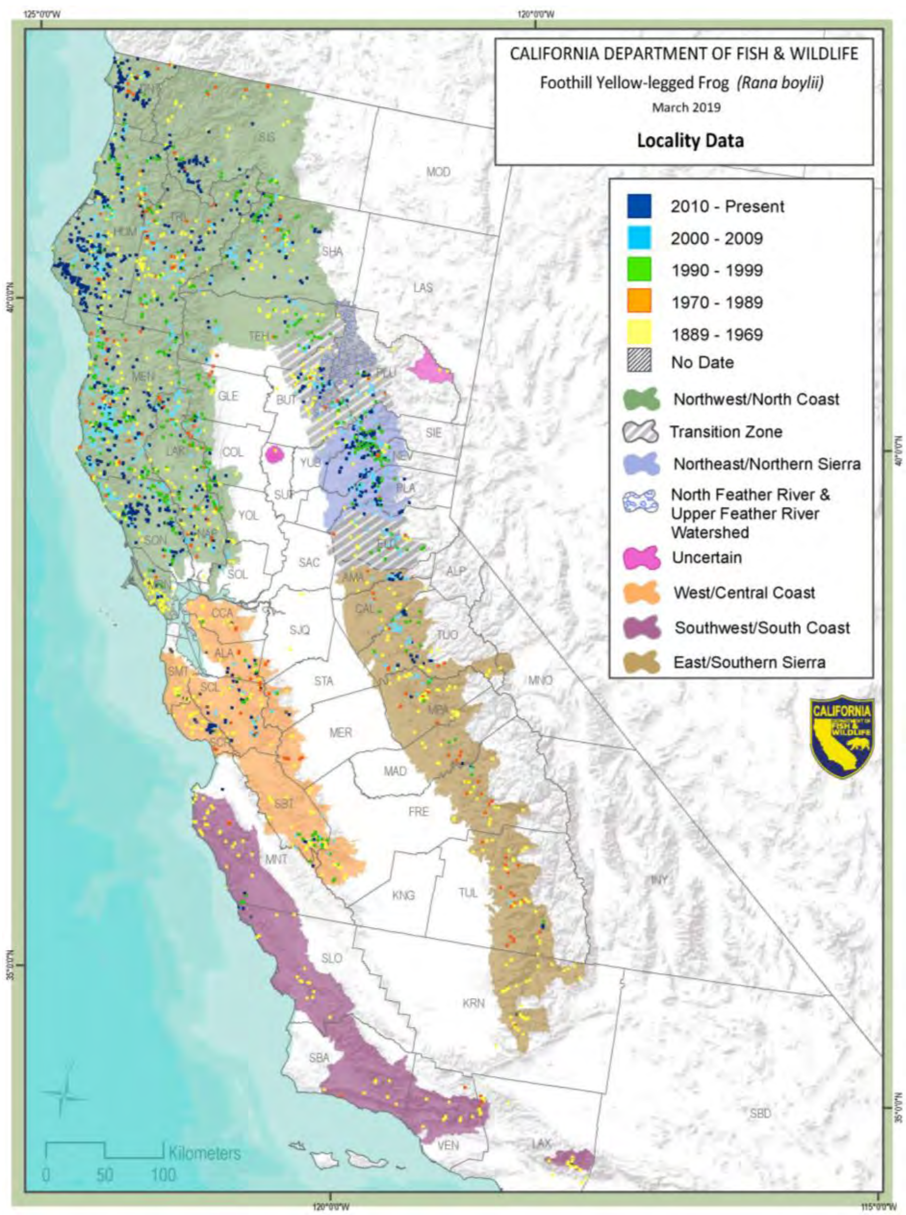

Figure 5. Foothill Yellow-legged Frog occurrence data from 1889-2019 overlaying the six clades by most recent sighting in a Public Lands Survey System section (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

several robust populations. The Green Diamond Resources Company has been monitoring a stretch of the Mad River near Blue Lake (Humboldt County) since 2008 (GDRC 2018). The greatest published density of Foothill Yellow-legged Frog egg masses was documented here in 2009 at 323.6 egg masses/km (520.7/mi) (Bourque and Bettaso 2011). However, in 2017, surveyors counted 625.1 egg masses/km (1,006/mi) along the same reach (GDRC 2018). At its lowest during this period, egg mass density was calculated at 71.54/km (115.1/mi) in 2010, although this count occurred after a flooding event that likely scoured over half of the egg masses laid that season (GDRC 2018, R. Bourque pers. comm. 2019). During a single day survey in 2017 along approximately 2 km (1.3 mi) of Redwood Creek in Redwood National Park (Humboldt County), 2,009 young and 126 adult Foothill Yellow-legged Frogs were found (D. Anderson pers. comm. 2017). Some reaches of the South Fork Eel River (Mendocino County) also support high densities of Foothill Yellow-legged Frogs. Kupferberg (pers. comm. 2018) recorded 206.9 and 106.2 egg masses/km (333 and 171/mi) along two stretches in 2016, and 201.7 and 117.5 egg masses/km (324 and 189/mi) in 2017. However, other reaches yielded counts as low as 6.1 and 8.4 egg masses/km (9.8 and 13.5/mi) (Ibid.). In the Angelo Reserve (an unregulated reach), the 24-year mean density was 109 egg masses/km (175.4/mi) (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015). In contrast, a 10-year mean density of egg masses below Lewiston Dam on the Trinity River (Trinity County) was 0.89/km (1.43/mi) (Ibid.).

Figure 6 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, Biological Information Observation System datasets, and personal communications that are color coded by the most recent date of detection. Within this clade, Foothill Yellow-legged Frogs were observed in at least 343 areas in the past 5 years (CNDDB 2019). The species remains widespread within many watersheds, although most observations only verify presence, or fewer than ten individuals or egg masses are recorded (Ibid.). Documented extirpations are comparatively rare, but also likely undetected or under-reported, and nearly all occurred just north of the high-populated San Francisco Bay area (Figure 7; Ibid.).

West/Central Coast

This clade extends south from the San Francisco Bay through the Diablo Range and down the peninsula through the Santa Cruz and Gabilan Mountains in the Coast Range east of the Salinas Valley. It includes most of Contra Costa, Alameda, San Mateo, Santa Cruz, Santa Clara, and San Benito counties; western San Joaquin, Stanislaus, Merced, and Fresno counties; and a small portion of eastern Monterey County. Records of Foothill Yellow-legged Frogs occurring south of San Francisco Bay did not exist until specimens were collected in 1918 around what is now Pinnacles National Park in San Benito County, and little information exists on historical distribution and abundance within this clade (Storer 1923).

Within this clade, Foothill Yellow-legged Frogs were observed in at least 24 areas in the past five years (Figure 8; CNDDB 2019). Documented and possible extirpations are concentrated around the San Francisco Bay and sites at the southern portion of the clade's range, although these may not have been resurveyed since their original observations in the 1940s through 1960s, except for a site in Pinnacles National Park that was surveyed in 1994 (Figure 9; Ibid.). In addition, although not depicted,

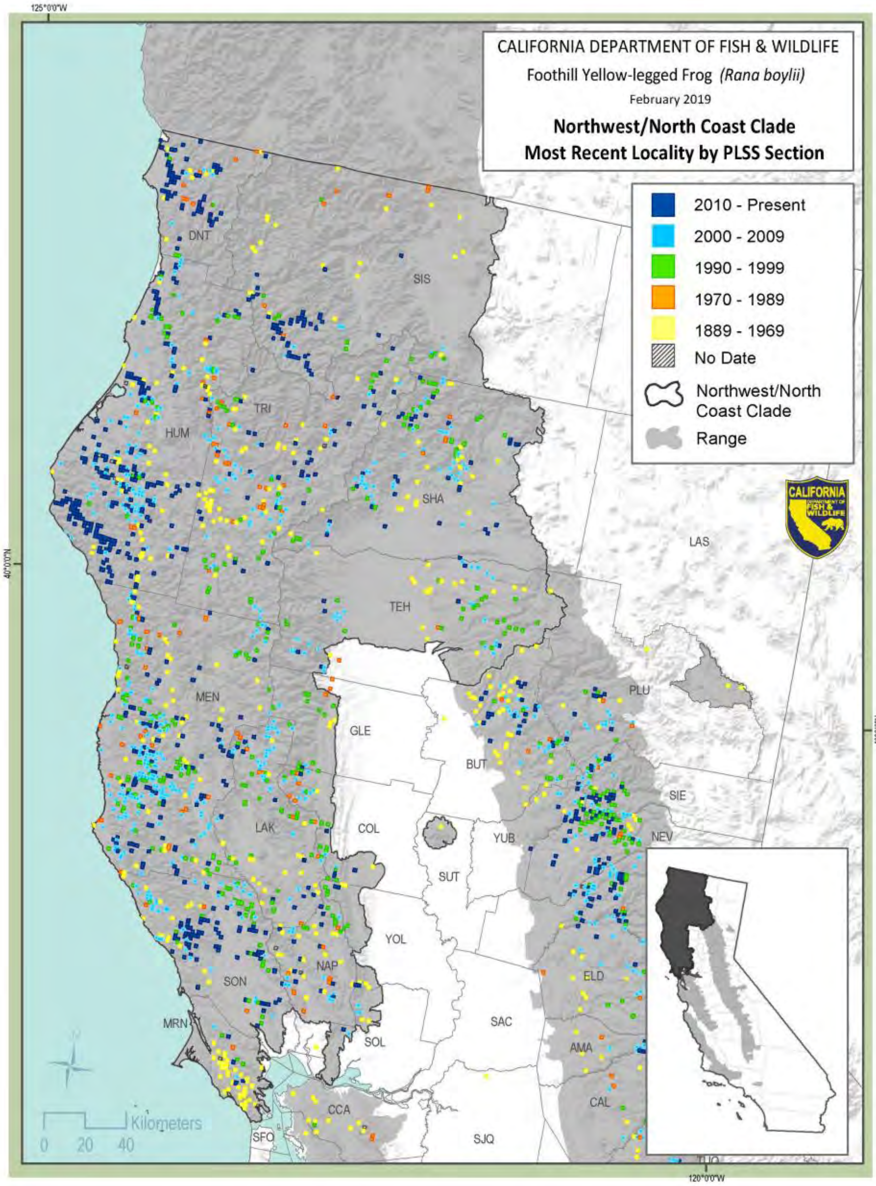

Figure 6. Close-up of Northwest/North Coast Foothill Yellow-legged Frog clade observations from 1889-2019 (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

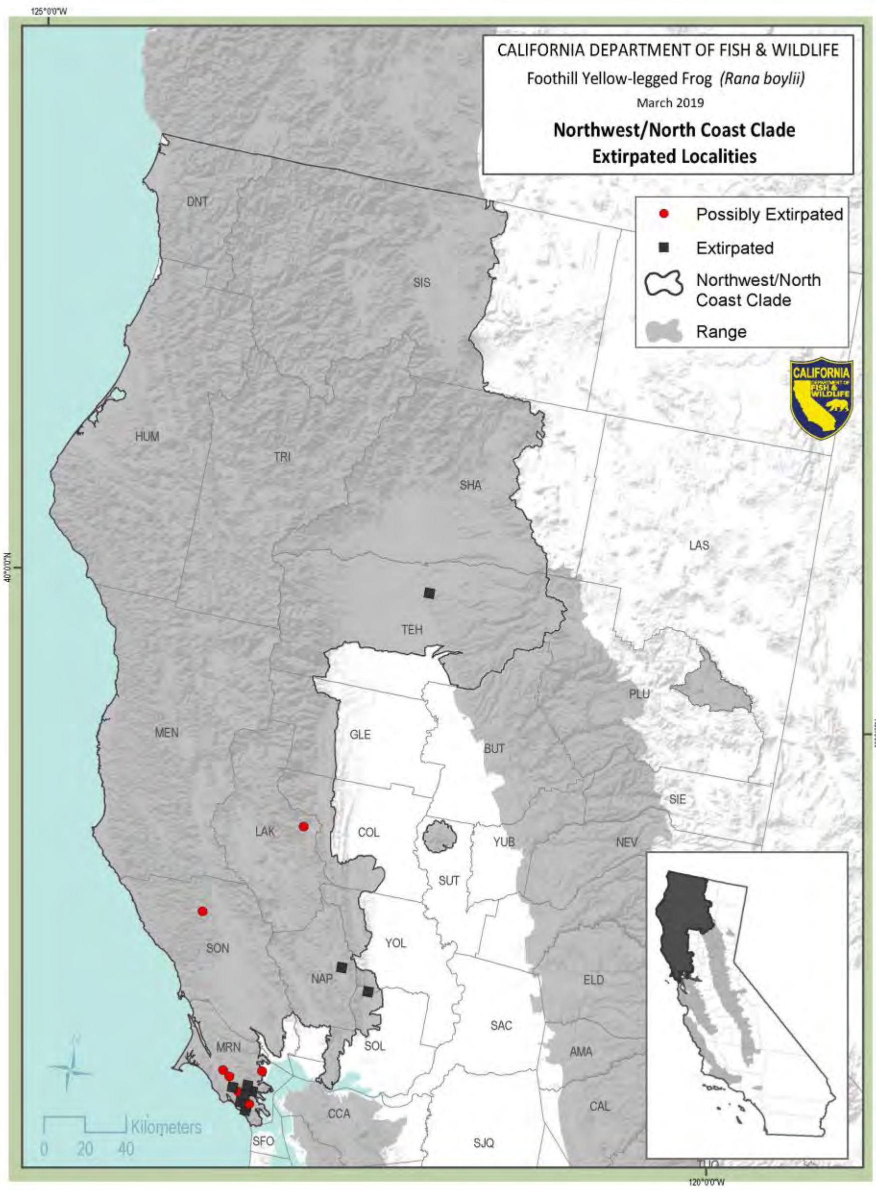

Figure 7. Possibly extirpated and extirpated Northwest/North Coast Foothill Yellow-legged Frog clade sites (CNDDB)

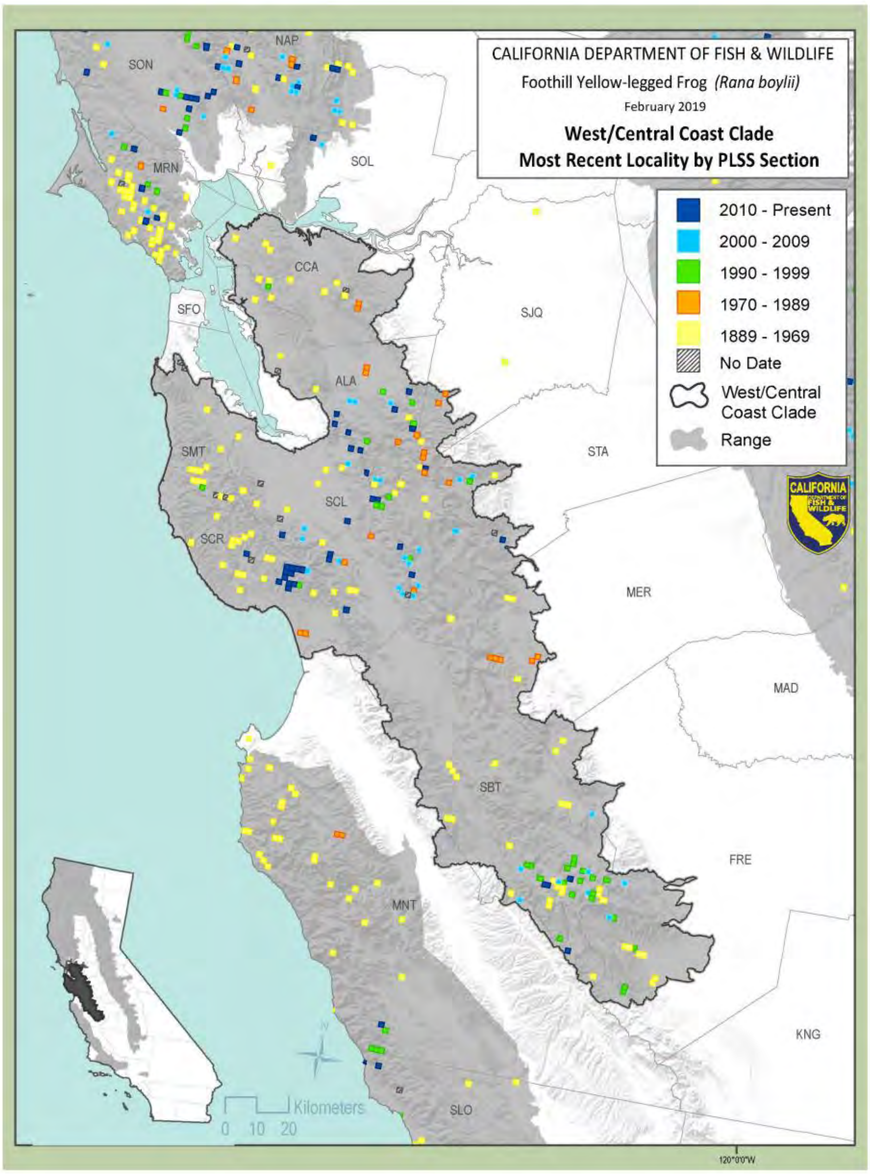

Figure 8. Close-up of West/Central Coast clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

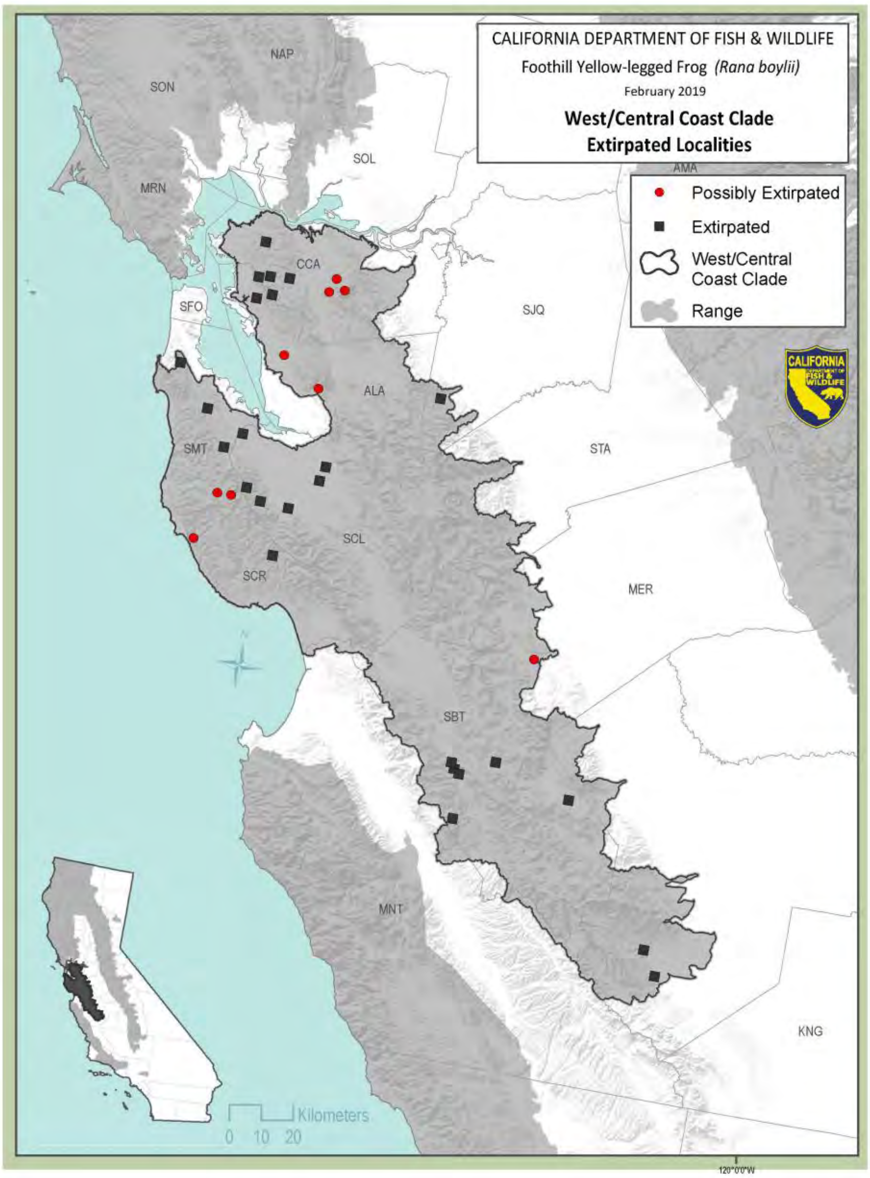

Figure 9. Possibly extirpated and extirpated West/Central Coast Foothill Yellow-legged Frog clade sites (CNDDB)

two populations on Arroyo Mocho and Arroyo Valle south of Livermore (Alameda County) are also likely extirpated (M. Grefsrud pers. comm. 2019).

The San Francisco Bay Area is heavily urbanized. Foothill Yellow-legged Frogs may be gone from Contra Costa County; eight of the nine CNDDB records from the county are museum specimens collected between 1891 and 1953, and the most recent observation was two adults in a plunge pool in an intermittent tributary to Moraga Creek in 1997. No recent (2010 or later) observations exist from San Mateo County (Ibid.). Historically occupied lower-elevation sites surrounding the San Francisco Bay and inland appear to be extirpated, but there are (or were) some moderately abundant breeding populations remaining at higher elevations in Arroyo Hondo (Alameda County), Alameda Creek (Alameda and Santa Clara counties), Coyote and Upper Llagas creeks (Santa Clara County), and Soquel Creek (Santa Cruz County) with some scattered smaller populations also persisting in these counties (J. Smith pers. comm. 2016, 2017; CNDDB 2019). The Alameda Creek and Coyote Creek populations recently underwent large-scale mortality events, so their numbers are likely substantially lower than what is currently reported in the CNDDB (Adams et al. 2017a, Kupferberg and Catenazzi 2019). In addition, the Arroyo Hondo population will lose approximately 1.6 km (1 mi) of prime breeding habitat (i.e., ~~supported~~ supporting the highest density of egg masses on the creek) as the Calaveras Reservoir is refilled following its dam replacement project in 2019 (M. Grefsrud pers. comm. 2019). Foothill Yellow-legged Frogs may be extirpated from Corral Hollow Creek in San Joaquin County, but a single individual was observed five years ago further up the drainage in Alameda County within an Off-Highway Vehicle park (CNDDB 2019). Few recent sightings of Foothill Yellow-legged Frogs in the east-flowing creeks are documented. They may still be extant in the headwaters of Del Puerto Creek (western Stanislaus County), but the records further downstream indicate bullfrogs (known predators and disease reservoirs) are moving up the system (Ibid.). Several locations in southern San Benito, western Fresno, and eastern Monterey counties have relatively recent (2000 and later) detections (Ibid.). However, while many of these sites supported somewhat large populations in the 1990s, the more recent records report fewer than ten individuals (Ibid.). The exception is a Monterey County site where around 25 to 30 were observed in 2012 (Ibid.).

Southwest/South Coast

Widespread extirpations occurred decades ago, primarily in the 1960s and 1970s, in this area (Adams et al. 2017b). As a result, genetic samples were largely unavailable, and the boundaries are speculative. The clade is presumed to include the Coast Range from Monterey Bay south to the Transverse Range across to the San Gabriel Mountains. This clade includes portions of Monterey, San Luis Obispo, Santa Barbara, Ventura, and Los Angeles counties. Storer (1923) reported that Foothill Yellow-legged Frogs were collected for the first time in Monterey County in 1919 and that a specimen collected by Cope in 1889 in Santa Barbara and listed as *Rana temporaria pretiosa* may refer to the Foothill Yellow-legged Frog because as previously mentioned, the taxonomy of this species changed several times over the first century after it was named.

Foothill Yellow-legged Frogs had been widespread and fairly abundant in this area until the late 1960s (Figure 10) but were rapidly extirpated throughout the southern Coast Ranges and western Transverse

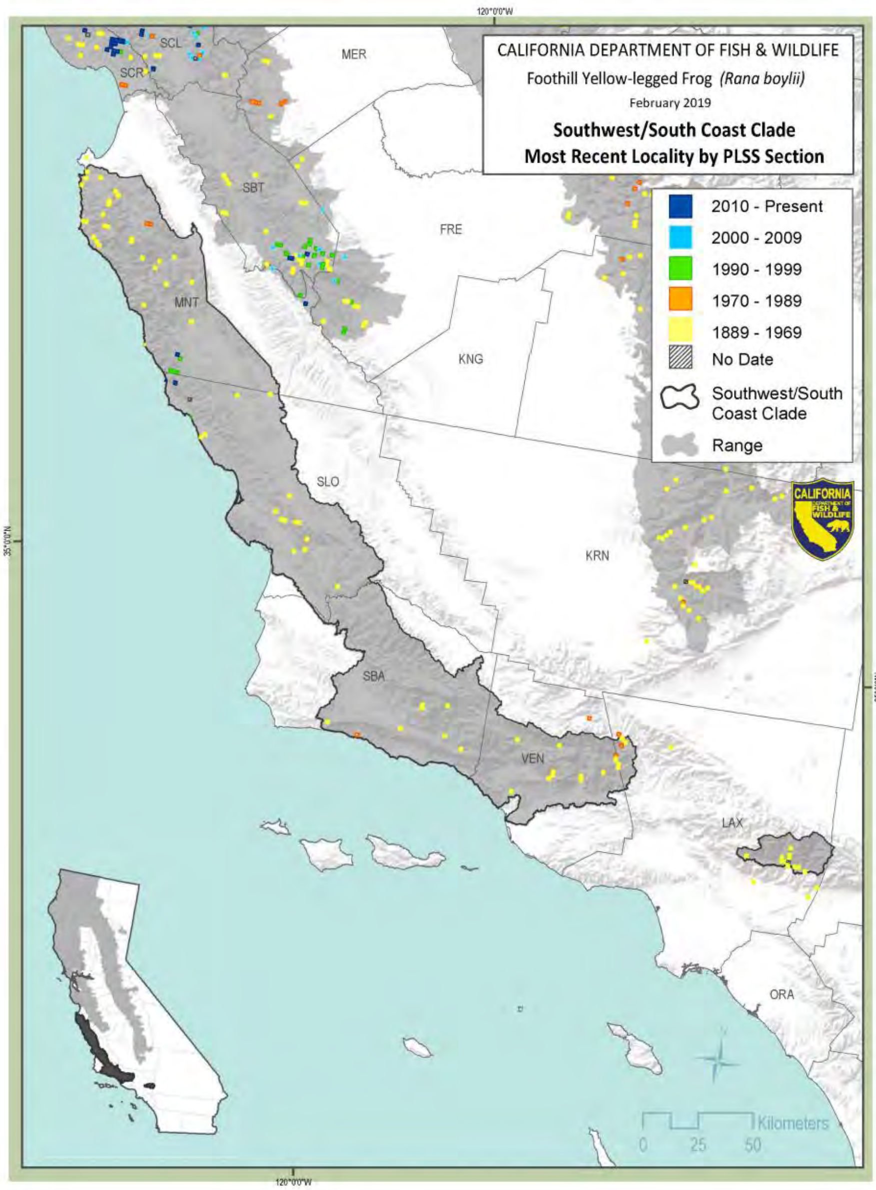

Figure 10. Close-up of Southwest/South Coast clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

Ranges by the mid-1970s (Figure 11; Sweet 1983, Adams et al. 2017b). Only two known extant populations exist from this clade, located near the border of Monterey and San Luis Obispo counties (S. Sweet pers. comm. 2017, McCartney-Melstad et al. 2018, Peek 2018, CNDDB 2019). They appear to be extremely small and rapidly losing genetic diversity, making them at high risk of extirpation (McCartney-Melstad et al. 2018, Peek 2018).

Northeast/Feather River and Northern Sierra

The exact clade boundaries in the Sierra Nevada are unclear and will require additional sampling and testing to define (Figure 12). The Northeast clade presumably encompasses the Feather River and Northern Sierra clades. The Feather River clade is located primarily in Plumas and Butte counties. The Northern Sierra clade roughly extends from the Feather River watershed south to the Middle Fork American River. It includes portions of El Dorado, Placer, Nevada, Sierra, and Plumas counties. It may also include portions of Amador, Butte, and eastern Tehama counties. No genetic samples were available to test in the Sutter Buttes or the disjunct population in northeastern Plumas County to determine which clades they belonged to before they were extirpated (Figure 13; Olson et al. 2016, CNDDB 2019).

In general, there is a paucity of historical Foothill Yellow-legged Frog data for west-slope Sierra Nevada streams, particularly in the lower elevations of the Sacramento Valley, and no quantitative abundance data exist prior to major changes in the landscape (i.e., mining, dams, and diversions) or the introduction of non-native species (Hayes et al. 2016). Foothill Yellow-legged Frogs ~~have been~~were collected frequently from the Plumas National Forest area in small numbers from the turn of the 20th century through the 1970s (Ibid.). Estimates of relative abundance are not clear from the records, but they suggest the species was somewhat widespread in this area.

More recently, Foothill Yellow-legged Frog populations in the Sierra Nevada have been the subject of a substantial number of surveys and focused research associated with recent and ongoing relicensing of hydroelectric power generating dams by the Federal Energy Regulatory Commission (FERC). Consequently, Foothill Yellow-legged Frogs have been observed in at least 30 areas in Plumas and Butte counties (roughly the Feather River clade) over the past five years (CNDDB 2019). As with the rest of the range, most records are observations of only a few individuals; however, many observations occurred over multiple years, and in some cases all life stages were observed over multiple years (Ibid). The populations appear to persist even with the small numbers reported. The only long-term consistent survey effort has been occurring on the North Fork Feather River along the Cresta and Poe reaches (GANDA 2018). The Cresta reach's subpopulation declined significantly in 2006 and never recovered despite modification of the flow regime to reduce egg mass and tadpole scouring and some habitat restoration (Ibid.). A pilot project to augment the Cresta reach's subpopulation through in situ captive rearing was initiated in 2017 (Dillingham et al. 2018). It resulted in the highest number of young-of-year Foothill Yellow-legged Frogs recorded during fall surveys since researchers started keeping count (Ibid.). The number of egg masses laid in the Poe reach varies substantially year-to-year from a low of 26 in 2001 to a high of 154 in 2015 and back down to 36 in 2017 (GANDA 2018).

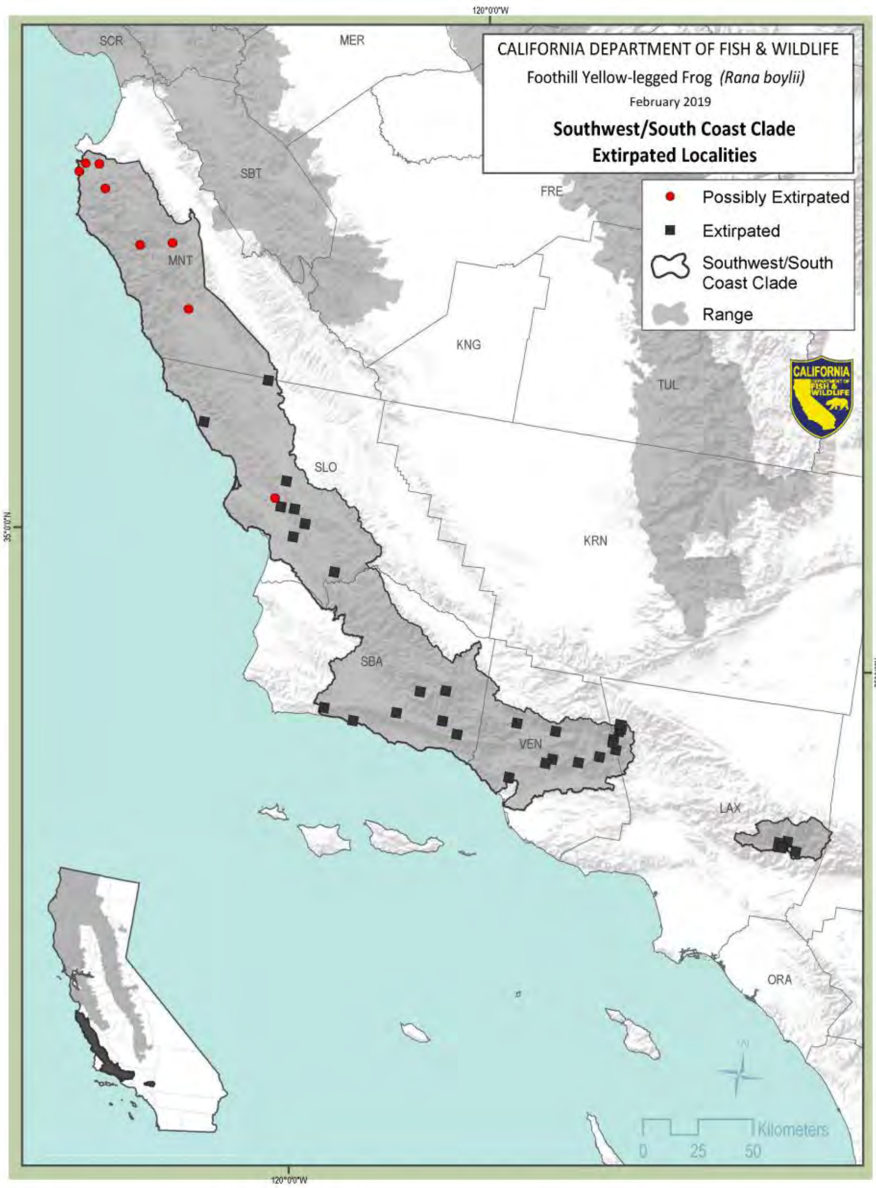

Figure 11. Possibly extirpated and extirpated Southwest/South Coast Foothill Yellow-legged Frog clade sites (CNDDB)

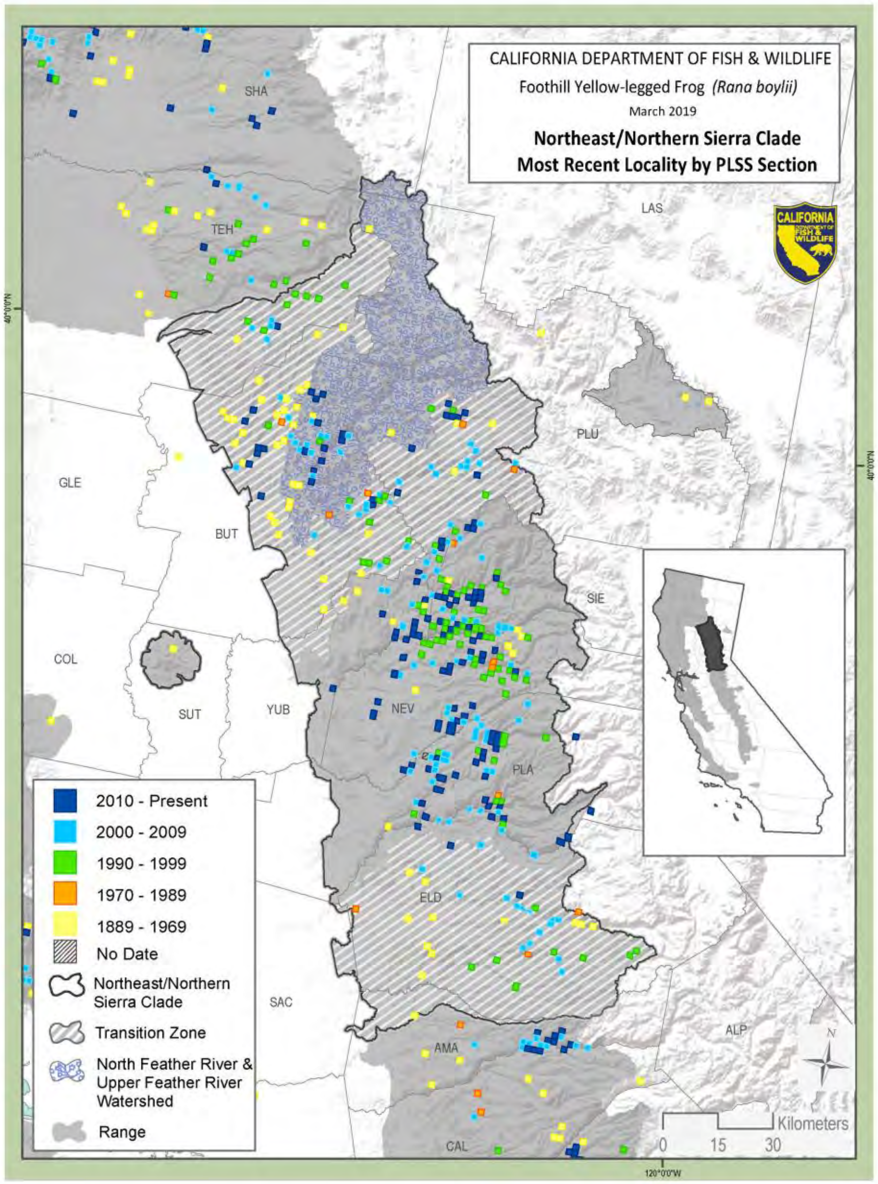

Figure 12. Close-up of Northeast/Feather River and Northern Sierra clades observations from 1889-2019 (ARSSC, BIOS, CNDDB)

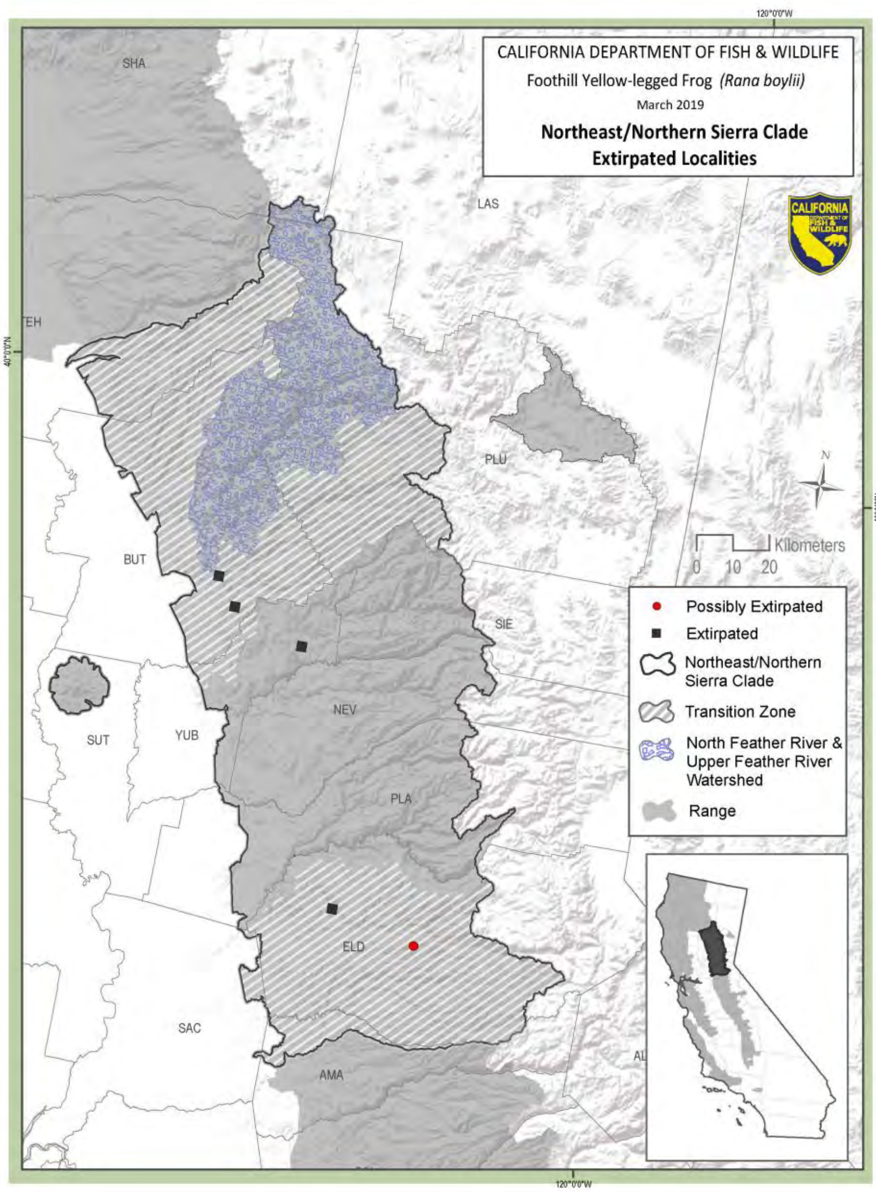

Figure 13. Possibly extirpated and extirpated Northeast/Feather River and Northern Sierra Foothill Yellow-legged Frog clades sites (CNDDB)

Foothill Yellow-legged Frogs have been observed in at least 71 areas in the past 5 years in the presumptive Northeast/Northern Sierra clade. The general pattern in this clade, and across the range for that matter, is that unregulated rivers or reaches have more areas that are occupied more consistently and in larger numbers than regulated rivers or reaches (CNDDB 2019, S. Kupferberg pers. comm. 2019). Foothill Yellow-legged Frogs were rarely observed in the hydropeaking reach of the Middle Fork American River and were observed in low numbers in the bypass reach, but they were present and breeding in small tributary populations (PCWA 2008). Relatively robust populations appear to inhabit the North Fork American River and Lower Rubicon River (Gaos and Bogan 2001, PCWA 2008, Hogan and Zuber 2012, K. Kundargi pers. comm. 2014, S. Kupferberg pers. comm. 2019). Additional apparently sufficiently large and relatively stable populations occur on Clear Creek, South Fork Greenhorn Creek, and Shady Creek (Nevada County) and the North and Middle Yuba River (Sierra County), but the remaining observations are of small numbers in tributaries with minimal connectivity among them (CNDDB 2019, S. Kupferberg pers. comm. 2019).

East/Southern Sierra

The East/Southern Sierra clade is presumed to range from the South Fork American River watershed, the northernmost site where individuals from this clade were collected, south to where the Sierra Nevada meets the Tehachapi Mountains. It likely includes El Dorado, Amador, Calaveras, Tuolumne, Mariposa, Madera, Fresno, Tulare, and Kern counties (Figure 14; Peek 2018). The proportion of extirpated sites in this clade is second only to the Southwest/South Coast and follows the pattern of greater losses in the south (Figure 15). Like the southern coastal clade, the southern Sierra clade has low genetic variability and a trajectory of continued loss of diversity (Ibid.).

Historical collections of small numbers of Foothill Yellow-legged Frogs occurred in every major river system within this clade beginning as early as the turn of the 20th century, indicating widespread distribution but little information on abundance (Hayes et al. 2016). By the early 1970s, declines in Foothill Yellow-legged Frog populations from this area were already apparent; Moyle (1973) found them at 30 of 95 sites surveyed in 1970. Notably bullfrogs inhabited the other 65 sites formerly occupied by Foothill Yellow-legged Frogs, and they co-occurred at only 3 sites (Ibid.). In 1992, Drost and Fellers (1996) revisited the sites around Yosemite National Park (Tuolumne and Mariposa counties) that Grinnell and Storer (1924) surveyed in 1915 and 1919. Foothill Yellow-legged Frogs had disappeared from all seven historically occupied sites and were not found at any new sites surveyed surrounding the park (Ibid.). Resurveys of previously occupied sites on the Stanislaus (Tuolumne County), Sierra (Fresno County), and Sequoia (Tulare County) National Forests were also undertaken (Lind et al. 2003b). Foothill Yellow-legged Frogs were absent from the sites in Sierra and Sequoia National Forests, six at each forest; however, a new population was discovered in the Sierra and two in the Sequoia forests (Ibid.). These populations remain extant but are small and isolated (CNDDB 2019). Two of the six sites on the Stanislaus were still occupied, and 19 new populations were found with evidence of breeding at seven of them (Lind et al. 2003b). Twenty of the 24 populations extant at the time inhabited unregulated waterways (Ibid.). Most of the CNDDB (2019) records of Foothill Yellow-legged Frogs on the Stanislaus are at least a decade old and are represented by low numbers.

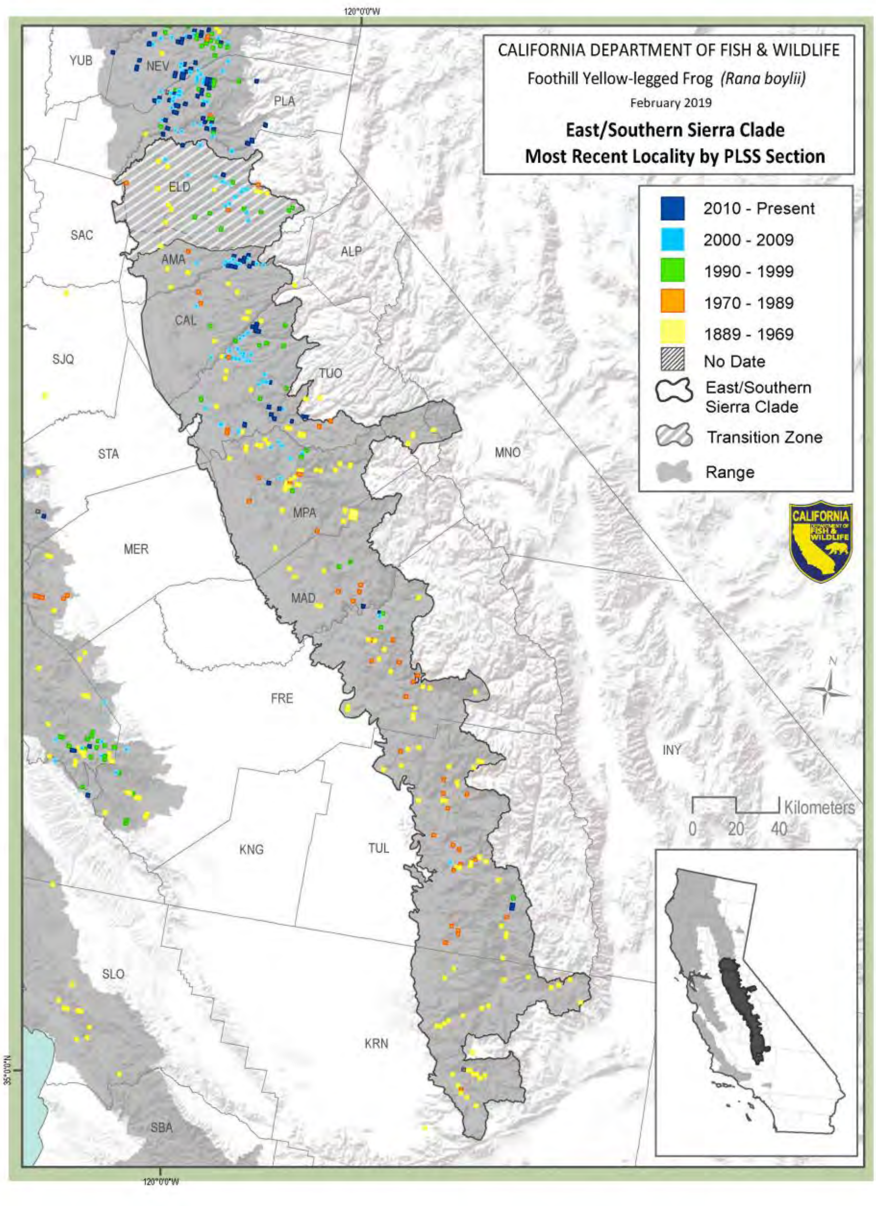

Figure 14. Close-up of East/Southern Sierra clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

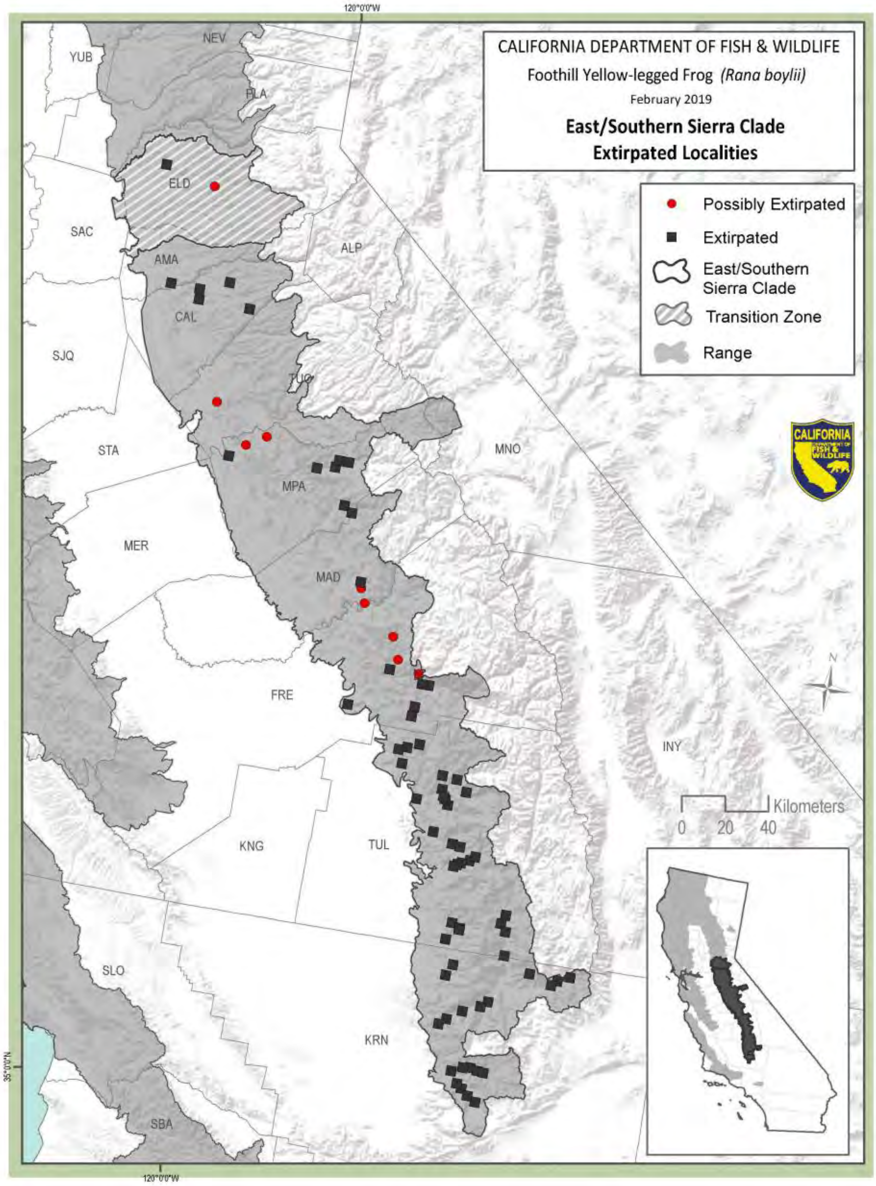

Figure 15. Possibly extirpated and extirpated East/Southern Sierra Foothill Yellow-legged Frog clade sites (CNDDB)

More recently, surveys for Foothill Yellow-legged Frogs were conducted along the South Fork American River as part of the El Dorado Hydroelectric Project's FERC license amphibian monitoring requirements (GANDA 2017). Between 2002 and 2016 counts of different life stages varied significantly by year but the trend for every life stage was a decline over that period (Ibid.). There appears to be a small population persisting along the North Fork Mokelumne River (Amador and Calaveras counties), but it was only productive during the 2012-2014 drought years (Ibid.). Small numbers have also been observed recently in several locations on private timberlands in Tuolumne County (CNDDB 2019).

FACTORS AFFECTING ABILITY TO SURVIVE AND REPRODUCE

"The fortunes of the boylii *population fluctuate with those of the stream"* - Tracy I. Storer, 1925

Several past and ongoing activities have changed the watersheds upon which Foothill Yellow-legged Frogs depend, and many interact with each other exacerbating their adverse impacts. With such an expansive range in California, the degree and severity of these impacts on the species often vary by location. To the extent feasible based on the best scientific information available, those differences are discussed below.

Dams, Diversions, and Water Operations

Foothill Yellow-legged Frogs evolved in a Mediterranean climate with predictable cool, wet winters and hot, dry summers, ~~with~~ and their life cycle is adapted to these conditions. In California and other areas with a Mediterranean climate, human demands for water are at the highest when runoff and precipitation are lowest, and annual water supply varies significantly but always follows the general pattern of peak discharge declining to baseflow in the late spring or summer (Grantham et al. 2010). The Foothill Yellow-legged Frog's life cycle depends on this discharge pattern and the specific habitat conditions it produces (see the Breeding and Rearing Habitat section). Dams are ubiquitous, but not evenly distributed, in California. Figure 16 depicts the locations of dams under the jurisdiction of the Army Corps of Engineers (ACOE) and the California Department of Water Resources (DWR). Figure 17 depicts the number of surface diversions per PLSS section within the Foothill Yellow-legged Frog's range (eWRIMS 2019).

Dam operations frequently change the amount and timing of water availability; its temperature, depth, and velocity; and its sediment transport and channel morphology altering functions, which can result in dramatic consequences ~~on~~ for the Foothill Yellow-legged Frog's ability to survive and successfully reproduce. Several studies comparing Foothill Yellow-legged Frog populations in regulated and unregulated reaches within the same watershed investigate potential dam-effects. These studies demonstrated that dams and their operations can result in several factors that contribute to population declines and possible extirpation. These factors include confusing breeding cues, scouring and stranding of egg masses and tadpoles, reduced quality and quantity of breeding and rearing habitat, reduced tadpole growth rate, barriers to gene flow, and establishment and spread of non-native species (Hayes et al. 2016). In addition, as previously discussed in the Population Structure and Genetic Diversity section, subpopulations of Foothill Yellow-legged Frogs on regulated rivers are more isolated, and the

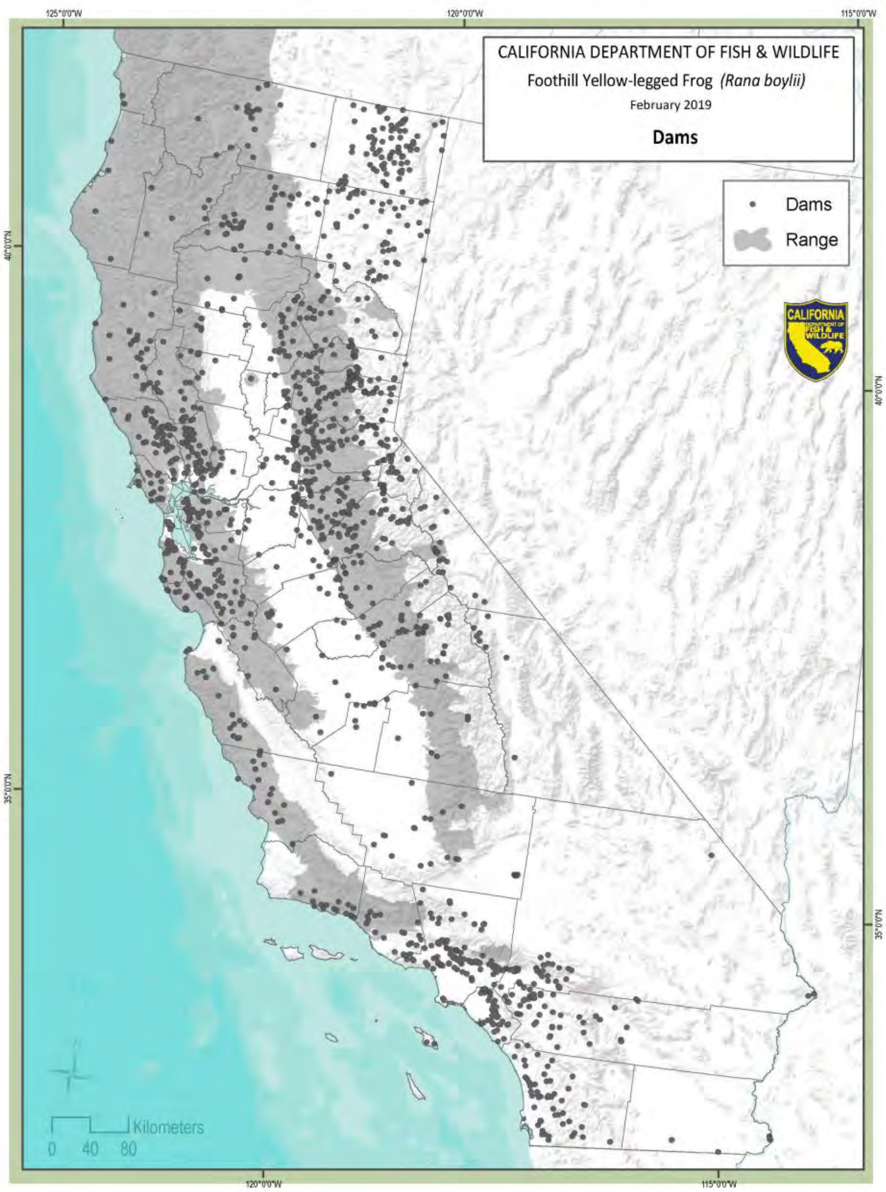

Figure 16. Locations of ACOE and DWR jurisdictional dams (DWR, FRS)

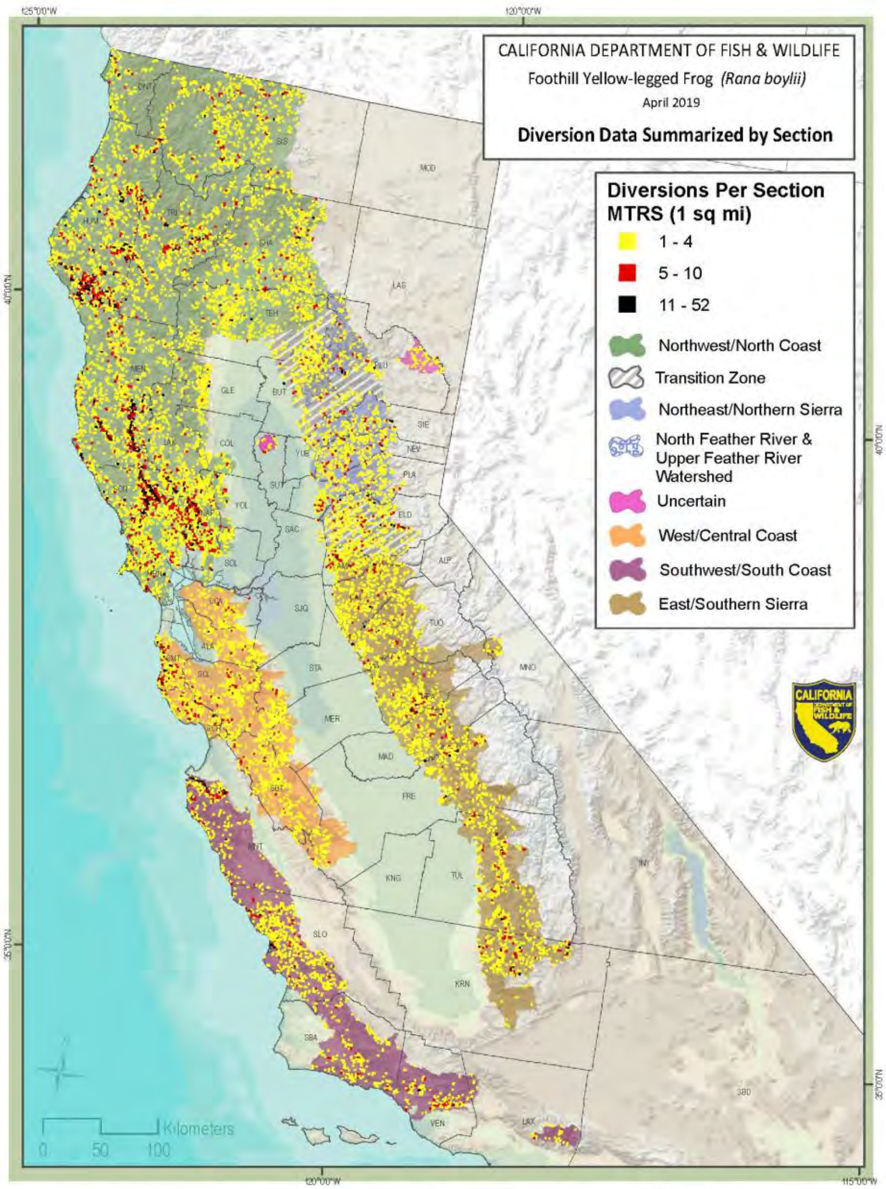

Figure 17. Number of surface water diversions per Public Lands Survey System section within the Foothill Yellow-legged Frog's range in California (eWRIMs)

type of water operations (hydropeaking vs. bypass flows) significantly affects the degree of gene flow loss among them (Peek 2011, 2018). Figure 18 depicts the locations of hydroelectric power plants.

As discussed in the Seasonal Activity and Movements section, cues for Foothill Yellow-legged Frogs to start breeding appear to involve water temperature and velocity, two features altered by dams. Dam operations typically result in reduced flows that are more stable over the course of a year than unimpaired conditions, and dam managers are frequently required to maintain thermally appropriate water temperatures and flows for cold-water-adapted salmonids (USFWS and Hoopa Valley Tribe 1999, Wheeler et al. 2014). For example, late-spring and summer water temperatures on the mainstem Trinity River below Lewiston Dam have been reported to be up to 10°C (20°F) cooler than average pre-dam temperatures, while average winter temperatures are slightly warmer (USFWS and Hoopa Valley Tribe 1999). As a result, Foothill Yellow-legged Frogs breed later on the mainstem Trinity River compared to six nearby tributaries, and some mainstem reaches may never attain the minimum required temperature for breeding (Wheeler et al. 2014, Snover and Adams 2016). In addition, annual discharges past Lewiston Dam have been 10-30% of pre-dam flows and do not mimic the natural hydrograph (Lind et al. 1996).

Aseasonal discharges from dams occur for several reasons including increased flow in late-spring and early summer to facilitate outmigration of salmonids, channel maintenance pulse flows, short-duration releases for recreational whitewater boating, rapid reductions after a spill (uncontrolled flows released down a spillway when reservoir capacity is exceeded) to retain water for power generation or water supply later in the year, peaking flows for hydroelectric power generation, and sustained releases to maintain the seismic integrity of the dam (Lind et al. 1996, Jackman et al. 2004, Kupferberg et al. 2011b, Kupferberg et al. 2012, Snover and Adams 2016). The results of a Foothill Yellow-legged Frog population viability analysis (PVA) suggest that the likelihood a population will persist is very sensitive to early life stage mortality; the 30-year probability of extinction increases significantly with high levels of egg or tadpole scouring or stranding (Kupferberg et al. 2009c). For instance, in 1991 and 1992, all egg masses laid before high flow releases to encourage outmigration of salmonids on the Trinity River were scoured away (Lind et al. 1996). According to the PVA, even a single annual pulse flow such as this or for recreational boating, can result in a three- to five-fold increase in the 30-year extinction risk based on amount of tadpole mortality experienced (Kupferberg et al. 2009c). Management after natural spills can also lead to substantial mortality. For example, in 2006, Foothill Yellow-legged Frogs on the North Fork Feather River bred during a prolonged spill, and the rapid recession below Cresta Dam that followed stranded and desiccated all the eggs laid (Kupferberg et al. 2009b). Rapid flows can also increase predation risk if tadpoles are forced to seek shelter under rocks where crayfish and other invertebrate predators are more common or if they are displaced into the water column where their risk of predation by fish is greater (Ibid.).

The overall reduction of flows and frequency of large winter floods below dams can produce extensive changes to Foothill Yellow-legged Frog habitat quality. They reduce the formation of river bars that are regularly used as breeding habitat, and they create deeper and steeper channels with less complexity and fewer warm, calm, shallow edge-water habitats for tadpole rearing (Lind et al. 1996, Wheeler and Welsh 2008, Kupferberg et al. 2011b, Wheeler et al. 2014). For example, 26 years after construction of

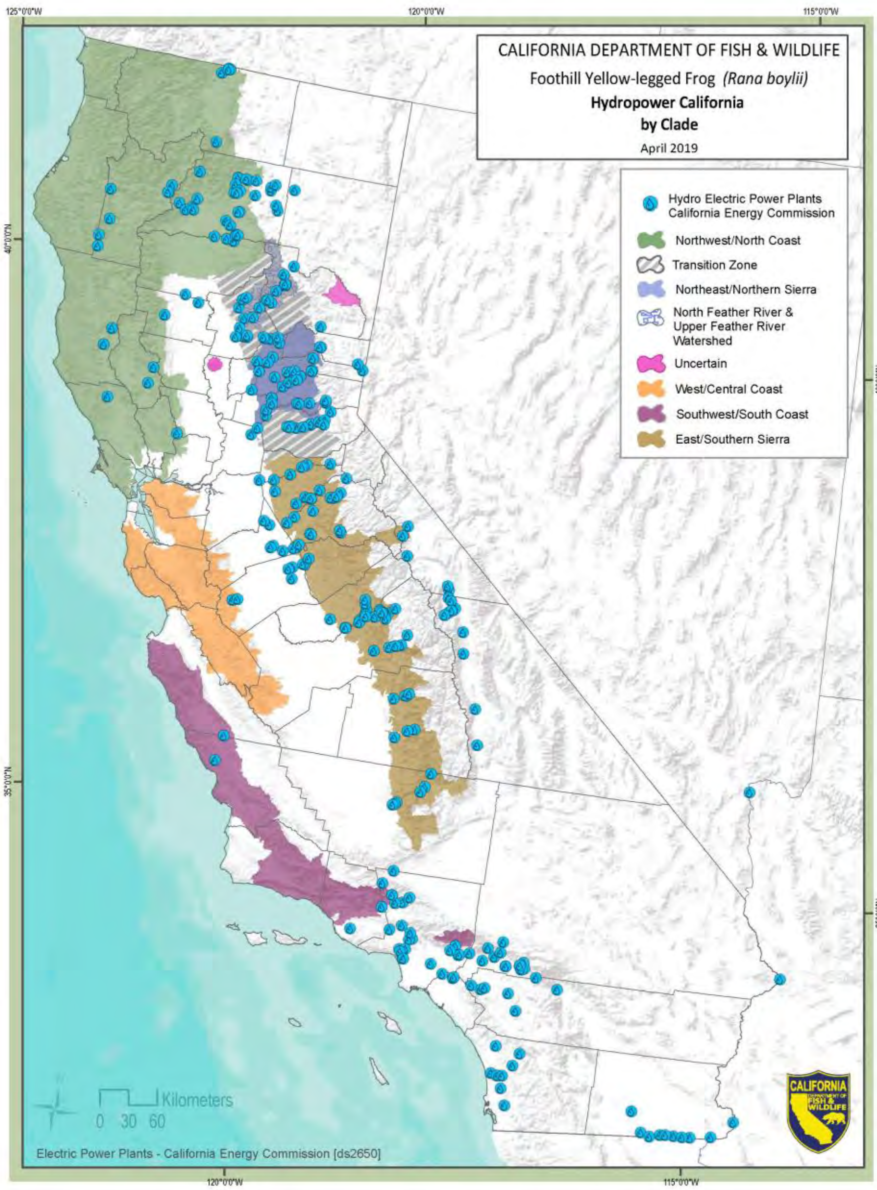

Figure 18. Locations of hydroelectric power generating dams (BIOS)

the Lewiston Dam on the Trinity River, habitat changes in a 63 km (39 mi) stretch from the dam downstream were evaluated (Lind et al. 1996). Riparian vegetation went from covering 30% of the riparian area pre-dam to 95% (Ibid.). Additionally, river bars made up 70% of the pre-dam riparian area compared to 4% post-dam, amounting to a 94% decrease in available Foothill Yellow-legged Frog breeding habitat (Ibid.).

Several features of riverine habitat below dams can decrease tadpole growth rate and other measures of fitness. As ectotherms, Foothill Yellow-legged Frogs require temperatures that support their metabolism, food conversion efficiency, growth, and development, and these temperatures may not be reached until late in the season, or not at all, when the water released is colder than their lower thermal limit (Kupferberg et al. 2011a, Catenazzi and Kupferberg 2013, Wheeler et al. 2014). Colder temperatures and higher flows reduce time spent feeding and efficiency at food assimilation, resulting in slower growth and development (Kupferberg et al. 2011a,b; Catenazzi and Kupferberg 2018). Large bed-scouring winter floods promote greater *Cladophora glomerate* blooms, the filamentous green alga that dominates primary producer biomass during the tadpole rearing season (Power et al. 2008, Kupferberg et al. 2011a). The period of most rapid tadpole growth often coincides with blooms of highly nutritious and more easily assimilated epiphytic diatoms, so reduced flows can have food-web impacts on tadpole growth and survival (Power et al. 2008, Kupferberg et al. 2011a, Catenazzi and Kupferberg 2018). In addition, colder temperatures and fluctuating summer flows, such as those released for hydroelectric power generation, can reduce the amount of algae available for grazing and can change the algal assemblage to one dominated by mucilaginous stalked diatoms like *Didymosphenia geminate* that have low nutritional value (Spring Rivers Ecological Sciences 2003, Kupferberg et al 2011a, Furey et al. 2014). Altered temperatures, flows, and food quality can contribute to slower growth and development, longer time to metamorphosis, smaller size at metamorphosis, and reduced body condition, which adversely impact fitness (Kupferberg et al. 2011b, Catenazzi and Kupferberg 2018).

As discussed in more detail in the Population Structure and Genetic Diversity section, both are strongly affected by river regulation (Peek 2011, 2018; Stillwater Sciences 2012). Foothill Yellow-legged Frogs primarily use watercourses as movement corridors, so the reservoirs created behind dams are often uninhabitable and represent barriers to gene flow (Bourque 2008; Peek 2011, 2018). This decreased connectivity can lead to loss of genetic diversity, ~~inducing~~ reducing a species' ability to adapt to changing conditions (Palstra and Ruzzante 2008).

Decreased winter discharge below dams facilitates establishment and expansion of invasive bullfrogs, whose tadpoles require overwintering and are not well-adapted to flooding events (Lind et al. 1996, Doubledee et al. 2003). Where they occur, bullfrogs tend to dominate areas more altered by dam operations than less impaired areas that support a higher proportion of native species (Moyle 1973, Fuller et al. 2011). In addition to downstream effects, the reservoirs created behind dams directly destroy lotic (flowing) Foothill Yellow-legged Frog habitat, typically do not retain natural riparian communities due to fluctuating water levels, are often managed for human activities not compatible with the species' needs, and act as a source of introduced species upstream and downstream (Brode and Bury 1984, PG&E 2018). Moyle and Randall (1998) identified characteristics of sites with low native biodiversity in the Sierra Nevada foothills; they were often drainages that had been dammed and

diverted in lower- to middle-elevations and dominated by introduced fishes and bullfrogs. Even small-scale operations can have significant effects. Some farming operations divert water during periods of high flows and store it in small impoundments for use during low flow-high need times; these ponds can serve as sources for introduced species like bullfrogs to spread into areas where the habitat would otherwise be unsuitable (Kupferberg 1996b).

The mechanisms described above result in the widespread pattern of greater Foothill Yellow-legged Frog density in unregulated rivers and in reaches far enough downstream of a dam to experience minimal effects from it (Lind et al. 1996, Kupferberg 1996a, Bobzien and DiDonato 2007, Peek 2011). Abundance in unregulated rivers averages five times greater than population abundance downstream of large dams (Kupferberg et al. 2012). Figure 19 depicts a comprehensive collection of egg mass density data where at least four years of surveys have been undertaken, showing much lower abundance in regulated rivers (S. Kupferberg pers. comm. 2019). In California, Foothill Yellow-legged Frog presence is associated with an absence of dams or with only small dams far upstream (Lind 2005, Kupferberg et al. 2012). Hydroelectric power generation from Sierra Nevada rivers accounts for nearly half its statewide production and about 9% of all electrical power used in California (Dettinger et al. 2018). Every major stream below 600 m (1968 ft) in the Sierra Nevada has at least one large reservoir (≥ 0.12 km^3 [100,000 ac-ft]), and many have multiple medium and small ones (Hayes et al. 2016). Because of this, Catenazzi and Kupferberg (2017) posit that the dam-effect on Foothill Yellow-legged Frog populations is likely greater in the Sierra Nevada than the Coast Range because dams are more often constructed in a series along a river in the former and spaced close enough together such that suitable breeding temperatures may never occur in the intervening reaches.

Pathogens and Parasites

Perhaps the most widely recognized amphibian disease is chytridiomycosis, which is caused by the fungal pathogen *Batrachochytrium dendroabatidis* (Bd). Implicated in the decline of over 500 amphibian species, including 90 presumed extinctions, it represents the greatest recorded loss of biodiversity attributable to a disease (Scheele et al. 2019). The global trade in American Bullfrogs (primarily for food) is connected to the disease's spread because the species can persist with low-level Bd infections without developing chytridiomycosis (Yap et al. 2018). Previous studies suggested Foothill Yellow-legged Frogs may not be susceptible to Bd-associated mass mortality; skin peptides strongly inhibited growth of the fungus in the lab, and the only detectable difference between Bd+ and Bd- juvenile Foothill Yellow-legged Frogs was slower growth (Davidson et al. 2007). At Pinnacles National Park in 2006, 18% of post-metamorphic Foothill Yellow-legged Frogs tested positive for Bd; all were asymptomatic and at least one Bd+ Foothill Yellow-legged Frog subsequently tested negative, demonstrating an ability to shed the fungus (Lowe 2009). However, recent studies have found historical evidence of Bd contributing to the extirpation of Foothill Yellow-legged Frogs in southern California, an acute die-off in 2013 in the Alameda Creek watershed, and another in 2018 in Coyote Creek (Adams et al. 2017a,b; Kupferberg and Catenazzi 2019). Evaluation of museum specimens indicates lower Bd prevalence (proportion of individuals infected) in Foothill Yellow-legged Frogs than most other co-occurring amphibians in southern California in the first part of the 20th century, but it spiked in the 1970s just prior to the last observation of an individual in 1977 (Adams et al. 2017b). Two museum specimens collected in 1966,

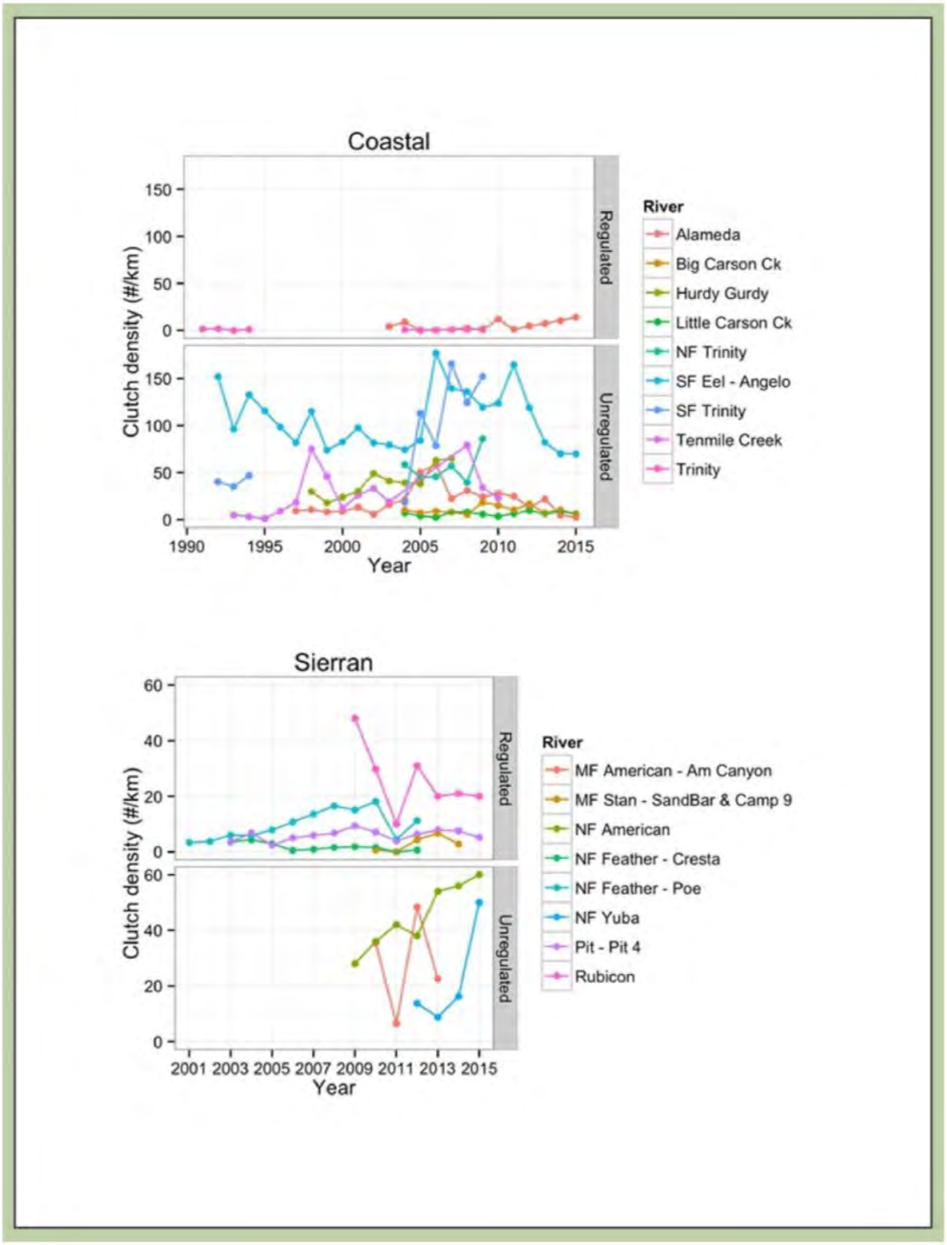

Figure 19. Foothill Yellow-legged Frog Egg mass density estimates along the coast from 1990-2015 and the Sierra Nevada from 2001-2015 from multiple studies compiled by S. Kupferberg (2019)

one from Santa Cruz County and the other from Alameda County, provide the earliest evidence of Bd in Foothill Yellow-legged Frogs in central California (Padgett-Flohr and Hopkins 2009). In contrast to the southern California results, Foothill Yellow-legged Frogs possessed the highest Bd prevalence among all amphibians tested in coastal Humboldt County in 2013 and 2014; however, zoospore (the aquatic dispersal agent) loads were well below the presumed lethal density threshold (Ecoclub Amphibian Group et al. 2016).

In addition to bullfrogs, the native Pacific Treefrog (~~*Pseudacris*~~ *Hyliola* ***regilla***) seems immune to the lethal effects of chytridiomycosis, and owing to its broad ecological tolerances, more terrestrial lifestyle, and relatively large home range size and dispersal ability, the species is ubiquitous across California (Padgett-Flohr and Hopkins 2009). In a laboratory experiment, Bd-infected Pacific Treefrogs shed an average of 68 zoospores per minute, making them the prime candidate for spreading and maintaining Bd in areas where bullfrogs do not occur (Padgett-Flohr and Hopkins 2009, Reeder et al. 2012). In the wild, Pacific Treefrog populations persisted at 100% of sites in the Sierra Nevada (above 1500 m [4920 ft]) where a sympatric ranid species had been extirpated from 72% of its formerly occupied sites due to a Bd outbreak (Reeder et al. 2012). This is consistent with the results of a model that incorporated Bd habitat suitability, host availability, and invasion history in North America, which concluded west coast mountain ranges were at the greatest risk from the disease (Yap et al. 2018).

Several other pathogens and parasites have been encountered with Foothill Yellow-legged Frogs, but none have been ascribed to large-scale mortality events. Another fungus, a water mold (*Saprolegnia* sp.) carried by fish, is an important factor in amphibian embryo mortality in the Pacific Northwest (Blaustein et al. 1994, Kiesecker and Blaustein 1997). Fungal infections of Foothill Yellow-legged Frog egg masses, potentially from *Saprolegnia*, have been observed in the mainstem Trinity River (Ashton et al. 1997). *Saprolegnia* infection is more likely to occur in ponds and lakes, particularly if stocked by hatchery-raised fish into previously fishless areas and when frogs use communal oviposition sites, so it likely does not represent a major source of mortality in Foothill Yellow-legged Frogs (Blaustein et al. 1994, Kiesecker and Blaustein 1997). However, they may be more susceptible to *Saprolegnia* infection when exposed to other environmental stressors that compromise their immune defenses (Blaustein et al. 1994, Kiesecker and Blaustein 1997).

The trematode parasite *Ribeiroia ondatrae* is responsible for limb malformations in ranids (Stopper et al. 2002). *Ribeiroia ondatrae* was detected on a single Foothill Yellow-legged Frog during a study on malformations, but its morphology was normal (Kupferberg et al. 2009a). The results of the study instead linked malformations in Foothill Yellow-legged Frog tadpoles and young-of-year to the Anchor Worm (*Lernae cyprinacea*), a parasitic copepod from Eurasia (Ibid.). Prevalence of malformations was low, under 4% of the population in both years of study, but there was a pattern of infected individuals metamorphosing at a smaller size, which as previously mentioned can have implications on fitness (Ibid.). Three other species of helminths (parasitic worms) were encountered during the study (*Echinostoma* sp., *Manodistomum* sp., and *Gyrodactylus* sp.); their relative impact on their hosts is unknown, but at least one Foothill Yellow-legged Frog had 700 echinstome cysts in its kidney (Ibid.). Bursey et al. (2010) discovered 13 species of helminths in and on Foothill Yellow-legged Frogs from

Humboldt County. Most are common in anurans, and some are generalists with multiple possible hosts, but studies on their impact on Foothill Yellow-legged Frogs are lacking (Ibid.).

Introduced Species

Species not native to an area, but introduced, can alter food webs and ecosystem processes through predation, competition, hybridization, disease transmission, and habitat modification. Native species lack evolutionary history with introduced species, and early life stages of native anurans are particularly susceptible to predation by aquatic non-native species (Kats and Ferrer 2003). Because introduced species often establish in highly modified habitats, it can be difficult to differentiate between impacts from habitat degradation and the introduced species (Fisher and Shaffer 1996). However, native amphibians have been frequently found successfully reproducing in heavily altered habitats when introduced species were absent, suggesting introduced species themselves can impose an appreciable adverse effect (Ibid.). Numerous introduced species have been documented to adversely impact Foothill Yellow-legged Frogs or are suspected of doing so.

American Bullfrogs were introduced to California from the eastern U.S. around the turn of the 20th century, likely in response to overharvest of native ranids by the frog-leg industry that accompanied the Gold Rush (Jennings and Hayes 1985). Nearly 50 years ago, Moyle (1973) reported that distributions of Foothill Yellow-legged Frogs and bullfrogs in the Sierra Nevada foothills were nearly mutually exclusive. He speculated that bullfrog predation and competition may be causal factors in their disparate distributions in addition to the habitat degradation from dams and diversions that facilitated the bullfrog invasion in the first place. In a study along the South Fork Eel River and one of its tributaries, Foothill Yellow-legged Frog abundance was nearly an order of magnitude lower in reaches were bullfrogs were well established (Kupferberg 1997a). At a site in Napa Valley, after bullfrogs were eradicated, Foothill Yellow-legged Frogs, among other native species, recolonized the area (J. Alvarez pers. comm. 2018). In a mesocosm experiment, Foothill Yellow-legged Frog survival in control enclosures measured half that of enclosures containing bullfrog and Foothill Yellow-legged Frog tadpoles, and they weighed approximately one-quarter lighter at metamorphosis (Kupferberg 1997a). The mechanism for these declines appeared to be the reduction of high quality algae by bullfrog tadpole grazing, as opposed to any behavioral or chemical interference (Ibid.). Adult bullfrogs, which can get very large (9.0-15.2 cm [3.5-6.0 in]), also directly consume Foothill Yellow-legged Frogs, including adults (Moyle 1973, Crayon 1998, Powell et al. 2016). Silver (2017) noted that she never heard Foothill Yellow-legged Frogs calling in areas with bullfrogs, which has implications for breeding success; she speculated the lack of vocalizations may have been a predator avoidance strategy.

As discussed briefly in the Pathogens and Parasites section, American Bullfrogs act as reservoirs and vectors of the lethal chytrid fungus. In museum specimens from both southern and central California, Bd was detected in bullfrogs before it was detected in Foothill Yellow-legged Frogs in the same area (Padgett-Flohr and Hopkins 2009, Adams et al. 2017b). During a die-off from chytridiomycosis that commenced in 2013, Bd prevalence and load in Foothill Yellow-legged Frogs was positively predicted by bullfrog presence (Adams et al. 2017a). A similar die-off in 2018 from a nearby county appears to be related to transmission by bullfrogs as well (Kupferberg and Catenazzi 2019). In addition, male Foothill

Yellow-legged Frogs have been observed amplexing female bullfrogs, which may not only constitute wasted reproductive effort but could serve to increase their likelihood of contracting Bd (Lind et al. 2003a). In fact, adult males were more likely to be infected with Bd than females or juveniles during the recent die-off in Alameda Creek (Adams et al. 2017a). African Clawed Frogs (*Xenopus laevis*) have also been implicated in the spread of Bd in California because like bullfrogs, they are asymptomatic carriers (Padgett-Flohr and Hopkins 2009). However, African Clawed-Frog distribution only minimally overlaps with the Foothill Yellow-legged Frog's range unlike the widespread bullfrog (Stebbins and McGuinness 2012).

Hayes and Jennings (1986) observed a negative association between the abundance of introduced fish and Foothill Yellow-legged Frogs. Rainbow trout (*Onchorynchus mykiss*) and green sunfish (*Lepomis cyanellus*) are suspected of destroying egg masses (Van Wagner 1996). Bluegill sunfishes (*L. macrochirus*) are likely predators; in captivity when offered eggs and tadpoles of two ranid species, they consumed both life stages but a significantly greater number of tadpoles (Werschkul and Christensen 1977). Common hatchery-stocked fish like brook (*Salvelinus fontinalis*) and rainbow trout commonly carry of *Saprolegnia* (Blaustein et al. 1994). In addition, presence of non-native fish can facilitate bullfrog invasions by reducing the density of macroinvertebrates that prey on their tadpoles (Adams et al. 2003). Foothill Yellow-legged Frog tadpoles raised from eggs from sites with and without smallmouth bass (*Micropterus dolomieu*) did not differ in their responses to exposure to the non-native, predatory bass and a native, non-predatory fish (Paoletti et al. 2011). This result suggests that Foothill Yellow-legged Frogs have not yet evolved a recognition of bass as a threat, which makes them more vulnerable to predation (Ibid.).

Introduced into several areas within the Coast Range and Sierra Nevada, signal crayfish have been recorded preying on Foothill Yellow-legged Frog egg masses and are suspected of preying on their tadpoles based on observations of tail injuries that looked like scissor snips (Riegel 1959, Wiseman et al. 2005). The introduced red swamp crayfish (*Procambarus clarkii*) likely also preys on Foothill Yellow-legged Frogs. Because Foothill Yellow-legged Frogs evolved with native crayfish in northern California, individuals from those areas may more effectively avoid crayfish predation than in other parts of the state where they are not native (Riegel 1959, USFWS 1998, Kats and Ferrer 2003). The Foothill Yellow-legged Frog's naivety to crayfish was demonstrated in a study that showed they did not change behavior when exposed to signal crayfish chemical cues, but once the crayfish was released and consuming Foothill Yellow-legged Frog tadpoles, the survivors, likely reacting to chemical cues from dead tadpoles, did respond (Kerby and Sih 2015).

Sedimentation

Several anthropogenic activities, some of which are described in greater detail below, can artificially increase sedimentation into waterways occupied by Foothill Yellow-legged Frogs and adversely impact biodiversity (Moyle and Randall 1998). These activities include but are not limited to mining, agriculture, overgrazing, timber harvest, and poorly constructed roads (Ibid.). Increased fine sediments can substantially degrade Foothill Yellow-legged Frog habitat quality. Heightened turbidity decreases light penetration that phytoplankton and other aquatic plants require for photosynthesis (Cordone and Kelley

1961). When silt particles fall out of the water column, they can destroy algae by covering the bottom of the stream (Ibid.). Algae are not only important for Foothill Yellow-legged Frog tadpoles as forage but also oxygen production (Ibid.). Sedimentation may impede attachment of egg masses to substrate (Ashton et al. 1997). The effect of silt accumulation on embryonic development is unknown, but it does make them less visible, which could decrease predation risk (Fellers 2005). Fine sediments can fill interstitial spaces between rocks that tadpoles use for shelter from high velocity flows and cover from predators and that serve as sources for aquatic invertebrate prey for post-metamorphic Foothill Yellow-legged Frogs (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b).

Mining

Current mining practices, as well as legacy effects from historical mining operations, may adversely impact Foothill Yellow-legged Frogs through contaminants, direct mortality, habitat destruction and degradation, and behavioral disruption. While mercury in streams can result from atmospheric deposition, storm-induced runoff of naturally occurring mercury, agricultural runoff, and geothermal springs, runoff from historical mine sites mobilizes a significant amount of mercury (Foe and Croyle 1998, Alpers et al. 2005, Hothem et al. 2010). Beginning in the mid-1800s, extensive mining occurred in the Coast Range to supply mercury for gold mining in the Sierra Nevada, causing widespread contamination of both mountain ranges and the rivers in the Central Valley (Foe and Croyle 1998). Studies on Foothill Yellow-legged Frog tissues collected from the Cache Creek (Coast Ranges) and Greenhorn Creek (Sierra Nevada) watersheds revealed mercury bioaccumulation concentrations as high as 1.7 and 0.3 µg/g (ppm), respectively (Alpers et al. 2005, Hothem et al. 2010). For context, the U.S. Environmental Protection Agency's mercury criterion for issuance of health advisories for fish consumption is 0.3 µg/g; concentrations exceeded this threshold in Foothill Yellow-legged Frog tissues at 62% of sampling sites in the Cache Creek watershed (Hothem et al. 2010). Bioaccumulation of this powerful neurotoxin can cause deleterious impacts on amphibians including inhibited growth, decreased survival to metamorphosis, increased malformations, impaired reproduction, and other sublethal effects (Zillioux et al. 1993, Unrine et al. 2004). In a study measuring Sierra Nevada watershed health, Moyle and Randall (1998) reportedly found very low biodiversity in streams that were heavily polluted by acidic water leaching from historical mines. Acidic drainage measured as low as pH 3.4 ~~pH~~ from some mined areas in the northern Sierra Nevada (Alpers et al. 2005).

Widespread suction dredging for gold occurred in the Foothill Yellow-legged Frog's California range until enactment of a moratorium on issuing permits in 2009 (Hayes et al. 2016). Suction dredging vacuums up the contents of the streambed, passes them through a sluice box to separate the gold, and then deposits the tailings on the other side of the box (Harvey and Lisle 1998). While most habitat disturbance is localized and minor, it can be especially detrimental if it degrades or destroys breeding and rearing habitat through direct disturbance or sedimentation (Ibid.). In addition, this activity can lead to direct mortality of early life stages through entrainment, and those eggs and tadpoles that do survive passing through the suction dredge may experience greater mortality due to subsequent unfavorable physiochemical conditions and possible increased predation risk (Ibid.). Suction dredging can also reduce the availability of invertebrate prey, although this impact is typically short-lived (Ibid.). Suction dredging alters stream morphology, and relict tailing ponds can serve as breeding habitat for bullfrogs in areas

that would not normally support them (Fuller et al. 2011). However, in some areas these mining holes have reportedly benefited Foothill Yellow-legged Frogs by creating cool persistent pools that adult females appeared to prefer at one Sierra Nevada site (Van Wagner 1996). Senate Bill 637 (2015) directs the Department to work with the State Water Resources Control Board (SWRCB) to develop a statewide water quality permit that would authorize the use of vacuum or suction dredge equipment in California under conditions set forth by the two agencies. SWRCB staff, in coordination with Department staff, are in the process of collecting additional information to inform the next steps that will be taken by the SWRCB (SWRCB 2019).

Instream aggregate (gravel) mining continues today and can have similar impacts to suction dredge mining by removing, processing, and relocating stream substrates (Olson and Davis 2009). This type of mining typically removes bars used as Foothill Yellow-legged Frog breeding habitat and reduces habitat heterogeneity by creating flat wide channels (Kupferberg 1996a). Typically when listed salmonids are present, mining must be conducted above the wetted edge, but this practice can create perennial off-channel bullfrog breeding ponds (M. van Hattem pers. comm. 2018).

Agriculture

Direct loss of Foothill Yellow-legged Frog habitat from wildland conversion to agriculture is rare because the typically rocky riparian areas they inhabit are usually not conducive to farming, but removal of riparian vegetation directly adjacent to streams for agriculture is more common and widespread. The U.S. Department of Agriculture classifies 3.9 million ha (9.6 million ac) in California as cropland, which amounts to less than 10% of the state's land area, and 70% of this occurs in the Central Valley between Redding and Bakersfield (Martin et al. 2018). In addition, several indirect impacts can adversely affect Foothill Yellow-legged Frogs at substantial distances from agricultural operations such as effects from runoff (sediments and agrochemicals), drift and deposition of airborne pollutants, water diversions, and creation of novel habitats like impoundments that facilitate spread of detrimental non-native species. As sedimentation and introduced species impacts were previously discussed, this section instead focuses on the other possible adverse impacts.

Agrochemicals

Many species of amphibians, particularly ranids, have experienced declines throughout California, but the most dramatic declines have occurred in the Sierra Nevada east of the San Joaquin Valley where 60% of the total pesticide usage in the state was sprayed (Sparling et al. 2001). Agrochemicals applied to crops in the Central Valley can volatilize and travel in the atmosphere and deposit in higher elevations (LeNoir et al. 1999). Pesticide concentrations diminish as elevations increase in the lower foothills but change little from 533 to 1,920 m (1,750-6,300 ft), which coincides with the Foothill Yellow-legged Frog's elevational range (Ibid). Foothill Yellow-legged Frog absence at historically occupied sites in California significantly correlated with agricultural land use within 5 km (3 mi), and a positive relationship exists between Foothill Yellow-legged Frog declines and the amount of upwind agriculture, suggesting airborne agrochemicals may be a contributing factor (Figure 20; Davidson et al. 2002). Cholinesterase-inhibitors (most organophosphates and carbamates), which disrupt nerve impulse transmission, were

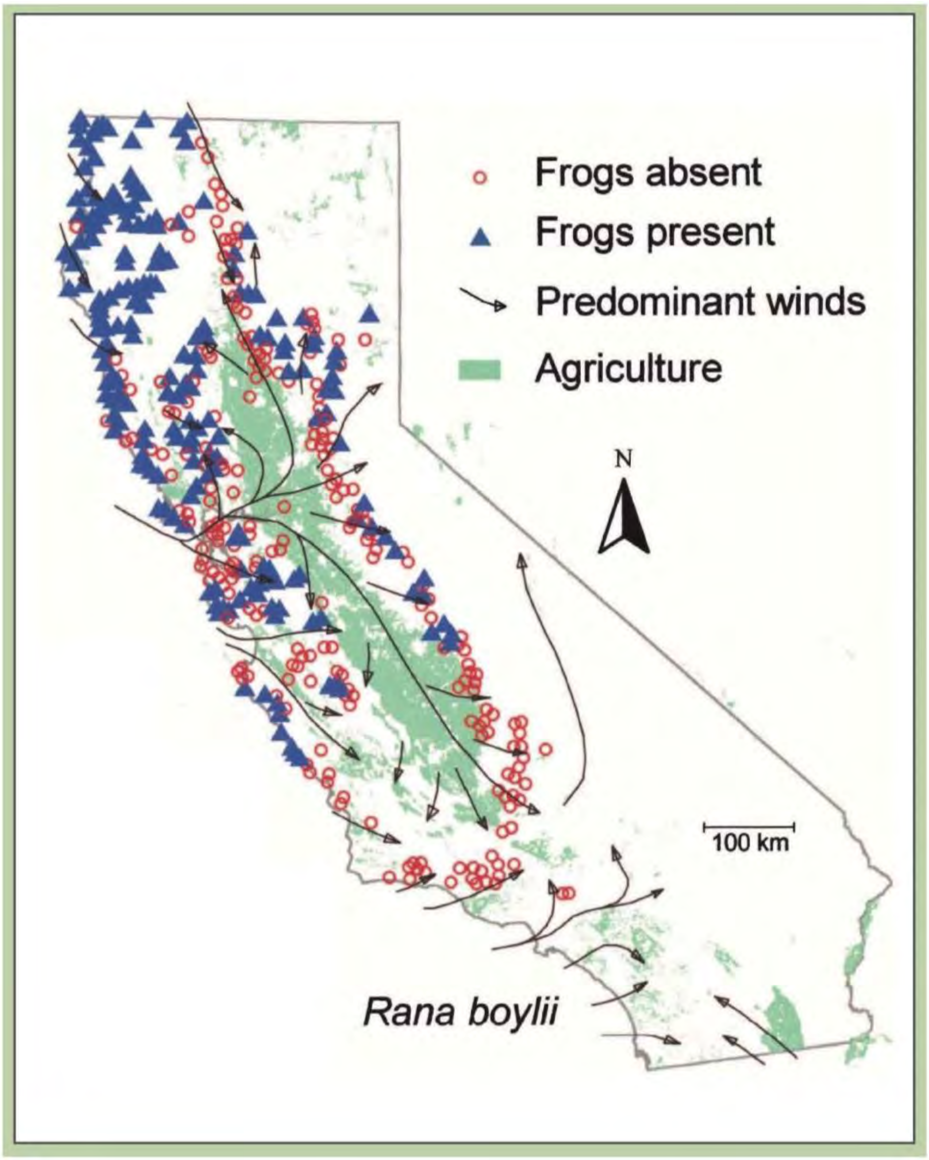

Figure 20. Relationship of Foothill Yellow-legged Frog occupancy to agriculture from Davidson et al. (2002)

more strongly associated with population declines than other pesticide types (Davidson 2004). Olson and Davis (2009) and Lind (2005) also reported a negative correlation between Foothill Yellow-legged Frog presence and proximity and quantity of nearby agriculture in Oregon and across the species' entire range, respectively.

Lethal and sublethal effects of agrochemicals on amphibians can take two general forms: direct toxicity and food-web effects. Sublethal doses of agrochemicals can interact with other environmental stressors to reduce fitness. Foothill Yellow-legged Frog tadpoles showed significantly greater vulnerability to the lethal and sublethal effects of carbaryl than Pacific Treefrogs (Kerby and Sih 2015). An inverse relationship exists between carbaryl concentration and Foothill Yellow-legged Frog activity, and their 72-h LC_{50} (concentration at which 50% die) measured one-fifth that of Pacific Treefrogs (Ibid.). Carbaryl slightly decreased Foothill Yellow-legged Frog development rate, but it significantly increased susceptibility to predation by signal crayfish despite nearly no mortality in the pesticide- and predator-only treatments (Ibid.). Sparling and Fellers (2009) also found Foothill Yellow-legged Frogs were significantly more sensitive to pesticides (chlorpyrifos and endosulfan in this study) than Pacific Treefrogs; their 96-hr LC_{50} was nearly five-times less than for treefrogs. Endosulfan was nearly 121 times more toxic to Foothill Yellow-legged Frogs than chlorpyrifos, and water samples from the Sierra Nevada have contained endosulfan concentrations within their lethal range and sometimes greater than the LC_{50} for the species (Ibid.). Sublethal effects included smaller body size, slower development rate, and increased time to metamorphosis (Ibid.). Sparling and Fellers (2007) determined the organophospates chlorpyrifos, malathion, and diazinon can harm Foothill Yellow-legged Frog populations, and their oxon derivatives (the resultant compounds once they begin breaking down in the body) were 10 to 100 times more toxic than their respective parental forms.

Extrapolating the results of studies on other ranids to Foothill Yellow-legged Frogs should be undertaken with caution; however, those studies can demonstrate additional potential adverse impacts of exposure to agrochemicals. Relyea (2005) discovered that Roundup®, a common herbicide, could cause rapid and widespread mortality in amphibian tadpoles via direct toxicity, and overspray at the manufacturer's recommended application concentrations would be highly lethal. Atrazine, another common herbicide, has been implicated in disrupting reproductive processes in male Northern Leopard Frogs (*Rana pipiens*) by slowing gonadal development, inducing hermaphroditism, and even oocyte (egg) growth (Hayes et al. 2003). However, recent research on sex reversal in wild populations of Green Frogs (*R. clamitans*) suggests it may be a relatively common natural process unrelated to environmental contaminants, requiring more research (Lambert et al. 2019). Malathion, a common organophosphate insecticide, that rapidly breaks down in the environment, applied at low concentrations caused a trophic cascade that resulted in reduced growth and survival of two species of ranid tadpoles (Relyea and Diecks 2008). Malathion caused a reduction in the amount of zooplankton, which resulted in a bloom of phytoplankton and an eventual decline in periphyton, an important food source for tadpoles (Ibid.). In contrast, Relyea (2005) found that some insecticides increased amphibian tadpole survival by reducing their invertebrate predators. Runoff from agricultural areas can contain fertilizers that input nutrients into streams and increase productivity, but they can also result in harmful algal blooms (Cordone and

Kelley 1961). In addition, exposure to pesticides can result in immunosuppression and reduce resistance to the parasites that cause limb malformations (Kiesecker 2002, Hayes et al. 2006).

Cannabis

An estimated 60-70% of the cannabis (*Cannabis indica* and *C. sativa*) used in the U.S. from legal and illegal sources is grown in California, and most comes from the Emerald Triangle, an area comprised of Humboldt, Mendocino, and Trinity counties (Ferguson 2019). Small-scale illegal cannabis farms have operated in this area since at least the 1960s but have expanded rapidly, particularly trespass grows on public land primarily by Mexican cartels, since the passage of the Compassionate Use Act in 1996 (Mallery 2010, Bauer et al. 2015). Like other forms of agriculture, it involves clearing the land, diverting water, and using herbicides and pesticides; however, in addition, many of these illicit operations use large quantities of fertilizers and highly toxic banned pesticides to kill anything that may threaten the crop, and they leave substantial amounts of non-biodegradable trash and human excrement (Mallery 2010, Thompson et al. 2014, Carah et al. 2015).

Measurements of environmental impacts of illegal cannabis grows have been hindered by the difficult and dangerous nature of accessing many of these sites; however, some analyses have been conducted, often using aerial images and geographic information systems (GIS). An evaluation of 54% of watersheds within and bordering Humboldt County revealed that while cannabis grow sites are generally small (< 0.5 ha [1.2 ac]) and comprised a tiny fraction of the study area (122 ha [301 ac]), they were widespread (present in 83% of watersheds) but unevenly distributed, indicating impacts are concentrated in certain watersheds (Butsic and Brenner 2016, Wang et al. 2017). The results also showed that 68% of grows were > 500 m (0.3 mi) from developed roads, 23% were located on slopes steeper than 30%, and 5% were within 100 m (328 ft) of critical habitat for threatened salmonids (Butsic and Brenner 2016). These characteristics suggest wildlands adjacent to cannabis cultivations are at heightened risk of habitat fragmentation, erosion, sedimentation, landslides, and impacts to waterways critical to imperiled species (Ibid.).

A separate analysis in the same general area estimated potentially significant impacts from water diversions alone. Cannabis requires a substantial amount of water during the growing season, so it is often cultivated near sources of perennial surface water for irrigation, commonly diverting from springs and headwater streams (Bauer et al. 2015). In the least impacted of the study watersheds, Bauer et al. (2015) calculated that diversions for cannabis cultivation could reduce the annual seven-day low flow by up to 23%, and in some of the heavily impacted watersheds, water demands for cannabis could exceed surface water availability. If not regulated carefully, cannabis cultivation could have substantial impacts on sensitive aquatic species like Foothill Yellow-legged Frogs in watersheds in which it is concentrated.

For context, cannabis cultivation was responsible for approximately 1.1% of forest cover lost within study watersheds in Humboldt County from 2000 to 2013, while timber harvest accounted for 53.3% (Wang et al. 2017). Cannabis requires approximately two times as much water per day as wine grapes, the other major irrigated crop in the region (Bauer et al. 2015). Impacts from cannabis cultivation have been observed by Foothill Yellow-legged Frog researchers working on the Trinity River and South Fork

Eel River in the form of lower flows in summer, increased egg stranding, and more algae earlier in the season in recent years (S. Kupferberg and M. Power pers. comm. 2015; D. Ashton pers. comm. 2017; S. Kupferberg, M. van Hattem, and W. Stokes pers. comm. 2017). In addition, Gonsolin (2010) reported illegal cannabis cultivations on four headwater streams that drained into his study area along Coyote Creek, three of which were occupied by Foothill Yellow-legged Frogs. The cultivators had removed vegetation adjacent to the creeks, terraced the slopes, diverted water, constructed small water impoundments, poured fertilizers directly into the impoundments, and applied herbicides and pesticides, as evidenced by leftover empty containers littering the site.

Commercial sale of cannabis for recreational use became legal in California on January 1, 2018, through passage of the Control, Regulate and Tax Adult Use of Marijuana Act (2016), and with it an environmental permitting system and habitat restoration fund was established. The number of applications for temporary licenses per watershed is depicted in Figure 21. Two of the expected outcomes of passage of this law were that the profit-margin on growing cannabis would fall to the point that it would discourage illegal trespass grows and move the bulk of the cultivation out of remote forested areas into existing agricultural areas like the Central Valley (CSOS 2016). However, until cannabis is legalized at the federal level, these results may not occur since banks are reluctant to work with growers due to federal prohibitions subjecting them to prosecution for money laundering (ABA 2019). Additional details on cannabis permitting at the state level can be found under the Existing Management section.

Vineyards

Vineyard operators historically built on-stream dams and removed almost all the riparian vegetation to make room for vines and for ease of irrigation (M. van Hattem pers. comm. 2019). They still divert a substantial amount of water for irrigation, and they build on- and off-stream impoundments that support bullfrogs (Ibid.). The acreage of land planted in wine grapes in California began rising dramatically in the 1970s and now accounts for 90% of wine produced in the U.S. (Geisseler and Horwath 2016, Alston et al. 2018). The number of wineries in California rose from approximately 330 to nearly 2,500 between 1975 and 2006; however, expansion slowed and has reversed slightly recently with 24,300 ha (60,000 ac), or 6.5% of total area planted, removed between 2015 and 2017 (Volpe et al. 2010, CDFA 2018). In 2015, 347,000 ha (857,000 ac) were planted in grapes with 70% located in the San Joaquin Valley; 66%, 21%, and 13% were planted in wine, raisin, and table grapes, respectively (Alston et al. 2018).

Expansion of wineries in the coastal counties converted natural areas such as oak woodlands and forests to vineyards (Merenlender 2000, Napa County 2010). The area of Sonoma County covered in grapes increased by 32% from 1990 to 1997, and 42% of these new vineyards were planted above 100 m (328 ft) with 25% on slopes greater than 18% (Merelender 2000). For context, only 18% of vineyards planted before 1990 occurred above 100 m (328 ft) and less than 6% on slopes greater than 18% (Ibid.). This conversion took place on approximately 773 ha (1,909 ac) of conifer and dense hardwood forest, 149 ha (367 ac) of shrubland, and 2,925 ha (7,229 ac) of oak grassland savanna (Ibid.).

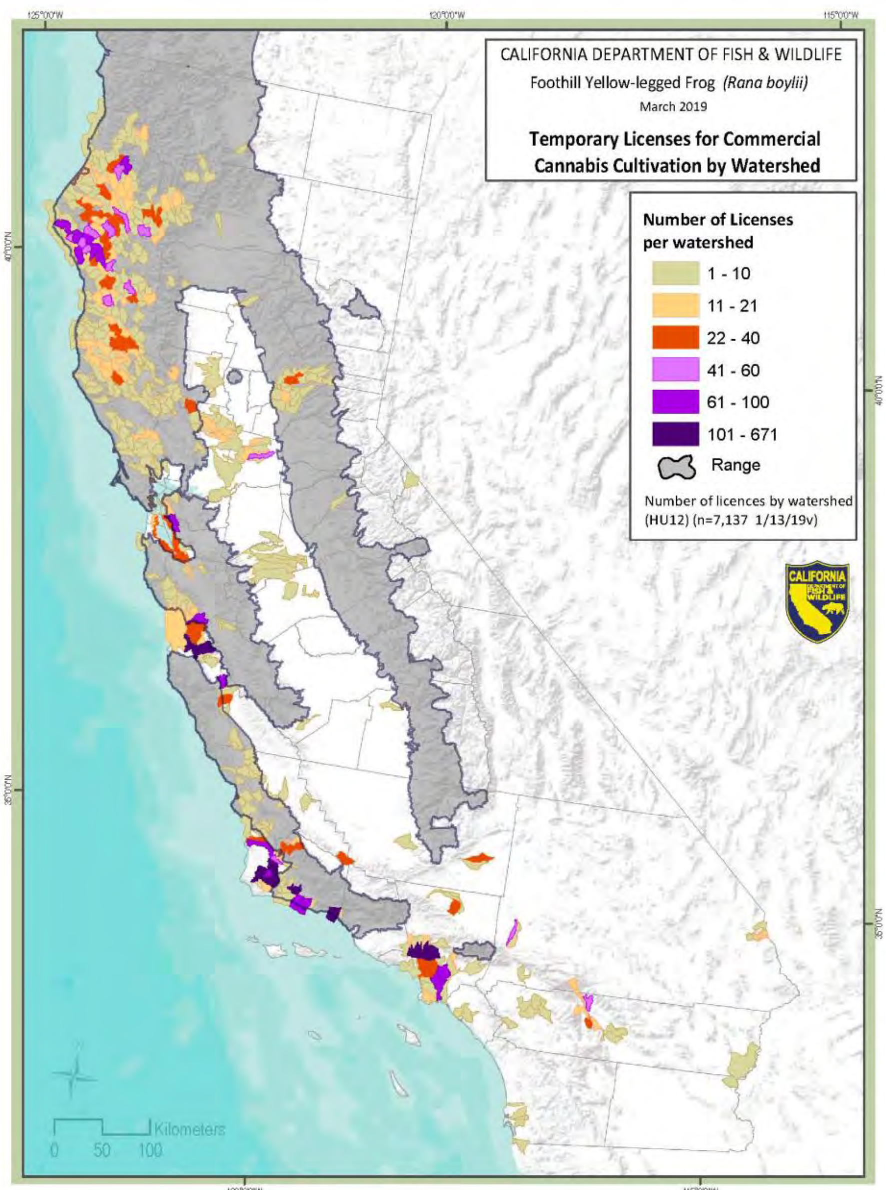

Figure 21. Cannabis cultivation temporary licenses by watershed in California (CDFA, NHD)

Recent expansion of oak woodland conversion to vineyards in Napa County was highest in its eastern hillsides (Napa County 2010). The County estimates that 1,085 and 1,240 ha (2,682-3,065 ac) of woodlands will be converted to vineyards between 2005 and 2030 (Ibid.). For context, 297 ha (733 ac) were converted from 1992 to 2003 (Ibid.). In addition, wine grapes were second only to almonds in terms of overall quantity of pesticides applied in California in 2016, but the quantity per unit area (2.9 kg/ha [2.6 lb/ac]) was 160% greater for the wine grapes (CDPR 2018). Vineyard expansion into hillsides has continued into sensitive headwater areas, and like cannabis cultivation, even small vineyards can have substantial impacts on Foothill Yellow-legged Frog habitat through sedimentation, water diversions, spread of harmful non-native species, and pesticide contamination (Merelender 2000, K. Weiss pers. comm. 2018).

Livestock Grazing

Livestock grazing can be an effective habitat management tool, including control of riparian vegetation encroachment, but overgrazing can significantly degrade the environment (Siekert et al. 1985). Cattle display a strong preference for riparian areas and have been implicated as a major source of habitat damage in the western U.S. where the adverse impacts of overgrazing on riparian vegetation are intensified by arid and semi-arid climates (Behnke and Raleigh 1978, Kauffman and Krueger 1984, Belsky et al. 1999). The severity of grazing impacts on riparian systems can be influenced by the number of animals, duration and time of year, substrate composition, and soil moisture (Benhke and Raleigh 1978, Kauffman et al. 1983, Marlow and Pogacnik 1985, Siekert et al. 1985). In addition to habitat damage, cattle can directly trample any life stage of Foothill Yellow-legged Frog.

Signs of overgrazing include impacts to the streambanks such as increased slough-offs and cave-ins that collapse undercuts used as refuge (Kauffman et al. 1983). Overgrazing reduces riparian cover, increases erosion and sedimentation, which as described above can result in silt degradation of breeding, rearing, and invertebrate food-producing areas (Cordone and Kelley 1961, Behnke and Raleigh 1978, Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). Loss of streamside and instream vegetative cover and changes to channel morphology can increase water temperatures and velocities (Behnke and Raleigh 1978). Water quality can be affected by increased turbidity and nutrient input from excrement, and seasonal water quantity can be impacted through changes to channel morphology (Belsky et al. 1999). In addition, increased nutrients and temperatures can promote blooms of harmful cyanobacteria like *Microcystis aeruginosa*, which releases a toxin when it expires that can cause liver damage to amphibians as well as other animals including humans (Bobzien and DiDonato 2007, Zhang et al. 2013).

While some recent studies indicate livestock grazing continues to damage stream and riparian ecosystems, its impact on Foothill Yellow-legged Frogs in California is unknown (Belsky et al. 1999, Hayes et al. 2016). In Oregon, the species' presence was correlated with significantly less grazing than where they were absent according to Borisenko and Hayes's 1999 report (as cited in Olson and Davis 2009). However, Fellers (2005) reported that apparently some Coast Range foothill populations occupying streams draining east into the San Joaquin Valley were doing well at the time of publication despite being heavily grazed.

Urbanization and Road Effects

Habitat conversion and fragmentation combined with modified environmental disturbance regimes can substantially jeopardize biological diversity (Tracey et al. 2018). This threat is most severe in areas like California with Mediterranean-type ecosystems that are biodiversity hot spots, fire-prone, and heavily altered by human land use (Ibid.). From 1990 to 2010, the fastest-growing land use type in the conterminous U.S. was new housing construction, which rapidly expanded the wildland-urban interface (WUI) where houses and natural vegetation meet or intermix on the landscape (Radeloff et al. 2018).

Of several variables tested, proportion of urban land use within a 5 km (3.1 mi) radius of a site was associated with Foothill Yellow-legged Frog declines (Davidson et al. 2002). Lind (2005) also found significantly less urban development nearby and upwind of sites occupied by Foothill Yellow-legged Frogs, suggesting pollutant drift may be a contributing factor. Changes in wildfires may also contribute to the species' declines; 95% of California's fires are human-caused, and wildfire issues are greatest at the WUI (Syphard et al. 2009, Radeloff et al. 2018). Population density, intermix WUI (where wildland and development intermingle as opposed to an abrupt interface), and distance to WUI explained the most variability in fire frequency (Syphard et al. 2007). In addition to wildfires, habitat loss, and fragmentation, urbanization can impact adjacent ecosystems through non-native species introduction, native predator subsidization, and disease transmission (Bar-Massada et al. 2014).

Projections show growth in California's population to 51 million people by 2060 from approximately 40 million currently (PPIC 2019). This will increase urbanization, the WUI, and habitat fragmentation. The Department of Finance projects the Inland Empire, the San Joaquin Valley, and the Sacramento metropolitan area will be the fastest-growing regions of the state over the next several decades (Ibid.). This puts the greatest pressure in areas outside of the Foothill Yellow-legged Frog's range; however, because the environmental stressors associated with urbanization can span far beyond its physical footprint, they may still adversely affect the species.

Highways are frequently recognized as barriers to dispersal that fragment habitats and populations; however, single-lane roads can pose significant risks to wildlife as well (Cook et al. 2012, Brehme et al. 2018). Foothill Yellow-legged Frogs are at risk of being killed by vehicles when roads are located near their habitat (Cook et al. 2012, Brehme et al. 2018). Fifty-six juvenile Foothill Yellow-legged Frogs were found on a road adjacent to Sulphur Creek (Mendocino County), seven of which had been struck and killed (Cook et al. 2012). When fords (naturally shallow areas) are used as vehicle crossings, they can create sedimentation and poor water quality, and in some cases, the fords are gravel or cobble bars used by Foothill Yellow-legged Frogs for breeding that could result in direct mortality (K. Blanchard pers. comm. 2018, R. Bourque pers. comm. 2018). Construction of culverts under roads to keep vehicles out of the streambed can result in varying impacts. In some cases, they can impede dispersal and create deep scoured pools that support predatory fish and frogs, but when properly constructed, they can facilitate frog movement up and down the channel with reduced road mortality (Van Wagner 1996, GANDA 2008). In areas where non-native species are not a threat, but premature drying is, pools created by culverts can provide habitat in otherwise unsuitable areas (M. Grefsrud pers. comm. 2019). An evaluation of the impact of roads on 166 native California amphibians and reptiles through direct

morality and barriers to movement concluded that Foothill Yellow-legged Frogs, at individual and population levels, were at moderate risk of road impacts in aquatic habitat but very low risk of impacts in terrestrial habitat (Brehme et al. 2018). For context, all chelonids (turtles and tortoises), 72% of snakes, 50% of anurans, 18% of lizards, and 17% of salamander species in California were ranked as having a high or very high risk of negative road impacts in the same evaluation (Ibid.).

Poorly constructed roadways near rivers and streams can result in substantial erosion and sedimentation, leading to reduced amphibian densities (Welsh and Ollivier 1998). Proximity of roads to Foothill Yellow-legged Frog habitat contributes to petrochemical runoff and poses the threat of spills (Ashton et al. 1997). A diesel spill on Hayfork Creek (Trinity County) resulted in mass mortality of Foothill Yellow-legged Frog tadpoles and partial metamorphs (Bury 1972). Roads have also been implicated in the spread of disease and may have aided in the spread of Bd in California (Adams et al. 2017b).

Frogs use auditory and visual cues to defend territories and attract mates, and some studies reveal that realistic levels of traffic noise can impede transmission and reception of these signals (Bee and Swanson 2007). Some male frogs have been observed changing the frequency of their calls to increase the distance they can be heard over traffic noise, but if females have evolved to recognize lower pitched calls as signs of superior fitness, this potential trade-off between audibility and attractiveness could have implications for reproductive success (Parris et al. 2009). In a separate study, traffic noise caused a change in male vocal sac coloration and an increase in stress hormones, which changed sexual selection processes and suppressed immunity (Troïanowski et al. 2017). Because Foothill Yellow-legged Frogs mostly call underwater and are not known to use color displays, communication cues may not be adversely affected by traffic noise, but their stress response is unknown.

Timber Harvest

Because Foothill Yellow-legged Frogs tend to remain close to the water channel (i.e., within the riparian corridor) and current timber harvest practices minimize disturbance in riparian areas for the most part, adverse effects from timber harvest are expected to be relatively low (Hayes et al. 2016, CDFW 2018b). However, some activities have a potential to negatively impact Foothill Yellow-legged Frogs or their habitat, including direct mortality and increased sedimentation during construction and decommissioning of watercourse crossings and infiltration galleries, tree felling, log hauling, and entrainment by water intakes or desiccation of eggs and tadpoles through stranding from dewatering during drafting operations (CDFW 2018b,c). In addition to impacts previously described under the Sedimentation and Road Effects section, when silt runoff into streams is accompanied by organic materials, such as logging debris, impaired water quality can result, including reduced dissolved oxygen, which is important in embryonic and tadpole development (Cordone and Kelley 1961).

Because Foothill Yellow-legged Frogs are heliotherms (i.e, they bask in the sun to raise their body temperature) and sensitive to thermal extremes, some moderate timber harvest may benefit the species (Zweifel 1955, Fellers 2005). Ashton (2002) reported 85% of his Foothill Yellow-legged Frog observations occurred in second-growth forests (37-60 years post-harvest) as opposed to late-seral forests and postulated that the availability of some open canopy areas played a major part in this

disparity. Foothill Yellow-legged Frogs are typically absent in areas with closed canopy (Welsh and Hodgson 2011). Reduced canopy also raises stream temperatures, which could improve tadpole development and promote algal and invertebrate productivity in otherwise cold streams (Olson and Davis 2009; Catenazzi and Kupferberg 2013,2017).

Recreation

Several types of recreation can adversely impact Foothill Yellow-legged Frogs, and some are more severe and widespread than others. One of the main potential factors identified by herpetologists as contributing to disappearance of Foothill Yellow-legged Frogs in southern California was increased and intensified recreation in streams (Adams et al. 2017b). The greater number of people traveling into the backcountry may have facilitated the spread Bd to these areas, and while no evidence shows stress from disturbance or other environmental pressures increases susceptibility to Bd, the stress hormone corticosterone has been implicated in immunosuppression (Hayes et al. 2003, Adams et al. 2017b).

The amount of Foothill Yellow-legged Frog habitat disturbed by off-highway motor vehicles (OHV) throughout its range in California is unknown, but its impacts can be significant, particularly in areas with small isolated populations (Kupferberg et al. 2009c, Kupferberg and Furey 2015). An example is the Carnegie State Vehicular Recreation Area (CVSRA), located in the hills southwest of Tracy in the Corral Hollow Creek watershed (Alameda and San Joaquin counties). The above-described road effects apply: sedimentation, crushing along trail crossings, and potential noise effects (Ibid.). In addition, dust suppression activities employed by CSVRA use magnesium chloride ($MgCl_2$), which has the potential to harm developing embryos and tadpoles (Karraker et al. 2008, Hopkins et al. 2013, OHMVRC 2017). Based on museum records, Foothill Yellow-legged Frogs were apparently abundant in Corral Hollow Creek, but they are extremely rare now and are already extirpated or at risk of extirpation (Kupferberg et al. 2009c, Kupferberg and Furey 2015).

Motorized and non-motorized recreational boating can also impact Foothill Yellow-legged Frogs. The impacts of jet boat traffic were investigated in Oregon; in areas with frequent use and high wakes breaking on shore, Foothill Yellow-legged Frogs were absent (Borisenko and Hayes 1999 as cited in Olson and Davis 2009). This wake action had the potential to dislodge egg masses, strand tadpoles, disrupt adult basking behavior, and erode shorelines (Ibid.). Jet boat tours and races on the Klamath River (Del Norte and Humboldt counties) may have an impact on Foothill Yellow-legged Frog use of the mainstem (M. van Hattem pers. comm. 2019). In addition, using gravel bars as launch and haul out sites for boat trailers, kayaks, or river rafts can result in direct loss of egg masses and tadpoles or damage to breeding and rearing habitat and can disrupt post-metamorphic frog behavior (Ibid.). As described above, pulse flows released for whitewater boating in the late spring and summer can result in scouring and stranding of egg masses and tadpoles (Borisenko and Hayes 1999 as cited in Olson and Davis 2009, Kupferberg et al. 2009b). In addition, the velocities that resulted in stunted growth and increased vulnerability to predation in Foothill Yellow-legged Frog tadpoles were less than the increased velocities experienced in nearshore habitats during intentional release of recreational flows for whitewater boating, as well as hydropeaking for power generation (Kupferberg et al. 2011b).

Hiking, horse-riding, camping, fishing, and swimming, particularly in sensitive breeding and rearing habitat can also adversely impact Foothill Yellow-legged Frog populations (Borisenko and Hayes 1999 in Olson and Davis 2009). Because Foothill Yellow-legged Frog breeding activity was being disturbed and egg masses were being trampled by people and dogs using Carson Falls (Marin County), the land manager established an educational program, including employing docents on weekends that remind people to stay on trails and tread lightly to try to reduce the loss of Foothill Yellow-legged Frog reproductive effort (Prado 2005). In addition, within his study site, Van Wagner (1996) reported that a property owner moved rocks that were being used as breeding habitat to create a swimming hole. The extent to which this is more than a small, local problem is unknown, but as the population of California increases, recreational pressures in Foothill Yellow-legged Frog habitat are likely to increase commensurately.

Drought

Drought is a common phenomenon in California and is characterized by lower than average precipitation. Lower precipitation in general results in less surface water, and water availability is critical for obligate stream-breeding species. Even in the absence of drought, a positive relationship exists between precipitation and latitude within the Foothill Yellow-legged Frog's range in California, and mean annual precipitation has a strong influence on Foothill Yellow-legged Frog presence at historically occupied sites (Davidson et al. 2002, Lind 2005). Figure 22 depicts the recent historical annual average precipitation across the state as well as during the most recent drought and how they differ. Southern California is normally drier than northern California, but the severity of the drought was even greater in the south.

Reduced precipitation can result in deleterious effects to Foothill Yellow-legged Frogs beyond the obvious premature drying of aquatic habitat. When stream flows recede during the summer and fall, sometimes the isolated pools that stay perennially wet are the only remaining habitat. This phenomenon concentrates aquatic species, resulting in several potentially significant adverse impacts. Stream flow volume was negatively correlated with Bd load during a recent chytridiomycosis outbreak in the Alameda Creek watershed (Adams et al. 2017a). The absence of high peak flows in winter coupled with wet years allowed bullfrogs to expand their distribution upstream, and the drought-induced low flows in the fall concentrated them with Foothill Yellow-legged Frogs in the remaining drying pools (Ibid.). This mass mortality event appeared to have been the result of a combination of drought, disease, and dam effects (Ibid.). This die-off occurred in a regulated reach that experiences heavy recreational use and presence of crayfish and bass (Ibid.). Despite these threats, the density of breeding females in this reach was greater in 2014 and 2015 than the in the unregulated reach upstream because the latter dried completely before tadpoles could metamorphose during the preceding drought years (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015).

In addition to increasing the spread of pathogens, drought-induced stream drying can increase predation and competition by introduced fish and frogs in the pools they are forced to share (Moyle 1973, Hayes and Jennings 1988, Drost and Fellers 1996). This concentration in isolated pools can also result in increased native predation as well as facilitate spread of Bd. An aggregation of six adult Foothill

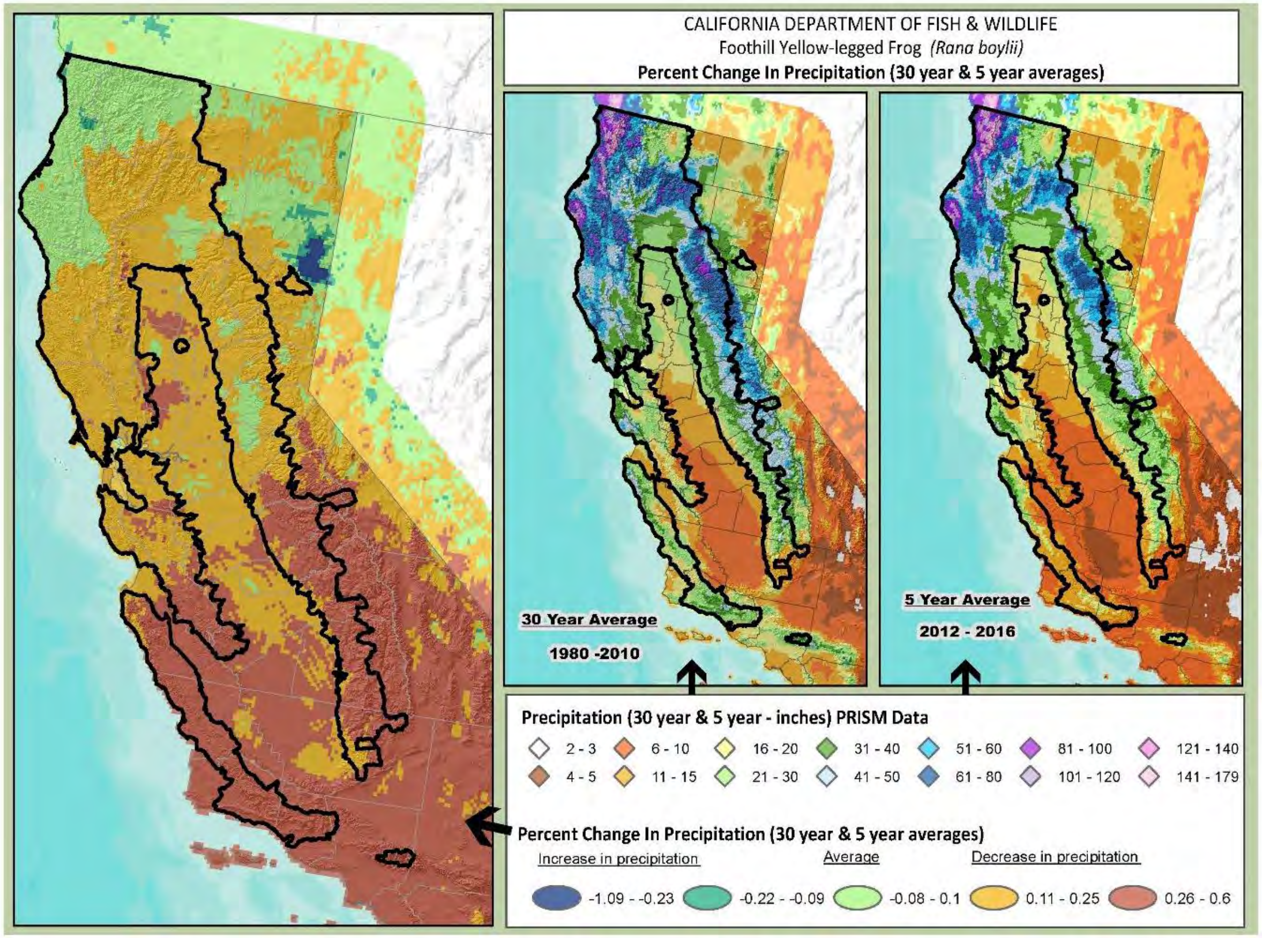

Figure 22. Change in precipitation from 30-year average and during the recent drought (PRISM)

Yellow-legged Frogs was observed perched on a rock above an isolated pool where a garter snake was foraging on tadpoles during the summer; this close contact may reduce evaporative water loss when they are forced out of the water during high temperatures, but it can also increase disease transmission risk (Leidy et al. 2009.). Gonsolin (2010) also documented a late summer aggregation of juvenile Foothill Yellow-legged Frogs out of water during extremely high temperatures. In addition, drought-induced low flow, high water temperatures, and high densities of tadpoles were associated with outbreaks of malformation-inducing parasitic copepods (Kupferberg et al. 2009a).

Rapidly receding spring flows can result in stranding egg masses and tadpoles. However, this risk is likely less significant when it is drought-induced on an unregulated stream vs. a result of dam operations since Foothill Yellow-legged Frogs have evolved to initiate breeding earlier and shorten the breeding period in drought years (Kupferberg 1996a). If pools stay wet long enough to support metamorphosis, complete drying at the end of the season may benefit Foothill Yellow-legged Frogs if it eliminates introduced species like warm water fish and bullfrogs. Moyle (1973) noted that the only intermittent streams occupied by Foothill Yellow-legged Frogs in the Sierra Nevada foothills had no bullfrogs. At a long-term study site in upper Coyote Creek in 2015, Foothill Yellow-legged Frogs had persisted in reaches that had at least some summer water through the three preceding years of the most severe drought in over a millennium, albeit at much lower abundance than a decade before (Gonsolin 2010, Griffin and Anchokaitis 2014, J. Smith pers. comm. 2015). The population's abundance appeared to have never recovered from the 2007-2009 drought before the 2012-2016 drought began (J. Smith pers. comm. 2015). In 2016, after a relatively wet winter, Foothill Yellow-legged Frogs bred en masse, and only a single adult bullfrog was detected, an unusually low number for that area (CDWR 2016, J. Smith pers. comm. 2016). It appeared the population may rebound; however, in 2018, it experienced lethal chytridiomycosis outbreak, and like the Alameda Creek die-off probably resulted from crowding during drought, presence of bullfrogs as Bd-reservoirs and predators and competitors, and the stress associated with the combination of the two (Kupferberg and Catenazzi 2019).

Drought effects can also exacerbate other environmental stressors. During the most recent severe drought, tree mortality increased dramatically from 2014 to 2017 and reached approximately 129 million dead trees (OEHHA 2018). Multiple years of high temperatures and low precipitation left them weakened and more susceptible to pathogens and parasites (Ibid.). Vast areas of dead and dying trees are more prone to severe wildfires, and they lose their carbon sequestration function while also emitting methane, which is an extremely damaging greenhouse gas (CNRA 2016). Post-wildfire storms can result in erosion of fine sediments from denuded hillsides into the stream channel (Florsheim et al. 2017). If the storms are short duration and low precipitation, as happens during droughts, their magnitude may not be sufficient to transport the material downstream, resulting in a longer temporal loss or degradation of stream habitat (Ibid.). Reduced rainfall may also infiltrate the debris leading to subsurface flows rather than the surface water Foothill Yellow-legged Frogs require (Ibid.). Extended droughts increase risk of the stream being uninhabitable or inadequate for breeding for multiple years, which would result in population-level impacts and possible extirpation (Ibid.).

Wildland Fire and Fire Management

Fire is an important element for shaping and maintaining the species composition and integrity of many California ecosystems (Syphard et al. 2007, SBFFP 2018). Prior to European settlement, an estimated 1.8 to 4.9 million ha (4.5-12 million ac) burned annually (4-11% of total area of the state), ignited both deliberately by Native Americans and through lightning strikes (Keeley 2005, SBFFP 2018). The impacts of wildland fires on Foothill Yellow-legged Frogs are poorly understood and likely vary significantly across the species' range with differences in climate, vegetation, soils, stream-order, slope, frequency, and severity (Olson and Davis 2009). Mortality from direct scorching is unlikely because Foothill Yellow-legged Frogs are highly aquatic, and most wildfires occur during the dry period of the year when the frogs are most likely to be in or near the water (Pilliod et al. 2003, Bourque 2008). Field observations support this presumption; sightings of post-metamorphic Foothill Yellow-legged Frogs immediately after fires in the northern Sierra Nevada and North Coast indicate they are not very vulnerable to the direct effects of fire (S. Kupferberg and R. Peek pers. comm. 2018). Similarly, Foothill Yellow-legged Frogs were observed two months, and again one year, after a low- to moderate-intensity fire burned an area in the southern Sierra Nevada in 2002, and the populations were extant and breeding as recently as 2017 (Lind et al. 2003b, CNDDB 2019). While water may provide a refuge during the fire, it is also possible for temperatures during a fire, or afterward due to increased solar exposure, to near or exceed a threshold resulting in lethal or sublethal harm; this would likely impact embryos and tadpoles with limited dispersal abilities (Pilliod et al. 2003).

Intense fires remove overstory canopy, which provides insulation from extreme heat and cold, and woody debris that increases habitat heterogeneity (Pilliod et al. 2003, Olson and Davis 2009). If this happens frequently enough, it can permanently change the landscape. For example, frequent high-severity burning of crown fire-adapted ecosystems can prevent forest regeneration since seeds require sufficient time between fires to mature, and repeated fires can deplete the seed bank (Stephens et al. 2014). Smoke and ash change water chemistry through increased nutrient and heavy metal inputs that can reach concentrations harmful to aquatic species during the fire and for days, weeks, or years thereafter (Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Erosion rates on granitic soils, which make up a large portion of the Foothill Yellow-legged Frog's range, can be over 60 times greater in burned vs. unburned areas and can increase sedimentation for over 10 years (Megahan et al. 1995, Hayes et al. 2016). Post-fire nutrient inputs into streams could benefit Foothill Yellow-legged Frogs through increased productivity and more rapid growth and development (Pilliod et al. 2003). While the loss of leaf litter that accompanies fire alters the food web, insects are expected to recolonize rapidly, and the lack of cover could increase their vulnerability to predation by Foothill Yellow-legged Frogs (Ibid.).

Low-intensity fires likely have no adverse effect on Foothill Yellow-legged Frogs (Olson and Davis 2009). If they occur in areas with dense canopy, wildfires can improve habitat quality for Foothill Yellow-legged Frogs by reducing riparian cover, providing areas to bask, and increasing habitat heterogeneity, which is likely to outweigh any adverse effects from some fire-induced mortality (Russell et al. 1999, Olson and Davis 2009). In a preliminary analysis of threats to Foothill Yellow-legged Frogs in Oregon, proximity to stand-replacing fires was not associated with absence (Olson and Davis 2009).

Euro-American colonization of California significantly altered the pattern of periodic fires with which California's native flora and fauna evolved through fire exclusion, land use practices, and development (OEHHA 2018). Fire suppression can lead to canopy closure, which reduces habitat quality by limiting thermoregulatory opportunities (Olson and Davis 2009). In addition, fire suppression and its subsequent increase in fuel loads combined with expanding urbanization and rising temperatures have resulted in a greater likelihood of catastrophic stand-replacing fires that can significantly alter riparian systems for decades (Pilliod et al. 2003). Firebreaks, in which vegetation is cleared from a swath of land, can result in similar impacts to roads and road construction (Ibid.). Fire suppression can also include bulldozing within streams to create temporary reservoirs for pumping water, which can cause more damage than the fire itself to Foothill Yellow-legged Frogs in some cases (S. Kupferberg and R. Peek pers. comm. 2018). In addition, fire suppression practices can involve applying hundreds of tons of ammonia-based fire retardants and surfactant-based fire suppressant foams from air tankers and fire engines (Pilliod et al. 2003). Some of these chemicals are highly toxic to some anurans (Little and Calfee 2000).

Fire suppression has evolved into fire management with a greater understanding of its importance in ecosystem health (Keeley and Syphard 2016). Several strategies are employed including prescribed burns, mechanical fuels reduction, and allowing some fires to burn instead of necessarily extinguishing them (Pilliod et al. 2003). Like wildfires themselves, fire management strategies have the potential to benefit or harm Foothill Yellow-legged Frogs. Prescribed fires and mechanical fuels removal lessen the likelihood of catastrophic wildfires, but they can also result in loss of riparian vegetation, excessive sedimentation, and increased water temperatures (Ibid.). Salvage logging after a fire may result in similar impacts to timber harvest but with higher rates of erosion and sedimentation (Ibid.). A balanced approach to wildland fires is likely to have the greatest beneficial impact on species and ecosystem health (Stephens et al. 2012).

Floods and Landslides

As previously described, Foothill Yellow-legged Frog persistence is highly sensitive to early life stage mortality (Kupferberg et al. 2009c). While aseasonal dam releases are a major source of egg mass and tadpole scouring, storm-driven floods are also capable of ~~it~~ inducing the same effects (Ashton et al. 1997). Van Wagner (1996) concluded that the high discharge associated with heavy rainfall could account for a significant source of mortality in post-metamorphic Foothill Yellow-legged Frogs as well as eggs and tadpoles; he observed two adult females and several juveniles swept downstream with fatal injuries post-flooding. Severe flooding, specifically two 500-year flood events in early 1969 in Evey Canyon (Los Angeles County), resulted in massive riparian habitat destruction (Sweet 1983). Prior to the floods, Foothill Yellow-legged Frogs were widespread and common, but only four subsequent sightings were documented between 1970 and 1974 and none since (Sweet 1983, Adams 2017b). Sweet (1983) speculates that because Foothill Yellow-legged Frogs overwinter in the streambed in that area, the floods may have reduced the population's abundance below an extinction threshold. Four other herpetologists interviewed about Foothill Yellow-legged Frog extirpations in southern California listed severe flooding as a likely cause (Adams et al. 2017b).

As mentioned above, landslides are a frequent consequence of post-fire rainstorms and can result in lasting impacts to stream morphology, water quality, and Foothill Yellow-legged Frog populations. On the other hand, Olson and Davis (2009) suggest that periodic landslides can have beneficial effects by transporting woody debris into the stream that can increase habitat complexity and by replacing sediments that are typically washed downstream over time. Whether a landslide is detrimental or beneficial is likely heavily influenced by amount of precipitation and the underlying system. As previously described, too little precipitation could lead to prolonged loss of habitat through failure to transport material downstream, and too much precipitation can result in large-scale habitat destruction and direct mortality.

Climate Change

Global climate change threatens biodiversity and may lead to increased frequency and severity of drought, wildfires, flooding, and landslides (Williams et al. 2008, Keely and Syphard 2016). Data show a consistent trend of warming temperatures in California and globally; 2014 was the warmest year on record, followed by 2015, 2017, and 2016 (OEHHA 2018). Climate model projections for annual temperature in California in the 21st century range from 1.5 to 4.5°C (2.7-8.1°F) greater than the 1961-1990 mean (Cayan et al. 2008). Precipitation change projections are less consistent than those for temperature, but recent studies indicate increasing variability in precipitation, and increasingly dry conditions in California resulting from increased evaporative water loss primarily due to rising temperatures (Cayan et al. 2005, Williams et al. 2015, OEHHA 2018). Precipitation variability and proportion of dry years were negatively associated with Foothill Yellow-legged Frog presence in a range-wide analysis (Lind 2005). In addition, low precipitation intensified the adverse effects of dams on the species (Ibid.).

California recently experienced the longest drought since the U.S. Drought Monitor began reporting in 2000 (NIDIS 2019). Until March 5, 2019, California experienced drought effects in at least a portion of the state for 376 consecutive weeks; the most intense period occurred during the week of October 28, 2014 when D4 (the most severe drought category) affected 58.4% of California's land area (Figure 23; NIDIS 2019). A recent modeling effort using data on historical droughts, including the Medieval megadrought between 1100 and 1300 CE, indicates the mean state of drought from 2050 to 2099 in California will likely exceed the Medieval-era drought, under both high and moderate greenhouse gas emissions models (Cook et al. 2015). The probability of a multidecadal (35 yr) drought occurring during the late 21st century is greater than 80% in all models used by Cook et al. (2015). If correct, this would represent a climatic shift that not only falls outside of contemporary variability in aridity but would also be unprecedented in the past millennium (Ibid.).

As a result of increasing temperatures, a decreasing proportion of precipitation falls as snow, resulting in more runoff from rainfall during the winter and a shallower snowpack that melts more rapidly (Stewart 2009). A combination of reduced seasonal snow accumulation and earlier streamflow timing significantly reduces surface water storage capacity and increases the risk for winter and spring floods, which may require additional and taller dams and result in alterations to hydroelectric power generation flow regimes (Cayan et al. 2005, Knowles et al. 2006, Stewart 2009). The reduction in snowmelt volume

is expected to impact the northern Sierra (Feather, Yuba, and American River watersheds) to a greater extent than the southern portion (Young et al. 2009). The earlier shift in peak snowmelt timing is predicted to exceed four to six weeks across the entire Sierra Nevada depending on the amount of warming that occurs this century (Ibid.). In addition, the snow water equivalent is predicted to significantly decline by 2070-2099 over the 1961-1990 average in the Trinity, Sacramento, and San Joaquin drainages from -32% to -79%, and effectively no snow is expected to fall below 1000 m (3280 ft) in the high emissions/sensitive model (Cayan et al. 2008).

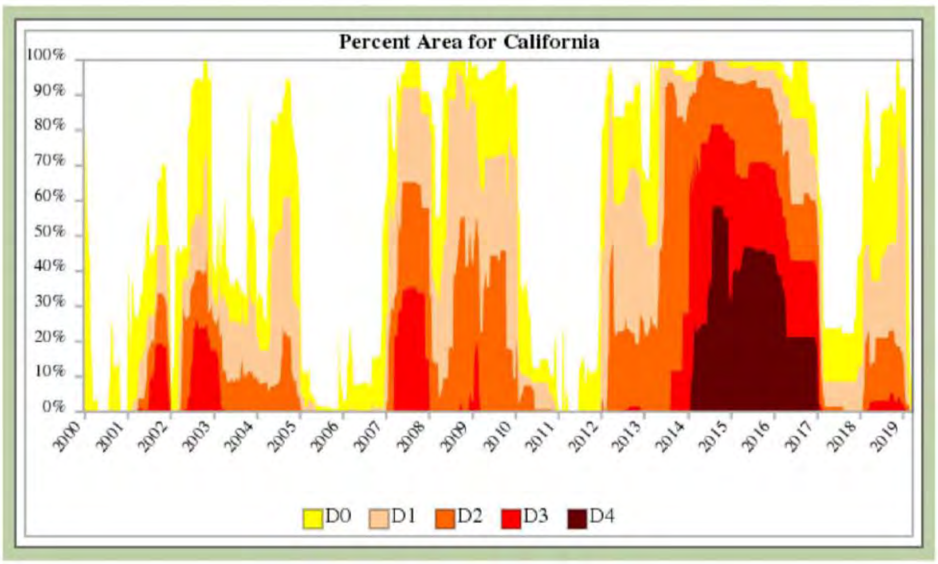

Figure 23. Palmer Hydrological Drought Indices 2000-present (NIDIS)

The earlier shift of snowmelt and lower water content will result in lower summer flows, which will intensify the competition for water among residential, agricultural, industrial, and environmental needs (Field et al. 1999, Cook et al. 2015). In unregulated systems, as long as water is present through late summer, an earlier hydrograph recession that triggers Foothill Yellow-legged Frog breeding could result in a longer time to grow larger prior to metamorphosis, which improves probability of survival (Yarnell et al. 2010, Kupferberg 2011b). However, if duration from peak to base flow shortens, it can result in increased sedimentation and reduced habitat complexity in addition to stranding (Yarnell et al. 2010).

Fire frequency relates to temperature, fuel loads, and fuel moisture (CCSP 2008). Therefore, increasing periods of drought combined with extreme heat and low humidity that stress or kill trees and other vegetation create ideal conditions for wildland fires (Ibid). Not surprisingly, the area burned by wildland fires over the western U.S. increased since 1950 but rose rapidly in the mid-1980s (Westerling et al. 2006, OEHHA 2018). As temperatures warmed and snow melted earlier, large-wildfire frequency and duration increased, and wildfire seasons lengthened (Westerling et al. 2006, OEHHA 2018).

In California, latitude inversely correlates with temperature and annual area burned, but the climate-fire relationship is substantially different across the state, and future wildfire regimes are difficult to predict (Keeley and Syphard 2016). For example, the relationship between spring and summer temperature and area burned in the Sierra Nevada is highly significant but not in southern California (Ibid.). Climate has a greater influence on fire regimes in mesic than arid environments, and the most influential climatological factor (e.g., precipitation, temperature, season, or their interactions) shifts over time (Ibid.). Nine of the 10 largest fires in California since 1932 have occurred in the past 20 years, 4 within the past 2 years (Figure 24; CAL FIRE 2019). However, it is possible this trend will not continue; climate- and wildfire-induced changes in vegetation could reduce wildfire severity in the future (Parks et al. 2016).

Wildfires themselves can accelerate the effects of climate change. Wildfires emit short-lived climate pollutants like black carbon (soot) and methane that are tens to thousands of times greater than carbon dioxide (the main focus of greenhouse gas reduction) in terms of warming effect and are responsible for 40% or more of global warming to date (CNRA 2016). Healthy forests can sequester large amounts of carbon from the atmosphere, but recently carbon emissions from wildfires have exceeded their uptake by vegetation in California (Ackerly et al. 2018).

With increased variability and changes in precipitation type, magnitude, and timing comes more variable and extreme stream flows (Mallakpour et al. 2018). Models for stream flow in California project higher high flows, lower low flows, wetter rainy seasons, and drier dry seasons (Ibid.). The projected water cycle extremes are related to strengthening El Niño and La Niña events, and both severe flooding and intense drought are predicted to increase by at least 50% by the end of the century (Yoon et al. 2015). These changes increase the likelihood of Foothill Yellow-legged Frog egg mass and tadpole scouring and stranding, even in unregulated rivers.

A species' vulnerability to climate change is a function of its sensitivity to climate change effects, its exposure to them, and its ability to adapt its behaviors to survive with them (Dawson et al. 2011). Myriad examples exist of species shifting their geographical distribution toward the poles and to higher elevations and changing their growth and reproduction with increases in temperature over time (Parmesan and Yohe 2003). However, in many places, fragmentation of suitable habitat by anthropogenic barriers (e.g., urbanization, agriculture, and reservoirs) limits a species' ability to shift its range (Pounds et al. 2007). The proportion of sites historically occupied by Foothill Yellow-legged Frogs that are now extirpated increases significantly on a north-to-south latitudinal gradient and at drier sites within California, suggesting climate change may contribute to the spatial pattern of the species' declines (Davidson et al. 2002).

Commented [MOU3]: Also Moritz et al. in Science for Yosemite..

An analysis of the climate change sensitivity of 195 species of plants and animals in northwestern North America revealed that, as a group, amphibians and reptiles were estimated to be the most sensitive (Case et al. 2015). Nevertheless, examples exist of amphibians adjusting their breeding behaviors (e.g., calling and migrating to breeding sites) to occur earlier in the year as global warming increases (Beebee 1995, Gibbs and Breisch 2001). Because of the rapid change in temperature, Beebee (1995) posits these are examples of behavioral and physiological plasticity rather than natural selection. However, for

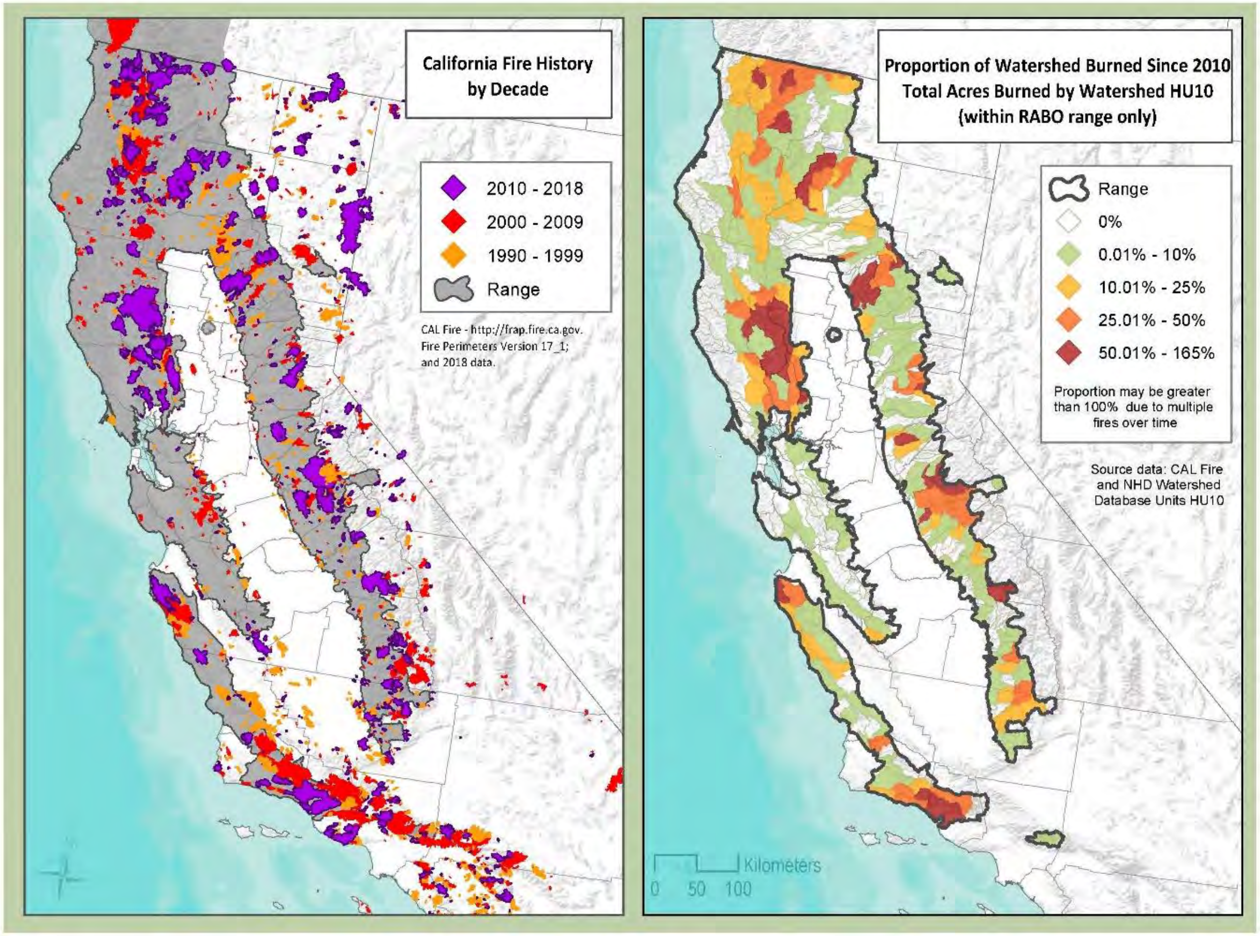

Figure 24. Fire history (1990-2018) and proportion of watershed burned (2010-2018) in California (CAL FIRE, NHD)

species with short generation times or in areas less affected by climate change, populations may be able to undergo evolutionary adaptation to the changing local environmental conditions (Hoffman and Sgrò 2011).

As previously described in the Seasonal Activity and Movements section, Foothill Yellow-legged Frog breeding is closely tied to water temperature, flow, and stage, and the species already adjusts its timing of oviposition by as much as a month in the same location during different water years, so the species may have enough inherent flexibility to reduce their vulnerability. The species appears fairly resilient to drought, fire, and flooding, at least in some circumstances. For example, after the 2012-2016 drought, the Loma Fire in late 2016, and severe winter flooding and landslides in 2016 and 2017, Foothill Yellow-legged Frog adults and metamorphs, as well as aquatic insects and rainbow trout, were abundant throughout Upper Llagas Creek in fall of 2017, and the substrate consisted of generally clean gravels and cobbles with only a slight silt coating in some pools (J. Smith pers. comm. 2017). The frogs and fish likely took refuge in a spring-fed pool, and the heavy rains scoured the fine sediments that eroded downstream (Ibid.). These refugia from the effects of climate change reduce the species' exposure, thereby reducing their vulnerability (Case et al. 2015).

Climate change models that evaluate the Foothill Yellow-legged Frog's susceptibility from a species and habitat perspective yield mixed results. An investigation into the possible effects of climate on California's native amphibians and reptiles used ecological niche models, future climate scenarios, and general circulation models to predict species-specific climatic suitability in 2050 (Wright et al. 2013). The results suggested approximately 90-100% of localities currently occupied by Foothill Yellow-legged Frogs are expected to remain climatically suitable in that time, and the proportion of currently suitable localities predicted to change ranges from -20% to 20% (Ibid.). However, a second study performed by the same research team using a subset of these models found that 66.4% of currently occupied cells will experience reduced environmental suitability in 2050 (Warren et al. 2014). This analysis included 90 species of native California mammals, birds, reptiles, and amphibians. For context, over half of the taxa were predicted to experience > 80% reductions, a consistent pattern reflected across taxonomic groups (Ibid.).

A third analysis investigated the long-term risk of climate change by modeling the relative environmental stress a vegetative community would undergo in 2099 given different climate and greenhouse gas emission scenarios (Thorne et al. 2016). This model does not incorporate any Foothill Yellow-legged Frog-specific data; it strictly projects climatic stress levels vegetative communities will experience within the species' range boundaries (Ibid.). Unsurprisingly, higher emissions scenarios resulted in a greater proportion of habitat undergoing climatic stress (Figure 25). Perhaps counterintuitively, the warm and wet scenario resulted in a greater amount of stress than the hot and dry scenario. When high emissions and warm and wet changes are combined, a much greater proportion of the vegetation communities will experience "non-analog" conditions, those outside of the range of conditions currently known in California (Ibid.).

Habitat Restoration and Species Surveys

Potential conflicts between managing riverine habitat below dams for both cold-water adapted salmonids and Foothill Yellow-legged Frogs was discussed previously. In addition to problems with temperatures and pulse flows, some stream restoration projects aimed at physically creating or improving salmonid habitat can also adversely affect the species. For example, boulder deflectors were placed in Hurdygurdy Creek (Del Norte County) to create juvenile steelhead rearing habitat; deflectors change broad, shallow, low-velocity reaches into narrower, deeper, faster reaches preferred by the fish (Fuller and Lind 1992). Foothill Yellow-legged Frogs were documented using the restoration reach as breeding habitat annually prior to placement of the boulders, but no breeding was detected in the following three years, suggesting this project eliminated the conditions the frogs require (Ibid.). In addition, a fish ladder to facilitate salmonid migration above the Alameda Creek Diversion Dam was recently constructed on a Foothill Yellow-legged Frog lek site, and the frogs may become trapped in the ladder (M. Grefsrud pers. comm. 2019). Use of rotenone to eradicate non-native fish as part of a habitat restoration project is rare, but if it is applied in streams occupied by Foothill Yellow-legged Frogs, it can kill tadpoles but is unlikely to impact post-metamorphic frogs (Fontenot et al. 1994). Metamorphosing tadpoles may be able to stay close enough to the surface to breathe air and survive but may display lethargy and experience increased susceptibility to predation (Ibid.).

Commonly when riparian vegetation is removed, regulatory agencies require a greater amount to be planted as mitigation to offset the temporal loss of habitat. This practice can have adverse impacts on Foothill Yellow-legged Frogs by reducing habitat suitability. Foothill Yellow-legged Frogs have been observed moving into areas where trees were recently removed, and they are known to avoid heavily shaded areas (Welsh and Hodgson 2011, M. Grefsrud pers. comm. 2019).

Biologists conducting surveys in Foothill Yellow-legged Frog habitat can trample egg masses or larvae if they are not careful. One method for sampling fish is electroshocking, which runs a current through the water that stuns the fish temporarily allowing them to be captured. Post-metamorphic frogs are unlikely to be killed by electroshocking; however, at high frequencies (60 Hz), they may experience some difficulty with muscle coordination for a few days (Allen and Riley 2012). This could increase their risk of predation. At 30 Hz, there were no differences between frogs that were shocked and controls (Ibid.). Tadpoles are more similar to fish in tail muscle and spinal structure and are at higher risk of injuries; however, researchers who reported observing stunned tadpoles noted they appeared to recover completely within several seconds (Ibid.). Adverse effects to Foothill Yellow-legged Frogs from electrofishing may only happen at frequencies higher than those typically used for fish sampling (Ibid.)

Small Population Sizes

Small populations are at greater risk of extirpation, primarily through the disproportionately greater impact of demographic, environmental, and genetic stochasticity on them compared to large populations, so any of the threats previously discussed will likely have an even greater adverse impact on small populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). This risk of extinction from genetic stochasticity is amplified when connectivity between the small populations, and thus gene flow,

is impeded (Fahrig and Merriam 1985, Taylor et al. 1993, Lande and Shannon 1996, Palstra and Ruzzante 2008). Genetic diversity provides capacity to evolve in response to environmental changes, and the "rescue effect" of gene flow is important in minimizing probability of local extinction (Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). However, the rescue effect is diminished in conditions of high local environmental stochasticity of recruitment or survival (Eriksson et al. 2014). In addition, populations living near their physiological limits and lacking adaptive capacity may not be able to evolve in response to rapid changes (Hoffmann and Sgrò 2011). Furthermore, while pathogens or parasites rarely result in host extinction, they can increase its likelihood in small populations by driving the host populations below a critically low threshold beneath which demographic stochasticity can lead to extinction, even if they possess the requisite genetic diversity to adapt to a changed environment (Gomulkiewicz and Holt 1995, Adams et al. 2017b).

A Foothill Yellow-legged Frog PVA revealed that, even with no dam effects considered (e.g., slower growth and increased egg and tadpole mortality), populations with the starting average density of adult females in regulated rivers (4.6/km [2.9/mi]) were four times more likely to go extinct within 30 years than those with the starting average density of adult females from unregulated rivers (32/km [120/mi]) (Kupferberg et al. 2009c). When the density of females in sparse populations was used (2.1/km [1.3/mi], the 30-year risk of extinction increased 13-fold (Ibid.). With dam effects, a number of the risk factors above contribute to the additional probability of local extinction such as living near their lower thermal tolerance and reduced recruitment and survival from scouring and stranding flows, poor food quality, and increased predation and competition (Kupferberg 1997a; Hoffmann and Sgrò 2011; Kupferberg et al. 2011a,b; Kupferberg et al. 2012; Eriksson et al. 2014). These factors act synergistically, contributing in part to the small size, high divergence, and low genetic diversity exhibited by many Foothill Yellow-legged Frog populations located in highly regulated watersheds (Kupferberg et al. 2012, Peek 2018).

EXISTING MANAGEMENT

Land Ownership within the California Range

Using the Department's Foothill Yellow-legged Frog range boundary and the California Protected Areas Database (CPAD), a GIS dataset of lands that are owned in fee title and protected for open space purposes by over 1,000 public agencies or non-profit organizations, the total area of the species' range in California comprises 13,620,447 ha (33,656,857 ac) (CPAD 2019, CWHR 2019). Approximately 37% is owned by federal agencies, 80% of which (4,071,178 ha [10,060,100 ac]) is managed by the Forest Service (Figure 26). Department of Fish and Wildlife-managed lands, State Parks, and other State agency-managed lands constitute around 2.6% of the range. The remainder of the range includes < 1% Tribal lands, 2.3% other conserved lands (e.g., local and regional parks), and 57% private and government-managed lands that are not protected for open space purposes. It is important to note that even if included in the CPAD, a property's management does not necessarily benefit Foothill Yellow-legged Frogs, but in some cases changes in management to conserve the species may be easier to undertake than on private lands or public lands not classified as conserved.

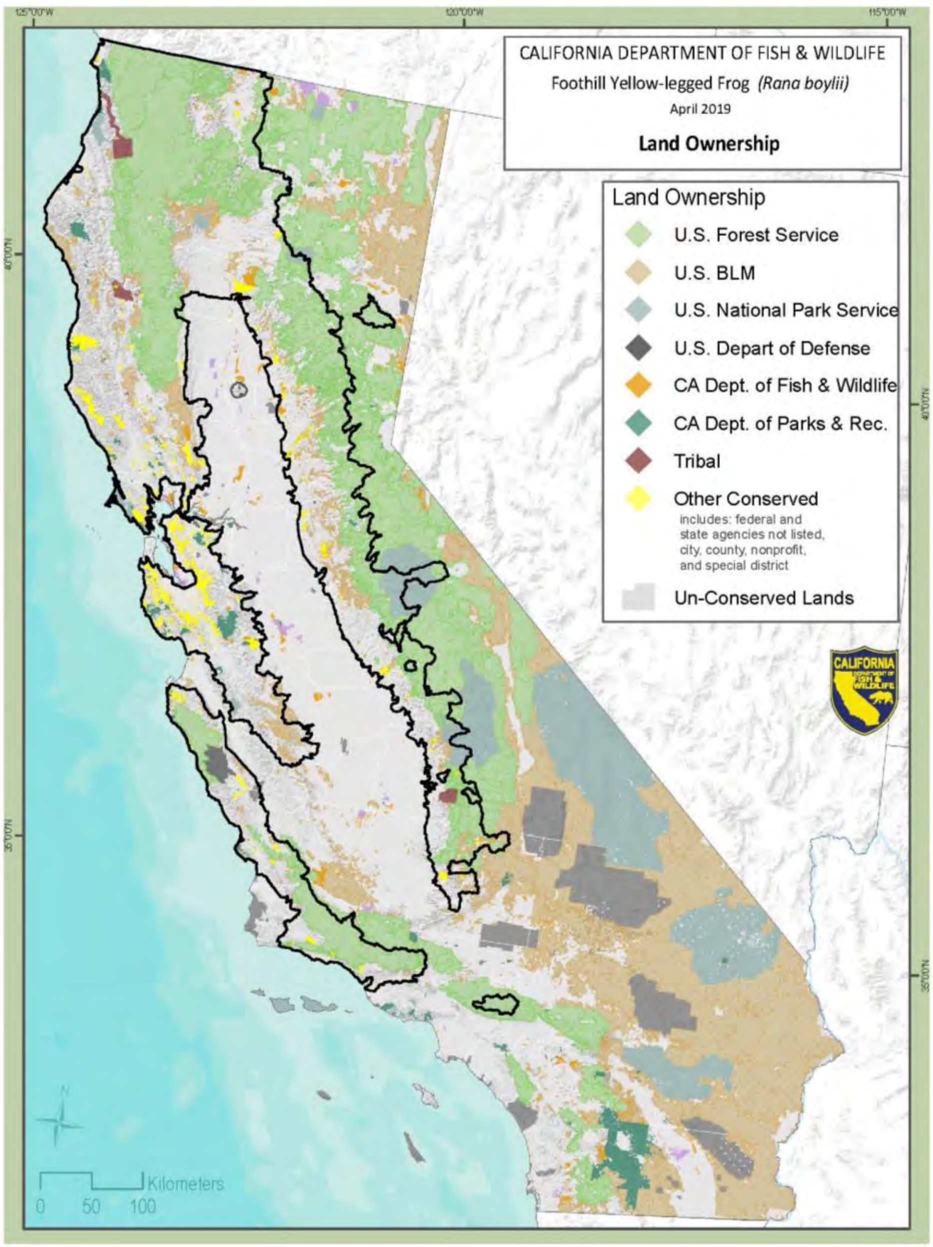

Figure 26. Conserved, Tribal, and other lands (BLM, CMD, CPAD, CWHR, DOD)

Statewide Laws

The laws and regulations governing land management within the Foothill Yellow-legged Frog's range vary by ownership. Several state and federal environmental laws apply to activities undertaken in California that may provide some level of protection for Foothill Yellow-legged Frogs and their habitat. The following is not an exhaustive list.

National Environmental Policy Act and California Environmental Quality Act

Most federal land management actions must undergo National Environmental Policy Act of 1969 (NEPA; 42 U.S.C. § 4321, et seq.) analysis. NEPA requires federal agencies to document, consider alternatives, and disclose to the public the impacts of major federal actions and decisions that may significantly impact the environment. As a BLM and Forest Service Sensitive Species, impacts to Foothill Yellow-legged ~~Legged~~ Frogs are considered during NEPA analysis; however, the law has no requirement to minimize or mitigate adverse effects.

The California Environmental Quality Act (CEQA) is similar to NEPA; it requires state and local agencies to identify, analyze, and consider alternatives, and to publicly disclose environmental impacts from projects over which they have discretionary authority (Pub. Resources Code § 21000 et seq.). CEQA differs substantially from NEPA in requiring mitigation for significant adverse effects to a less than significant level unless overriding considerations are documented. CEQA requires an agency find projects that? may have a significant effect on the environment if they have the potential to substantially reduce the habitat, decrease the number, or restrict the range of any rare, threatened, or endangered species (Cal. Code Regs., tit. 14, §§ 15065(a)(1), 15380.). CEQA establishes a duty for public agencies to avoid or minimize such significant effects where feasible (Cal. Code regs., tit. 14, § 15021). Impacts to Foothill Yellow-legged Frogs, as an SSC, should be identified, evaluated, disclosed, and mitigated or justified under the Biological Resources section of an environmental document prepared pursuant to CEQA. However, a lead agency is not required to make a mandatory finding of significance conclusion unless it determines on a project-specific basis that the species meets the CEQA criteria for rare, threatened, or endangered.

Clean Water Act and Porter-Cologne Water Quality Control Act

The Clean Water Act originated in 1948 as the Federal Water Pollution Control Act of 1948. It was heavily amended in 1972 and became known as the Clean Water Act (CWA). The purpose of the CWA was to establish regulations for the discharge of pollutants into waters of the United States and establish quality standards for surface waters. Section 404 of the CWA forbids the discharge of dredged or fill material into waters and wetlands without a permit from the ACOE. The CWA also requires an alternatives analysis, and the ACOE is directed to issue their permit for the least environmentally damaging practicable alternative. The definition of waters of the United States has changed substantially over time based on Supreme Court decisions and agency rule changes.

The Porter-Cologne Water Quality Act was established by the State in 1969 and is similar to the CWA in that it establishes water quality standards and regulates discharge of pollutants into state waters, but it

also administers water rights which regulate water diversions and extractions. The SWRCB and nine Regional Water Boards share responsibility for implementation and enforcement of Porter-Cologne as well as the CWA's National Pollutant Discharge Elimination System permitting.

Federal and California Wild and Scenic Rivers Acts

In 1968, the U.S. Congress passed the federal Wild and Scenic Rivers Act (WSRA) (16 U.S.C. § 1271, et seq.) which created the National Wild and Scenic River System. The WSRA requires the federal government to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The WSRA prohibits the federal government from building, licensing, funding or otherwise aiding in the building of dams or other project works on rivers or segments of designated rivers. The WSRA does not give the federal government control of private property including development along protected rivers.

California's Wild and Scenic Rivers Act was enacted in 1972 so rivers that "possess extraordinary scenic, recreational, fishery, or wildlife values shall be preserved in their free-flowing state, together with their immediate environments, for the benefit and enjoyment of the people of the state." (Pub. Res. Code, § 5093.50). Designated waterways are codified in Public Resources Code sections 5093.50-5093.70. In 1981, most of California's designated Wild and Scenic Rivers were adopted into the federal system. Currently in California, 3,218 km (1,999.6 mi) of 23 rivers are protected by the WSRA, most of which are located in the northwest. Foothill Yellow-legged Frogs have been observed in 11 of the 17 designated rivers within their range (CNDDB 2019).

Lake and Streambed Alteration Agreements

Fish and Game Code Section 1602 requires entities to notify the Department of activities that "divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake." If the activity may substantially adversely affect an existing fish and wildlife resource, the Department may enter into a lake or streambed alteration agreement with the entity that includes reasonable measures necessary to protect the fish or wildlife resource (Fish & G. Code, §1602, subd. (a)(4)(B)). A lake or stream alteration agreement does not authorize take of species listed as candidates, threatened, or endangered under CESA (see Protection Afforded by Listing for CESA compliance requirements).

Medicinal and Adult-Use Cannabis Regulation and Safety Act

The commercial cannabis cultivation industry is unique in that any entity applying for an annual cannabis cultivation license from California Department of Food and Agriculture (CDFA) must include "a copy of any final lake or streambed alteration agreement…or written verification from the California Department of Fish and Wildlife that a lake or streambed alteration agreement is not required" with their license application (Cal. Code Regs., tit. 3, § 8102, subd. (v)). The SWRCB also enforces the laws related to waste discharge and water diversions associated with cannabis cultivation (Cal. Code Regs., tit. 3, § 8102, subd. (p)).

Forest Practice Act

The Forest Practice Act was originally enacted in 1973 to ensure that logging in California is undertaken in a manner that will also preserve and protect the State's fish, wildlife, forests, and streams. This law and the regulations adopted by the California Board of Forestry and Fire Protection (BOF) pursuant to it are collectively referred to as the Forest Practice Rules. The Forest Practice Rules implement the provisions of the Forest Practice Act in a manner consistent with other laws, including CEQA, Porter-Cologne, CESA, and the Timberland Productivity Act of 1982. The California Department of Forestry and Fire Protection (CAL FIRE) enforces these laws and regulations governing logging on private land.

Federal Power Act

The Federal Power Act and its major amendments are implemented and enforced by FERC and require licenses for dams operated to generate hydroelectric power. One of the major amendments required that these licenses "shall include conditions for the protection, mitigation and enhancement of fish and wildlife including related spawning grounds and habitat" (ECPA 1986). Hydropower licenses granted by FERC are usually valid for 30-50 years. If a licensee wants to renew their license, it must file a Notice of Intent and a pre-application document five years before the license expires to provide time for public scoping, any potentially new studies necessary to analyze project impacts and alternatives, and preparation of environmental documents. The applicant must officially apply for the new license at least two years before the current license expires.

As a federal agency, FERC must comply with federal environmental laws prior to issuing a new license or relicensing an existing hydropower project, which includes NEPA and ESA. As a result of environmental compliance or settlement agreements formed during the relicensing process, some operations have been modified and habitat restored to protect fish and wildlife. For example, the Lewiston Dam relicensing resulted in establishment of the Trinity River Restoration Program, which takes an ecosystem-approach to studying dam effects and protecting and restoring fish and wildlife populations downstream of the dam (Snover and Adams 2016). Similarly, relicensing of the Rock Creek-Cresta Project on the North Fork Feather River resulted in establishment of a multi-stakeholder Ecological Resources Committee (ERC). As a result of the ERC's studies and recommendations, pulse flows for whitewater boating were suspended for several years following declines of Foothill Yellow-legged Frogs, and the ERC is currently working toward augmenting the population in an attempt to increase abundance to a viable level.

Administrative and Regional Plans

Forest Plans

NORTHWEST FOREST PLAN

In 1994, BLM and the Forest Service adopted the Northwest Forest Plan to guide the management of over 97,000 km^2 (37,500 mi^2) of federal lands in portions of northwestern California, Oregon, and Washington. The Northwest Forest Plan created an extensive network of forest reserves including

Riparian Reserves. Riparian Reserves apply to all land designations to protect riparian dependent resources. With the exception of silvicultural activities consistent with Aquatic Conservation Strategy objectives, timber harvest is not permitted within Riparian Reserves, which can vary in width from 30 to 91 m (100-300 ft) on either side of streams, depending on the classification of the stream or waterbody (USFS and BLM 1994). Fuel treatment and fire suppression strategies and practices implemented within these areas are designed to minimize disturbance.

Sierra Nevada Forest Plan

Land and Resource Management Plans for forests in the Sierra Nevada were changed in 2001 by the Sierra Nevada Forest Plan Amendment and subsequently adjusted via a supplemental Environmental Impact Statement and Record of Decision in 2004, referred to as the Sierra Nevada Framework (USFS 2004). This established an Aquatic Management Strategy with Goals including maintenance and restoration of habitat to support viable populations of riparian-dependent species; spatial and temporal connectivity for aquatic and riparian species within and between watersheds to provide physically, chemically, and biologically unobstructed movement for their survival, migration, and reproduction; instream flows sufficient to sustain desired conditions of riparian, aquatic, wetland, and meadow habitats; the physical structure and condition of streambanks and shorelines to minimize erosion and sustain desired habitat diversity; and prevention of new introductions of invasive species and reduction of invasive species impacts that adversely affect the viability of native species. The Sierra Nevada Framework also includes Riparian Conservation Objectives and associated standards and guidelines specific to aquatic-dependent species, including the Foothill Yellow-legged Frog.

Resource Management Plans

Sequoia, Kings Canyon, and Yosemite National Parks fall within the historical range of the Foothill Yellow-legged Frog, but the species has been extirpated from these areas. The guiding principles for managing biological resources on National Park Service lands include maintenance of animal populations native to park ecosystems (Hayes et al. 2016). They also commit the agency to work with other land managers on regional scientific and planning efforts and maintenance or reintroduction of native species to the parks including conserving Foothill Yellow-legged Frogs in the Sierra Nevada (USDI NPS 1999 as cited in Hayes et al. 2016). A Sequoia and Kings Canyon National Parks Resource Management Plan does not include specific management goals for Foothill Yellow-legged Frogs, but it does include a discussion of the factors leading to the species' decline and measures to restore the integrity of aquatic ecosystems (Ibid.). The Yosemite National Park Resource Management Plan includes a goal of restoring Foothill Yellow-legged Frogs to the Upper Tuolumne River below Hetch Hetchy Reservoir (USDI NPS 2003 as cited in Hayes et al. 2016).

FERC Licenses

Dozens of hydropower dams have been relicensed in California since 1999, and several are in the process of relicensing (FERC 2019). In addition to following the Federal Power Act and other applicable federal laws, Porter-Cologne Water Quality Act requires non-federal dam operators to obtain a Water Quality Certification (WQC) from the SWRCB. Before it can issue the WQC, the SWRCB must consult with

the Department regarding the needs of fish and wildlife. Consequently, SWRCB includes conditions in the WQC that seek to minimize adverse effects to native species, and Foothill Yellow-legged Frogs have received some special considerations due to their sensitivity to dam operations during these licensing processes. As discussed above, the typical outcome is formation of an ERC-type group to implement the environmental compliance requirements and recommend changes to flow management to reduce impacts. Foothill Yellow-legged Frog-specific requirements fall into three general categories: data collection, modified flow regimes, and standard best management practices.

Data Collection

When little is known about the impacts of different flows and temperatures on Foothill Yellow-legged Frog occupancy and breeding success, data are collected and analyzed to inform recommendations for future modifications to operations such as temperature trigger thresholds. These surveys include locating egg masses and tadpoles, monitoring temperatures and flows, and recording their fate (e.g., successful development and metamorphosis, displacement, desiccation) during different flow operations and different water years. Examples of licenses with these conditions include the Lassen Lodge Project (FERC 2018), Rock Creek-Cresta Project (FERC 2009a), and El Dorado Project (EID 2007).

Modified Flow Regimes

When enough data exist to understand the effect of different operations on Foothill Yellow-legged Frog occupancy and success, license conditions may include required minimum seasonal instream flows, specific thermal regimes, gradual ramping rates to reduce the likelihood of early life stage scour or stranding, or freshet releases (winter/spring flooding simulation) to maintain riparian processes, and cancellation or prohibition of recreational pulse flows during the breeding season. Examples of licenses with these conditions include the Poe Hydroelectric Project (SWRCB 2017), Upper American Project (FERC 2014), and Pit 3, 4, 5 Project (FERC 2007b).

Best Management Practices

Efforts to reduce the impacts from maintenance activities and indirect operations include selective herbicide and pesticide application, aquatic invasive species monitoring and control, erosion control, and riparian buffers. Examples of licenses with these conditions include the South Feather Project (SWRCB 2018), Spring Gap-Stanislaus Project (FERC 2009b), and Chili Bar Project (FERC 2007a).

Habitat Conservation Plans and Natural Community Conservation Plans

Non-federal entities can obtain authorization for take of federally threatened and endangered species incidental to otherwise lawful activities through development and implementation of a Habitat Conservation Plan (HCP) pursuant to Section 10 of the ESA. The take authorization can extend to species not currently listed under ESA but which may become listed as threatened or endangered over the term of the HCP, which is often 25-75 years. California's companion law, the Natural Community Conservation Planning Act of 1991, takes a broader approach than either CESA or ESA. A Natural Community Conservation Plan (NCCP) identifies and provides for the protection of plants, animals, and their

habitats, while allowing compatible and appropriate economic activity. There are currently four HCPs that include Foothill Yellow-legged Frogs as a covered species, two of which are also NCCPs.

HUMBOLDT REDWOOD (FORMERLY PACIFIC LUMBER) COMPANY

The Humboldt Redwood Company (HRC) HCP covers 85,672 ha (211,700 ac) of private Coast Redwood and Douglas-fir forest in Humboldt County (HRC 2015). It is a 50-year HCP/incidental take permit (ITP) that was executed in 1999, revised in 2015 as part of its adaptive management strategy, and expires on March 1, 2049. The HCP includes an Amphibian and Reptile Conservation Plan and an Aquatics Conservation Plan with measures designed to sustain viable populations of Foothill Yellow-legged Frogs and other covered aquatic herpetofauna. These conservation measures include prohibiting or limiting tree harvest within Riparian Management Zones (RMZ), controlling sediment by maintaining roads and hillsides, restricting controlled burns to spring and fall in areas outside of the RMZ, conducting effectiveness monitoring throughout the life of the HCP, and use the data collected to adapt monitoring and management plans accordingly.

Watershed assessment surveys include observations of Foothill Yellow-legged Frogs and have documented their widespread distribution on HRC lands with a pattern of fewer near the coast in the fog belt and more inland (S. Chinnici pers. comm. 2017). The watersheds within the property are largely unaffected by dam-altered flow regimes or non-native species, so aside from the operations described under Timber Harvest above that are minimized to the extent feasible, the focus on suitable temperatures and denser canopy cover for salmonids may reduce habitat suitability for Foothill Yellow-legged Frogs over time (Ibid.).

SAN JOAQUIN COUNTY MULTI-SPECIES HABITAT CONSERVATION AND OPEN SPACE PLAN

The San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) is a 50-year HCP/ITP that was signed by the USFWS on November 14, 2000 (San Joaquin County 2000). The SJMSCP covers almost all of San Joaquin County except federal lands, a few select projects, and some properties with certain land uses, roughly 364,000 ha (900,000 ac). At the time of execution, approximately 70 ha (172 ac) of habitat within the SJMSCP area in the southwest portion of the county were considered occupied by Foothill Yellow-legged Frogs with another 1,815 ha (4,484 ac) classified as potential habitat, but it appears the species had been considered extirpated before then (Jennings and Hayes 1994, San Joaquin County 2000, Lind 2005). The HCP estimates around 8% of the combined modeled habitat would be converted to other uses over the permit term, but the establishment of riparian preserves with buffers around Corral Hollow Creek, where the species occurred historically, was expected to offset those impacts (San Joaquin County 2000, SJCOG 2018). However, the HCP did not require surveys to determine if Foothill Yellow-legged Frogs are benefiting (M. Grefsrud pers. comm. 2019).

EAST CONTRA COSTA COUNTY HABITAT CONSERVATION PLAN/NATURAL COMMUNITY CONSERVATION PLAN

The East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan (ECCC HCP/NCCP) is a multi-jurisdictional 30-year plan adopted in 2007 that covers over 70,423 ha (174,018 ac) in eastern Contra Costa County (Jones & Stokes 2006). The Foothill Yellow-legged Frog appears to be

extirpated from the ECCC HCP/NCCP area (CNDDB 2019). Nevertheless, suitable habitat was mapped, and impacts were estimated at well under 1% of both breeding and migratory habitat (Jones & Stokes 2006). One of the HCP/NCCP's objectives is acquiring high-quality Foothill Yellow-legged Frog habitat that has been identified along Marsh Creek (Ibid.). In 2017, the Viera North Peak 65 ha (160 ac) property was acquired that possesses suitable habitat for Foothill Yellow-legged Frogs (ECCCHC 2018).

Santa Clara Valley Habitat Plan

The Santa Clara Valley Habitat Plan (SCVHP) is a 50-year HCP/NCCP covering over 210,237 ha (519,506 ac) in Santa Clara County (ICF 2012). As previously mentioned, Foothill Yellow-legged Frogs appear to have been extirpated from lower elevation sites, particularly below reservoirs in this area. Approximately 17% of modeled Foothill Yellow-legged Frog habitat, measured linearly along streams, was already permanently preserved, and the SCVHP seeks to increase that to 32%. The maximum allowable habitat loss is 11 km (7 mi) permanent loss and 3 km (2 mi) temporary loss, while 167 km (104 mi) of modeled habitat is slated for protection. By mid-2018, 8% of impact area had been accrued and 3% of habitat protected (SCVHA 2019).

Green Diamond Aquatic Habitat Conservation Plan

Green Diamond Resources Company has an Aquatic Habitat Conservation Plan (AHCP) covering 161,875 ha (400,000 ac) of their land that is focused on cold-water adapted species, but many of the conservation measures are expected to benefit Foothill Yellow-legged Frogs as well (K. Hamm pers. comm. 2017). Examples include slope stability and road management measures to reduce stream sedimentation from erosion and landslides, and limiting water drafting during low flow periods with screens over the pumps to avoid entraining animals (Ibid.). Although creating more open canopy areas and warmer water temperatures is not the goal of the AHCP, the areas that are suitable for Foothill Yellow-legged Frog breeding are likely to remain that way because they are wide channels that receive sufficient sunlight (Ibid.).

SUMMARY OF LISTING FACTORS

CESA's implementing regulations identify key factors relevant to the Department's analyses and the Fish and Game Commission's decision on whether to list a species as threatened or endangered. A species will be listed as endangered or threatened if the Commission determines that the species' continued existence is in serious danger or is threatened by any one or any combination of the following factors: (1) present or threatened modification or destruction of its habitat; (2) overexploitation; (3) predation; (4) competition; (5) disease; or (6) other natural occurrences or human-related activities (Cal. Code Regs., tit. 14, § 670.1, subd. (i).

This section provides summaries of information from the foregoing sections of this status review, arranged under each of the factors to be considered by the Commission in determining whether listing is warranted.

Present or Threatened Modification or Destruction of Habitat

Most of the factors affecting ability to survive and reproduce listed above involve destruction or degradation of Foothill Yellow-legged Frog habitat. The most widespread, and potentially most significant, threats are associated with dams and their flow regimes, particularly in areas where they are concentrated and occur in a series along a river. Dams and the way they are operated can have up- and downstream impacts to Foothill Yellow-legged Frogs. They can result in confusing natural breeding cues, scouring and stranding of egg masses and tadpoles, reducing quality and quantity of breeding and rearing habitat, reducing tadpole growth rate, impeding gene flow among populations, and establishing and spreading non-native species (Hayes et al. 2016). These impacts appear to be most severe when the dam is operated for the generation of hydropower utilizing hydropeaking and pulse flows (Kupferberg et al. 2009c, Peek 2018). Foothill Yellow-legged Frog abundance below dams is an average of five times lower than in unregulated rivers (Kupferberg et al. 2012). The number, height, and distance upstream of dams in a watershed influenced whether Foothill Yellow-legged Frogs still occurred at sites where they had been present in 1975 in California (Ibid.). Water diversions for agricultural, industrial, and municipal uses also reduce the availability and quality of Foothill Yellow-legged Frog habitat. Dams are concentrated in the Bay Area, Sierra Nevada, and southern California (Figure 17), while hydropower plants are densest in the northern and central Sierra Nevada (Figure 18).

With predicted increases in the human population, ambitious renewable energy targets, higher temperatures, and more extreme and variable precipitation falling increasingly ~~more~~ as rain rather than snow, the need for more and taller dams and water diversions for hydroelectric power generation, flood control, and water storage and delivery is not expected to abate in the future. California voters approved Proposition 1, the Water Quality, Supply and Infrastructure Improvement Act of 2014, which dedicated $2.7 billion to water storage projects (PPIC 2018). In 2018, the California Water Commission approved funding for four new dams in California: expansion of Pacheco Reservoir (Santa Clara County), expansion of Los Vaqueros Reservoir (Contra Costa County), Temperance Flat Dam (new construction) on the San Joaquin River (Fresno County), and the off-stream Sites Reservoir (new construction) diverting the Sacramento River (Colusa County) (CWC 2019). No historical records of Foothill Yellow-legged Frogs from the Los Vaqueros or Sites Reservoir areas exist in the CNDDB, and one historical (1950) collection is documented from the Pacheco Reservoir area (CNDDB 2019). However, the proposed Temperance Flat Dam site is downstream of one of the only known extant populations of Foothill Yellow-legged Frogs in the East/Southern Sierra clade (Ibid.).

The other widespread threat to Foothill Yellow-legged Frog habitat is climate change, although the severity of its impacts is somewhat uncertain. While drought, wildland fires, floods, and landslides are natural and ostensibly necessary disturbance events for preservation of native biodiversity, climate change is expected to result in increased frequency and severity of these events in ways that may exceed species' abilities to adapt (Williams et al. 2008, Hoffmann and Sgrò 2011, Keely and Syphard 2016). These changes can lead to increased competition, predation, and disease transmission as species become concentrated in areas that remain wet into the late summer (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Loss of riparian vegetation from wildland fires can result in increased stream temperatures or concentrations of nutrients and trace heavy metals that inhibit growth and survival

(Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Stream sedimentation from landslides following fire or excessive precipitation can destroy or degrade breeding and rearing habitat (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). At least some models predict unprecedented dryness in the latter half of the century (Cook et al. 2015). The effects of climate change will be realized across the Foothill Yellow-legged Frog's range, and their severity will likely differ in ways that are difficult to predict. However, the impacts from extended droughts will likely be greatest in the areas that are naturally more arid, the lower elevations and latitudes of southern California and the foothills surrounding the Central Valley (Figure 21).

While most future urbanization is predicted to occur in areas outside of the Foothill Yellow-legged Frog's range, it has already contributed to the loss and fragmentation of Foothill Yellow-legged Frog habitat in California. In addition, the increased predation, wildland fires, introduced species, road mortality, disease transmission, air and water pollution, and disturbance from recreation that can accompany urbanization expand its impact far beyond its physical footprint (Davidson et al. 2002, Syphard et al. 2007, Cook et al. 2012, Bar-Massada et al. 2014). Within the Foothill Yellow-legged Frog's historical range, these effects appear most significant and extensive in terms of population extirpations in southern California and the San Francisco Bay Area.

Several other activities have the potential to destroy or degrade Foothill Yellow-legged Frog habitat, but they are less common across the range. They also tend to have relatively small areas of impact, although they can be significant in those areas, particularly if populations are already small and declining. These include impacts from mining, cannabis cultivation, vineyard expansion, overgrazing, timber harvest, recreation, and some stream habitat restoration projects (Harvey and Lisle 1998, Belsky et al. 1999, Merelender 2000, Pilliod et al. 2003, Bauer et al. 2015, Kupferberg and Furey 2015).

Overexploitation

Foothill Yellow-legged Frogs are not threatened by overexploitation. There is no known pet trade for Foothill Yellow-legged Frogs (Lind 2005). During the massive frog harvest that accompanied the Gold Rush, some Foothill Yellow-legged Frogs were collected, but because they are relatively small and have irritating skin secretions, there was much less of a market for them (Jennings and Hayes 1985). Within these secretions is a peptide with antimicrobial activity that is particularly potent against *Candida albicans*, a human pathogen that has been developing resistance to traditional antifungal agents (Conlon et al. 2003). However, the peptide's therapeutic potential is limited by its strong hemolytic activity, so further studies will focus on synthesizing analogs that can be used as antifungals, and collection of Foothill Yellow-legged Frogs for lab cultures is unlikely (Ibid.).

Like all native California amphibians, collection of Foothill Yellow-legged Frogs is unlawful without a permit from the Department. They may only be collected for scientific, educational, or propagation reasons through a Scientific Collecting Permit (Fish & G. Code § 1002 et seq.). The Department has the discretion to limit or condition the number of individuals collected or handled to ensure no significant adverse effects. Incidental harm from authorized activities on other aquatic species can be avoided or minimized by the inclusion of special terms and conditions in permits.

Predation

Predation is a likely contributor to Foothill Yellow-legged Frog population declines where the habitat is degraded by one or many other risk factors (Hayes and Jennings 1986). Predation by native garter snakes can be locally substantial; however, it may only have an appreciable population-level impact if the availability of escape refugia is diminished. For example, when streams dry and only pools remain, Foothill Yellow-legged Frogs are more vulnerable to predation by native and non-native species because they are concentrated in a small area with little cover.

Several studies have demonstrated the synergistic impacts of predators and other stressors. Foothill Yellow-legged Frogs, primarily as demonstrated through studies on tadpoles, are more susceptible to predation when exposed to some agrochemicals, cold water, high velocities, excess sedimentation, and even the presence of other species of predators (Harvey and Lisle 1998, Adams et al. 2003, Olson and Davis 2009, Kupferberg et al. 2011b, Kerby and Sih 2015, Catenazzi and Kupferberg 2018). Foothill Yellow-legged Frog tadpoles appear to be naïve to chemical cues from some non-native predators; they have not evolved those species-specific predator avoidance behaviors (Paoletti et al. 2011). Furthermore, early life stages are often more sensitive to environmental stressors, making them more vulnerable to predation, and Foothill Yellow-legged Frog population dynamics are highly sensitive to egg and tadpole mortality (Kats and Ferrer, 2003, Kupferberg et al. 2009c). Predation pressure is likely positively associated with proximity to anthropogenic changes in the environment, so in more remote or pristine places, it probably does not have a serious population-level impact.

Competition

Intra- and interspecific competition in Foothill Yellow-legged Frogs has been documented. Intraspecific male-to-male competition for females has been reported (Rombough and Hayes 2007). Observations include physical aggression and a non-random mating pattern in which larger males were more often engaged in breeding (Rombough and Hayes 2007, Wheeler and Welsh 2008). A behavior resembling clutch-piracy, where a satellite male attempts to fertilize already laid eggs, has also been documented (Rombough and Hayes 2007). These acts of competition play a role in population genetics, but they likely do not result in serious physical injury or mortality. Intraspecific competition among Foothill Yellow-legged Frog tadpoles was negligible (Kupferberg 1997a).

Interspecific competition appears to have a greater possibility of resulting in adverse impacts. Kupferberg (1997a) did not observe a significant change in tadpole mortality for Foothill Yellow-legged Frogs raised with Pacific Treefrogs compared to single-species controls. However, when reared together, Foothill Yellow-legged Frog tadpoles lost mass, while Pacific Treefrog tadpoles increased mass (Kerby and Sih 2015). As described previously under Introduced Species, Foothill Yellow-legged Frog tadpoles experienced significantly higher mortality and smaller size at metamorphosis when raised with bullfrog tadpoles (Kupferberg 1997a). The mechanism of these declines appeared to be exploitative competition, as opposed to interference, through the reduction of available algal resources from bullfrog tadpole grazing in the shared enclosures (Ibid.).

The degree to which competition threatens Foothill Yellow-legged Frogs likely depends on the number and density of non-native species in the area rather than intraspecific competition, and co-occurrence of Foothill Yellow-legged Frog and bullfrog tadpoles may be somewhat rare since the latter tends to breed in lentic (still water) environments (M. van Hattem pers. comm. 2019). Interspecific competition with other native species may have some minor adverse consequences on fitness.

Disease

Currently, the only disease known to pose a serious risk to Foothill Yellow-legged Frogs is Bd. Until 2017, the only published studies on the impact of Bd on Foothill Yellow-legged Frogs suggested it could reduce growth and body condition but was not lethal (Davidson et al. 2007, Lowe 2009, Adams et al. 2017b). However, two recent mass mortality events caused by chytridiomycosis proved they are susceptible to lethal effects, at least under certain conditions like drought-related concentration and presence of bullfrogs (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Some evidence indicates disease may have played a principal role in the disappearance of the species from southern California (Adams et al. 2017b). Bd is likely present in the environment~~al~~ throughout the Foothill Yellow-legged Frog's range, and with bullfrogs and treefrogs acting as carriers, it will remain a threat to the species; however, given the dynamics of the two recent die-offs in the San Francisco Bay area, the probability of future outbreaks may be greater in areas where the species is under additional stressors like drought and introduced species (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Therefore, as with predation, Foothill Yellow-legged Frogs are less likely to experience the adverse impacts of diseases in more remote areas with fewer anthropogenic changes to the environment.

Other Natural Events or Human-Related Activities

Agrochemicals, particularly organophosphates that act as endocrine disruptors, can travel substantial distances from the area of application through atmospheric drift and have been implicated in the disappearance and declines of many species of amphibians in California including Foothill Yellow-legged Frogs (LeNoir et al. 1999, Davidson 2004, Lind 2005, Olson and Davis 2009). Foothill Yellow-legged Frogs appear to be significantly more sensitive to the adverse impacts of some pesticides than other native species (Sparling and Fellers 2009, Kerby and Sih 2015). These include smaller body size, slower development rate, increased time to metamorphosis, immunosuppression, and greater vulnerability to predation and malformations (Kiesecker 2002, Hayes et al. 2006, Sparling and Fellers 2009, Kerby and Sih 2015). Some of the most dramatic declines experienced by ranids in California occurred in the Sierra Nevada east of the San Joaquin Valley where over half of the state's total pesticide usage occurs (Sparling et al. 2001).

Many Foothill Yellow-legged Frog populations are small, isolated from other populations, and possess low genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). Genetic diversity is important in providing a population the capacity to evolve in response to environmental changes, and connectivity among populations is important for gene exchange and in minimizing probability of local extinction (Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). Small populations are at much greater risk of extirpation primarily through the disproportionate impact of demographic, environmental, and genetic stochasticity than robust populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). Based on a Foothill Yellow-legged Frog PVA, populations in regulated rivers face a 4- to 13-fold greater extinction risk in 30 years than populations in unregulated rivers due to smaller population sizes (Kupferberg et al. 2009c). The threat posed by small population sizes is significant and the general pattern shows increases in severity from north to south; however, many sites, primarily in the northern Sierra Nevada, in watersheds with large hydropower projects are also at high risk.

PROTECTION AFFORDED BY LISTING

It is the policy of the State to conserve, protect, restore and enhance any endangered or threatened species and its habitat (Fish & G. Code, § 2052). The conservation, protection, and enhancement of listed species and their habitat is of statewide concern (Fish & G. Code, § 2051(c)). CESA defines "take" as hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill (Fish & G. Code, § 86). The Fish and Game Code provides the Department with related authority to authorize "take" of species listed as threatened or endangered under certain circumstances (see, e.g., Fish & G. Code, §§ 2081, 2081.1, 2086, & 2835).

If the Foothill Yellow-legged Frog is listed under CESA, impacts of take caused by activities authorized through incidental take permits must be minimized and fully mitigated according to state standards (Fish & G. Code, § 2081, subd. (b)). These standards typically include protection of land in perpetuity with an easement, development and implementation of a species-specific adaptive management plan, and funding through an endowment to pay for long-term monitoring and maintenance to ensure the mitigation land meets performance criteria. Obtaining an incidental take permit is voluntary. The Department cannot force compliance; however, any person violating the take prohibition may be criminally and civilly liable under state law.

Additional protection of Foothill Yellow-legged Frogs following listing would be expected to occur through state and local agency environmental review under CEQA. CEQA requires affected public agencies to analyze and disclose project-related environmental effects, including potentially significant impacts on rare, threatened, and endangered species. In common practice, potential impacts to listed species are examined more closely in CEQA documents than potential impacts to unlisted species. Where significant impacts are identified under CEQA, the Department expects project-specific avoidance, minimization, and mitigation measures to benefit the species. State listing, in this respect, and consultation with the Department during state and local agency environmental review under CEQA, would be expected to benefit the Foothill Yellow-legged Frog in terms of reducing impacts from individual projects, which might otherwise occur absent listing.

For some species, CESA listing may prompt increased interagency coordination and the likelihood that state and federal land and resource management agencies will allocate funds toward protection and recovery actions. In the case of the Foothill Yellow-legged Frog, some multi-agency efforts exist, often associated with FERC license requirements, to improve habitat conditions and augment declining populations. The USFWS is leading an effort to develop regional Foothill Yellow-legged Frog conservation strategies, and CESA listing may result in increased priority for limited conservation funds.

LISTING RECOMMENDATION

CESA directs the Department to prepare this report regarding the status of the Foothill Yellow-legged Frog in California based upon the best scientific information available (Fish & G. Code, § 2074.6). CESA also directs the Department based on its analysis to indicate in the status report whether the petitioned action (i.e., listing as threatened) is warranted (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

Under CESA, an endangered species is defined as "a native species or subspecies…which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish & G. Code, § 2062). A threatened species is defined as "a native species or subspecies…that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]" (Fish and G. Code, § 2067).

The Department includes and makes its recommendation in its status report as submitted to the Commission in an advisory capacity based on the best available science. In consideration of the scientific information contained herein, the Department has determined that listing the Foothill Yellow-legged Frog under CESA by genetic clade is the prudent approach due to the disparate degrees of imperilment among them. In areas of uncertainty, the Department recommends the higher protection status until clade boundaries can be better defined.

NORTHWEST/NORTH COAST: Not warranted at this time.

Clade-level Summary: This is the largest clade with the most robust populations (highest densities) and the greatest genetic diversity. This area is the least densely populated by humans; contains relatively few hydroelectric dams, particularly further north; and has the highest precipitation in the species' California range. The species is still known to occur in most, if not all, historically occupied watersheds; presumed extirpations are mainly concentrated in the southern portion of the clade around the heavily urbanized San Francisco Bay area. The proliferation of cannabis cultivation, particularly illicit grows in and around the Emerald Triangle, the apparent increase in severe wildland fires in the area, and potential climate change effects are cause for concern, so the species should remain a Priority 1 SSC here with continued monitoring for any change in its status.

WEST/CENTRAL COAST: Endangered.

Clade-level Summary: Foothill Yellow-legged Frogs appear to be extirpated from a relatively large proportion of historically occupied sites within this clade, particularly in the heavily urbanized northern portion around the San Francisco Bay. In the northern portion of the clade, nearly all the remaining populations (which may be fewer than a dozen) are located above dams, which line the mountains surrounding the Bay Area, and two are known to have undergone recent disease-associated die-offs. These higher elevation sites are more often intermittent or ephemeral streams than the lower in the watersheds. As a result, the more frequent and extreme droughts that have dried up large areas seem to have contributed to recent declines. Illegal cannabis cultivation, historical mining effects, overgrazing, and recreation likely contributed to declines and may continue to threaten remaining populations.

SOUTHWEST/SOUTH COAST: Endangered.

Clade-level Summary: The most extensive extirpations have occurred in this clade, and only two known extant populations remain. Both are small with apparently low genetic diversity, making them especially vulnerable to extirpation. This is also an area with a large human population, many dams, and naturally arid, fire-prone environments, particularly in the southern portion of the clade. Introduced species are widespread, and cannabis cultivation is rivaling the Emerald Triangle in some areas (e.g., Santa Barbara County). Introduced species, expanded recreation, disease, and flooding appear to have contributed to the widespread extirpations in southern California over 40 years ago.

FEATHER RIVER: Threatened.

Clade-level Summary: This is the smallest clade and has a high density of hydroelectric dams. It also recently experienced one of the largest, most catastrophic wildfires in California history. Despite these threats, Foothill Yellow-legged Frogs appear to continue to be relatively broadly distributed within the clade, although with all the dams in the area, most populations are likely disconnected. The area is more mesic and experienced less of a change in precipitation in the most recent drought than the clades south of it. The clade is remarkable genetically and morphologically as it is the only area where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs overlap and can hybridize. The genetic variation within the clade is greater than the other clades except for the Northwest/North Coast. Most of the area within the clade's boundaries is Forest Service-managed, and little urbanization pressure or known extirpations exist in this area. Recent FERC licenses in this area require Foothill Yellow-legged Frog specific conservation, which to date has included cancelling pulse flows, removing encroaching vegetation, and translocating egg masses and in situ head-starting to augment a population that had recently declined.

NORTHEAST/NORTHERN SIERRA: Threatened.

Clade-level Summary: The Northeast/Northern Sierra clade shares many of the same threats as the Feather River clade (e.g., relatively small area with many hydroelectric dams). The area is also more mesic and experienced less of a change in precipitation during the recent drought than more southern clades. However, this pattern may not continue as some models suggest loss of snowmelt will be greater in the northern Sierra Nevada, and one of the climate change exposure models suggests a comparatively large proportion of the lower elevations will experience climatic conditions not currently known from the area (i.e., non-analog) by the end of the century. Recent surveys suggest the area continues to support several populations of the species, some of which seem to remain robust, with a fairly widespread distribution. However, genetic analyses from several watersheds suggest many of these populations are isolated and diverging, particularly in regulated reaches with hydropeaking flows.

EAST/SOUTHERN SIERRA: Endangered.

Clade-level Summary: Like the Southwest/South Coast clade, widespread extirpations in this area were observed as early as the 1970s. Dams and introduced species were credited as causal factors in these declines in distribution and abundance, and mining and disease may also have contributed. This area is relatively arid, and drought effects appear greater here than in northern areas that exhibit both more precipitation and a smaller difference between drought years and the historical average. There is a relatively high number of hydroelectric power generating dams in series along the major rivers in this clade and at least one new proposed dam near one of the remaining populations. This area is also the most heavily impacted by agrochemicals from the San Joaquin Valley.

MANAGEMENT RECOMMENDATIONS

The Department has evaluated existing management recommendations and available literature applicable to the management and conservation of the Foothill Yellow-legged Frog to arrive at the following recommendations. These recommendations, which represent the best available scientific information, are largely derived ~~the~~ from the Foothill Yellow-legged Frog Conservation Assessment, the California Energy Commission's Public Interest Energy Research Reports, the Recovery Plans of West Coast Salmon and Steelhead, and the California Amphibian and Reptile Species of Special Concern (Kupferberg et al. 2009b,c; 2011a; NMFS 2012, 2013, 2014, 2016; Hayes et al. 2016, Thomson et al. 2016).

Conservation Strategies

Maintain current distribution and genetic diversity by protecting existing Foothill Yellow-legged Frog populations and their habitats and providing opportunities for genetic exchange. Increase abundance to viable levels in populations at risk of extirpation due to small sizes, when appropriate, through in situ or ex situ captive rearing and/or translocations. Use habitat suitability and hydrodynamic habitat models to identify historically occupied sites that may currently support Foothill Yellow-legged Frogs, or they could with minor habitat improvements or modified management. Re-establish extirpated populations in suitable habitat through captive propagation, rearing, and/or translocations. Prioritize areas in the southern portions of the species' range where extirpations and loss of diversity have been the most severe.

If establishing reserves, prioritize areas containing high genetic variation in Foothill Yellow-legged Frogs (and among various native species) and climatic gradients where selection varies over small geographical area because environmental heterogeneity can provide a means of maintaining phenotypic variability which increases the adaptive capacity of populations as conditions change. These reserves should provide connectivity to other occupied areas to facilitate gene flow and allow for ongoing selection to fire, drought, thermal stresses, and changing species interactions.

Research and Monitoring

Attempt to rediscover potentially remnant populations in areas where they are considered extirpated, prioritizing the southern portions of the species' range. Collect environmental DNA in addition to conducting visual encounter surveys to improve detectability. Concurrently assess presence of threats and habitat suitability to determine if future reintroductions may be possible. Collect genetic samples from any Foothill Yellow-legged Frogs captured for use in landscape genomics analyses and possible future translocation or captive propagation efforts. Attempt to better clarify clade boundaries where there is uncertainty. Study whether small populations are at risk of inbreeding depression, whether genetic rescue should be attempted, and if so, whether that results in hybrid vigor or outbreeding depression.

Continue to evaluate how water operations affect Foothill Yellow-legged Frog population demographics. Establish more long-term monitoring programs in regulated and unregulated (reference) rivers across the species' range but particularly in areas like the Sierra Nevada where most large hydropower dams in the species' range are concentrated. Assess whether the timing of pulse flows influences population dynamics, particularly whether early releases have a disproportionately large adverse effect by eliminating the reproductive success of the largest, most fecund females, who appear to breed earlier in the season. Investigate survival rates in poorly-understood life stages, such as tadpoles, young of the year, and juveniles. Determine the extent to which pulse flows contribute to displacement and mortality of post-metamorphic life stages.

Collect habitat variables that correlate with healthy populations to develop more site-specific habitat suitability and hydrodynamic models. Study the potential synergistic effect of increased flow velocity and decreased temperature on tadpole fitness. Examine the relationship between changes in flow, breeding and rearing habitat connectivity, and scouring and stranding to develop site-specific benign ramping rates. Incorporate these data and demographic data into future PVAs for use in establishing frog-friendly flow regimes in future FERC relicensing or license amendment efforts and habitat restoration projects. Ensure long-term funding for post-license or restoration monitoring to evaluate attainment of expected results and for use in adapting management strategies accordingly.

Evaluate the distribution of other threats such as cannabis cultivation, vineyard expansion, livestock grazing, mining, timber harvest, and urbanization and roads in the Foothill Yellow-legged Frog's range. Study the short- and long-term effects of wildland fires and fire management strategies. Assess the extent to which these potential threats pose a risk to Foothill Yellow-legged Frog persistence in both regulated and unregulated systems.

Investigate how reach-level or short-distance habitat suitability and hydrodynamic models can be extrapolated to a watershed level. Study habitat connectivity needs such as the proximity of breeding sites and other suitable habitats along a waterway necessary to maintain gene flow and functioning meta-population dynamics.

Habitat Restoration and Watershed Management

Remove or update physical barriers like dams and poorly constructed culverts and bridges to improve connectivity and natural stream processes. Remove anthropogenic features that support introduced predators and competitors such as abandoned mine tailing ponds that support bullfrog breeding. Conduct active eradication and management efforts to decrease the abundance of bullfrogs, non-native fish, and crayfish (where they are non-native). In managed rivers, manipulate stream flows to negatively affect non-native species not adapted to a winter flood/summer drought flow regime.

Adopt a multi-species approach to channel restoration projects and managed flow regimes (thermal, velocity, timing) and mimic the natural hydrograph to the greatest extent possible. When this is impractical or infeasible, focus on minimizing adverse impacts by gradually ramping discharge up and down, creating and maintaining gently sloping and sun-lit gravel bars and warm calm edgewater habitats for tadpole rearing, and mixing hypolimnetic water (from the lower colder stratum in a reservoir) with warmer surface water before release if necessary to ensure appropriate thermal conditions for successful metamorphosis. Promote restoration and maintenance of habitat heterogeneity (different depths, velocities, substrates, etc.) and connectivity to support all life stages and gene flow. Avoid damaging Foothill Yellow-legged Frog breeding habitat when restoring habitat for other focal species like anadromous salmonids.

Regulatory Considerations and Best Management Practices

Develop range-wide minimum summer baseflow requirements that protect Foothill Yellow-legged Frogs and their habitat with appropriate provisions to address regional differences using new more ecologically-meaningful approaches such as modified percent-of-flow strategies for watersheds (e.g., Mierau et al. 2018). Limit water diversions during the dry season and construction of new dams by focusing on off-stream water storage strategies.

Ensure and improve protection of riparian systems. Require maintenance of appropriate riparian buffers and canopy coverage (i.e., partly shaded) around occupied habitat or habitat that has been identified for potential future reintroductions. Restrict instream work to dry periods where possible. Prohibit fording in and around breeding habitat. Avoid working near streams after the first major rains in the fall when Foothill Yellow-legged Frogs may be moving upslope toward tributaries and overwintering sites. Use a 3 mm (0.125 in) mesh screen on water diversion pumps and limit the rate and amount of water diverted such that depth and flow remain sufficient to support Foothill Yellow-legged Frogs of all life stages occupying the immediate area and downstream. Install exclusion fencing where appropriate, and if Foothill Yellow-legged Frog relocation is required, conduct it early in the season because moving egg masses is easier than moving tadpoles.

Reduce habitat degradation from sedimentation, pesticides, herbicides, and other non-point source waste discharges from adjacent land uses including along tributaries of rivers and streams. Limit mining to parts of rivers not used for oviposition, such as deeper pools or reaches with few tributaries, and at times of year when frogs are more common in tributaries (i.e., fall and winter). Manage recreational activities in or adjacent to Foothill Yellow-legged Frog habitat (e.g., OHV and hiking trails, camp sites, boating ingress/egress, flows, and speeds) in a way that minimizes adverse impacts. Siting cannabis grows in areas with better access to roads, gentler slopes, and ample water resources could significantly reduce threats to the environment. Determine which, when, and where agrochemicals should be restricted to reduce harm to Foothill Yellow-legged Frogs and other species. Ensure all new road crossings and upgrades to existing crossings (bridges, culverts, fills, and other crossings) accommodate at least 100-year flood flows and associated bedload and debris.

Partnerships and Coordination

Establish collaborative partnerships with agencies, universities, and non-governmental organizations working on salmon and steelhead recovery and stream restoration. Anadromous salmonids share many of the same threats as Foothill Yellow-legged Frogs, and recovery actions such as barrier removal, restoration of natural sediment transport processes, reduction in pollution, and eradication of non-native predators would benefit frogs as well. Ensure Integrated Regional Water Management Plans and fisheries restoration programs take Foothill Yellow-legged Frog conservation into consideration during design, implementation, and maintenance.

Encourage local governments to place conditions on new developments to minimize negative impacts on riparian systems. Promote and implement initiatives and programs that improve water conservation use efficiency, reduce greenhouse gas emissions, promote sustainable agriculture and smart urban growth, and protect and restore riparian ecosystems. Shift reliance from on-stream storage to off-stream storage, resolve frost protection issues (water withdrawals), and ensure necessary flows for all life stages in all water years.

Establish a Department-coordinated staff and citizen scientist program to systematically monitor occupied stream reaches across the species' range.

Education and Enforcement

Support programs to provide educational outreach and local involvement in restoration and watershed stewardship, such as Project Wild, Adopt a Watershed, school district environmental camps, and other programs teaching the effects of human land and water use on Foothill Yellow-legged Frog survival.

Provide additional funding for increased law enforcement to reduce ecologically harmful stream alterations and water pollution and to ensure adequate protection for Foothill Yellow-legged Frogs at pumps and diversions. Identify and address illegal water diverters and out-of-compliance diverters, seasons of diversion, off-stream reservoirs, well pumping, and bypass flows to protect Foothill Yellow-legged Frogs. Prosecute violators accordingly.

ECONOMIC CONSIDERATIONS

The Department is charged in an advisory capacity in the present context to provide a written report and a related recommendation to the Commission based on the best scientific information available regarding the status of Foothill Yellow-legged Frog in California. The Department is not required to prepare an analysis of economic impacts (See Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

Subject: Re: Peer Review Request: Foothill Yellow-legged Frog Status Review
Attachments: DRAFT FYLF Status Review-RAP.docx

Hi Laura,
Attached is my review of the draft FYLF status report. I'm sending this now because I leave tomorrow at 6am for about 9 days on the Yampa/Green River, so will be completely out of contact. If you have questions/concerns, I can follow up then. Overall, this is a really amazing compendium of all the research/knowledge about RABO, so kudos to you for all your hard work! It shows...this was simultaneously really cool to read (because after all this time I still really am fascinated by this species and always interested in learning more), and very depressing. I hope folks recognize just how dire things look for this species across much of the range. Most of my comments are pretty minor (hopefully) and I added an updated figure and a few citations you may want to check out or add.

I'll touch base when I get back.

Adios,
Ryan

Hi Laura,

I would be willing to review the draft status review, and I have no financial or other conflicts of interest.

Thanks very much,

Adios,
Ryan

On Thu, Apr 25, 2019 at 9:04 AM Patterson, Laura@Wildlife <Laura.Patterson@wildlife.ca.gov> wrote:

Dear Dr. Peek,

The Fish and Game Commission (Commission) was petitioned to list the Foothill Yellow-legged Frog as threatened under the California Endangered Species Act (CESA) by the Center for Biological Diversity in December 2016. The California Department of Fish and Wildlife (Department) is tasked with writing a status review and providing a recommendation to the Commission on whether or not the best scientific information available supports the petitioner's position that listing is warranted. Part of the status review process is external peer review of the draft status review.

I am contacting you as a Foothill Yellow-legged Frog subject matter expert to request your participation in the peer review process. The Department expects the draft will be ready on for distribution to peer reviewers on or around May 17th. We would ask that you focus your review on the scientific information available regarding the status of Foothill Yellow-legged Frogs in California. Your peer review of the science and analysis regarding each of the listing factors prescribed in CESA (i.e., present or threatened habitat modification, overexploitation, predation, competition, disease, and other natural occurrences or human-related activities that could affect the species) is particularly valuable. We request that comments be submitted on or before one month from the date of receipt (on or around June 17th).

In addition, per the Department's Peer Review Policy (Department Bulletin 2017-03), I must ensure that you have no financial or other conflict of interest with the outcome or implications of the peer reviewed product.

Please respond to whether you are willing and able to participate in this important part of the listing determination process by Friday May 3rd.

Thank you for your consideration,

Laura

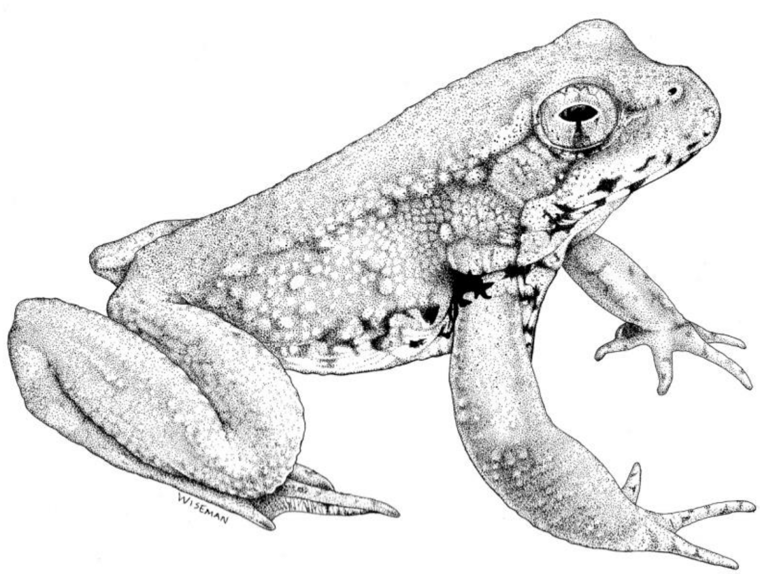
LIST OF FIGURES

Commented [RAP1]: Pretty sure I made this figure in R, and this was part of the stuff Sarah and I did as part of the 2016 poster (Peek and Kupferberg). I don't care if it says Kupferberg and Peek or Peek and Kupferberg, but please add me to this figure when it's used.

LIST OF TABLES



ACKNOWLEDGMENTS

Laura Patterson prepared this report. Stephanie Hogan, Madeleine Wieland, and Margaret Mantor assisted with portions of the report, including the sections on Status and Trends in California and Existing Management. Kristi Cripe provided GIS analysis and figures. Review of a draft document was provided by the following California Department of Fish and Wildlife (Department) staff: Ryan Bourque, Marcia Grefsrud, and Mike van Hattem.

The Department is extremely grateful for the valuable comments provided on this report by the following peer reviewers: Dr. Sarah Kupferberg, Dr. Amy Lind, Dr. Jimmy McGuire, and Dr. Ryan Peek. The conclusions in this report are those of the Department and do not necessarily reflect those of the reviewers.

EXECUTIVE SUMMARY

[To be completed after external peer review]

REGULATORY SETTING

Petition Evaluation Process

A petition to list the Foothill Yellow-legged Frog (*Rana boylii*) as threatened under the California Endangered Species Act (CESA) was submitted to the Fish and Game Commission (Commission) on December 14, 2016 by the Center for Biological Diversity. Commission staff transmitted the petition to the Department of Fish and Wildlife (Department) pursuant to Fish and Game Code section 2073 on December 22, 2016 and published a formal notice of receipt of the petition on January 20, 2017 (Cal. Reg. Notice Register 2017, No. 3-Z, p. 46). A petition to list or delist a species under CESA must include "information regarding the population trend, range, distribution, abundance, and life history of a species, the factors affecting the ability of the population to survive and reproduce, the degree and immediacy of the threat, the impact of existing management efforts, suggestions for future management, and the availability and sources of information. The petition shall also include information regarding the kind of habitat necessary for species survival, a detailed distribution map, and any other factors that the petitioner deems relevant" (Fish & G. Code, § 2072.3).

On April 17, 2017, the Department provided the Commission with its evaluation of the petition, "Evaluation of the Petition from the Center For Biological Diversity to List the Foothill Yellow-legged Frog (*Rana boylii*) as Threatened under the California Endangered Species Act," to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5 & 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & (e)). Focusing on the information available to the Department relating to each of the relevant categories, the Department recommended to the Commission that the petition be accepted.

At its scheduled public meeting on June 21, 2017, in Smith River, California, the Commission considered the petition, the Department's petition evaluation and recommendation, and comments received. The Commission found that sufficient information existed to indicate the petitioned action may be warranted and accepted the petition for consideration. Upon publication of the Commission's notice of its findings, the Foothill Yellow-legged Frog was designated a candidate species on July 7, 2017 (Cal. Reg. Notice Register 2017, No. 27-Z, p. 986).

Status Review Overview

The Commission's action designating the Foothill Yellow-legged Frog as a candidate species triggered the Department's process for conducting a status review to inform the Commission's decision on whether listing the species is warranted. At its scheduled public meeting on June 21, 2018, in Sacramento, California, the Commission granted the Department a six-month extension to complete the status review and facilitate external peer review.

This status review report is not intended to be an exhaustive review of all published scientific literature relevant to the Foothill Yellow-legged Frog; rather, it is intended to summarize the key points from the best scientific information available relevant to the status of the species. This final report, based upon the best scientific information available to the Department, is informed by independent peer review of a draft report by scientists with expertise relevant to the Foothill Yellow-legged Frog. This review is intended to provide the Commission with the most current information on the Foothill Yellow-legged Frog and to serve as the basis for the Department's recommendation to the Commission on whether the petitioned action is warranted. The status review report also identifies habitat that may be essential to continued existence of the species and provides management recommendations for recovery of the species (Fish & G. Code, § 2074.6). Receipt of this report is to be placed on the agenda for the next available meeting of the Commission after delivery. At that time, the report will be made available to the public for a 30-day public comment period prior to the Commission taking any action on the petition.

Federal Endangered Species Act Review

The Foothill Yellow-legged Frog is currently under review for possible listing as threatened or endangered under the federal Endangered Species Act (ESA) in response to a July 11, 2012 petition submitted by the Center for Biological Diversity. On July 1, 2015, the U.S. Fish and Wildlife Service (USFWS) published its 90-day finding that the petition presented substantial scientific or commercial information indicating that the petitioned action may be warranted and initiated a status review of the species (USFWS 2015). On March 16, 2016, the Center for Biological Diversity sued the USFWS to compel issuance of a 12-month finding on whether listing under the ESA is warranted. On August 30, 2016, the parties reached a stipulated settlement agreement that the USFWS shall publish its 12-month finding in the Federal Register on or before September 30, 2020 (*Center for Biological Diversity v. S.M.R. Jewell* (D.D.C. Aug. 30, 2016, No. 16-CV-00503)).

BIOLOGY AND ECOLOGY

Species Description and Life History

> *"In its life-history* boylii *exhibits several striking specializations which are in all probability related to the requirements of life of a stream-dwelling species"* – Tracy I. Storer, 1925

The Foothill Yellow-legged Frog is a small- to medium-sized frog; adults range from 38 to 81 mm (1.5-3.2 in) snout to urostyle length (SUL) with females attaining a larger size than males and males possessing paired internal vocal sacs (Zweifel 1955, Nussbaum et al. 1983, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs are typically gray, brown, olive, or reddish with brown-black flecking and mottling, which generally matches the substrate of the stream in which they reside (Nussbaum et al. 1983, Stebbins and McGinnis 2012). They often have a pale triangle between the eyes and snout and broad dark bars on the hind legs (Zweifel 1955, Stebbins and McGinnis 2012). Foothill Yellow-legged Frogs have a relatively squat body and granular skin, giving them a rough appearance similar to a toad, and fully webbed feet with slightly expanded toe tips (Nussbaum et al. 1983). The tympanum is also rough

and relatively small compared to congeners at around one-half the diameter of the eye (Zweifel 1955). The dorsolateral folds (glandular ridges extending from the eye area to the rump) in Foothill Yellow-legged Frogs are indistinct compared to other western North American ranids (Stebbins and McGinnis 2012). Ventrally, the abdomen is white with variable amounts of dark mottling on the chest and throat, which are unique enough to be used to identify individuals (Marlow et al. 2016). As their name suggests, the underside of their hind limbs and lower abdomen are often yellow; however, individuals with orange and red have been observed within the range of the California Red-legged Frog (*Rana draytonii*), making hindlimb coloration a poor diagnostic characteristic for this species (Jennings and Hayes 2005).

Adult females likely lay one clutch of eggs per year and may breed every year (Storer 1925, Wheeler et al. 2006). Foothill Yellow-legged Frog egg masses resemble a compact cluster of grapes approximately 45 to 90 mm (1.8-3.5 in) in diameter length-wise and contain anywhere from around 100 to over 3,000 eggs (Kupferberg et al. 2009c, Hayes et al. 2016). The individual embryos are dark brown to black with a lighter area at the vegetative pole and surrounded by three jelly envelopes that range in diameter from approximately 3.9 to 6.0 mm (0.15-0.25 in) (Storer 1925, Zweifel 1955, Hayes et al. 2016).

Foothill Yellow-legged Frog tadpoles hatch out around 7.5 mm (0.3 in) long and are a dark brown or black (Storer 1925, Zweifel 1955). They grow rapidly to 37 to 56 mm (1.5-2.2 in) and turn olive with a coarse brown mottling above and an opaque silvery color below (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012). Their eyes are positioned dorsally when viewed from above (i.e., within the outline of the head), and their mouths are large, downward-oriented, and suction-like with several tooth rows (Storer 1925, Zweifel 1955, Stebbins and McGinnis 2012, Hayes et al. 2016). Foothill Yellow-legged Frogs metamorphose at around 14-17 mm (0.55-0.67 in) SUL (Fellers 2005). Sexual maturity is attained at around 30-40 mm (1.2-1.6 in) SUL and 1 year for males and around 40-50 mm (1.6-2.0 in) SUL and 3 years for females, although in some populations this has been accelerated by a year (Zweifel 1955, Kupferberg et al. 2009c, Breedveld and Ellis 2018). During the breeding season, males can be distinguished from females by the presence of nuptial pads (swollen darkened thumb bases that aid in holding females during amplexus) and calling, which frequently occurs underwater but sometimes from the surface (MacTague and Northen 1993, Stebbins 2003, Silver 2017).

The reported lifespan of Foothill Yellow-legged Frogs varies widely by study. Storer (1925) and Van Wagner (1996) estimated a maximum age of 2 years for both sexes and the vast majority of the population. Breedveld and Ellis (2018) calculated the typical lifespan of males at 3-4 years and 5-6 years for females. Bourque (2008), using skeletochronology, found an individual over 7 years old and a mean age of 4.7 and 3.6 years for males and females, respectively. Drennan et al. (2015) estimated maximum age at 13 years for both sexes in a Sierra Nevada population and 12 for males and 11 for females in a Coast Range population.

Range and Distribution

Foothill Yellow-legged Frogs historically ranged from the Willamette River drainage in Oregon west of the Sierra-Cascade crest to at least the San Gabriel River drainage in Los Angeles County, California (Figure 1; Zweifel 1955, Stebbins 2003). In addition, a disjunct population was reported from 2,040 m

Figure 1. Foothill Yellow-legged Frog historical range (adapted from CWHR, Loomis [1965], Nussbaum et al. [1983])

Commented [RAP2]: Similarly the blip that extends into the east side near mono lake…I know that Bob Thomson mentioned some erroneous records they followed up on for the ARSSC report/book. This feels like it may be in the same vicinity. As drawn, it indicates RABO may have been in Tuolumne Meadows and down into Lee Vining Creek…which may be true I've just never read/heard that to be the case.

Commented [RAP3]: The population/records near Lassen (looks like near Last Chance Creek, etc) seem unlikely, but I could be convinced. Based on what Brad said, I'm a bit more dubious of records from that vicinity, not to mention that area is largely >6,000 ft in elevation.

(6,700 ft) in the Sierra San Pedro Mártir, Baja California Norte, México (Loomis 1965). In California, the species occupies foothill and mountain streams in the Klamath, Cascade, Sutter Buttes, Coast, Sierra Nevada, and Transverse ranges from sea level to 1,940 m (6,400 ft), but generally below 1,525 m (5,000 ft) (Hemphill 1952, Nussbaum et al. 1983, Stebbins 2003, Olson et al. 2016). Zweifel (1955) considered Foothill Yellow-legged Frogs to be present and abundant throughout their range where streams possessed suitable habitat.

Commented [RAP4]: See my comments on the map above…if this (or the more likely current value of 5,000 ft) is true, then some of the range highlighted is over that elevation limit…

Taxonomy and Phylogeny

Foothill Yellow-legged Frogs belong to the family Ranidae (true frogs), which inhabits every continent except Antarctica and contains more than 700 species (Stebbins 2003). The species was first described by Baird (1854) as *Rana boylii*. After substantial taxonomic uncertainty with respect to its relationship to other ranids (frogs in the family Ranidae) and several name changes over the next century, the Foothill Yellow-legged Frog (*R. boylii* with no subspecific epithet) was eventually recognized as a distinct species again by Zweifel (1955, 1968). The phylogenetic relationships among the western North American *Rana* spp. have been revised several times and are still not entirely resolved (Thomson et al. 2016). The Foothill Yellow-legged Frog was previously thought to be most closely related to the higher elevation Mountain Yellow-legged Frog (*R. muscosa*) (Zweifel 1955; Green 1986a,b). However, genetic analyses undertaken by Macey et al. (2001) and Hillis and Wilcox (2005) suggest they are more closely related to Oregon Spotted Frogs (*R. pretiosa*) and Columbia Spotted Frogs (*R. luteiventris*), respectively.

Commented [RAP5]: Can also add a more recent paper by Yuan et al. 2016 on Ranidae frog phylogeny which supports RABO as more closely related to Columbia spotted frogs (see figure 1 in paper).

Spatiotemporal diversification of the true frogs (Genus Rana): A historical framework for a widely studied group of model organisms. *Systematic Biology*, *65*(5), 824–842. https://doi.org/10.1093/sysbio/syw055

Population Structure and Genetic Diversity

Foothill Yellow-legged Frog populations exhibit varying levels of partitioning and genetic diversity at different spatial scales. At the coarse landscape level across the species' extant range, McCartney-Melstad et al. (2018) recovered five deeply divergent, geographically cohesive, genetic clades (Figure 2), while Peek (2018) recovered six (Figure 3). Genetic divergence is the process of speciation; it is a measure of the number of mutations accumulated by populations over time from a shared ancestor. This accumulation of genetic differentiation between groups is what ~~that~~ differentiates one population from another population ~~them from the other populations~~ in a species. When genetic divergence among ~~clades~~ groups with common ancestors (clades) is large enough, it can be used as a tool to define new species or subspecies.

The geographic breaks among the five Foothill Yellow-legged Frog clades were similar between the studies, but Peek (2018) identified a separate deeply divergent genetic clade in the Feather River watershed that is distinct from the rest of the northern Sierra Nevada clade. The five clades the two studies shared include the following [Note: naming conventions follow McCartney-Melstad et al. (2018) and Peek (2018)]:

(1) Northwest/North Coast: north of San Francisco Bay in the Coast Ranges and east into Tehama County;
(2) Northeast/Northern Sierra: northern El Dorado County (North Fork American River watershed, includes Middle Fork American) and north in the Sierra Nevada to southern Plumas County (Upper Yuba River watershed);

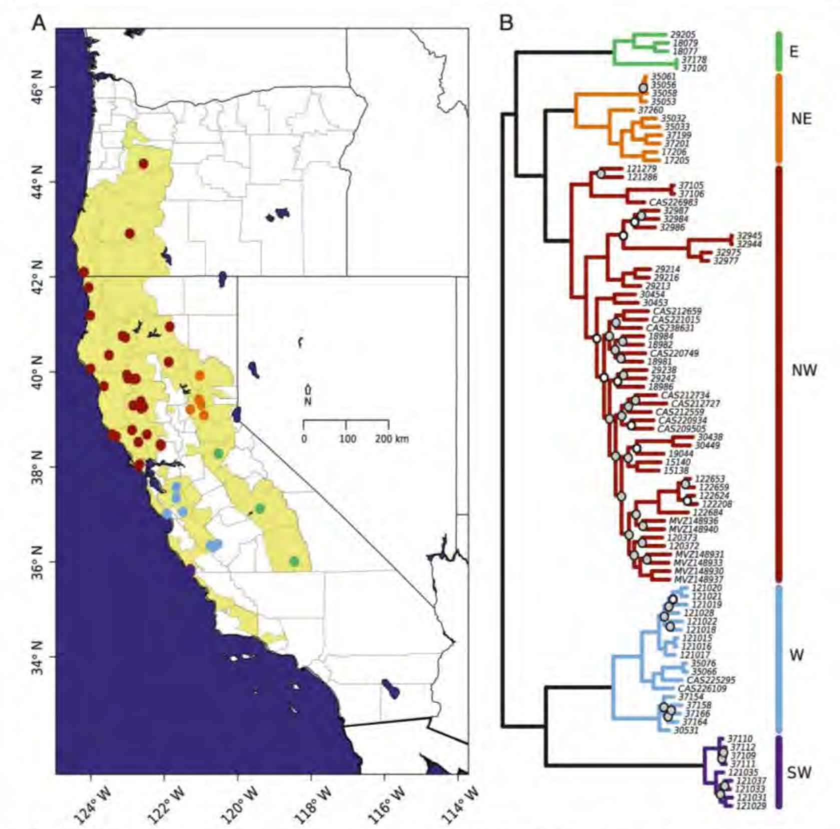

Fig. 1 **a** Map of *Rana boylii* sample localities. County outlines are shown within California and Oregon. Light yellow indicates the IUCN range map of *R. boylii*, excluding a small disjunct population at Sierra San Pedro Martir, Baja California, Mexico. Dots are colored by major grouping as determined in the **b** RAxML phylogeny, with midpoint rooting. Nodes without dots received >95% bootstrap support, those with white dots received <95% but greater than or equal to 75% bootstrap support, while nodes with gray dots received <75% bootstrap support

Figure 2. Foothill Yellow-legged Frog clades by McCartney-Melstad et al. (2018)

(3) East/Southern Sierra: El Dorado County (South Fork American River watershed) and south in the Sierra Nevada [no samples from Amador County were tested, but they would most likely fall within this clade because it is located between two other populations that occur within this clade];

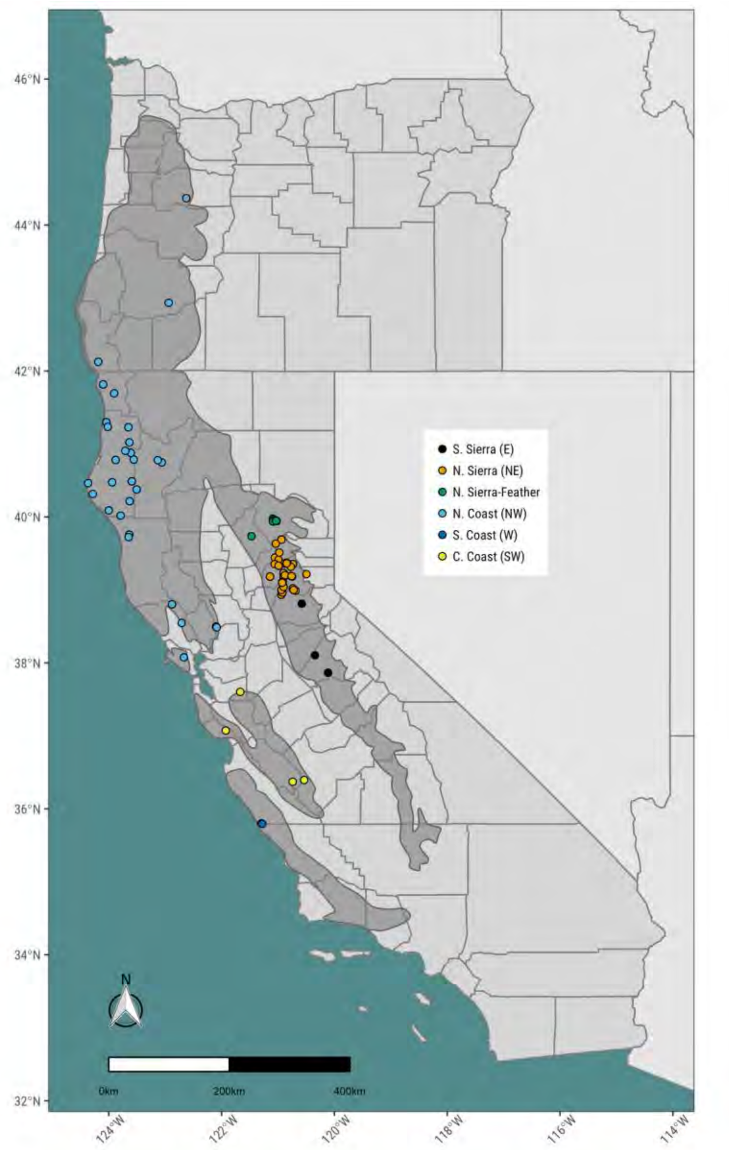

Figure 3. Foothill Yellow-legged Frog clades by Peek (2018)

Commented [RAP6]: This is an updated figure, feel free to email me if you want a higher res version, but I suspect this should do just fine.

(4) West/Central Coast: south of San Francisco Bay in the Coast Ranges to San Benito and Monterey counties, presumably east of the San Andreas Fault/Salinas Valley;
(5) Southwest/South Coast presumably west of the San Andreas Fault/Salinas Valley in Monterey County and south in the Coast Ranges.

The Feather River clade is found primarily in Plumas and Butte counties (Peek 2018). Peek's analysis found that this clade is as distinct ~~as~~from the other Sierra Nevada clades as the Sierra Nevada populations are distinct from ~~the rest of the Sierra Nevada as a cohesive group and~~ all the coastal ~~populations~~ clades~~as one group~~, meaning it was found to be deeply divergent from the rest of the clades. McCartney-Melstad et al. (2018) also recognized the Feather River watershed as distinct from the rest of the northern Sierra but not as deeply divergent from the other clades as Peek. The Feather River watershed is also the only known location where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs (*R. sierrae*) co-occur and where two F1 hybrids (50% ancestry from each species) were found (Peek 2018). In addition, Peek's genetic data provided ~~Peek~~weak support for ~~'s modeling results only weakly supported~~ dividing the West/Central Coast and Southwest/South Coast groups into separate clades, but had fewer samples from these localities than McCartney-Melstad et al.

Previous work conducted by Lind et al. (2011) found a somewhat similar pattern, that populations on the periphery of the species' range are considerably genetically divergent from the rest of the range. Their results suggested that hydrologic regions and river basins were important landscape features that influenced the genetic structure of Foothill Yellow-legged Frog populations. However, using more modern genomic techniques, McCartney-Melstad et al. (2018) found nearly twice the variation among the five phylogenetic clades than among drainage basins, indicating other factors contributed to current population structure. They report that the depth of genetic divergence among Foothill Yellow-legged Frog clades exceeds that of any anuran (frog or toad) for which similar data are available and recommend using them as management units instead of the previously suggested watershed boundaries.

Levels of genetic diversity within the clades differed significantly. Genetic diversity provides populations with the evolutionary capacity to adapt to changing conditions ~~gives species the ability to adapt to changing conditions~~ (i.e., evolve), and its loss often signals extreme population ~~and range~~ reductions as well as potential inbreeding depression that can reduce survival and reproductive success (Lande and Shannon 1996, Hoffmann and Sgrò 2011, McCartney-Melstad et al. 2018). Loss of genetic diversity in Foothill Yellow-legged Frogs largely follows a north-to-south pattern, with the southern clades in particular (Southwest/South Coast and East/Southern Sierra) showing the greatest loss of nucleotide diversity ~~possessing the least amount~~ (McCartney-Melstad et al. 2018, Peek 2018). In addition, these study results demonstrate that Foothill Yellow-legged Frogs have lost genetic diversity over time across their entire range except for the large Northwest/North Coast clade, which appears to have undergone a relatively recent population expansion (McCartney-Melstad et al. 2018, Peek 2018).

At a watershed scale, Dever (2007) found that tributaries to rivers and streams are important for preserving genetic diversity, and populations separated by more than 10 km (6.2 mi) show signs of genetic isolation. In other words, even in the absence of anthropogenic barriers to dispersal (e.g., dams and reservoirs), individuals located more than 10 km (6.2 mi) are not typically considered part of a single interbreeding population (Olson and Davis 2009). Peek (~~2011~~2010, 2018) reported that at this finer-scale, population structure and genetic diversity appear to be more strongly influenced by river regulation type (i.e., dammed or undammed) than to geographic distance or watershed boundaries. In general, regulated (dammed) rivers had limited gene flow and higher genetic divergence among subpopulations compared with unregulated (undammed) rivers (Peek ~~2011~~2010, 2018). In addition, differences in river hydrologic~~water flow~~ regimes within regulated rivers affected genetic connectivity and diversity (Peek ~~2011~~2010, 2018). Subpopulations in hydropeaking reaches, in which pulsed flows are used for electricity generation or whitewater boating, exhibited significantly lower gene flow and genetic diversity than those in bypass reaches where water is diverted from upstream in the basin down to power generating facilities (Figure 4; Peek 2018). River regulation had a greater influence on genetic differentiation among sites than geographic distance in the Alameda Creek watershed as well (Stillwater Sciences 2012). Reduced connectivity among sites leads to lower gene flow and a loss of genetic diversity through genetic drift, which can diminish adaptability to changing environmental conditions (Palstra and Ruzzante 2008). Peek (2011) posits that given the *R. boylii* species group is estimated to be 8 million years old (Macey et al. 2001), the significant reductions in connectivity and genetic diversity over short evolutionary time periods in regulated rivers (often less than 50 years from the time of dam construction) is cause for concern, particularly when combined with small population sizes.

Habitat Associations and Use

> *"These frogs are so closely restricted to streams that it is unusual to find one at a greater distance from the water than it could cover in one or two leaps."* – Richard G. Zweifel, 1955

Foothill Yellow-legged Frogs inhabit rivers and streams ranging from primarily rain-fed (coastal populations) to primarily snow-influenced (most Sierra Nevada and Klamath-Cascade populations) from headwater streams to large rivers (Bury and Sisk 1997, Wheeler et al. 2014). Occupied rivers and streams flow through a variety of vegetation types including hardwood, conifer, and valley-foothill riparian forests; mixed chaparral; and wet meadows (Hayes et al. 2016). Because the species is so widespread and can be found in so many types of habitats, the vegetation community is likely less important in determining Foothill Yellow-legged Frog occupancy and abundance than the aquatic biotic and abiotic conditions in the specific river, stream, or reach (Zweifel 1955). The species is an obligate stream-breeder, which sets it apart from other western North American ranids (Wheeler et al. 2014). Foothill Yellow-legged Frog habitat is generally characterized as partly-shaded, shallow, perennial rivers and streams with a low gradient and rocky substrate that is at least cobble-sized (Zweifel 1955, Hayes and Jennings 1988). However, the use of intermittent and ephemeral streams by post-metamorphic Foothill Yellow-legged Frogs may not be all that uncommon in some parts of the species' range in California (R. Bourque pers. comm. 2019). The species has been reported from some atypical habitats as well, including ponds, isolated pools in intermittent streams, and meadows along the edge of streams that lack a rocky substrate (Fitch 1938, Zweifel 1955, J. Alvarez pers. comm. 2017, CDFW 2018a).

As stream-breeding poikilotherms (animals whose internal temperature varies with ambient temperature), appropriate flow velocity, temperature, and water availability are critically important to

Foothill Yellow-legged Frogs (Kupferberg 1996a, Van Wagner 1996, Wheeler et al. 2006, Lind et al. 2016). Habitat quality is also influenced by hydrologic regime (regulated vs. unregulated), substrate, presence of non-native predators and competitors, water depth, and availability of high-quality food and basking sites (Lind et al. 1996, Yarnell 2005, Wheeler et al. 2006, Catenazzi and Kupferberg 2017). Habitat suitability and use vary by life stage, sex, geographic location, watershed size, and season and

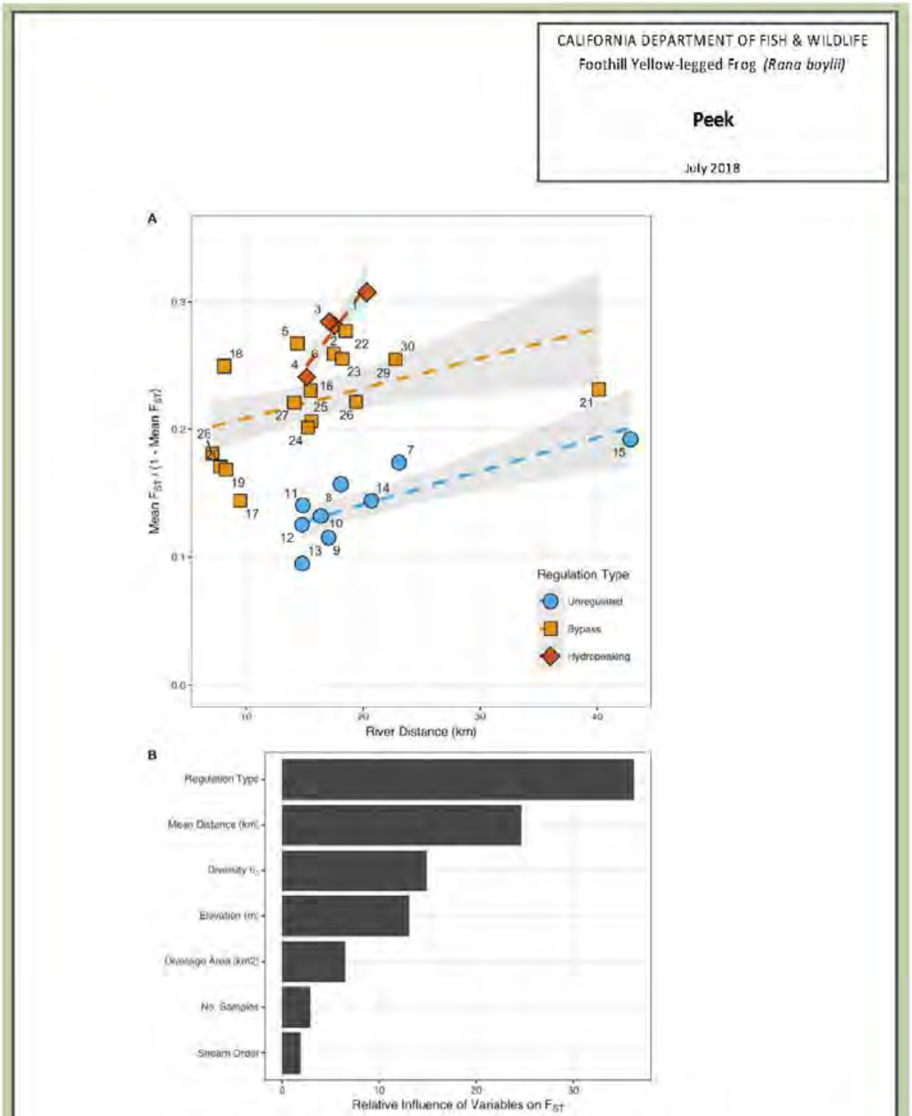

Figure 3. Relationship between river regulation and genetic differentiation in FYLF. A) Mean pairwise F_{ST} vs. mean river distance for each location; B) Relative influence of variables on F_{ST} from boosted regression tree models.

Figure 4. River regulation's relative influence on genetic differentiation from Peek (2018)

can generally be categorized as breeding and rearing habitat, nonbreeding active season habitat, and overwintering habitat (Van Wagner 1996, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011, Hayes et al. 2016, Catenazzi and Kupferberg 2017). Yarnell (2005) located higher densities of Foothill Yellow-legged Frogs in areas with greater habitat heterogeneity and suggested that they were selecting for sites that possessed the diversity of habitats necessary to support each life stage within a relatively short distance.

Breeding and Rearing Habitat

Suitable breeding habitat must be connected to suitable rearing habitat for metamorphosis to be successful. When this connectivity exists, as flows decline through the season, tadpoles can follow the receding shoreline into areas of high productivity and lower predation risk as opposed to becoming trapped in isolated pools with a high risk of overheating, desiccation, and predation (Kupferberg et al. 2009c).

Several studies on Foothill Yellow-legged Frog breeding habitat, carried out across the species' range in California, reported similar findings. Foothill Yellow-legged Frogs select oviposition (egg-laying) sites within a narrow range of depths, velocities, and substrates and exhibit fidelity to breeding sites that consistently possess suitable microhabitat characteristics over time (Kupferberg 1996a, Bondi et al. 2013, Lind et al. 2016). At a coarse-spatial scale, breeding sites in rivers and large streams are often located near the confluence of tributary streams in sunny, wide, shallow reaches (Kupferberg 1996a, Yarnell 2005, GANDA 2008, Peek 2010~~1~~). These areas are highly productive compared to cooler, deeper, closed-canopy sites (Catenazzi and Kupferberg 2013). At a fine-spatial scale, females prefer to lay eggs in low velocity areas dominated by cobble- and boulder-sized substrates, often associated with sparsely-vegetated point bars (Kupferberg 1996a, Lind et al. 1996, Van Wagner 1996, Bondi et al. 2013, Lind et al. 2016). They tend to select areas with less variable, more stable flows, and in areas with higher flows at the time of oviposition, they place their eggs on the downstream side of large cobblestones and boulders, which protects them from being washed away (Kupferberg 1996a, Wheeler et al. 2006).

Appropriate rearing temperatures are vital for successful metamorphosis. Tadpoles grow faster and larger in warmer water to a point (Zweifel 1955; Catenazzi and Kupferberg 2017, 2018). Zweifel (1955) conducted experiments on embryonic thermal tolerance and determined that the critical low was approximate 6°C (43°F), and the critical high was around 26°C (79°F). Welsh and Hodgson (2011) determined that best the single variable for predicting Foothill Yellow-legged Frog presence was temperature since none were observed below 13°C (55°F), but numbers increased significantly with increasing temperature. Catenazzi and Kupferberg (2013) measured tadpole thermal preference at 16.5-22.2°C (61.7-72.0°F), and the distribution of Foothill Yellow-legged Frog populations across a watershed was consistent within this temperature range. At temperatures below 16°C (61°F), tadpoles were absent under closed canopy and scarce even with an open canopy (Ibid.). Catenazzi and Kupferberg (2017) found regional differences in apparently suitable breeding temperatures. Inland populations from primarily snowmelt-fed systems with relatively cold water were relegated to reaches that are warmer on average during the warmest 30 days of the year than coastal populations in the chiefly rainfall-fed, and thus warmer, systems (17.6-24.2°C [63.7-75.6°F] vs. 15.7-22.0°C [60.3-71.6°F], respectively).

However, experiments on tadpole thermal preference demonstrated that individuals from different source populations selected similar rearing temperatures, which presumably optimized development (Ibid.). In regulated systems, where water released from dams is often colder than normal, suitable rearing temperatures downstream may be limited (Wheeler et al. 2014, Catenazzi and Kupferberg 2017).

Appropriate flow velocities are also critical for survival to metamorphosis. The velocity at which Foothill Yellow-legged Frog egg masses shear away from the substrate they are adhered to varies according to factors such as depth and degree to which the eggs are sheltered (Spring Rivers Ecological Sciences 2003). This critical velocity is expected to decrease as the egg mass ages due to the~~ir~~ reduced structural integrity of the protective jelly envelopes (Hayes et al. 2016). Short-duration increases in flow velocity may be tolerated if the egg masses are somewhat sheltered, but sustained high velocities increase the likelihood of detachment (Kupferberg 1996a, Spring Rivers Ecological Sciences 2003). Hatchlings and tadpoles about to undergo metamorphosis are relatively poor swimmers and require especially slow, stable flows during these stages of development (Kupferberg et al. 2011b). Tadpoles respond to increasing flows by swimming against the current to maintain position for a short period of time and eventually swimming to the bottom and seeking refuge in the rocky substrate's interstitial spaces (Ibid.). When tadpoles are exposed to repeated increases in velocities, their growth and development are delayed (Ibid.). Under experimental conditions, the critical velocity at which tadpoles were swept downstream ranged between 20 and 40 cm/s (0.66-1.31 ft/s); however, as they reach metamorphosis it decreases to as low as 10 cm/s (0.33 ft/s) (Ibid.).

Nonbreeding Active Season Habitat

Post-metamorphic Foothill Yellow-legged Frogs utilize a more diverse range of habitats and are much more dispersed during the nonbreeding active season than the breeding season. Microhabitat preferences appear to vary by location and season, but some patterns are common across the species' range. Foothill Yellow-legged Frogs tend to remain close to the water's edge (average < 3 m [10 ft]); select sunny areas with limited canopy cover; and are often associated with riffles and pools (Zweifel 1955, Hayes and Jennings 1988, Van Wagner 1996, Welsh et al. 2005, Haggarty 2006, Bourque 2008, Gonsolin 2010, Welsh and Hodgson 2011). Adequate water, food resources, cover from predators, ability to thermoregulate (e.g., presence of basking sites and cool refugia), and absence of non-native predators are important components of nonbreeding active season habitat (Hayes and Jennings 1988, Van Wagner 1996, Catenazzi and Kupferberg 2013).

Overwintering Habitat

Overwintering habitat varies depending on local conditions, but as with the rest of the year, Foothill Yellow-legged Frogs are most often found in or near water where they can forage and take cover from predators and high discharge events (Storer 1925, Zweifel 1955). In larger streams and rivers, Foothill Yellow-legged Frogs are often found along tributaries during the winter where the risk of being displaced by heavy flows is reduced (Kupferberg 1996a, Gonsolin 2010). Bourque (2008) found 36.4% of adult females used intermittent and ephemeral tributaries during the overwintering season. Van

Wagner (1996) located most overwintering frogs using pools with cover such as boulders, root wads, and woody debris. During high flow events, they moved to the stream's edge and took cover under vegetation like sedges (*Carex* sp.) or leaf litter (Ibid.). Rombough (2006) found most Foothill Yellow-legged Frogs under woody debris along the high-water line and often using seeps along the stream-edge, which provided them with moisture, a thermally stable environment, and prey.

Exceptions to the pattern of remaining near the stream's edge during winter have been reported. Cook et al. (2012) observed dozens of juvenile Foothill Yellow-legged Frogs traveling over land, as opposed to using riparian corridors. They were found using upland habitats with an average distance of 71.3 m (234 ft) from water (range: 16-331 m [52-1,086 ft]) (Ibid.). In another example, a single subadult that was found adjacent to a large wetland complex 830 m (2,723 ft) straight-line distance from the wetted edge of the Van Duzen River, although it is possible the wetland was connected to the river via a spillway or drainage that may have served as the movement corridor (CDFW 2018a, R. Bourque pers. comm. 2019).

Seasonal Activity and Movements

Because Foothill Yellow-legged Frogs occupy areas with relatively mild winter temperatures, they can be active year-round, although at low temperatures (< 7°C [44 °F], they become lethargic (Storer 1925, Zweifel 1955, Van Wagner 1996, Bourque 2008). They are active both day and night, and during the day adults are often observed basking on warm objects such as sun-heated rocks, although this is also when their detectability is highest (Fellers 2005, Wheeler et al. 2005). By contrast, Gonsolin (2010) tracked radio-telemetered Foothill Yellow-legged Frogs under substrate a third of the time and underwater a quarter of the time, although nearly all his detections of frogs without transmitters were basking.

Adult Foothill Yellow-legged Frogs migrate from their overwintering sites to breeding habitat in the spring, often from a tributary to its confluence with a larger stream or river. In areas where tributaries dry down, juveniles also make this downstream movement (Haggarty 2006). When the tributary itself is perennial and provides suitable breeding habitat, the frogs may not undertake these long-distance movements (Gonsolin 2010). Cues for adults to initiate this migration to breeding sites are somewhat enigmatic and vary by location, elevation, and amount of precipitation (S. Kupferberg and A. Lind pers. comm. 2017). They can also include day length, water temperature, and sex (GANDA 2008, Gonsolin 2010, Yarnell et al. 2010, Wheeler et al. 2018). Males initiate movements to breeding sites where they congregate in leks (areas of aggregation for courtship displays), and females arrive later and over a longer period (Wheeler and Welsh 2008, Gonsolin 2010). Most males utilize breeding sites associated with their overwintering tributaries, but some move substantial distances to other sites and may use more than one breeding site in the same season (Wheeler and Welsh 2006, GANDA 2008).

While the predictable hydrograph in California consists of wet winters with high flows and dry summers with low flows, the timing and quantity of seasonal discharge can vary significantly from year to year. The timing of oviposition can influence offspring growth and survival. Early breeders risk scouring of egg masses from their substrate by late spring storms in wet years or desiccation if waters recede rapidly, but when they successfully hatch, tadpoles benefit from a longer growing season, which can enable them to metamorphose at a larger size and increase their likelihood of survival (Railsback et al. 2016).

Later breeders are less likely to have their eggs scoured away or desiccated because flows are generally more stable, but they have fewer mate choices, and their tadpoles have a shorter growing period before metamorphosis, reducing their chance of survival (Ibid.). Some evidence indicates larger females, who coincidentally lay larger clutches, breed earlier (Kupferberg et al. 2009c, Gonsolin 2010). Consequently, early season scouring or stranding of egg masses or tadpoles can disproportionately impact the population's reproductive output because later breeders produce fewer and smaller eggs per clutch (Kupferberg et al. 2009c, Gonsolin 2010).

Timing of oviposition is often a function of water temperature and flow, but it consistently occurs on the descending limb of the hydrograph which corresponds to high ~~high winter discharge~~spring discharge gradually receding toward low summer baseflow (Kupferberg 1996a, GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010, Yarnell et al. 2010). Under natural conditions, the timing coincides with intermittent tributaries drying down and increases in algal blooms that provide forage for tadpoles (Haggarty 2006, Power et al. 2008). At lower elevations, breeding can start in late March or early April, and at mid-elevations, breeding typically occurs in mid-May to mid-June (Gonsolin 2010, S. Kupferberg and A. Lind pers. comm. 2017). The time of year a population initiates breeding can vary by a month among water years, occurring later at deeper sites when colder water becomes warmer (Wheeler et al. 2018). In wetter years, delayed breeding into early July can occur in some colder snowmelt systems (S. Kupferberg and A. Lind pers. comm. 2017, GANDA 2018).

Commented [RAP7]: We seen as much as 2 months…early May to late June early July (2011 and 2015/16) in the NF American and Rubicon rivers. You can use me or Sarah Y. as a pers comm if you'd like…I'm working on that manuscript still… ☺

A population's period of oviposition can also vary from two weeks to three months, meaning they could be considered explosive breeders at some sites and prolonged breeders at others (Storer 1925, Zweifel 1955, Van Wagner 1996, Ashton et al. 1997, Wheeler and Welsh 2008). Water temperature typically warms to over 10°C (50°F) before breeding commences (GANDA 2008, Gonsolin 2010, Wheeler et al. 2018). Wheeler and Welsh (2008) observed Foothill Yellow-legged Frogs breeding when flows were below 0.6 m/s (2 ft/s), pausing during increased flows until they receded, and GANDA (2008) reported breeding initiated when flow decreased to less than 55% above baseflow.

Male Foothill Yellow-legged Frogs spend more time at breeding sites during the season than females, many of whom leave immediately after laying their eggs (GANDA 2008, Wheeler and Welsh 2008, Gonsolin 2010). Daily movements are usually short (< 0.3 m [1 ft]), but some individuals travel substantial distances: median 70.7 m/day (232 ft/day) in spring and 37.1 m/day (104 ft/day) in fall/winter, nearly always using streams as movement corridors (Van Wagner 1996, Bourque 2008, Gonsolin 2010). The maximum reported movement rate is 1,386 m/d (0.86 mi/day), and the longest seasonal (post-breeding) daily distance reported is 7.04 km (4.37 mi) by a female that traveled up a dry tributary and over a ridge before returning to and moving up the mainstem creek (Bourque 2008). Movements during the non-breeding season are typically in response to drying channels or during rain events (Bourque 2008, Gonsolin 2010, Cook et al. 2012).

Hatchling Foothill Yellow-legged Frog tadpoles~~s~~ tend to remain with what is left of the egg mass for several days before dispersing into the interstitial spaces in the substrate (Ashton et al. 1997). They often move downstream in areas of moderate flow and will follow the location of warm water in the channel throughout the day (Brattstrom 1962, Ashton et al. 1997, Kupferberg et al. 2011a). Tadpoles usually metamorphose in late August or early September (S. Kupferberg and A. Lind pers. comm. 2017). Twitty et al. (1967) reported that newly metamorphosed Foothill Yellow-legged Frogs mostly migrated upstream, which may be an evolutionary mechanism to return to their natal site after being washed downstream (Ashton et al. 1997).

Home Range and Territoriality

Foothill Yellow-legged Frogs exhibit a lek-type mating system in which males aggregate at the breeding site and establish calling territories (Wheeler and Welsh 2008, Bondi et al. 2013). The species has a relatively large calling repertoire for western North American ranids with seven unique vocalizations recorded (Silver 2017). Some of these can be reasonably attributed to territory defense and mate attraction communications (MacTeague and Northen 1993, Silver 2017). Physical aggression among males during the breeding season has been reported (Rombough and Hayes 2007, Wheeler and Welsh 2008). In addition, Wheeler and Welsh (2008) observed a non-random mating pattern in which males engaged in amplexus with females were larger than males never seen in amplexus, suggesting either physical competition or female preference for larger individuals. Very little information has been published on Foothill Yellow-legged Frog home range size. Wheeler and Welsh (2008) studied males during a 17-day period during breeding season and classified some of them "site faithful" based on their movements and calculated their home ranges. Two-thirds of males tracked were site faithful, and their mean home range size was 0.58 m^2 (SE = 0.10 m^2; 6.24 ft^2 [SE = 1.08 ft^2]) (Ibid.). In contrast, perhaps because the study took place over a longer time period, Bourque (2008) reported approximately half of the males he tracked during the spring were mobile, and the other half were sedentary. The median distances traveled along the creek (a proxy for home range size since they rarely leave the riparian corridor) for mobile and sedentary males were 149 m (489 ft) and 5.5 m (18 ft), respectively.

Diet and Predators

Foothill Yellow-legged Frog diet varies by life stage and likely body size. Tadpoles graze on periphyton (algae growing on submerged surfaces) scraped from rocks and vegetation and grow faster, and to a larger size, when it contains a greater proportion of epiphytic diatoms with nitrogen-fixing endosymbionts (*Epithemia* spp.), which are high in protein and fat (Kupferberg 1997b, Fellers 2005, Hayes et al. 2016, Catennazi and Kupferberg 2017). Tadpoles may also forage on necrotic tissue from dead bivalves and other tadpoles, or more likely the algae growing on them (Ashton et al. 1997, Hayes et al. 2016). Post-metamorphic Foothill Yellow-legged Frogs primarily feed on a wide variety of terrestrial arthropods but also some aquatic invertebrates (Fitch 1936, Van Wagner 1996, Haggarty 2006). Most of their diet consists of insects and arachnids (Van Wagner 1996, Haggarty 2006, Hothem et al. 2009). Haggarty (2006) did not identify any preferred taxonomic groups, but she noted larger Foothill Yellow-legged Frogs consumed a greater proportion of large prey items compared to smaller individuals, suggesting the species may be gape-limited generalist predators. Hothem et al. (2009) found mammal hair and bones in a Foothill Yellow-legged Frog. Adult Foothill Yellow-legged Frogs, like many other ranids, also cannibalize conspecifics (Wiseman and Bettaso 2007). In the fall when young-of-year are abundant, they may provide an important source of nutrition for adults prior to overwintering (Ibid.).

Foothill Yellow-legged Frogs are preyed upon by several native and introduced species, including each other as described above. Some predators target specific life stages, while others may consume multiple stages. Several species of gartersnakes (genus *Thamnophis*) are the primary and most widespread group of native predators on Foothill Yellow-legged Frogs tadpoles through adults is (Fitch 1941, Fox 1952, Zweifel 1955, Lind and Welsh 1994, Ashton et al. 1997, Wiseman and Bettaso 2007, Gonsolin 2010). Table 1 lists other known and suspected predators of Foothill Yellow-legged Frogs.

Table 1. Confirmed and potential Foothill Yellow-legged Frog predators in California in addition to gartersnakes (*Thamnophis* spp.)

* Introduced to the Eel River, location of documented predation; Foothill Yellow-legged Frogs are extirpated from most areas of historical range overlap

Commented [RAP8]: Do you have a copy of Susan Corum's thesis from Humboldt State? It's from 2003 and is about the effects of sac pikeminnow on FYLF in coastal streams…should probably add as citation here too.

Corum, S. D. (2003). *Effects of Sacramento Pikeminnow on Foothill Yellow-Legged Frogs in Coastal Streams* (August). Humboldt State University.

STATUS AND TRENDS IN CALIFORNIA

Administrative Status

Sensitive Species

The Foothill Yellow-legged Frog is listed as a Sensitive Species by the U.S. Bureau of Land Management (BLM) and U.S. Forest Service (Forest Service). These agencies define Sensitive Species as those species that require special management consideration to promote their conservation and reduce the likelihood and need for future listing under the ESA.

California Species of Special Concern

The Department's Species of Special Concern (SSC) designation is similar to the federal Sensitive Species designation. It is administrative, rather than regulatory in nature, and intended to focus attention on animals at conservation risk. The designation is used to stimulate needed research on poorly known species and to target the conservation and recovery of these animals before they meet the CESA criteria for listing as threatened or endangered (Thomson et al. 2016). The Foothill Yellow-legged Frog is listed as a Priority 1 (highest risk) SSC (Ibid.).

Trends in Distribution and Abundance

Range-wide in California

Range is the general geographical area in which an organism occurs. For purposes of CESA and this Status Review, the range is the species' California range (*Cal. Forestry Assn. v. Cal. Fish and Game Com.* (2007) 156 Cal.App.4th 1535, 1551). Systematic, focused, range-wide assessments of Foothill Yellow-legged Frog distribution and abundance are rare, both historically and contemporarily. A detailed account of what has been documented within the National Parks and National Forests in California can be found in Appendix 3 of the *Foothill Yellow-legged Frogs Conservation Assessment in California* (Hayes et al. 2016).

Most Foothill Yellow-legged Frog records are incidental observations made during stream surveys for ESA-listed salmonids and simply document presence at a particular date and location, although some include counts or estimates of abundance by life stage. This makes assessing trends in distribution and abundance difficult despite a relatively large number of observations compared to many other species tracked by the California Natural Diversity Database (CNDDB). The CNDDB contained 2,366 Foothill Yellow-legged Frog occurrences in its March 2019 edition, 500 of which are documented from the past 5 years.

A few wide-ranging survey efforts that included Foothill Yellow-legged Frogs exist. Reports from early naturalists suggest Foothill Yellow-legged Frogs were relatively common in the Coast Ranges as far south as central Monterey County, in eastern Tehama County, and in the foothills in and near Yosemite National Park (Grinnell and Storer 1924, Storer 1925, Grinnell et al. 1930, Martin 1940). In addition to

these areas, relatively large numbers of Foothill Yellow-legged Frogs (17-35 individuals) were collected at sites in the central and southern Sierra Nevada and the San Gabriel Mountains between 1911 and 1950 (Hayes et al. 2016). Widespread disappearances of Foothill Yellow-legged Frog populations were documented as early as the 1970s and 80s in southern California, the southern Coast Range, and the central and southern Sierra Nevada foothills (Moyle 1973, Sweet 1983).

Twenty-five years ago, the Department published the first edition of *Amphibians and Reptile Species of Special Concern in California* (Jennings and Hayes 1994). The authors revisited hundreds of localities that had historically been occupied by Foothill Yellow-legged Frogs between 1988 and 1991 and consulted local experts to determine presumed extant or extirpated status. Based on these survey results and stressors observed on the landscape, they considered Foothill Yellow-legged Frogs endangered in central and southern California south of the Salinas River in Monterey County. They considered the species threatened in the west slope drainages of the Cascade Mountains and Sierra Nevada east of the Central Valley, and they considered the remainder of the range to be of special concern (Ibid.).

Fellers (2005) and his field crews conducted surveys for Foothill Yellow-legged Frogs throughout California. They visited 804 sites across 40 counties with suitable habitat within the species' historical range. They detected at least one individual at 213 sites (26.5% of those surveyed) over 28 counties. They located Foothill Yellow-legged Frogs in approximately 40% of streams in the North Coast, 30% in the Cascade Mountains and south of San Francisco in the Coast Range, and 12% in the Sierra Nevada. Fellers estimated population abundance was 20 or more adults at only 14% of the sites where the species was found and noted the largest and most robust populations occurred along the North Coast. In addition, to determine status of Foothill Yellow-legged Frogs across the species' range and potential causes for declines, Lind (2005) used previously published status accounts, species expert and local biologist professional opinions, and field visits to historically occupied sites between 2000-2002. She determined that Foothill Yellow-legged Frogs had disappeared from 201 of 394 of the sites, representing just over 50%. The coarse-scale trend in California is one of greater population declines and extirpations of amphibians? Or just FYLF? in lower elevations and latitudes (Davidson et al. 2002).

Few site-specific population trend data are available from which to evaluate status. However, long-term monitoring efforts often use egg mass counts as a proxy to estimate adult breeding females. The results of these studies often reveal extreme interannual variability in number of egg masses laid (Ashton et al. 2010, S. Kupferberg and M. Power pers. comm. 2015, Peek and Kupferberg 2016). In a meta-analysis of egg mass count data collected across the species' range in California over the past 25 years, Peek and Kupferberg (2016) reported declines in two unregulated rivers and an increase in another. Their models did not detect any significant trends in abundance across different locations or regulation type (dammed or undammed); however, high interannual variability can render trend detection difficult. Interannual variability was substantially greater in regulated rivers vs. unregulated; the median coefficient of variation was 66.9% and 41.6%, respectively (Ibid.). The greater variability in regulated rivers decreases the probability of detecting significant declines, and coupled with low abundance, it can lead to populations dropping below a density necessary for persistence without detection, resulting in extirpation.

Regional differences in Foothill Yellow-legged Frog persistence across its range have been recognized for nearly 50 years (i.e., more extirpations documented in the south). Because of these differences and the recent availability of new landscape genomic data, more detailed descriptions of trends in Foothill Yellow-legged Frog population distribution and abundance in California are evaluated by clade below. Figure 5 depicts Foothill Yellow-legged Frog localities across all clades in California by the most recent confirmed sighting in the datasets available to the Department within a Public Lands Survey System (PLSS) section. "Transition Zones" are those areas where the exact clade boundaries are unknown due to a lack of samples. In addition, while not depicted as an area of uncertainty, no genetic samples have been tested south of the extant population in northern San Luis Obispo County, in the Sutter Buttes in Sutter County, or northeastern Plumas County. It is possible there were historically more clades than currently understood.

Caution should be exercised in comparing the following observation data across the species' range and across time since survey effort and reporting are not standardized. These data can be useful for making some general inferences about distribution, abundance, and trends. For instance, assuming the observation correctly identifies the species, the date on the record is the last time the species was confirmed to have occurred at that location. However, this only works in the affirmative. For example, at a site where the last time the species was seen was 75 years ago, the species may still persist there if no one has surveyed it since the original observation. CNDDB staff use information on land use conversion, follow-up visits, and biological reports to categorize an occurrence location as "extirpated" or "possibly extirpated".

Northwest/North Coast Clade

This clade extends from north of San Francisco Bay through the Coast Range and Klamath Mountains to the northern limit of the Foothill Yellow-legged Frog's range and east through the Cascade Range. It includes Del Norte, Siskiyou, Humboldt, Trinity, Shasta, Tehama, Mendocino, Glenn, Colusa, Lake, Sonoma, Napa, Yolo, Solano, and Marin counties. This clade covers the largest geographic area and contains the greatest amount of genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). In addition, it is the only clade with an increasing trend in genetic diversity (Peek 2018).

Early records note the comparatively high abundance of Foothill Yellow-legged Frogs in this area. Storer (1925) described Foothill Yellow-legged Frogs as very common in many of Coast Range streams north of San Francisco Bay, and Cope (1879,1883 as cited in Hayes et al. 2016) noted they were "rather abundant in the mountainous regions of northern California." In addition, relatively large collections occurred over short periods of time in this region in the late 1800s and the first half of the 20th century (Hayes et al. 2016). Nineteen were taken over two weeks in 1893 along Orrs Creek, a tributary to the Russian River, and 40 from near Willits (both in Mendocino County) in 1911; 112 were collected over three days at Skaggs Spring (Sonoma County) in 1911; 57 were taken in one day along Lagunitas Creek (Marin County) in 1928; and 50 were collected in one day near Denny (Trinity County) in 1955 (Ibid.).

A few long-term Foothill Yellow-legged Frog egg mass monitoring efforts undertaken within this clade's boundaries found densities vary significantly, often based on river regulation type, and documented

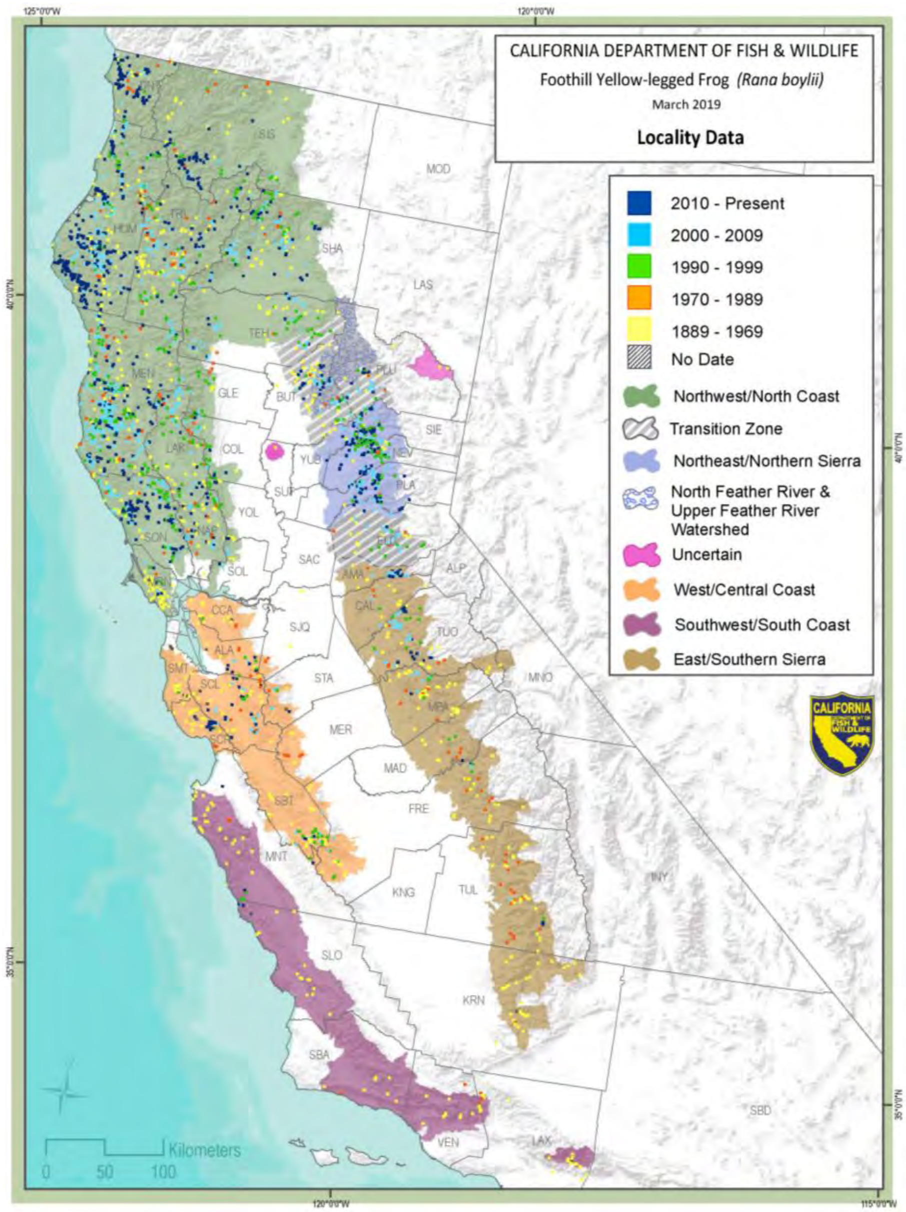

Figure 5. Foothill Yellow-legged Frog occurrence data from 1889-2019 overlaying the six clades by most recent sighting in a Public Lands Survey System section (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

several robust populations. The Green Diamond Resources Company has been monitoring a stretch of the Mad River near Blue Lake (Humboldt County) since 2008 (GDRC 2018). The greatest published density of Foothill Yellow-legged Frog egg masses was documented here in 2009 at 323.6 egg masses/km (520.7/mi) (Bourque and Bettaso 2011). However, in 2017, surveyors counted 625.1 egg masses/km (1,006/mi) along the same reach (GDRC 2018). At its lowest during this period, egg mass density was calculated at 71.54/km (115.1/mi) in 2010, although this count occurred after a flooding even that likely scoured over half of the egg masses laid that season (GDRC 2018, R. Bourque pers. comm. 2019). During a single day survey in 2017 along approximately 2 km (1.3 mi) of Redwood Creek in Redwood National Park (Humboldt County), 2,009 young and 126 adult Foothill Yellow-legged Frogs were found (D. Anderson pers. comm. 2017). Some reaches of the South Fork Eel River (Mendocino County) also support high densities of Foothill Yellow-legged Frogs. Kupferberg (pers. comm. 2018) recorded 206.9 and 106.2 egg masses/km (333 and 171/mi) along two stretches in 2016, and 201.7 and 117.5 egg masses/km (324 and 189/mi) in 2017. However, other reaches yielded counts as low as 6.1 and 8.4 egg masses/km (9.8 and 13.5/mi) (Ibid.). In the Angelo Reserve (an unregulated reach), the 24-year mean density was 109 egg masses/km (175.4/mi) (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015). In contrast, a 10-year mean density of egg masses below Lewiston Dam on the Trinity River (Trinity County) was 0.89/km (1.43/mi) (Ibid.).

Figure 6 depicts PLSS sections with positive sightings of Foothill Yellow-legged Frogs from the CNDDB, Biological Information Observation System datasets, and personal communications that are color coded by the most recent date of detection. Within this clade, Foothill Yellow-legged Frogs were observed in at least 343 areas in the past 5 years (CNDDB 2019). The species remains widespread within many watersheds, although most observations only verify presence, or fewer than ten individuals or egg masses are recorded (Ibid.). Documented extirpations are comparatively rare, but also likely undetected or under-reported, and nearly all occurred just north of the high-populated San Francisco Bay area (Figure 7; Ibid.).

West/Central Coast

This clade extends south from the San Francisco Bay through the Diablo Range and down the peninsula through the Santa Cruz and Gabilan Mountains in the Coast Range east of the Salinas Valley. It includes most of Contra Costa, Alameda, San Mateo, Santa Cruz, Santa Clara, and San Benito counties; western San Joaquin, Stanislaus, Merced, and Fresno counties; and a small portion of eastern Monterey County. Records of Foothill Yellow-legged Frogs occurring south of San Francisco Bay did not exist until specimens were collected in 1918 around what is now Pinnacles National Park in San Benito County, and little information exists on historical distribution and abundance within this clade (Storer 1923).

Within this clade, Foothill Yellow-legged Frogs were observed in at least 24 areas in the past five years (Figure 8; CNDDB 2019). Documented and possible extirpations are concentrated around the San Francisco Bay and sites at the southern portion of the clade's range, although these may not have been resurveyed since their original observations in the 1940s through 1960s, except for a site in Pinnacles National Park that was surveyed in 1994 (Figure 9; Ibid.). In addition, although not depicted,

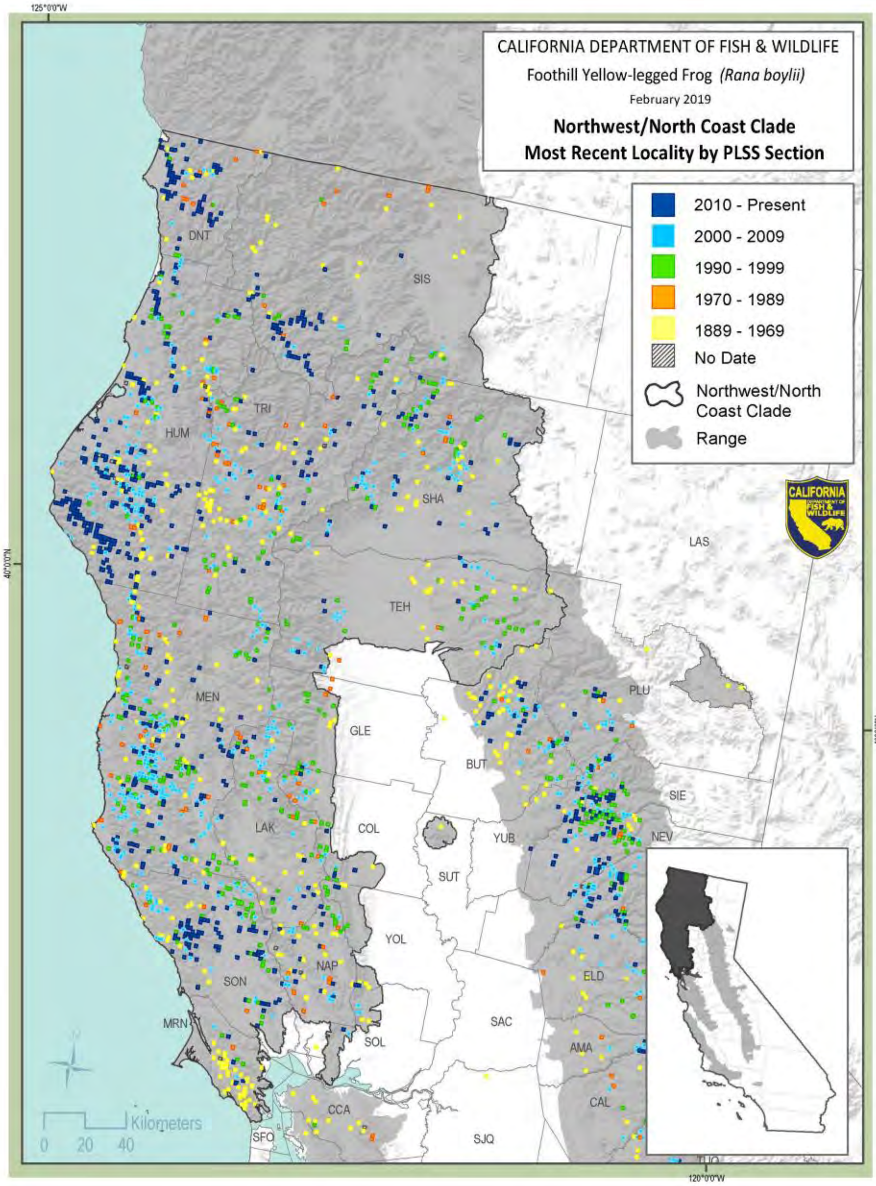

Figure 6. Close-up of Northwest/North Coast Foothill Yellow-legged Frog clade observations from 1889-2019 (ARSSC, BIOS, CDFW, CNDDB, HRC, MRC)

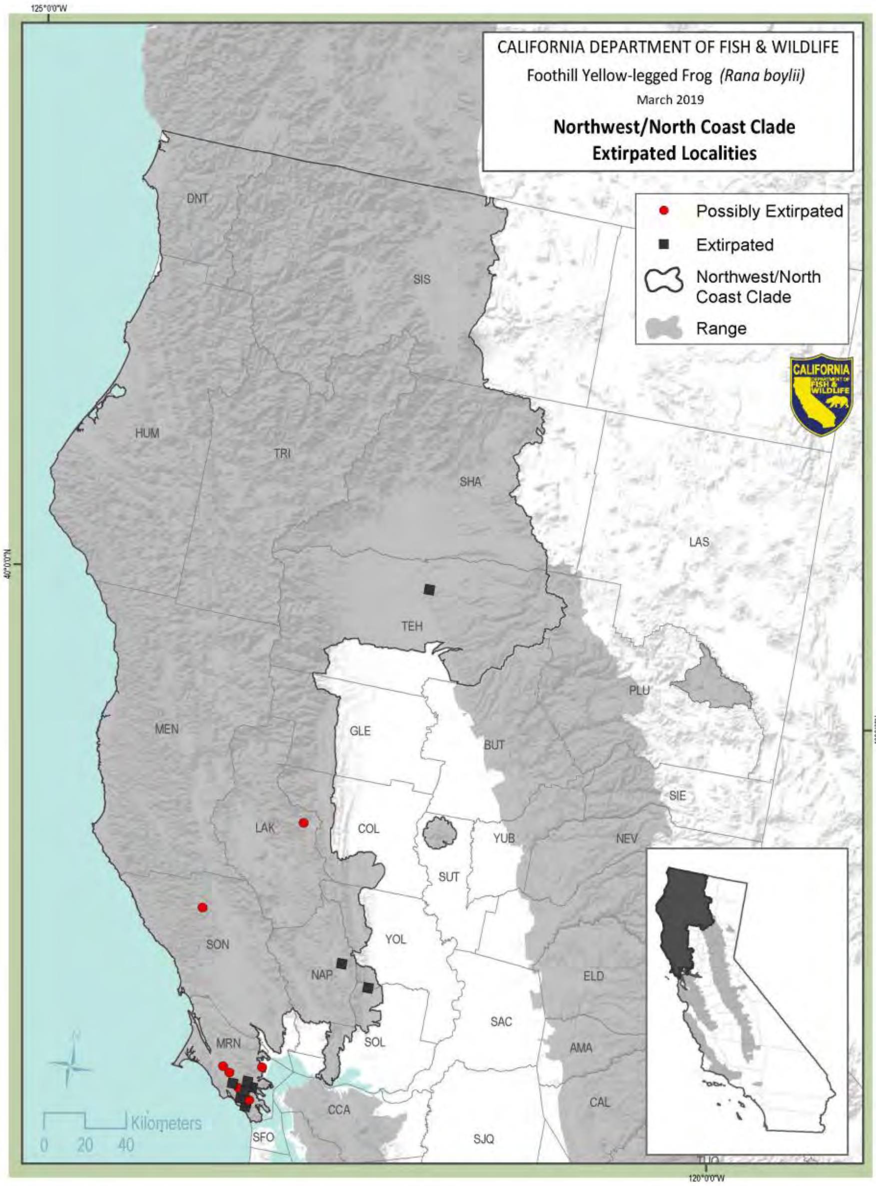

Figure 7. Possibly extirpated and extirpated Northwest/North Coast Foothill Yellow-legged Frog clade sites (CNDDB)

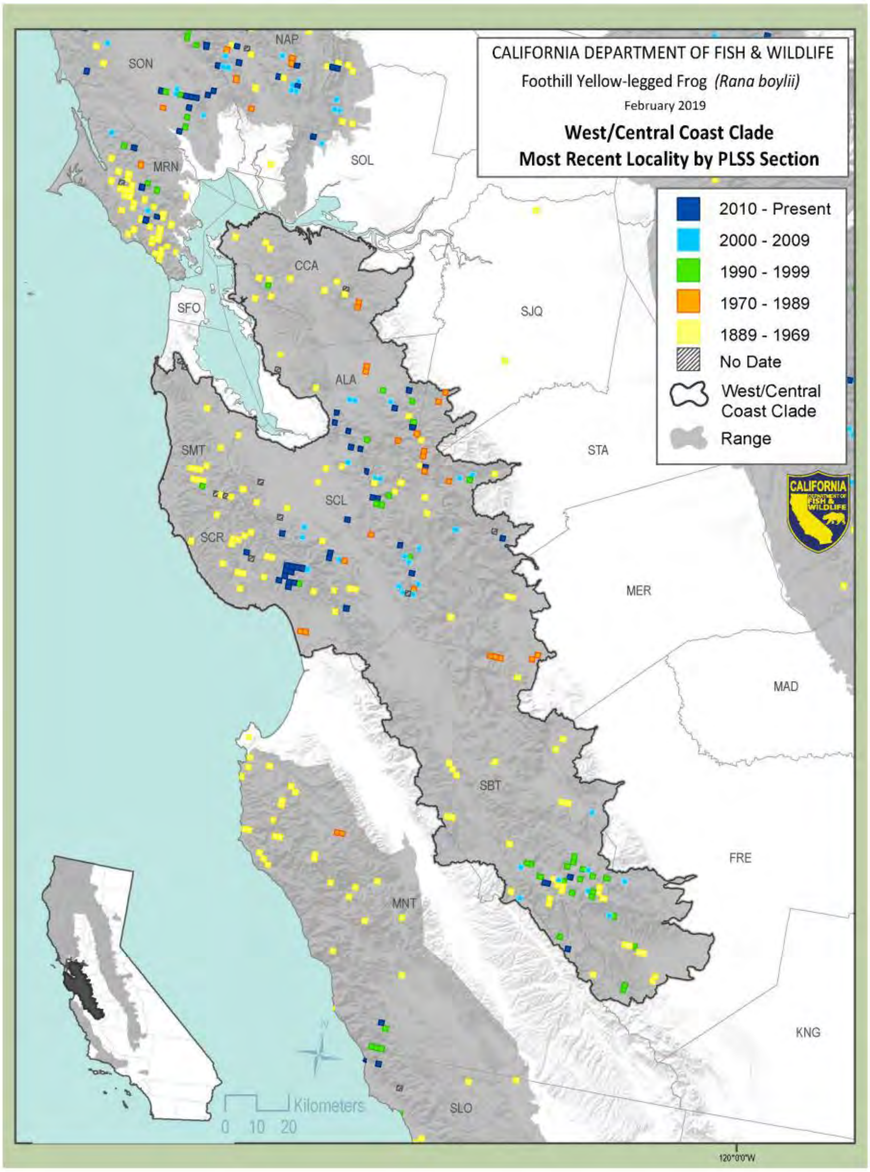

Figure 8. Close-up of West/Central Coast clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

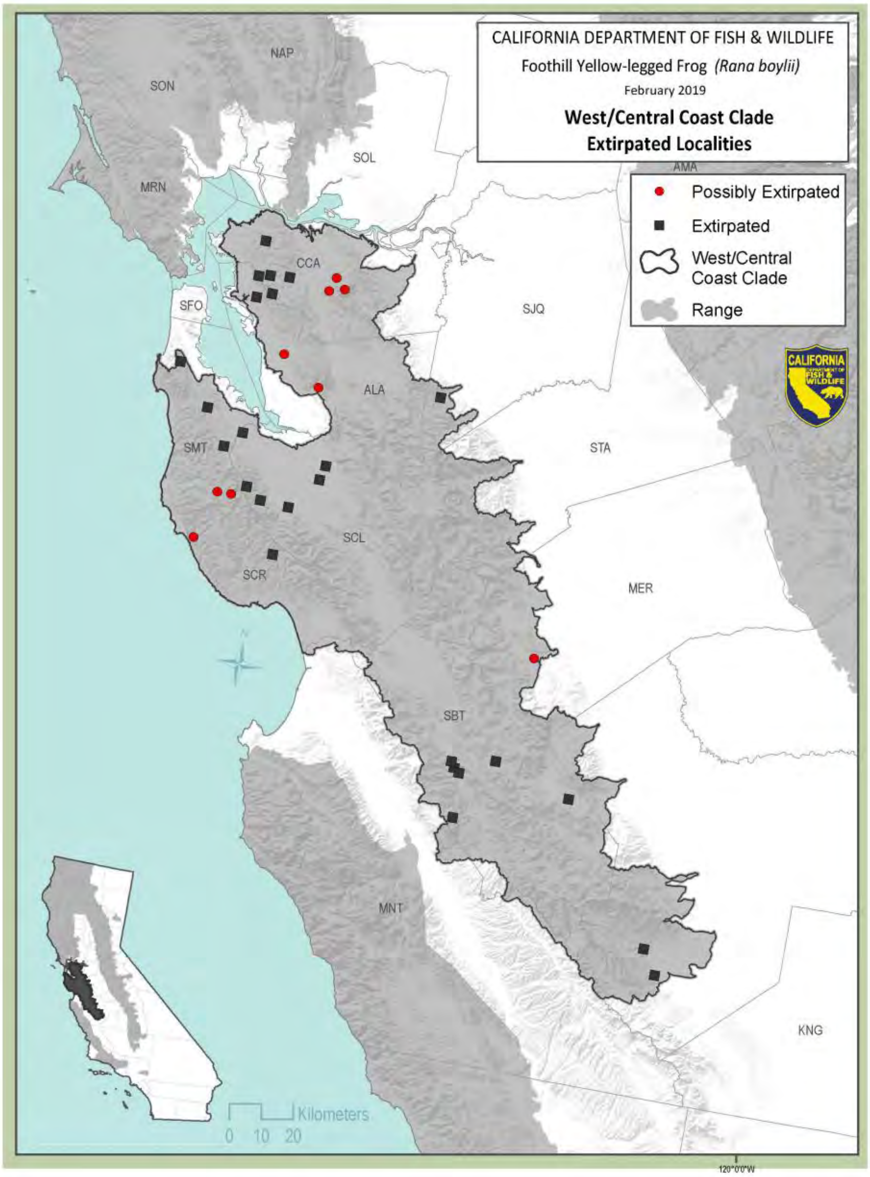

Figure 9. Possibly extirpated and extirpated West/Central Coast Foothill Yellow-legged Frog clade sites (CNDDB)

two populations on Arroyo Mocho and Arroyo Valle south of Livermore (Alameda County) are also likely extirpated (M. Grefsrud pers. comm. 2019).

The San Francisco Bay Area is heavily urbanized. Foothill Yellow-legged Frogs may be gone from Contra Costa County; eight of the nine CNDDB records from the county are museum specimens collected between 1891 and 1953, and the most recent observation was two adults in a plunge pool in an intermittent tributary to Moraga Creek in 1997. No recent (2010 or later) observations exist from San Mateo County (Ibid.). Historically occupied lower-elevation sites surrounding the San Francisco Bay and inland appear to be extirpated, but there are (or were) some moderately abundant breeding populations remaining at higher elevations in Arroyo Hondo (Alameda County), Alameda Creek (Alameda and Santa Clara counties), Coyote and Upper Llagas creeks (Santa Clara County), and Soquel Creek (Santa Cruz County) with some scattered smaller populations also persisting in these counties (J. Smith pers. comm. 2016, 2017; CNDDB 2019). The Alameda Creek and Coyote Creek populations recently underwent large-scale mortality events, so their numbers are likely substantially lower than what is currently reported in the CNDDB (Adams et al. 2017a, Kupferberg and Catenazzi 2019). In addition, the Arroyo Hondo population will lose approximately 1.6 km (1 mi) of prime breeding habitat (i.e., supported the highest density of egg masses on the creek) as the Calaveras Reservoir is refilled following its dam replacement project in 2019 (M. Grefsrud pers. comm. 2019). Foothill Yellow-legged Frogs may be extirpated from Corral Hollow Creek in San Joaquin County, but a single individual was observed five years ago further up the drainage in Alameda County within an Off-Highway Vehicle park (CNDDB 2019). Few recent sightings of Foothill Yellow-legged Frogs in the east-flowing creeks are documented. They may still be extant in the headwaters of Del Puerto Creek (western Stanislaus County), but the records further downstream indicate bullfrogs (known predators and disease reservoirs) are moving up the system (Ibid.). Several locations in southern San Benito, western Fresno, and eastern Monterey counties have relatively recent (2000 and later) detections (Ibid.). However, while many of these sites supported somewhat large populations in the 1990s, the more recent records report fewer than ten individuals (Ibid.). The exception is a Monterey County site where around 25 to 30 were observed in 2012 (Ibid.).

Southwest/South Coast

Widespread extirpations occurred decades ago, primarily in the 1960s and 1970s, in this area (Adams et al. 2017b). As a result, genetic samples were largely unavailable, and the boundaries are speculative. The clade is presumed to include the Coast Range from Monterey Bay south to the Transverse Range across to the San Gabriel Mountains. This clade includes portions of Monterey, San Luis Obispo, Santa Barbara, Ventura, and Los Angeles counties. Storer (1923) reported that Foothill Yellow-legged Frogs were collected for the first time in Monterey County in 1919 and that a specimen collected by Cope in 1889 in Santa Barbara and listed as *Rana temporaria pretiosa* may refer to the Foothill Yellow-legged Frog because as previously mentioned, the taxonomy of this species changed several times over the first century after it was named.

Foothill Yellow-legged Frogs had been widespread and fairly abundant in this area until the late 1960s (Figure 10) but were rapidly extirpated throughout the southern Coast Ranges and western Transverse

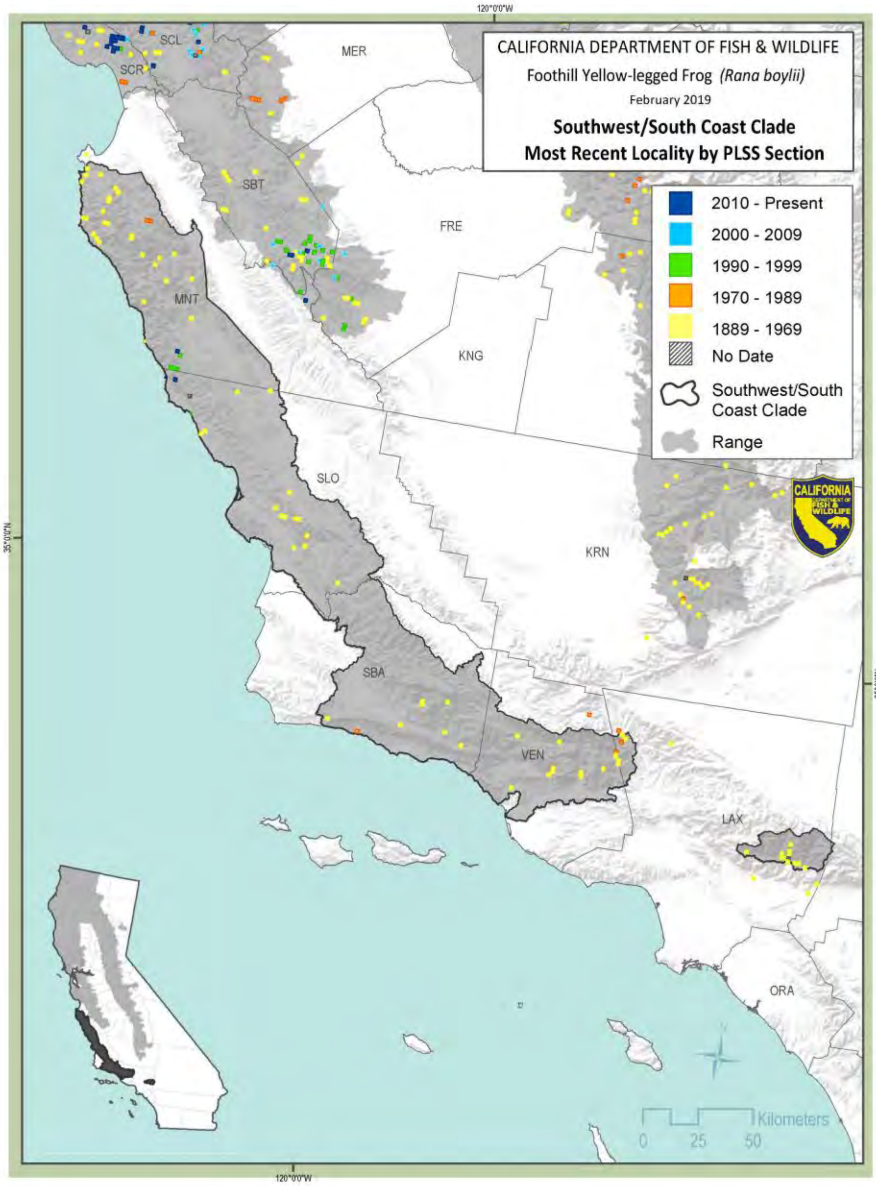

Figure 10. Close-up of Southwest/South Coast clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

Ranges by the mid-1970s (Figure 11; Sweet 1983, Adams et al. 2017b). Only two known extant populations exist from this clade, located near the border of Monterey and San Luis Obispo counties (S. Sweet pers. comm. 2017, McCartney-Melstad et al. 2018, Peek 2018, CNDDB 2019). They appear to be extremely small and rapidly losing genetic diversity, making them at high risk of extirpation (McCartney-Melstad et al. 2018, Peek 2018).

Northeast/Feather River and Northern Sierra

The exact clade boundaries in the Sierra Nevada are unclear and will require additional sampling and testing to define (Figure 12). The Northeast clade presumably encompasses the Feather River and Northern Sierra clades. The Feather River clade is located primarily in Plumas and Butte counties. The Northern Sierra clade roughly extends from the Feather River watershed south to the Middle Fork American River. It includes portions of El Dorado, Placer, Nevada, Sierra, and Plumas counties. It may also include portions of Amador, Butte, and eastern Tehama counties. No genetic samples were available to test in the Sutter Buttes or the disjunct population in northeastern Plumas County to determine which clades they belonged to before they were extirpated (Figure 13; Olson et al. 2016, CNDDB 2019).

In general, there is a paucity of historical Foothill Yellow-legged Frog data for west-slope Sierra Nevada streams, particularly in the lower elevations of the Sacramento Valley, and no quantitative abundance data exist prior to major changes in the landscape (i.e., mining, dams, and diversions) or the introduction of non-native species (Hayes et al. 2016). Foothill Yellow-legged Frogs have been collected frequently from the Plumas National Forest area in small numbers from the turn of the 20th century through the 1970s (Ibid.). Estimates of relative abundance are not clear from the records, but they suggest the species was somewhat widespread in this area.

More recently, Foothill Yellow-legged Frog populations in the Sierra Nevada have been the subject of a substantial number of surveys and focused research associated with recent and ongoing relicensing of hydroelectric power generating dams by the Federal Energy Regulatory Commission (FERC). Consequently, Foothill Yellow-legged Frogs have been observed in at least 30 areas in Plumas and Butte counties (roughly the Feather River clade) over the past five years (CNDDB 2019). As with the rest of the range, most records are observations of only a few individuals; however, many observations occurred over multiple years, and in some cases all life stages were observed over multiple years (Ibid). The populations appear to persist even with the small numbers reported. The only long-term consistent survey effort has been occurring on the North Fork Feather River along the Cresta and Poe reaches (GANDA 2018). The Cresta reach's subpopulation declined significantly in 2006 and never recovered despite modification of the flow regime to reduce egg mass and tadpole scouring and some habitat restoration (Ibid.). A pilot project to augment the Cresta reach's subpopulation through in situ captive rearing was initiated in 2017 (Dillingham et al. 2018). It resulted in the highest number of young-of-year Foothill Yellow-legged Frogs recorded during fall surveys since researchers started keeping count (Ibid.). The number of egg masses laid in the Poe reach varies substantially year-to-year from a low of 26 in 2001 to a high of 154 in 2015 and back down to 36 in 2017 (GANDA 2018).

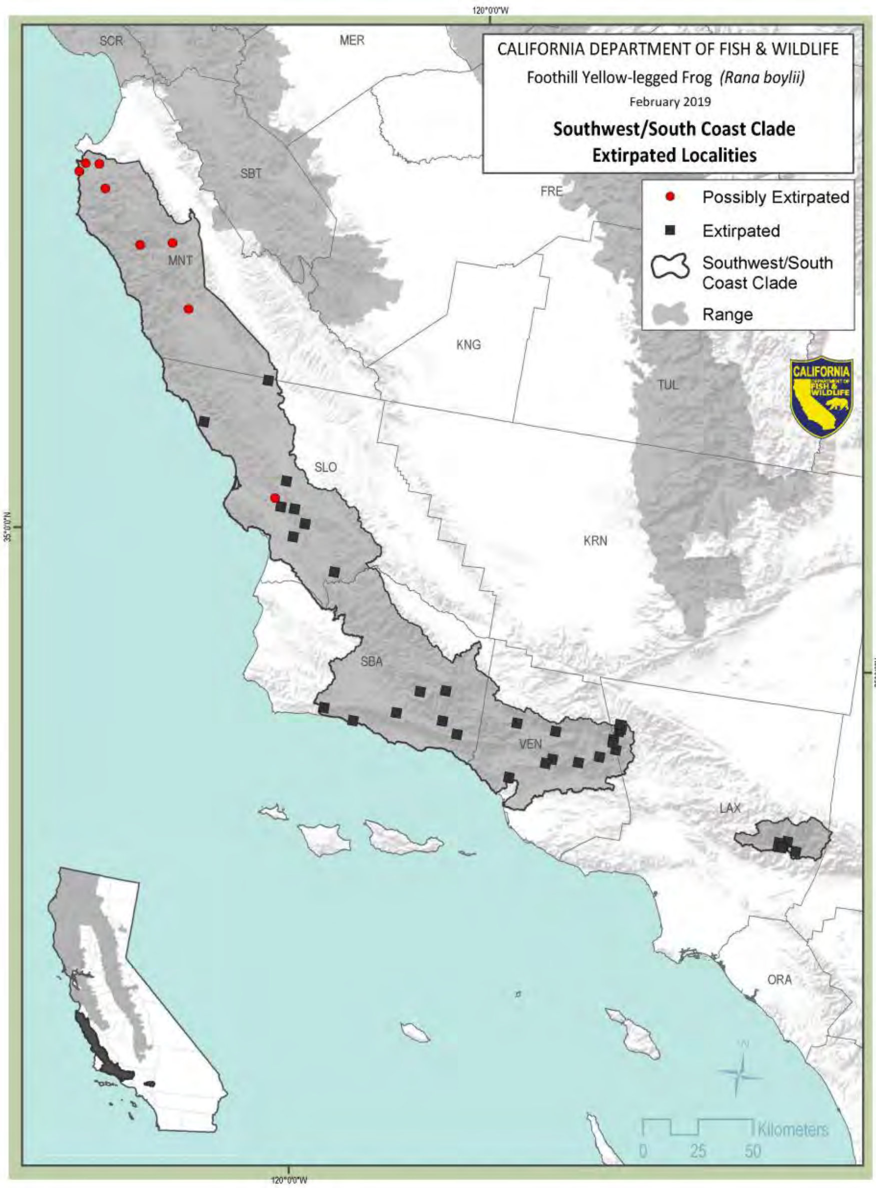

Figure 11. Possibly extirpated and extirpated Southwest/South Coast Foothill Yellow-legged Frog clade sites (CNDDB)

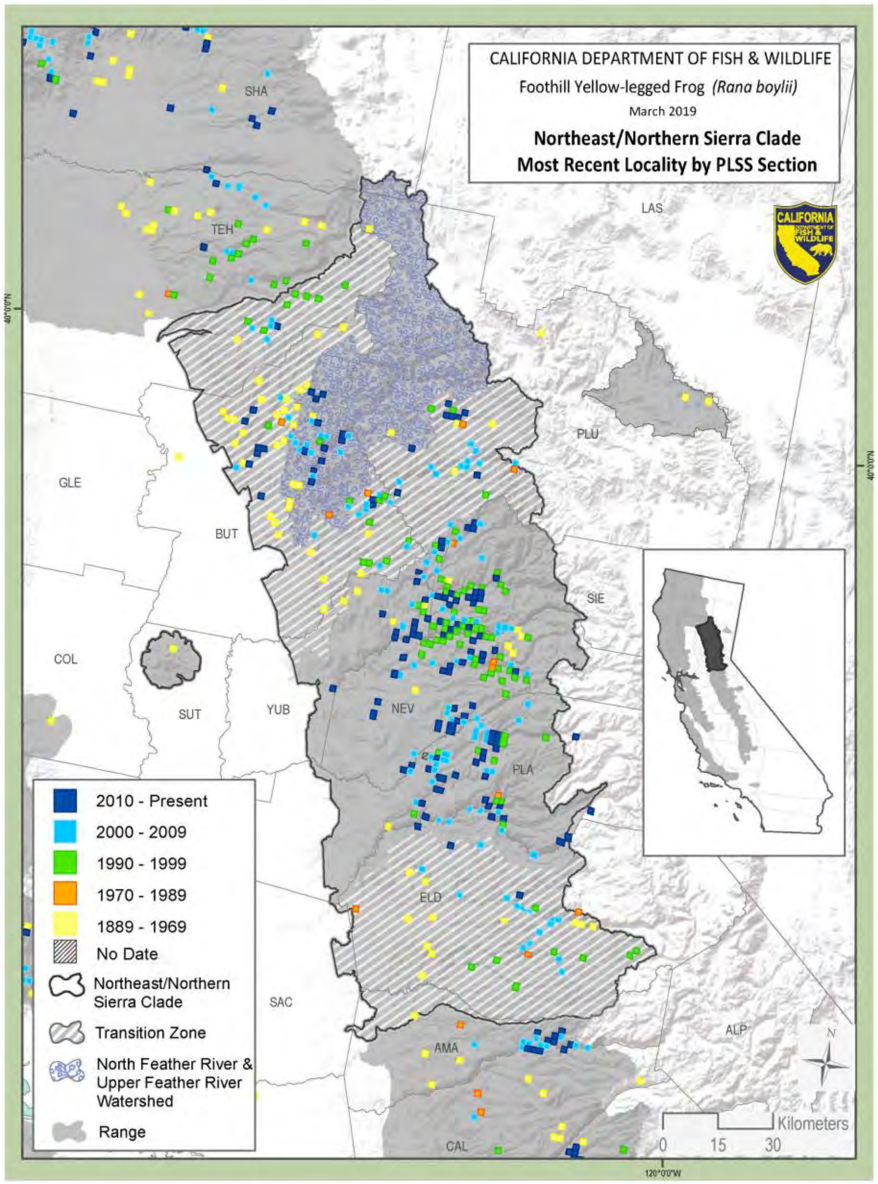

Figure 12. Close-up of Northeast/Feather River and Northern Sierra clades observations from 1889-2019 (ARSSC, BIOS, CNDDB)

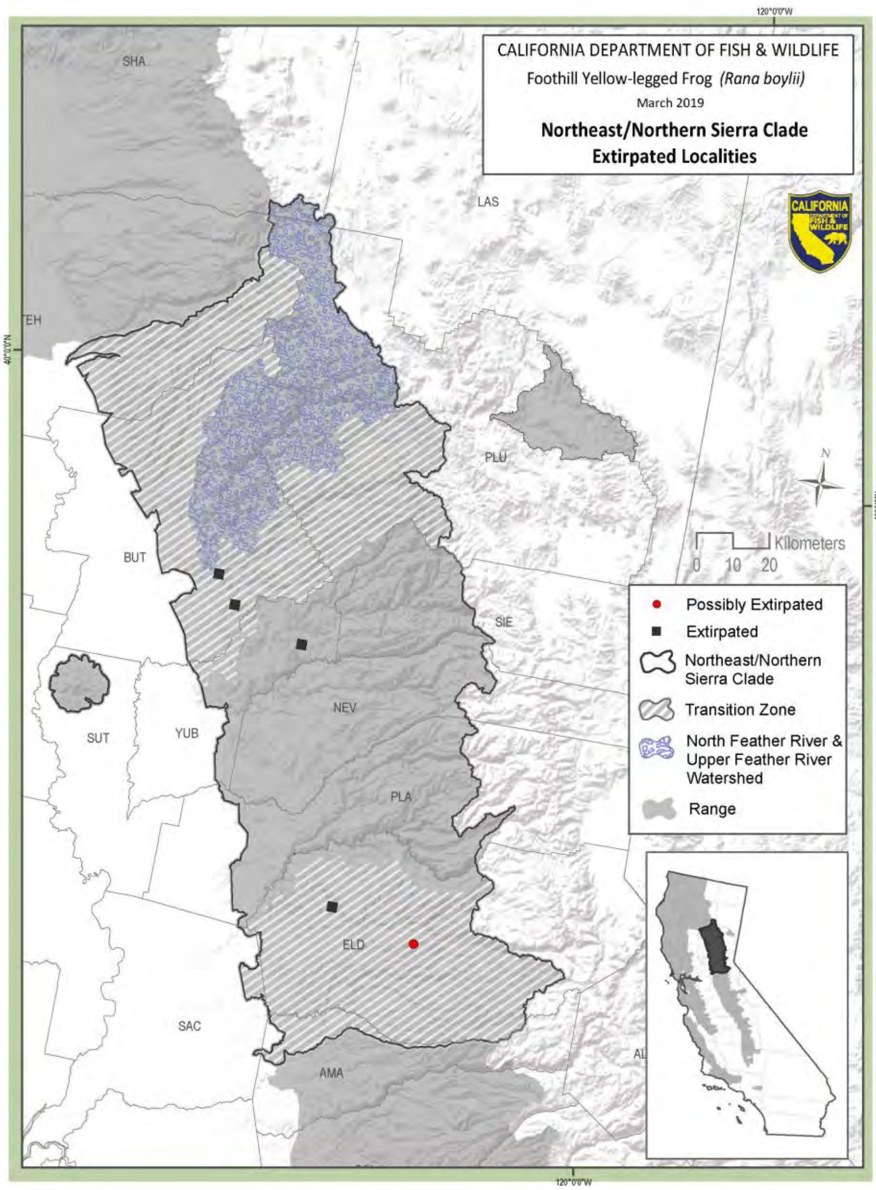

Figure 13. Possibly extirpated and extirpated Northeast/Feather River and Northern Sierra Foothill Yellow-legged Frog clades sites (CNDDB)

Foothill Yellow-legged Frogs have been observed in at least 71 areas in the past 5 years in the presumptive Northeast/Northern Sierra clade. The general pattern in this clade, and across the range ~~for that matter~~, is that unregulated rivers or reaches have more areas that are occupied more consistently and in larger numbers than regulated rivers or reaches (CNDDB 2019, S. Kupferberg pers. comm. 2019). Foothill Yellow-legged Frogs were rarely observed in the hydropeaking reach of the Middle Fork American River and were observed in low numbers in the bypass reach, but they were present and breeding in small tributary populations (PCWA 2008). Relatively robust populations appear to inhabit the North Fork American River and Lower Rubicon River (Gaos and Bogan 2001, PCWA 2008, Hogan and Zuber 2012, K. Kundargi pers. comm. 2014, S. Kupferberg pers. comm. 2019). Additional apparently sufficiently large and relatively stable populations occur on Clear Creek, South Fork Greenhorn Creek, and Shady Creek (Nevada County) and the North and Middle Yuba River (Sierra County), but the remaining observations are of small numbers in tributaries with minimal connectivity among them (CNDDB 2019, S. Kupferberg pers. comm. 2019).

East/Southern Sierra

The East/Southern Sierra clade is presumed to range from the South Fork American River watershed, the northernmost site where individuals from this clade were collected, south to where the Sierra Nevada meets the Tehachapi Mountains. It likely includes El Dorado, Amador, Calaveras, Tuolumne, Mariposa, Madera, Fresno, Tulare, and Kern counties (Figure 14; Peek 2018). The proportion of extirpated sites in this clade is second only to the Southwest/South Coast and follows the pattern of greater losses in the south (Figure 15). Like the southern coastal clade, the southern Sierra clade has low genetic variability and a trajectory of continued loss of diversity (Ibid.).

Historical collections of small numbers of Foothill Yellow-legged Frogs occurred in every major river system within this clade beginning as early as the turn of the 20th century, indicating widespread distribution but little information on abundance (Hayes et al. 2016). By the early 1970s, declines in Foothill Yellow-legged Frog populations from this area were already apparent; Moyle (1973) found them at 30 of 95 sites surveyed in 1970. Notably bullfrogs inhabited the other 65 sites formerly occupied by Foothill Yellow-legged Frogs, and they co-occurred at only 3 sites (Ibid.). In 1992, Drost and Fellers (1996) revisited the sites around Yosemite National Park (Tuolumne and Mariposa counties) that Grinnell and Storer (1924) surveyed in 1915 and 1919. Foothill Yellow-legged Frogs had disappeared from all seven historically occupied sites and were not found at any new sites surveyed surrounding the park (Ibid.). Resurveys of previously occupied sites on the Stanislaus (Tuolumne County), Sierra (Fresno County), and Sequoia (Tulare County) National Forests were also undertaken (Lind et al. 2003b). Foothill Yellow-legged Frogs were absent from the sites in Sierra and Sequoia National Forests, six at each forest; however, a new population was discovered in the Sierra and two in the Sequoia forests (Ibid.). These populations remain extant but are small and isolated (CNDDB 2019). Two of the six sites on the Stanislaus were still occupied, and 19 new populations were found with evidence of breeding at seven of them (Lind et al. 2003b). Twenty of the 24 populations extant at the time inhabited unregulated waterways (Ibid.). Most of the CNDDB (2019) records of Foothill Yellow-legged Frogs on the Stanislaus are at least a decade old and are represented by low numbers.

Commented [RAP9]: May want to clarify this a bit…sites or frogs? I'd split into a separate sentence specifying that frogs were absent from 6 sites in each forest…can't hurt to be explicit.

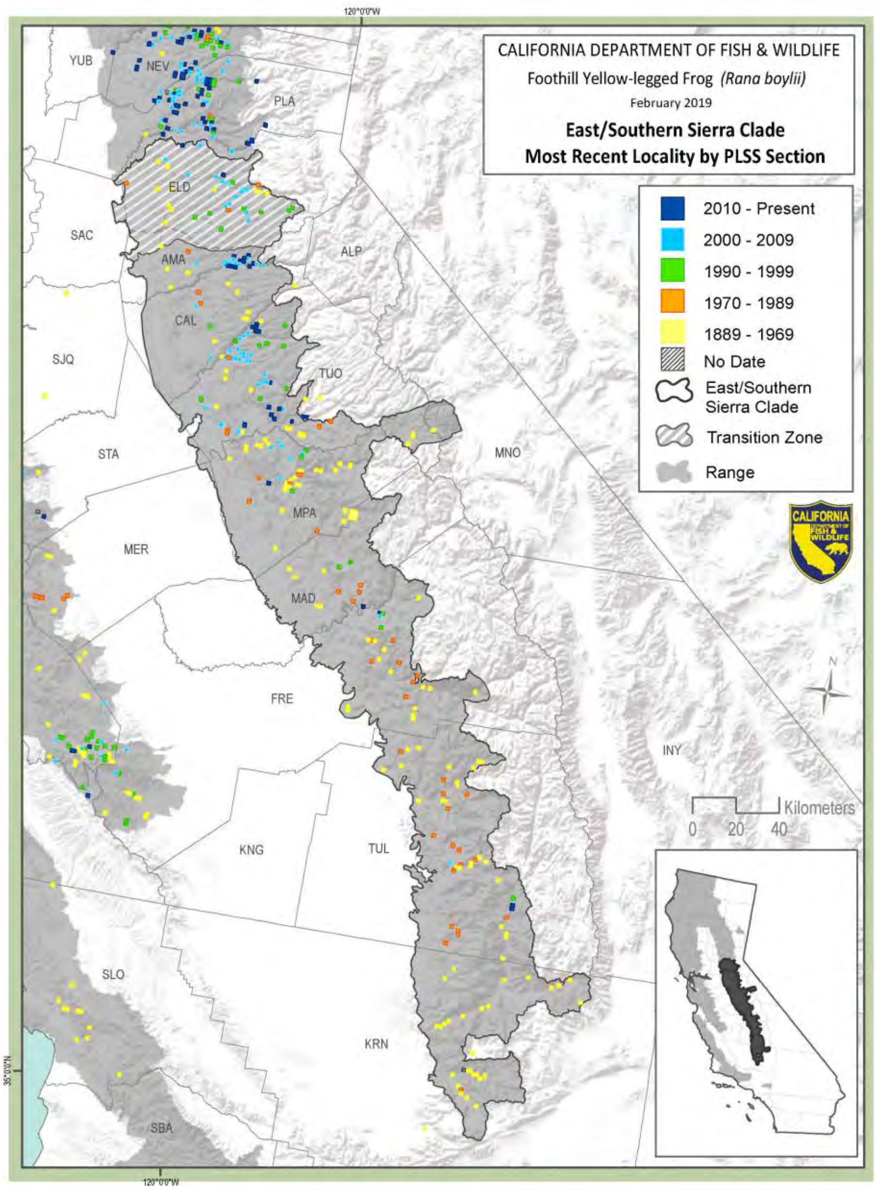

Figure 14. Close-up of East/Southern Sierra clade observations from 1889-2019 (ARSSC, BIOS, CNDDB)

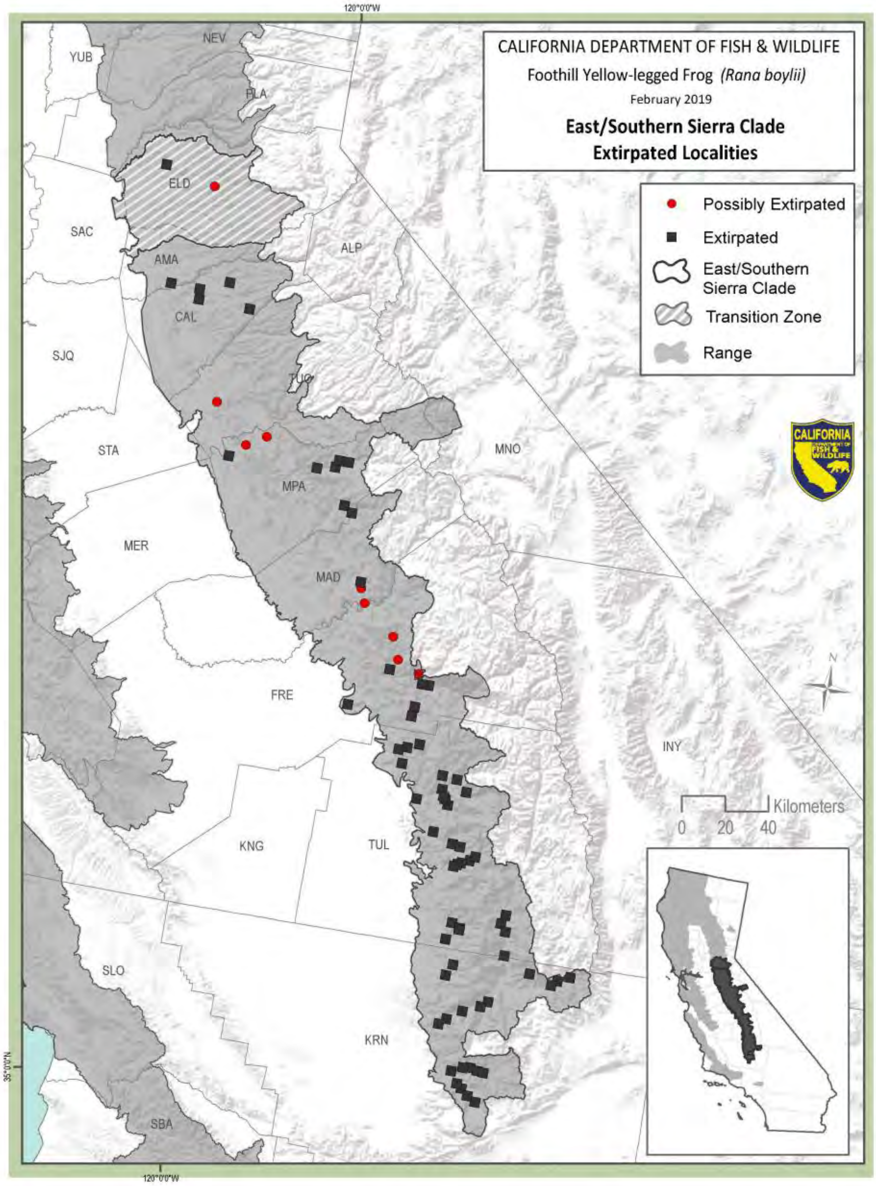

Figure 15. Possibly extirpated and extirpated East/Southern Sierra Foothill Yellow-legged Frog clade sites (CNDDB)

More recently, surveys for Foothill Yellow-legged Frogs were conducted along the South Fork American River as part of the El Dorado Hydroelectric Project's FERC license amphibian monitoring requirements (GANDA 2017). Between 2002 and 2016 counts of different life stages varied significantly by year but the trend for every life stage was a decline over that period (Ibid.). There appears to be a small population persisting along the North Fork Mokelumne River (Amador and Calaveras counties), but it was only productive during the 2012-2014 drought years (Ibid.). Small numbers have also been observed recently in several locations on private timberlands in Tuolumne County (CNDDB 2019).

FACTORS AFFECTING ABILITY TO SURVIVE AND REPRODUCE

"The fortunes of the boylii *population fluctuate with those of the stream"* - Tracy I. Storer, 1925

Several past and ongoing activities have changed the watersheds upon which Foothill Yellow-legged Frogs depend, and many interact with each other exacerbating their adverse impacts. With such an expansive range in California, the degree and severity of these impacts on the species often vary by location. To the extent feasible based on the best scientific information available, those differences are discussed below.

Dams, Diversions, and Water Operations

Foothill Yellow-legged Frogs evolved in a Mediterranean climate with predictable cool, wet winters and hot, dry summers, with their life cycle is adapted to these conditions. In California and other areas with a Mediterranean climate, human demands for water are at the highest when runoff and precipitation are lowest, and annual water supply varies significantly but always follows the general pattern of peak discharge declining to baseflow in the late spring or summer (Grantham et al. 2010). The Foothill Yellow-legged Frog's life cycle depends on this ~~discharge~~ flow pattern and the specific habitat conditions it produces (see the Breeding and Rearing Habitat section). Dams are ubiquitous, but not evenly distributed, in California. Figure 16 depicts the locations of dams under the jurisdiction of the Army Corps of Engineers (ACOE) and the California Department of Water Resources (DWR). Figure 17 depicts the number of surface diversions per PLSS section within the Foothill Yellow-legged Frog's range (eWRIMS 2019).

Dam operations frequently change the amount, ~~and~~ timing, and frequency of water availability; its temperature, depth, and velocity; and its sediment transport and channel morphology altering functions, which can result in dramatic consequences on the Foothill Yellow-legged Frog's ability to survive and successfully reproduce. Several studies comparing Foothill Yellow-legged Frog populations in regulated and unregulated reaches within the same watershed investigate potential dam-effects. These studies demonstrated that dams and their operations can result in several factors that contribute to population declines and possible extirpation. These factors include confusing breeding cues, scouring and stranding of egg masses and tadpoles, reduced quality and quantity of breeding and rearing habitat, reduced tadpole growth rate, barriers to gene flow, and establishment and spread of non-native species (Hayes et al. 2016). In addition, as previously discussed in the Population Structure and Genetic Diversity section, subpopulations of Foothill Yellow-legged Frogs on regulated rivers are more genetically isolated, and the

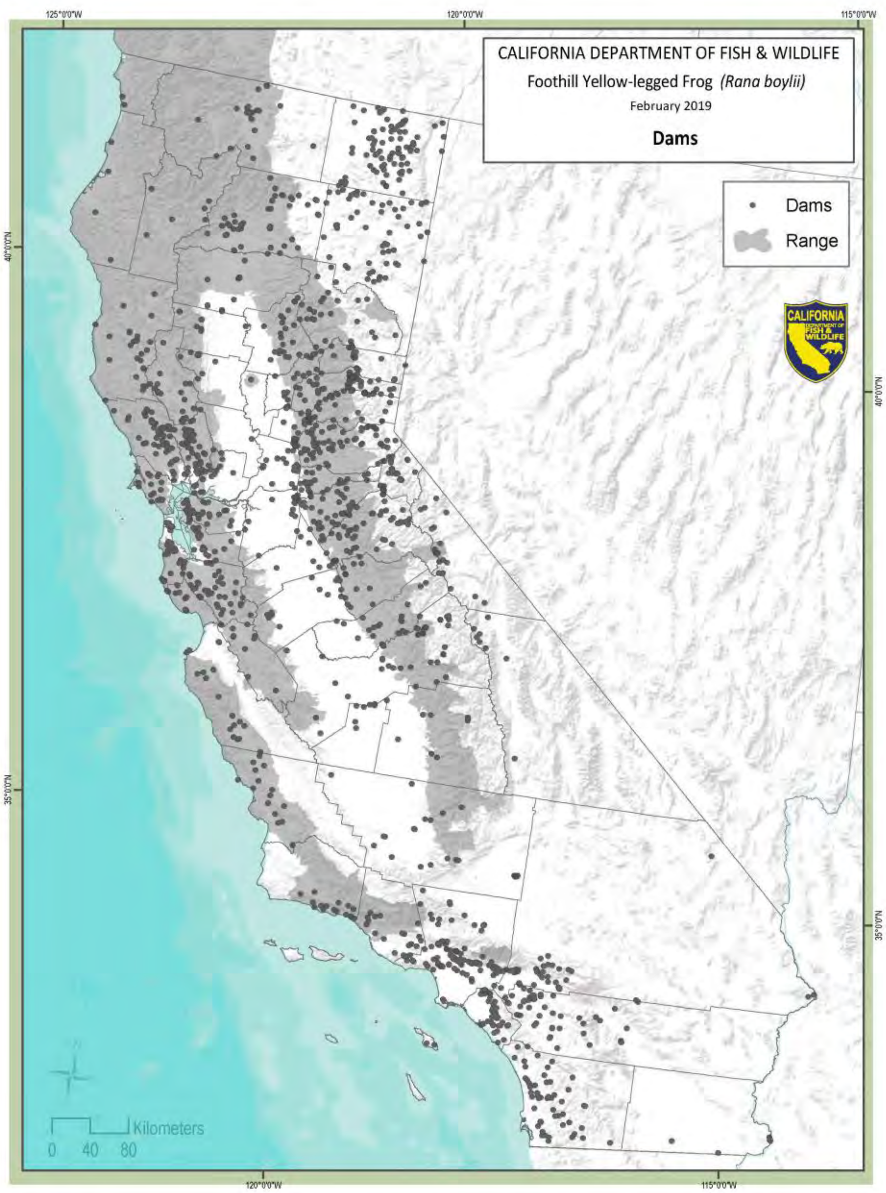

Figure 16. Locations of ACOE and DWR jurisdictional dams (DWR, FRS)

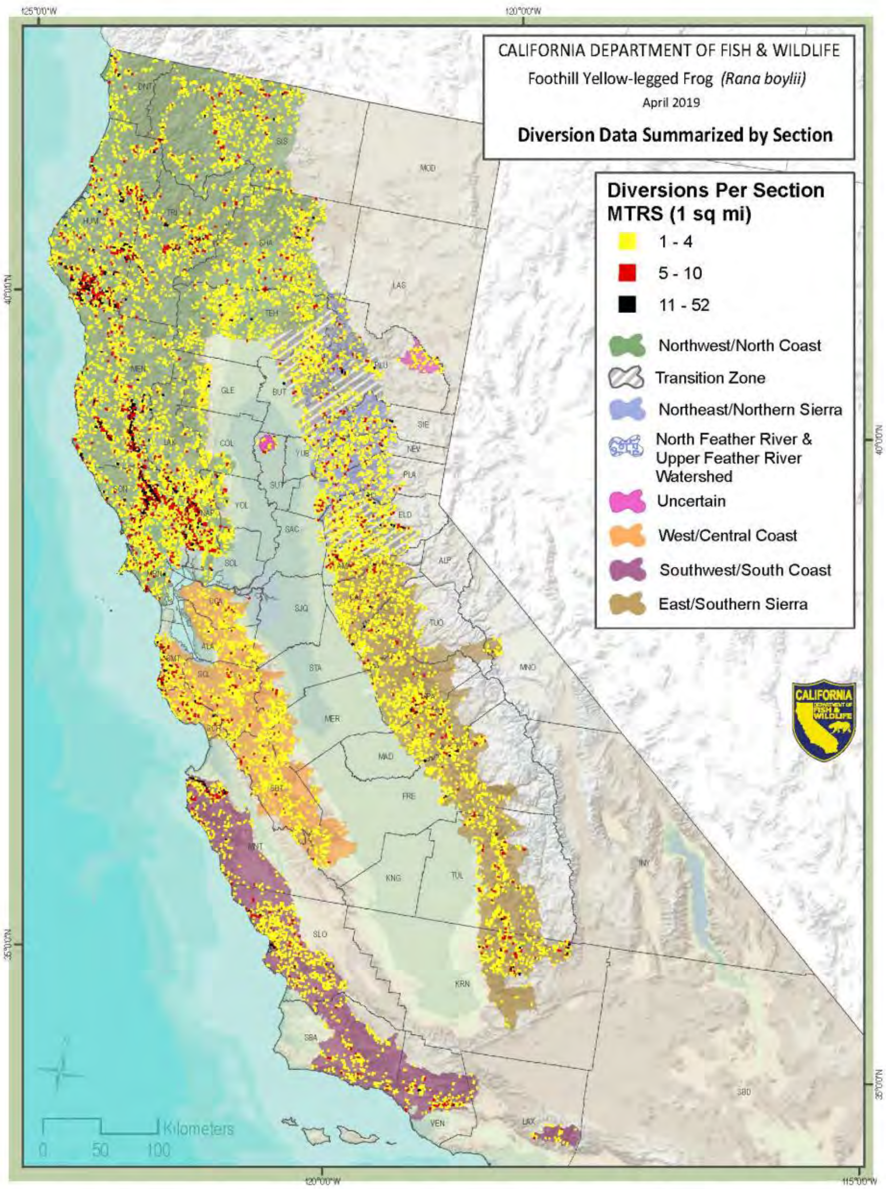

Figure 17. Number of surface water diversions per Public Lands Survey System section within the Foothill Yellow-legged Frog's range in California (eWRIMs)

type of water operations (hydropeaking vs. bypass flows) significantly affects the degree of connectivity and associated gene flow loss among them (Peek 2010~~1~~, 2018). Figure 18 depicts the locations of hydroelectric power plants.

As discussed in the Seasonal Activity and Movements section, cues for Foothill Yellow-legged Frogs to start breeding ~~appear~~ include~~to involve~~ water temperature and velocity, two features altered by dams. Dam operations typically result in reduced flows that are more stable over the course of a year than unimpaired conditions, and dam managers are frequently required to maintain thermally appropriate water temperatures and flows for cold-water-adapted salmonids (USFWS and Hoopa Valley Tribe 1999, Wheeler et al. 2014). For example, late-spring and summer water temperatures on the mainstem Trinity River below Lewiston Dam have been reported to be up to 10°C (20°F) cooler than average pre-dam temperatures, while average winter temperatures are slightly warmer (USFWS and Hoopa Valley Tribe 1999). As a result, Foothill Yellow-legged Frogs breed later on the mainstem Trinity River compared to six nearby tributaries, and some mainstem reaches may never attain the minimum required temperature for breeding (Wheeler et al. 2014, Snover and Adams 2016). In addition, annual discharges past Lewiston Dam have been 10-30% of pre-dam flows and do not mimic the natural hydrograph (Lind et al. 1996).

Aseasonal discharges from dams occur for several reasons including increased flow in late-spring and early summer to facilitate outmigration of salmonids, channel maintenance pulse flows, short-duration releases for recreational whitewater boating, rapid reductions after a spill (uncontrolled flows released down a spillway when reservoir capacity is exceeded) to retain water for power generation or water supply later in the year, peaking flows for hydroelectric power generation, and sustained releases to maintain the seismic integrity of the dam (Lind et al. 1996, Jackman et al. 2004, Kupferberg et al. 2011b, Kupferberg et al. 2012, Snover and Adams 2016). The results of a Foothill Yellow-legged Frog population viability analysis (PVA) suggest that the likelihood a population will persist is very sensitive to early life stage mortality; the 30-year probability of extinction increases significantly with high levels of egg or tadpole scouring or stranding (Kupferberg et al. 2009c). For instance, in 1991 and 1992, all egg masses laid before high flow releases to encourage outmigration of salmonids on the Trinity River were scoured away (Lind et al. 1996). According to the PVA, even a single annual pulse flow such as this or for recreational boating, can result in a three- to five-fold increase in the 30-year extinction risk based on amount of tadpole mortality experienced (Kupferberg et al. 2009c). Management after natural spills can also lead to substantial mortality. For example, in 2006, Foothill Yellow-legged Frogs on the North Fork Feather River bred during a prolonged spill, and the rapid recession below Cresta Dam that followed stranded and desiccated all the eggs laid (Kupferberg et al. 2009b). Rapid flows can also increase predation risk if tadpoles are forced to seek shelter under rocks where crayfish and other invertebrate predators are more common or if they are displaced into the water column where their risk of predation by fish is greater (Ibid.).

Commented [RAP10]: I think while this is true, it's also true that dams also artificially elevate flows over the course of the year (impaired summer baseflows are often much higher than natural flows), and they also can have much more aseasonal variability (i.e., hydropeaking). So here I'd rephrase/restructure this to focus more on the fact that flow regulation impairs natural patterns of flow variability and predictability/seasonality. You could mention the examples above or keep it broad…but I could see the "typically result in reduced flows that are more stable" comment as something that could be misconstrued or misused if taken by itself.

Commented [RAP11]: Many examples of baseflows as much higher than pre-dam, especially in the Sierras (NF Feather, MF American, Tuolumne, NF Mokelumne, SF American, etc.)

The overall reduction of flows and frequency of large winter floods below dams can produce extensive changes to Foothill Yellow-legged Frog habitat quality. They reduce the formation of river bars that are regularly used as breeding habitat, and they create deeper and steeper channels with less complexity and fewer warm, calm, shallow edgewater habitats for tadpole rearing (Lind et al. 1996, Wheeler and Welsh 2008, Kupferberg et al. 2011b, Wheeler et al. 2014). For example, 26 years after construction of

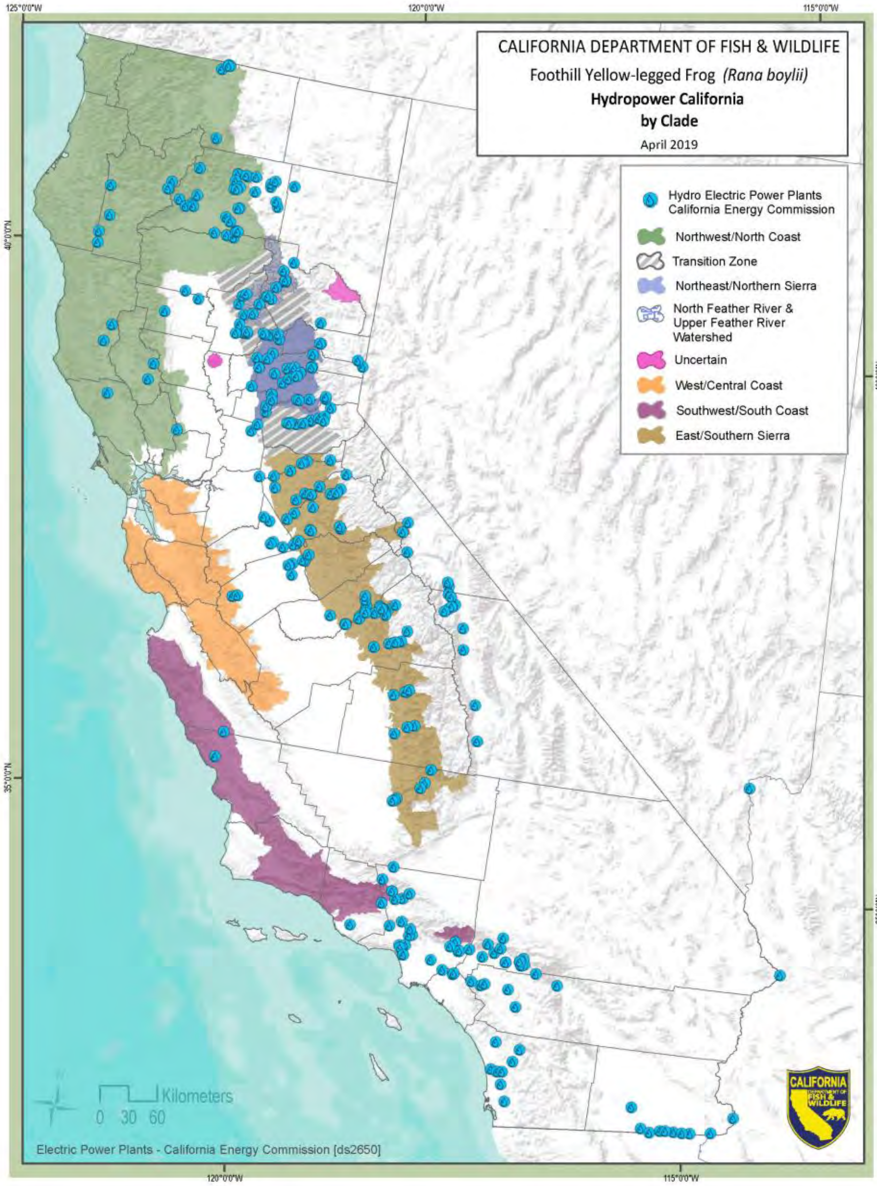

Figure 18. Locations of hydroelectric power generating dams (BIOS)

the Lewiston Dam on the Trinity River, habitat changes in a 63 km (39 mi) stretch from the dam downstream were evaluated (Lind et al. 1996). Riparian vegetation went from covering 30% of the riparian area pre-dam to 95% (Ibid.). Additionally, river bars made up 70% of the pre-dam riparian area compared to 4% post-dam, amounting to a 94% decrease in available Foothill Yellow-legged Frog breeding habitat (Ibid.).

Several features of riverine habitat below dams can decrease tadpole growth rate and other measures of fitness. As ectotherms, Foothill Yellow-legged Frogs require temperatures that support their metabolism, food conversion efficiency, growth, and development, and these temperatures may not be reached until late in the season, or not at all, when the water released is colder than their lower thermal limit (Kupferberg et al. 2011a, Catenazzi and Kupferberg 2013, Wheeler et al. 2014). Colder temperatures and higher flows reduce time spent feeding and efficiency at food assimilation, resulting in slower growth and development (Kupferberg et al. 2011a,b; Catenazzi and Kupferberg 2018). Large bed-scouring winter floods promote greater *Cladophora glomerate* blooms, the filamentous green alga that dominates primary producer biomass during the tadpole rearing season (Power et al. 2008, Kupferberg et al. 2011a). The period of most rapid tadpole growth often coincides with blooms of highly nutritious and more easily assimilated epiphytic diatoms, so reduced flows can have food-web impacts on tadpole growth and survival (Power et al. 2008, Kupferberg et al. 2011a, Catenazzi and Kupferberg 2018). In addition, colder temperatures and fluctuating summer flows, such as those released for hydroelectric power generation, can reduce the amount of algae available for grazing and can change the algal assemblage to one dominated by mucilaginous stalked diatoms like *Didymosphenia geminate* that have low nutritional value (Spring Rivers Ecological Sciences 2003, Kupferberg et al 2011a, Furey et al. 2014). Altered temperatures, flows, and food quality can contribute to slower growth and development, longer time to metamorphosis, smaller size at metamorphosis, and reduced body condition, which adversely impact fitness (Kupferberg et al. 2011b, Catenazzi and Kupferberg 2018).

As discussed in more detail in the Population Structure and Genetic Diversity section, both are strongly affected by river regulation (Peek 20101, 2018; Stillwater Sciences 2012). Foothill Yellow-legged Frogs primarily use watercourses as movement corridors, so the reservoirs created behind dams are often uninhabitable and represent barriers to gene flow (Bourque 2008; Peek 20101, 2018). This decreased connectivity can lead to loss of genetic diversity, ~~inducing~~ which can reduce a species' ability to adapt to changing conditions (Palstra and Ruzzante 2008).

Decreased winter discharge below dams facilitates establishment and expansion of invasive bullfrogs, whose tadpoles require overwintering and are not well-adapted to flooding events (Lind et al. 1996, Doubledee et al. 2003). Where they occur, bullfrogs tend to dominate areas more altered by dam operations than less impaired areas that support a higher proportion of native species (Moyle 1973, Fuller et al. 2011). In addition to downstream effects, ~~the~~ reservoirs ~~created~~ behind dams directly inundate and eliminate ~~destroy~~ lotic (flowing) Foothill Yellow-legged Frog habitat, typically do not retain natural riparian communities due to fluctuating water levels, are often managed for human activities not compatible with the species' needs, and act as a source of introduced species upstream and downstream (Brode and Bury 1984, PG&E 2018). Moyle and Randall (1998) identified characteristics of sites with low native biodiversity in the Sierra Nevada foothills; they were often drainages that had been

Commented [RAP12]: Could cite the 2013 CEC report that Sarah Yarnell & others did on spring recession characterization in reg/unreg rivers, we have figures/data showing algal abundance/biomass in the MF American and SF Yuba was extremely high and was driven by didymo growth. (https://www.energy.ca.gov/2014publications/CEC-500-2014-030/CEC-500-2014-030.pdf)
Yarnell, S. M., Peek, R. A., Rheinheimer, D. E., Lind, A. J., & Viers, J. H. (2013). *Management of the Spring Snowmelt Recession: An Integrated Analysis of Empirical, Hydrodynamic, and Hydropower Modeling Applications* (No. CEC-500-2014-030; Vol. CEC-500–2014–2030). California Energy Commission, PIER.

dammed and diverted in lower- to middle-elevations and dominated by introduced fishes and bullfrogs. Even small-scale operations can have significant effects. Some farming operations divert water during periods of high flows and store it in small impoundments for use during low flow-high ~~need~~ demand times; these ponds can serve as sources for introduced species like bullfrogs to spread into areas where the habitat would otherwise be unsuitable (Kupferberg 1996b).

The mechanisms described above result in the widespread pattern of greater Foothill Yellow-legged Frog density in unregulated rivers and in reaches far enough downstream of a dam to experience minimal effects from it (Lind et al. 1996, Kupferberg 1996a, Bobzien and DiDonato 2007, Peek 2010~~1~~). Abundance of Foothill Yellow-legged Frogs in unregulated rivers averages five times greater than population abundance downstream of large dams (Kupferberg et al. 2012). Figure 19 depicts a comprehensive collection of egg mass density data where at least four years of surveys have been undertaken, showing much lower abundance in regulated (S. Kupferberg pers. comm. 2019). In California, Foothill Yellow-legged Frog presence is associated with an absence of dams or with only small dams far upstream (Lind 2005, Kupferberg et al. 2012). Hydroelectric power generation from Sierra Nevada rivers accounts for nearly half its statewide production and about 9% of all electrical power used in California (Dettinger et al. 2018). Every major stream below 600 m (1968 ft) in the Sierra Nevada has at least one large reservoir (≥ 0.12 km^3 [100,000 ac-ft]), and many have multiple medium and small ones (Hayes et al. 2016). Because of this, Catenazzi and Kupferberg (2017) posit that the dam-effect on Foothill Yellow-legged Frog populations is likely greater in the Sierra Nevada than the Coast Range because dams are more often constructed in a series along a river in the former and spaced close enough together such that suitable breeding temperatures may never occur in the intervening reaches.

Commented [RAP13]: In case I miss one, all these should be 2010, when I finished my MS. Not sure if the library date shows 2011, but the MS was signed, sealed and delivered in Aug 2010. ☺

Pathogens and Parasites

Perhaps the most widely recognized amphibian disease is chytridiomycosis, which is caused by the fungal pathogen *Batrachochytrium dendroabatidis* (Bd). Implicated in the decline of over 500 amphibian species, including 90 presumed extinctions, it represents the greatest recorded loss of biodiversity attributable to a disease (Scheele et al. 2019). The global trade in American Bullfrogs (primarily for food) is connected to the disease's spread because the species can persist with low-level Bd infections without developing chytridiomycosis (Yap et al. 2018). Previous studies suggested Foothill Yellow-legged Frogs may not be susceptible to Bd-associated mass mortality; skin peptides strongly inhibited growth of the fungus in the lab, and the only detectable difference between Bd+ and Bd- juvenile Foothill Yellow-legged Frogs was slower growth (Davidson et al. 2007). At Pinnacles National Park in 2006, 18% of post-metamorphic Foothill Yellow-legged Frogs tested positive for Bd; all were asymptomatic and at least one Bd+ Foothill Yellow-legged Frog subsequently tested negative, demonstrating an ability to shed the fungus (Lowe 2009). However, recent studies have found historical evidence of Bd contributing to the extirpation of Foothill Yellow-legged Frogs in southern California, an acute die-off in 2013 in the Alameda Creek watershed, and another in 2018 in Coyote Creek (Adams et al. 2017a,b; Kupferberg and Catenazzi 2019). Evaluation of museum specimens indicates lower Bd prevalence (proportion of individuals infected) in Foothill Yellow-legged Frogs than most other co-occurring amphibians in southern California in the first part of the 20th century, but it spiked in the 1970s just prior to the last observation of an individual in 1977 (Adams et al. 2017b). Two museum specimens collected in 1966,

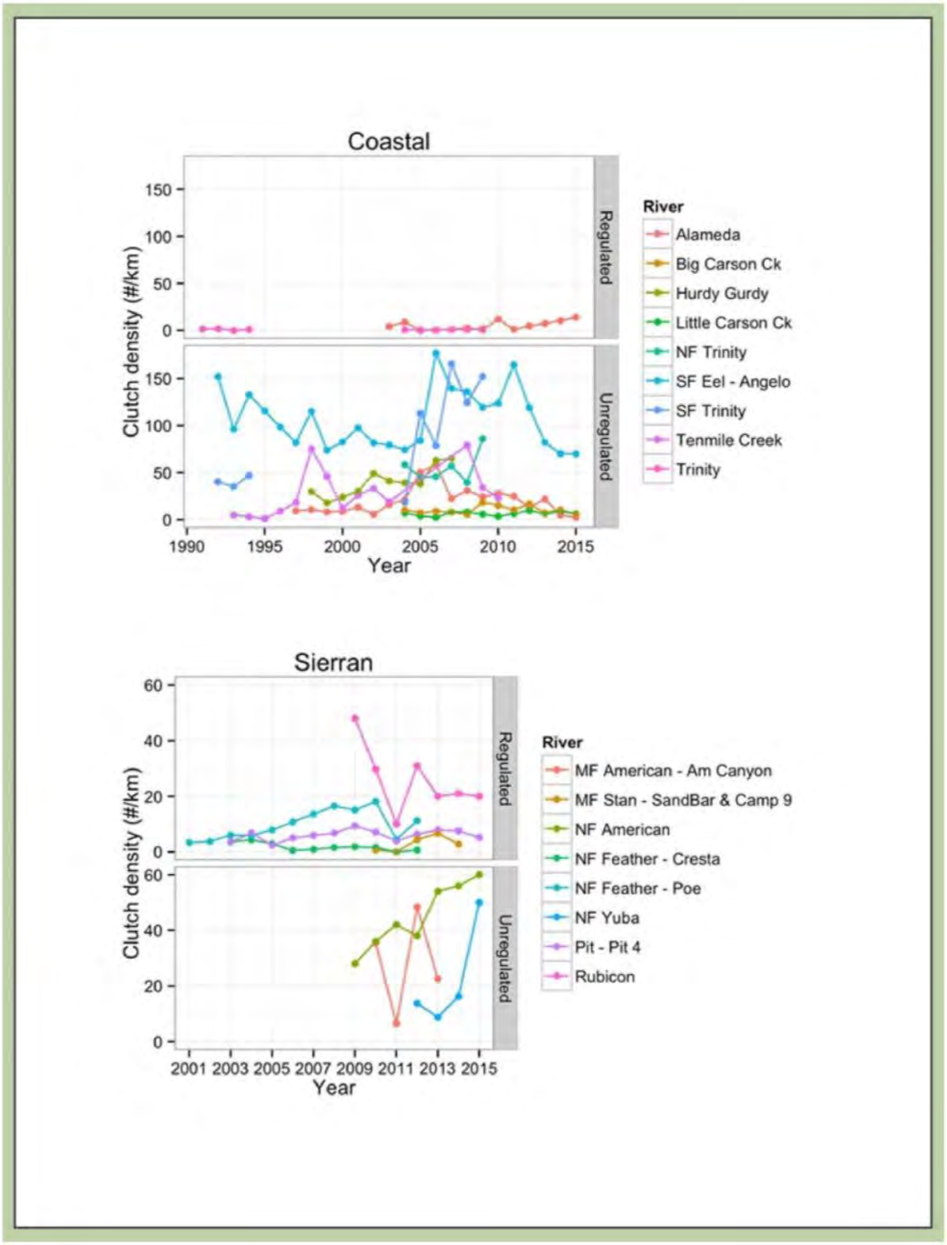

Figure 19. Foothill Yellow-legged Frog Egg mass density estimates along the coast from 1990-2015 and the Sierra Nevada from 2001-2015 from multiple studies compiled by R. Peek and S. Kupferberg (2019)

Commented [RAP14]: See comment in figure list at top, I'd cite this as Peek and Kupferberg 2016 (this is the figure we made for the poster)

one from Santa Cruz County and the other from Alameda County, provide the earliest evidence of Bd in Foothill Yellow-legged Frogs in central California (Padgett-Flohr and Hopkins 2009). In contrast to the southern California results, Foothill Yellow-legged Frogs possessed the highest Bd prevalence among all amphibians tested in coastal Humboldt County in 2013 and 2014; however, zoospore (the aquatic dispersal agent) loads were well below the presumed lethal density threshold (Ecoclub Amphibian Group et al. 2016).

In addition to bullfrogs, the native Pacific Treefrog (*Pseudacris regilla*) seems immune to the lethal effects of chytridiomycosis, and owing to its broad ecological tolerances, more terrestrial lifestyle, and relatively large home range size and dispersal ability, the species is ubiquitous across California (Padgett-Flohr and Hopkins 2009). In a laboratory experiment, Bd-infected Pacific Treefrogs shed an average of 68 zoospores per minute, making them the prime candidate for spreading and maintaining Bd in areas where bullfrogs do not occur (Padgett-Flohr and Hopkins 2009, Reeder et al. 2012). In the wild, Pacific Treefrog populations persisted at 100% of sites in the Sierra Nevada (above 1500 m [4920 ft]) where a sympatric ranid species had been extirpated from 72% of its formerly occupied sites due to a Bd outbreak (Reeder et al. 2012). This is consistent with the results of a model that incorporated Bd habitat suitability, host availability, and invasion history in North America, which concluded west coast mountain ranges were at the greatest risk from the disease (Yap et al. 2018).

Several other pathogens and parasites have been encountered with Foothill Yellow-legged Frogs, but none have been ascribed to large-scale mortality events. Another fungus, a water mold (*Saprolegnia* sp.) carried by fish, is an important factor in amphibian embryo mortality in the Pacific Northwest (Blaustein et al. 1994, Kiesecker and Blaustein 1997). Fungal infections of Foothill Yellow-legged Frog egg masses, potentially from *Saprolegnia*, have been observed in the mainstem Trinity River (Ashton et al. 1997). *Saprolegnia* infection is more likely to occur in ponds and lakes, particularly if stocked by hatchery-raised fish into previously fishless areas and when frogs use communal oviposition sites, so it likely does not represent a major source of mortality in Foothill Yellow-legged Frogs (Blaustein et al. 1994, Kiesecker and Blaustein 1997). However, they may be more susceptible to *Saprolegnia* infection when exposed to other environmental stressors that compromise their immune defenses (Blaustein et al. 1994, Kiesecker and Blaustein 1997).

The trematode parasite *Ribeiroia ondatrae* is responsible for limb malformations in ranids (Stopper et al. 2002). *Ribeiroia ondatrae* was detected on a single Foothill Yellow-legged Frog during a study on malformations, but its morphology was normal (Kupferberg et al. 2009a). The results of the study instead linked malformations in Foothill Yellow-legged Frog tadpoles and young-of-year to the Anchor Worm (*Lernae cyprinacea*), a parasitic copepod from Eurasia (Ibid.). Prevalence of malformations was low, under 4% of the population in both years of study, but there was a pattern of infected individuals metamorphosing at a smaller size, which as previously mentioned can have implications on fitness (Ibid.). Three other species of helminths (parasitic worms) were encountered during the study (*Echinostoma* sp., *Manodistomum* sp., and *Gyrodactylus* sp.); their relative impact on their hosts is unknown, but at least one Foothill Yellow-legged Frog had 700 echinstome cysts in its kidney (Ibid.). Bursey et al. (2010) discovered 13 species of helminths in and on Foothill Yellow-legged Frogs from

Humboldt County. Most are common in anurans, and some are generalists with multiple possible hosts, but studies on their impact on Foothill Yellow-legged Frogs are lacking (Ibid.).

Introduced Species

Species not native to an area, but introduced, can alter food webs and ecosystem processes through predation, competition, hybridization, disease transmission, and habitat modification. Native species lack evolutionary history with introduced species, and early life stages of native anurans are particularly susceptible to predation by aquatic non-native species (Kats and Ferrer 2003). Because introduced species often establish in highly modified habitats, it can be difficult to differentiate between impacts from habitat degradation and the introduced species (Fisher and Shaffer 1996). However, native amphibians have been frequently found successfully reproducing in heavily altered habitats when introduced species were absent, suggesting introduced species themselves can impose an appreciable adverse effect (Ibid.). Numerous introduced species have been documented to adversely impact Foothill Yellow-legged Frogs or are suspected of doing so.

American Bullfrogs were introduced to California from the eastern U.S. around the turn of the 20th century, likely in response to overharvest of native ranids by the frog-leg industry that accompanied the Gold Rush (Jennings and Hayes 1985). Nearly 50 years ago, Moyle (1973) reported that distributions of Foothill Yellow-legged Frogs and bullfrogs in the Sierra Nevada foothills were nearly mutually exclusive. He speculated that bullfrog predation and competition may be causal factors in their disparate distributions in addition to the habitat degradation from dams and diversions that facilitated the bullfrog invasion in the first place. In a study along the South Fork Eel River and one of its tributaries, Foothill Yellow-legged Frog abundance was nearly an order of magnitude lower in reaches were bullfrogs were well established (Kupferberg 1997a). At a site in Napa Valley, after bullfrogs were eradicated, Foothill Yellow-legged Frogs, among other native species, recolonized the area (J. Alvarez pers. comm. 2018). In a mesocosm experiment, Foothill Yellow-legged Frog survival in control enclosures measured half that of enclosures containing bullfrog and Foothill Yellow-legged Frog tadpoles, and they weighed approximately one-quarter ~~lighter~~ less at metamorphosis (Kupferberg 1997a). The mechanism for these declines appeared to be the reduction of ~~high quality~~high-quality algae by bullfrog tadpole grazing, as opposed to any behavioral or chemical interference (Ibid.). Adult bullfrogs, which can get very large (9.0-15.2 cm [3.5-6.0 in]), also directly consume Foothill Yellow-legged Frogs, including adults (Moyle 1973, Crayon 1998, Powell et al. 2016). Silver (2017) noted that she never heard Foothill Yellow-legged Frogs calling in areas with bullfrogs, which has implications for breeding success; she speculated the lack of vocalizations may have been a predator avoidance strategy.

As discussed briefly in the Pathogens and Parasites section, American Bullfrogs act as reservoirs and vectors of the lethal chytrid fungus. In museum specimens from both southern and central California, Bd was detected in bullfrogs before it was detected in Foothill Yellow-legged Frogs in the same area (Padgett-Flohr and Hopkins 2009, Adams et al. 2017b). During a die-off from chytridiomycosis that commenced in 2013, Bd prevalence and load in Foothill Yellow-legged Frogs was positively predicted by bullfrog presence (Adams et al. 2017a). A similar die-off in 2018 from a nearby county appears to be related to transmission by bullfrogs as well (Kupferberg and Catenazzi 2019). In addition, male Foothill

Yellow-legged Frogs have been observed amplexing female bullfrogs, which may not only constitute wasted reproductive effort but could serve to increase their likelihood of contracting Bd (Lind et al. 2003a). In fact, adult males were more likely to be infected with Bd than females or juveniles during the recent die-off in Alameda Creek (Adams et al. 2017a). African Clawed Frogs (*Xenopus laevis*) have also been implicated in the spread of Bd in California because like bullfrogs, they are asymptomatic carriers (Padgett-Flohr and Hopkins 2009). However, African Clawed-Frog distribution only minimally overlaps with the Foothill Yellow-legged Frog's range unlike the widespread bullfrog (Stebbins and McGuinness 2012).

Hayes and Jennings (1986) observed a negative association between the abundance of introduced fish and Foothill Yellow-legged Frogs. Rainbow trout (*Onchorynchus mykiss*) and green sunfish (*Lepomis cyanellus*) are suspected of destroying egg masses (Van Wagner 1996). Bluegill sunfishes (*L. macrochirus*) are likely predators; in captivity when offered eggs and tadpoles of two ranid species, they consumed both life stages but a significantly greater number of tadpoles (Werschkul and Christensen 1977). Common hatchery-stocked fish like brook (*Salvelinus fontinalis*) and rainbow trout commonly carry of *Saprolegnia* (Blaustein et al. 1994). In addition, presence of non-native fish can facilitate bullfrog invasions by reducing the density of macroinvertebrates that prey on their tadpoles (Adams et al. 2003). Foothill Yellow-legged Frog tadpoles raised from eggs from sites with and without smallmouth bass (*Micropterus dolomieu*) did not differ in their responses to exposure to the non-native, predatory bass and a native, non-predatory fish (Paoletti et al. 2011). This result suggests that Foothill Yellow-legged Frogs have not yet evolved a recognition of bass as a threat, which makes them more vulnerable to predation (Ibid.).

Introduced into several areas within the Coast Range and Sierra Nevada, signal crayfish have been recorded preying on Foothill Yellow-legged Frog egg masses and are suspected of preying on their tadpoles based on observations of tail injuries that looked like scissor snips (Riegel 1959, Wiseman et al. 2005). The introduced red swamp crayfish (*Procambarus clarkii*) likely also preys on Foothill Yellow-legged Frogs. Because Foothill Yellow-legged Frogs evolved with native crayfish in northern California, individuals from those areas may more effectively avoid crayfish predation than in other parts of the state where they are not native (Riegel 1959, USFWS 1998, Kats and Ferrer 2003). The Foothill Yellow-legged Frog's naivety to crayfish was demonstrated in a study that showed they did not change behavior when exposed to signal crayfish chemical cues, but once the crayfish was released and consuming Foothill Yellow-legged Frog tadpoles, the survivors, likely reacting to chemical cues from dead tadpoles, did respond (Kerby and Sih 2015).

Sedimentation

Several anthropogenic activities, some of which are described in greater detail below, can artificially increase sedimentation into waterways occupied by Foothill Yellow-legged Frogs and adversely impact biodiversity (Moyle and Randall 1998). These activities include but are not limited to mining, agriculture, overgrazing, timber harvest, and poorly constructed roads (Ibid.). Increased fine sediments can substantially degrade Foothill Yellow-legged Frog habitat quality. Heightened turbidity decreases light penetration that phytoplankton and other aquatic plants require for photosynthesis (Cordone and Kelley

1961). When silt particles fall out of the water column, they can destroy algae by covering the bottom of the stream (Ibid.). Algae are not only important for Foothill Yellow-legged Frog tadpoles as forage but also oxygen production (Ibid.). Sedimentation may impede attachment of egg masses to substrate (Ashton et al. 1997). The effect of silt accumulation on embryonic development is unknown, but it does make them less visible, which could decrease predation risk (Fellers 2005). Fine sediments can fill interstitial spaces between rocks that tadpoles use for shelter from high velocity flows and cover from predators and that serve as sources for aquatic invertebrate prey for post-metamorphic Foothill Yellow-legged Frogs (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b).

Mining

Current mining practices, as well as legacy effects from historical mining operations, may adversely impact Foothill Yellow-legged Frogs through contaminants, direct mortality, habitat destruction and degradation, and behavioral disruption. While mercury in streams can result from atmospheric deposition, storm-induced runoff of naturally occurring mercury, agricultural runoff, and geothermal springs, runoff from historical mine sites mobilizes a significant amount of mercury (Foe and Croyle 1998, Alpers et al. 2005, Hothem et al. 2010). Beginning in the mid-1800s, extensive mining occurred in the Coast Range to supply mercury for gold mining in the Sierra Nevada, causing widespread contamination of both mountain ranges and the rivers in the Central Valley (Foe and Croyle 1998). Studies on Foothill Yellow-legged Frog tissues collected from the Cache Creek (Coast Ranges) and Greenhorn Creek (Sierra Nevada) watersheds revealed mercury bioaccumulation concentrations as high as 1.7 and 0.3 µg/g (ppm), respectively (Alpers et al. 2005, Hothem et al. 2010). For context, the U.S. Environmental Protection Agency's mercury criterion for issuance of health advisories for fish consumption is 0.3 µg/g; concentrations exceeded this threshold in Foothill Yellow-legged Frog tissues at 62% of sampling sites in the Cache Creek watershed (Hothem et al. 2010). Bioaccumulation of this powerful neurotoxin can cause deleterious impacts on amphibians including inhibited growth, decreased survival to metamorphosis, increased malformations, impaired reproduction, and other sublethal effects (Zillioux et al. 1993, Unrine et al. 2004). In a study measuring Sierra Nevada watershed health, Moyle and Randall (1998) reportedly found very low biodiversity in streams that were heavily polluted by acidic water leaching from historical mines. Acidic drainage measured as low as 3.4 pH from some mined areas in the northern Sierra Nevada (Alpers et al. 2005).

Widespread suction dredging for gold occurred in the Foothill Yellow-legged Frog's California range until enactment of a moratorium on issuing permits in 2009 (Hayes et al. 2016). Suction dredging vacuums up the contents of the streambed, passes them through a sluice box to separate the gold, and then deposits the tailings on the other side of the box (Harvey and Lisle 1998). While most habitat disturbance is localized and minor, it can be especially detrimental if it degrades or destroys breeding and rearing habitat through direct disturbance or sedimentation (Ibid.). In addition, this activity can lead to direct mortality of early life stages through entrainment, and those eggs and tadpoles that do survive passing through the suction dredge may experience greater mortality due to subsequent unfavorable physiochemical conditions and possible increased predation risk (Ibid.). Suction dredging can also reduce the availability of invertebrate prey, although this impact is typically short-lived (Ibid.). Suction dredging alters stream morphology, and relict tailing ponds can serve as breeding habitat for bullfrogs in areas

that would not normally support them (Fuller et al. 2011). However, in some areas these mining holes have reportedly benefited Foothill Yellow-legged Frogs by creating cool persistent pools that adult females appeared to prefer at one Sierra Nevada site (Van Wagner 1996). Senate Bill 637 (2015) directs the Department to work with the State Water Resources Control Board (SWRCB) to develop a statewide water quality permit that would authorize the use of vacuum or suction dredge equipment in California under conditions set forth by the two agencies. SWRCB staff, in coordination with Department staff, are in the process of collecting additional information to inform the next steps that will be taken by the SWRCB (SWRCB 2019).

Instream aggregate (gravel) mining continues today and can have similar impacts to suction dredge mining by removing, processing, and relocating stream substrates (Olson and Davis 2009). This type of mining typically removes bars used as Foothill Yellow-legged Frog breeding habitat and reduces habitat heterogeneity by creating flat wide channels (Kupferberg 1996a). Typically when listed salmonids are present, mining must be conducted above the wetted edge, but this practice can create perennial off-channel bullfrog breeding ponds (M. van Hattem pers. comm. 2018).

Commented [RAP15]: May want to cite Yarnell 2005 here as well

Agriculture

Direct loss of Foothill Yellow-legged Frog habitat from wildland conversion to agriculture is rare because the typically rocky riparian areas they inhabit are usually not conducive to farming, but removal of riparian vegetation directly adjacent to streams for agriculture is more common and widespread. The U.S. Department of Agriculture classifies 3.9 million ha (9.6 million ac) in California as cropland, which amounts to less than 10% of the state's land area, and 70% of this occurs in the Central Valley between Redding and Bakersfield (Martin et al. 2018). In addition, several indirect impacts can adversely affect Foothill Yellow-legged Frogs at substantial distances from agricultural operations, such as effects from runoff (sediments and agrochemicals), drift and deposition of airborne pollutants, water diversions, and creation of novel habitats like impoundments that facilitate spread of detrimental non-native species. As sedimentation and introduced species impacts were previously discussed, this section instead focuses on the other possible adverse impacts.

Agrochemicals

Many species of amphibians, particularly ranids, have experienced declines throughout California, but the most dramatic declines have occurred in the Sierra Nevada east of the San Joaquin Valley where 60% of the total pesticide usage in the state was sprayed (Sparling et al. 2001). Agrochemicals applied to crops in the Central Valley can volatilize and travel in the atmosphere and deposit in higher elevations (LeNoir et al. 1999). Pesticide concentrations diminish as elevations increase in the lower foothills but change little from 533 to 1,920 m (1,750-6,300 ft), which coincides with the Foothill Yellow-legged Frog's elevational range (Ibid). Foothill Yellow-legged Frog absence at historically occupied sites in California significantly correlated with agricultural land use within 5 km (3 mi), and a positive relationship exists between Foothill Yellow-legged Frog declines and the amount of upwind agriculture, suggesting airborne agrochemicals may be a contributing factor (Figure 20; Davidson et al. 2002). Cholinesterase-inhibitors (most organophosphates and carbamates), which disrupt nerve impulse transmission, were

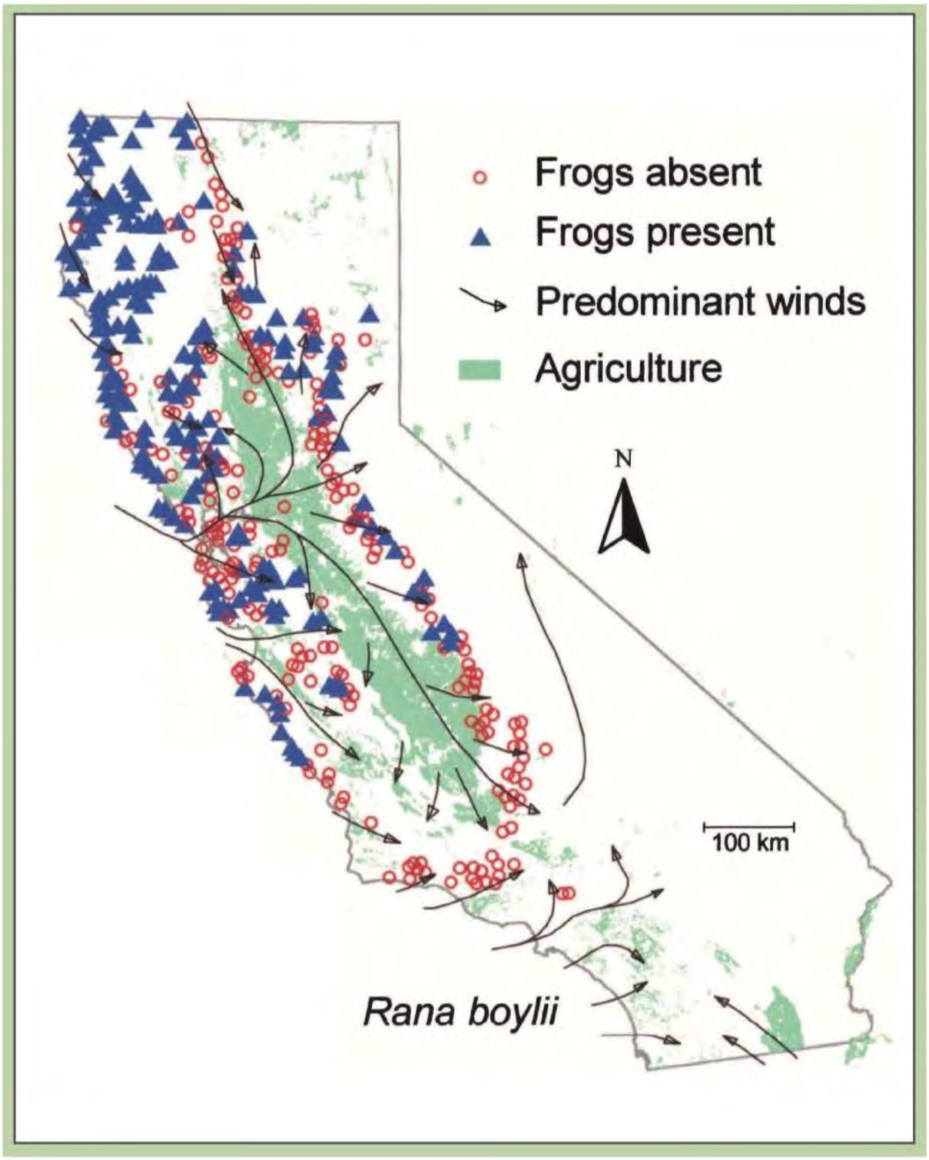

Figure 20. Relationship of Foothill Yellow-legged Frog occupancy to agriculture from Davidson et al. (2002)

more strongly associated with population declines than other pesticide types (Davidson 2004). Olson and Davis (2009) and Lind (2005) also reported a negative correlation between Foothill Yellow-legged Frog presence and proximity and quantity of nearby agriculture in Oregon and across the species' entire range, respectively.

Lethal and sublethal effects of agrochemicals on amphibians can take two general forms: direct toxicity and food-web effects. Sublethal doses of agrochemicals can interact with other environmental stressors to reduce fitness. Foothill Yellow-legged Frog tadpoles showed significantly greater vulnerability to the lethal and sublethal effects of carbaryl than Pacific Treefrogs (Kerby and Sih 2015). An inverse relationship exists between carbaryl concentration and Foothill Yellow-legged Frog activity, and their 72-h LC_{50} (concentration at which 50% die) measured one-fifth that of Pacific Treefrogs (Ibid.). Carbaryl slightly decreased Foothill Yellow-legged Frog development rate, but it significantly increased susceptibility to predation by signal crayfish despite nearly no mortality in the pesticide- and predator-only treatments (Ibid.). Sparling and Fellers (2009) also found Foothill Yellow-legged Frogs were significantly more sensitive to pesticides (chlorpyrifos and endosulfan in this study) than Pacific Treefrogs; their 96-hr LC_{50} was nearly five-times less than for treefrogs. Endosulfan was nearly 121 times more toxic to Foothill Yellow-legged Frogs than chlorpyrifos, and water samples from the Sierra Nevada have contained endosulfan concentrations within their lethal range and sometimes greater than the LC_{50} for the species (Ibid.). Sublethal effects included smaller body size, slower development rate, and increased time to metamorphosis (Ibid.). Sparling and Fellers (2007) determined the organophospates chlorpyrifos, malathion, and diazinon can harm Foothill Yellow-legged Frog populations, and their oxon derivatives (the resultant compounds once they begin breaking down in the body) were 10 to 100 times more toxic than their respective parental forms.

Extrapolating the results of studies on other ranids to Foothill Yellow-legged Frogs should be undertaken with caution; however, those studies can demonstrate additional potential adverse impacts of exposure to agrochemicals. Relyea (2005) discovered that Roundup®, a common herbicide, could cause rapid and widespread mortality in amphibian tadpoles via direct toxicity, and overspray at the manufacturer's recommended application concentrations would be highly lethal. Atrazine, another common herbicide, has been implicated in disrupting reproductive processes in male Northern Leopard Frogs (*Rana pipiens*) by slowing gonadal development, inducing hermaphroditism, and even oocyte (egg) growth (Hayes et al. 2003). However, recent research on sex reversal in wild populations of Green Frogs (*R. clamitans*) suggests it may be a relatively common natural process unrelated to environmental contaminants, requiring more research (Lambert et al. 2019). Malathion, a common organophosphate insecticide, that rapidly breaks down in the environment, applied at low concentrations caused a trophic cascade that resulted in reduced growth and survival of two species of ranid tadpoles (Relyea and Diecks 2008). Malathion caused a reduction in the amount of zooplankton, which resulted in a bloom of phytoplankton and an eventual decline in periphyton, an important food source for tadpoles (Ibid.). In contrast, Relyea (2005) found that some insecticides increased amphibian tadpole survival by reducing their invertebrate predators. Runoff from agricultural areas can contain fertilizers that input nutrients into streams and increase productivity, but they can also result in harmful algal blooms (Cordone and

Kelley 1961). In addition, exposure to pesticides can result in immunosuppression and reduce resistance to the parasites that cause limb malformations (Kiesecker 2002, Hayes et al. 2006).

Cannabis

An estimated 60-70% of the cannabis (*Cannabis indica* and *C. sativa*) used in the U.S. from legal and illegal sources is grown in California, and most comes from the Emerald Triangle, an area comprised of Humboldt, Mendocino, and Trinity counties (Ferguson 2019). Small-scale illegal cannabis farms have operated in this area since at least the 1960s but have expanded rapidly, particularly trespass grows on public land primarily by Mexican cartels, since the passage of the Compassionate Use Act in 1996 (Mallery 2010, Bauer et al. 2015). Like other forms of agriculture, it involves clearing the land, diverting water, and using herbicides and pesticides; however, in addition, many of these illicit operations use large quantities of fertilizers and highly toxic banned pesticides to kill anything that may threaten the crop, and they leave substantial amounts of non-biodegradable trash and human excrement (Mallery 2010, Thompson et al. 2014, Carah et al. 2015).

Measurements of environmental impacts of illegal cannabis grows have been hindered by the difficult and dangerous nature of accessing many of these sites; however, some analyses have been conducted, often using aerial images and geographic information systems (GIS). An evaluation of 54% of watersheds within and bordering Humboldt County revealed that while cannabis grow sites are generally small (< 0.5 ha [1.2 ac]) and comprised a tiny fraction of the study area (122 ha [301 ac]), they were widespread (present in 83% of watersheds) but unevenly distributed, indicating impacts are concentrated in certain watersheds (Butsic and Brenner 2016, Wang et al. 2017). The results also showed that 68% of grows were > 500 m (0.3 mi) from developed roads, 23% were located on slopes steeper than 30%, and 5% were within 100 m (328 ft) of critical habitat for threatened salmonids (Butsic and Brenner 2016). These characteristics suggest wildlands adjacent to cannabis cultivations are at heightened risk of habitat fragmentation, erosion, sedimentation, landslides, and impacts to waterways critical to imperiled species (Ibid.).

A separate analysis in the same general area estimated potentially significant impacts from water diversions alone. Cannabis requires a substantial amount of water during the growing season, so it is often cultivated near sources of perennial surface water for irrigation, commonly diverting from springs and headwater streams (Bauer et al. 2015). In the least impacted of the study watersheds, Bauer et al. (2015) calculated that diversions for cannabis cultivation could reduce the annual seven-day low flow by up to 23%, and in some of the heavily impacted watersheds, water demands for cannabis could exceed surface water availability. If not regulated carefully, cannabis cultivation could have substantial impacts on sensitive aquatic species like Foothill Yellow-legged Frogs in watersheds in which it is concentrated.

For context, cannabis cultivation was responsible for approximately 1.1% of forest cover lost within study watersheds in Humboldt County from 2000 to 2013, while timber harvest accounted for 53.3% (Wang et al. 2017). Cannabis requires approximately two times as much water per day as wine grapes, the other major irrigated crop in the region (Bauer et al. 2015). Impacts from cannabis cultivation have been observed by Foothill Yellow-legged Frog researchers working on the Trinity River and South Fork

Eel River in the form of lower flows in summer, increased egg stranding, and more algae earlier in the season in recent years (S. Kupferberg and M. Power pers. comm. 2015; D. Ashton pers. comm. 2017; S. Kupferberg, M. van Hattem, and W. Stokes pers. comm. 2017). In addition, Gonsolin (2010) reported illegal cannabis cultivations on four headwater streams that drained into his study area along Coyote Creek, three of which were occupied by Foothill Yellow-legged Frogs. The cultivators had removed vegetation adjacent to the creeks, terraced the slopes, diverted water, constructed small water impoundments, poured fertilizers directly into the impoundments, and applied herbicides and pesticides, as evidenced by leftover empty containers littering the site.

Commercial sale of cannabis for recreational use became legal in California on January 1, 2018, through passage of the Control, Regulate and Tax Adult Use of Marijuana Act (2016), and with it an environmental permitting system and habitat restoration fund was established. The number of applications for temporary licenses per watershed is depicted in Figure 21. Two of the expected outcomes of passage of this law were that the profit-margin on growing cannabis would fall to the point that it would discourage illegal trespass grows and move the bulk of the cultivation out of remote forested areas into existing agricultural areas like the Central Valley (CSOS 2016). However, until cannabis is legalized at the federal level, these results may not occur since banks are reluctant to work with growers due to federal prohibitions subjecting them to prosecution for money laundering (ABA 2019). Additional details on cannabis permitting at the state level can be found under the Existing Management section.

Vineyards

Vineyard operators historically built on-stream dams and removed almost all the riparian vegetation to make room for vines and for ease of irrigation (M. van Hattem pers. comm. 2019). They still divert a substantial amount of water for irrigation, and they build on- and off-stream impoundments that support bullfrogs (Ibid.). The acreage of land planted in wine grapes in California began rising dramatically in the 1970s and now accounts for 90% of wine produced in the U.S. (Geisseler and Horwath 2016, Alston et al. 2018). The number of wineries in California rose from approximately 330 to nearly 2,500 between 1975 and 2006; however, expansion slowed and has reversed slightly recently with 24,300 ha (60,000 ac), or 6.5% of total area planted, removed between 2015 and 2017 (Volpe et al. 2010, CDFA 2018). In 2015, 347,000 ha (857,000 ac) were planted in grapes with 70% located in the San Joaquin Valley; 66%, 21%, and 13% were planted in wine, raisin, and table grapes, respectively (Alston et al. 2018).

Expansion of wineries in the coastal counties converted natural areas such as oak woodlands and forests to vineyards (Merenlender 2000, Napa County 2010). The area of Sonoma County covered in grapes increased by 32% from 1990 to 1997, and 42% of these new vineyards were planted above 100 m (328 ft) with 25% on slopes greater than 18% (Merelender 2000). For context, only 18% of vineyards planted before 1990 occurred above 100 m (328 ft) and less than 6% on slopes greater than 18% (Ibid.). This conversion took place on approximately 773 ha (1,909 ac) of conifer and dense hardwood forest, 149 ha (367 ac) of shrubland, and 2,925 ha (7,229 ac) of oak grassland savanna (Ibid.).

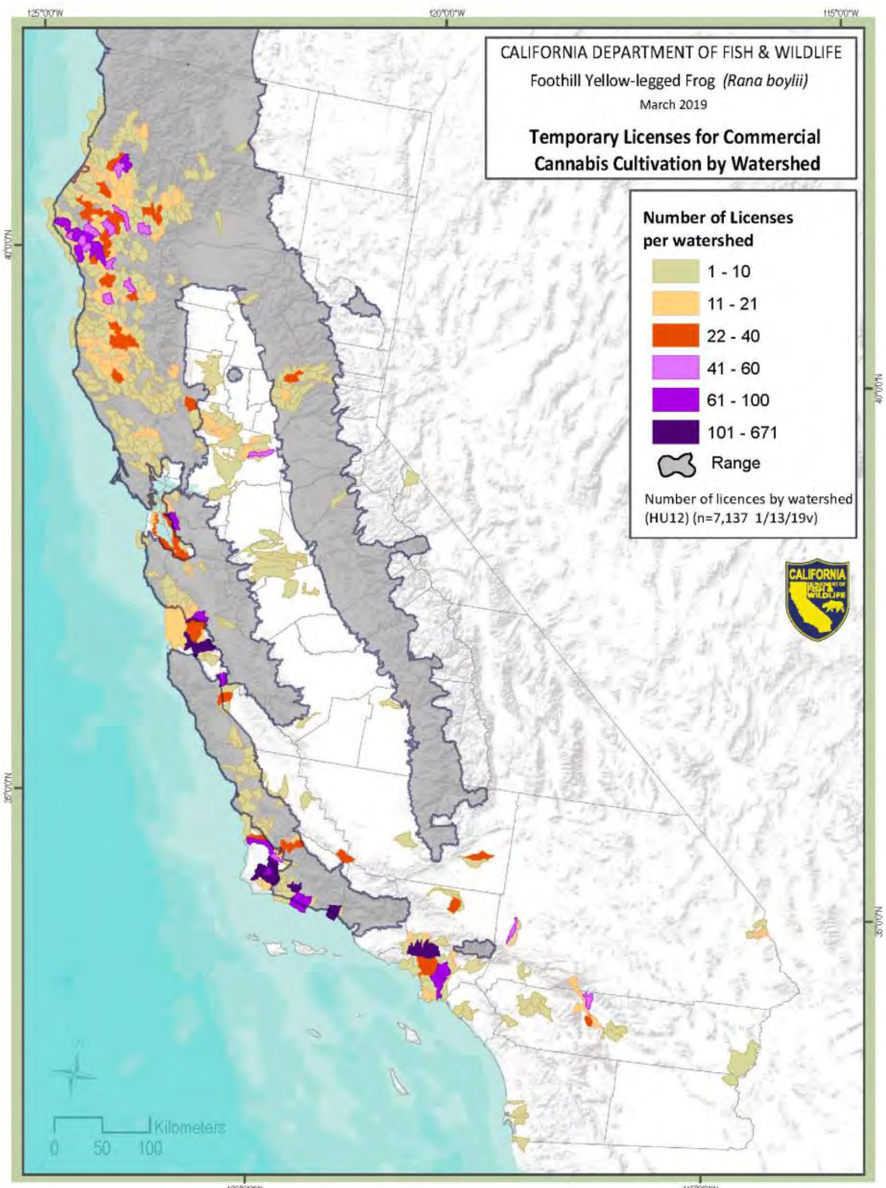

Figure 21. Cannabis cultivation temporary licenses by watershed in California (CDFA, NHD)

Recent expansion of oak woodland conversion to vineyards in Napa County was highest in its eastern hillsides (Napa County 2010). The County estimates that 1,085 and 1,240 ha (2,682-3,065 ac) of woodlands will be converted to vineyards between 2005 and 2030 (Ibid.). For context, 297 ha (733 ac) were converted from 1992 to 2003 (Ibid.). In addition, wine grapes were second only to almonds in terms of overall quantity of pesticides applied in California in 2016, but the quantity per unit area (2.9 kg/ha [2.6 lb/ac]) was 160% greater for the wine grapes (CDPR 2018). Vineyard expansion into hillsides has continued into sensitive headwater areas, and like cannabis cultivation, even small vineyards can have substantial impacts on Foothill Yellow-legged Frog habitat through sedimentation, water diversions, spread of harmful non-native species, and pesticide contamination (Merelender 2000, K. Weiss pers. comm. 2018).

Livestock Grazing

Livestock grazing can be an effective habitat management tool, including control of riparian vegetation encroachment, but overgrazing can significantly degrade the environment (Siekert et al. 1985). Cattle display a strong preference for riparian areas and have been implicated as a major source of habitat damage in the western U.S. where the adverse impacts of overgrazing on riparian vegetation are intensified by arid and semi-arid climates (Behnke and Raleigh 1978, Kauffman and Krueger 1984, Belsky et al. 1999). The severity of grazing impacts on riparian systems can be influenced by the number of animals, duration and time of year, substrate composition, and soil moisture (Benhke and Raleigh 1978, Kauffman et al. 1983, Marlow and Pogacnik 1985, Siekert et al. 1985). In addition to habitat damage, cattle can directly trample any life stage of Foothill Yellow-legged Frog.

Signs of overgrazing include impacts to the streambanks such as increased slough-offs and cave-ins that collapse undercuts used as refuge (Kauffman et al. 1983). Overgrazing reduces riparian cover, increases erosion and sedimentation, which as described above can result in silt degradation of breeding, rearing, and invertebrate food-producing areas (Cordone and Kelley 1961, Behnke and Raleigh 1978, Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). Loss of streamside and instream vegetative cover and changes to channel morphology can increase water temperatures and velocities (Behnke and Raleigh 1978). Water quality can be affected by increased turbidity and nutrient input from excrement, and seasonal water quantity can be impacted through changes to channel morphology (Belsky et al. 1999). In addition, increased nutrients and temperatures can promote blooms of harmful cyanobacteria like *Microcystis aeruginosa*, which releases a toxin when it expires that can cause liver damage to amphibians as well as other animals including humans (Bobzien and DiDonato 2007, Zhang et al. 2013).

While some recent studies indicate livestock grazing continues to damage stream and riparian ecosystems, its impact on Foothill Yellow-legged Frogs in California is unknown (Belsky et al. 1999, Hayes et al. 2016). In Oregon, the species' presence was correlated with significantly less grazing than where they were absent according to Borisenko and Hayes's 1999 report (as cited in Olson and Davis 2009). However, Fellers (2005) reported that apparently some Coast Range foothill populations occupying streams draining east into the San Joaquin Valley were doing well at the time of publication despite being heavily grazed.

Urbanization and Road Effects

Habitat conversion and fragmentation combined with modified environmental disturbance regimes can substantially jeopardize biological diversity (Tracey et al. 2018). This threat is most severe in areas like California with Mediterranean-type ecosystems that are biodiversity hot spots, fire-prone, and heavily altered by human land use (Ibid.). From 1990 to 2010, the fastest-growing land use type in the conterminous U.S. was new housing construction, which rapidly expanded the wildland-urban interface (WUI) where houses and natural vegetation meet or intermix on the landscape (Radeloff et al. 2018).

Of several variables tested, proportion of urban land use within a 5 km (3.1 mi) radius of a site was associated with Foothill Yellow-legged Frog declines (Davidson et al. 2002). Lind (2005) also found significantly less urban development nearby and upwind of sites occupied by Foothill Yellow-legged Frogs, suggesting pollutant drift may be a contributing factor. Changes in wildfires may also contribute to the species' declines; 95% of California's fires are human-caused, and wildfire issues are greatest at the WUI (Syphard et al. 2009, Radeloff et al. 2018). Population density, intermix WUI (where wildland and development intermingle as opposed to an abrupt interface), and distance to WUI explained the most variability in fire frequency (Syphard et al. 2007). In addition to wildfires, habitat loss, and fragmentation, urbanization can impact adjacent ecosystems through non-native species introduction, native predator subsidization, and disease transmission (Bar-Massada et al. 2014).

Projections show growth in California's population to 51 million people by 2060 from approximately 40 million currently (PPIC 2019). This will increase urbanization, the WUI, and habitat fragmentation. The Department of Finance projects the Inland Empire, the San Joaquin Valley, and the Sacramento metropolitan area will be the fastest-growing regions of the state over the next several decades (Ibid.). This puts the greatest pressure in areas outside of the Foothill Yellow-legged Frog's range; however, because the environmental stressors associated with urbanization can span far beyond its physical footprint, they may still adversely affect the species.

Highways are frequently recognized as barriers to dispersal that fragment habitats and populations; however, single-lane roads can pose significant risks to wildlife as well (Cook et al. 2012, Brehme et al. 2018). Foothill Yellow-legged Frogs are at risk of being killed by vehicles when roads are located near their habitat (Cook et al. 2012, Brehme et al. 2018). Fifty-six juvenile Foothill Yellow-legged Frogs were found on a road adjacent to Sulphur Creek (Mendocino County), seven of which had been struck and killed (Cook et al. 2012). When fords (naturally shallow areas) are used as vehicle crossings, they can create sedimentation and poor water quality, and in some cases, the fords are gravel or cobble bars used by Foothill Yellow-legged Frogs for breeding that could result in direct mortality (K. Blanchard pers. comm. 2018, R. Bourque pers. comm. 2018). Construction of culverts under roads to keep vehicles out of the streambed can result in varying impacts. In some cases, they can impede dispersal and create deep scoured pools that support predatory fish and frogs, but when properly constructed, they can facilitate frog movement up and down the channel with reduced road mortality (Van Wagner 1996, GANDA 2008). In areas where non-native species are not a threat, but premature drying is, pools created by culverts can provide habitat in otherwise unsuitable areas (M. Grefsrud pers. comm. 2019). An evaluation of the impact of roads on 166 native California amphibians and reptiles through direct

mortality and barriers to movement concluded that Foothill Yellow-legged Frogs, at individual and population levels, were at moderate risk of road impacts in aquatic habitat but very low risk of impacts in terrestrial habitat (Brehme et al. 2018). For context, all chelonids (turtles and tortoises), 72% of snakes, 50% of anurans, 18% of lizards, and 17% of salamander species in California were ranked as having a high or very high risk of negative road impacts in the same evaluation (Ibid.).

Commented [RAP16]: Direct mortality of frogs is a matter of morality‼ ☺

Poorly constructed roadways near rivers and streams can result in substantial erosion and sedimentation, leading to reduced amphibian densities (Welsh and Ollivier 1998). Proximity of roads to Foothill Yellow-legged Frog habitat contributes to petrochemical runoff and poses the threat of spills (Ashton et al. 1997). A diesel spill on Hayfork Creek (Trinity County) resulted in mass mortality of Foothill Yellow-legged Frog tadpoles and partial metamorphs (Bury 1972). Roads have also been implicated in the spread of disease and may have aided in the spread of Bd in California (Adams et al. 2017b).

Frogs use auditory and visual cues to defend territories and attract mates, and some studies reveal that realistic levels of traffic noise can impede transmission and reception of these signals (Bee and Swanson 2007). Some male frogs have been observed changing the frequency of their calls to increase the distance they can be heard over traffic noise, but if females have evolved to recognize lower pitched calls as signs of superior fitness, this potential trade-off between audibility and attractiveness could have implications for reproductive success (Parris et al. 2009). In a separate study, traffic noise caused a change in male vocal sac coloration and an increase in stress hormones, which changed sexual selection processes and suppressed immunity (Troïanowski et al. 2017). Because Foothill Yellow-legged Frogs mostly call underwater and are not known to use color displays, communication cues may not be adversely affected by traffic noise, but their stress response is unknown.

Timber Harvest

Because Foothill Yellow-legged Frogs tend to remain close to the water channel (i.e., within the riparian corridor) and current timber harvest practices minimize disturbance in riparian areas for the most part, adverse effects from timber harvest are expected to be relatively low (Hayes et al. 2016, CDFW 2018b). However, some activities have a potential to negatively impact Foothill Yellow-legged Frogs or their habitat, including direct mortality and increased sedimentation during construction and decommissioning of watercourse crossings and infiltration galleries, tree felling, log hauling, and entrainment by water intakes or desiccation of eggs and tadpoles through stranding from dewatering during drafting operations (CDFW 2018b,c). In addition to impacts previously described under the Sedimentation and Road Effects section, when silt runoff into streams is accompanied by organic materials, such as logging debris, impaired water quality can result, including reduced dissolved oxygen, which is important in embryonic and tadpole development (Cordone and Kelley 1961).

Because Foothill Yellow-legged Frogs are heliotherms (i.e, they bask in the sun to raise their body temperature) and sensitive to thermal extremes, some moderate timber harvest may benefit the species (Zweifel 1955, Fellers 2005). Ashton (2002) reported 85% of his Foothill Yellow-legged Frog observations occurred in second-growth forests (37-60 years post-harvest) as opposed to late-seral forests and postulated that the availability of some open canopy areas played a major part in this

disparity. Foothill Yellow-legged Frogs are typically absent in areas with closed canopy (Welsh and Hodgson 2011). Reduced canopy also raises stream temperatures, which could improve tadpole development and promote algal and invertebrate productivity in otherwise cold streams (Olson and Davis 2009; Catenazzi and Kupferberg 2013,2017).

Recreation

Several types of recreation can adversely impact Foothill Yellow-legged Frogs, and some are more severe and widespread than others. One of the main potential factors identified by herpetologists as contributing to disappearance of Foothill Yellow-legged Frogs in southern California was increased and intensified recreation in streams (Adams et al. 2017b). The greater number of people traveling into the backcountry may have facilitated the spread Bd to these areas, and while no evidence shows stress from disturbance or other environmental pressures increases susceptibility to Bd, the stress hormone corticosterone has been implicated in immunosuppression (Hayes et al. 2003, Adams et al. 2017b).

The amount of Foothill Yellow-legged Frog habitat disturbed by off-highway motor vehicles (OHV) throughout its range in California is unknown, but its impacts can be significant, particularly in areas with small isolated populations (Kupferberg et al. 2009c, Kupferberg and Furey 2015). An example is the Carnegie State Vehicular Recreation Area (CVSRA), located in the hills southwest of Tracy in the Corral Hollow Creek watershed (Alameda and San Joaquin counties). The above-described road effects apply: sedimentation, crushing along trail crossings, and potential noise effects (Ibid.). In addition, dust suppression activities employed by CSVRA use magnesium chloride ($MgCl_2$), which has the potential to harm developing embryos and tadpoles (Karraker et al. 2008, Hopkins et al. 2013, OHMVRC 2017). Based on museum records, Foothill Yellow-legged Frogs were apparently abundant in Corral Hollow Creek, but they are extremely rare now and are already extirpated or at risk of extirpation (Kupferberg et al. 2009c, Kupferberg and Furey 2015).

Motorized and non-motorized recreational boating can also impact Foothill Yellow-legged Frogs. The impacts of jet boat traffic were investigated in Oregon; in areas with frequent use and high wakes breaking on shore, Foothill Yellow-legged Frogs were absent (Borisenko and Hayes 1999 as cited in Olson and Davis 2009). This wake action had the potential to dislodge egg masses, strand tadpoles, disrupt adult basking behavior, and erode shorelines (Ibid.). Jet boat tours and races on the Klamath River (Del Norte and Humboldt counties) may have an impact on Foothill Yellow-legged Frog use of the mainstem (M. van Hattem pers. comm. 2019). In addition, using gravel bars as launch and haul out sites for boat trailers, kayaks, or river rafts can result in direct loss of egg masses and tadpoles or damage to breeding and rearing habitat and can disrupt post-metamorphic frog behavior (Ibid.). As described above, pulse flows released for whitewater boating in the late spring and summer can result in scouring and stranding of egg masses and tadpoles (Borisenko and Hayes 1999 as cited in Olson and Davis 2009, Kupferberg et al. 2009b). In addition, the velocities that resulted in stunted growth and increased vulnerability to predation in Foothill Yellow-legged Frog tadpoles were less than the increased velocities experienced in nearshore habitats during intentional release of recreational flows for whitewater boating, as well as hydropeaking for power generation (Kupferberg et al. 2011b).

Commented [RAP17]: May want to rephrase this sentence, I understand it but it may be less clear for folks that aren't familiar.

Hiking, horse-riding, camping, fishing, and swimming, particularly in sensitive breeding and rearing habitat can also adversely impact Foothill Yellow-legged Frog populations (Borisenko and Hayes 1999 in Olson and Davis 2009). Because Foothill Yellow-legged Frog breeding activity was being disturbed and egg masses were being trampled by people and dogs using Carson Falls (Marin County), the land manager established an educational program, including employing docents on weekends that remind people to stay on trails and tread lightly to try to reduce the loss of Foothill Yellow-legged Frog reproductive effort (Prado 2005). In addition, within his study site, Van Wagner (1996) reported that a property owner moved rocks that were being used as breeding habitat to create a swimming hole. The extent to which this is more than a small, local problem is unknown, but as the population of California increases, recreational pressures in Foothill Yellow-legged Frog habitat are likely to increase commensurately.

Drought

Drought is a common phenomenon in California and is characterized by lower than average precipitation. Lower precipitation in general results in less surface water, and water availability is critical for obligate stream-breeding species. Even in the absence of drought, a positive relationship exists between precipitation and latitude within the Foothill Yellow-legged Frog's range in California, and mean annual precipitation has a strong influence on Foothill Yellow-legged Frog presence at historically occupied sites (Davidson et al. 2002, Lind 2005). Figure 22 depicts the recent historical annual average precipitation across the state as well as during the most recent drought and how they differ. Southern California is normally drier than northern California, but the severity of the drought was even greater in the south.

Reduced precipitation can result in deleterious effects to Foothill Yellow-legged Frogs beyond the obvious premature drying of aquatic habitat. When stream flows recede during the summer and fall, sometimes the isolated pools that stay perennially wet are the only remaining habitat. This phenomenon concentrates aquatic species, resulting in several potentially significant adverse impacts. Stream flow volume was negatively correlated with Bd load during a recent chytridiomycosis outbreak in the Alameda Creek watershed (Adams et al. 2017a). The absence of high peak flows in winter coupled with wet years allowed bullfrogs to expand their distribution upstream, and the drought-induced low flows in the fall concentrated them with Foothill Yellow-legged Frogs in the remaining drying pools (Ibid.). This mass mortality event appeared to have been the result of a combination of drought, disease, and dam effects (Ibid.). This die-off occurred in a regulated reach that experiences heavy recreational use and presence of crayfish and bass (Ibid.). Despite these threats, the density of breeding females in this reach was greater in 2014 and 2015 than the in the unregulated reach upstream because the latter dried completely before tadpoles could metamorphose during the preceding drought years (S. Kupferberg, R. Peek, and A. Catenazzi pers. comm. 2015).

In addition to increasing the spread of pathogens, drought-induced stream drying can increase predation and competition by introduced fish and frogs in the pools they are forced to share (Moyle 1973, Hayes and Jennings 1988, Drost and Fellers 1996). This concentration in isolated pools can also result in increased native predation as well as facilitate spread of Bd. An aggregation of six adult Foothill

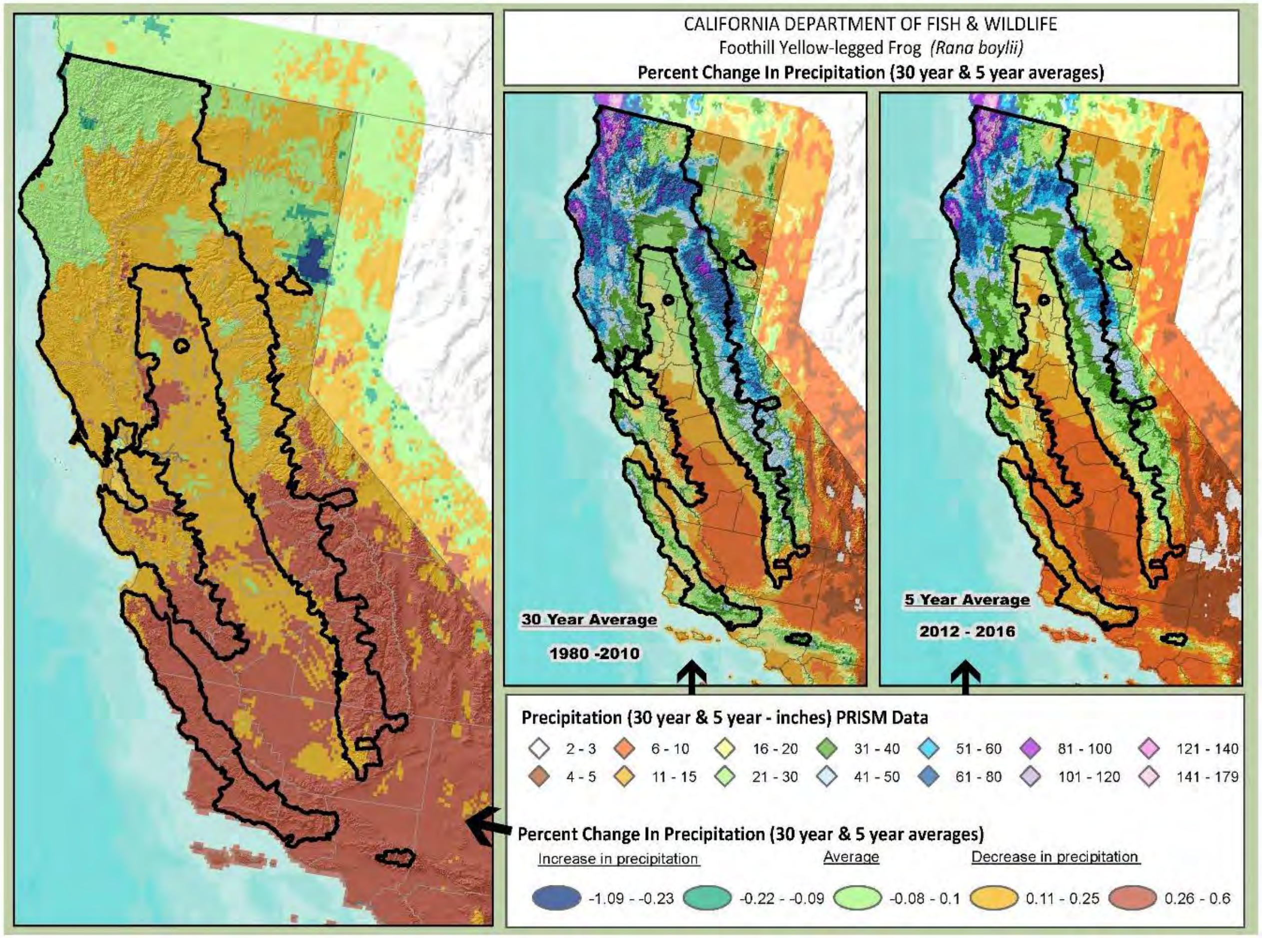

Figure 22. Change in precipitation from 30-year average and during the recent drought (PRISM)

Yellow-legged Frogs was observed perched on a rock above an isolated pool where a gartersnake was foraging on tadpoles during the summer; this close contact may reduce evaporative water loss when they are forced out of the water during high temperatures, but it can also increase disease transmission risk (Leidy et al. 2009.). Gonsolin (2010) also documented a late summer aggregation of juvenile Foothill Yellow-legged Frogs out of water during extremely high temperatures. In addition, drought-induced low flow, high water temperatures, and high densities of tadpoles were associated with outbreaks of malformation-inducing parasitic copepods (Kupferberg et al. 2009a).

Rapidly receding spring flows can result in stranding egg masses and tadpoles. However, this risk is likely less significant when it is drought-induced on an unregulated stream vs. a result of dam operations since Foothill Yellow-legged Frogs have evolved to initiate breeding earlier and shorten the breeding period in drought years (Kupferberg 1996a). If pools stay wet long enough to support metamorphosis, complete drying at the end of the season may benefit Foothill Yellow-legged Frogs if it eliminates introduced species like warm water fish and bullfrogs. Moyle (1973) noted that the only intermittent streams occupied by Foothill Yellow-legged Frogs in the Sierra Nevada foothills had no bullfrogs. At a long-term study site in upper Coyote Creek in 2015, Foothill Yellow-legged Frogs had persisted in reaches that had at least some summer water through the three preceding years of the most severe drought in over a millennium, albeit at much lower abundance than a decade before (Gonsolin 2010, Griffin and Anchokaitis 2014, J. Smith pers. comm. 2015). The population's abundance appeared to have never recovered from the 2007-2009 drought before the 2012-2016 drought began (J. Smith pers. comm. 2015). In 2016, after a relatively wet winter, Foothill Yellow-legged Frogs bred en-masse, and only a single adult bullfrog was detected, an unusually low number for that area (CDWR 2016, J. Smith pers. comm. 2016). It appeared the population may rebound; however, in 2018, it experienced lethal chytridiomycosis outbreak, and like the Alameda Creek die-off probably resulted from crowding during drought, presence of bullfrogs as Bd-reservoirs and predators and competitors, and the stress associated with the combination of the two (Kupferberg and Catenazzi 2019).

Drought effects can also exacerbate other environmental stressors. During the most recent severe drought, tree mortality increased dramatically from 2014 to 2017 and reached approximately 129 million dead trees (OEHHA 2018). Multiple years of high temperatures and low precipitation left them weakened and more susceptible to pathogens and parasites (Ibid.). Vast areas of dead and dying trees are more prone to severe wildfires, and they lose their carbon sequestration function while also emitting methane, which is an extremely damaging greenhouse gas (CNRA 2016). Post-wildfire, storms can result in erosion of fine sediments from denuded hillsides into the stream channel (Florsheim et al. 2017). If the storms are short duration and low precipitation, as happens during droughts, their magnitude may not be sufficient to transport the material downstream, resulting in a longer temporal loss or degradation of stream habitat (Ibid.). Reduced rainfall may also infiltrate the debris leading to subsurface flows rather than the surface water Foothill Yellow-legged Frogs require (Ibid.). Extended droughts increase risk of the stream being uninhabitable or inadequate for breeding for multiple years, which would result in population-level impacts and possible extirpation (Ibid.).

Wildland Fire and Fire Management

Fire is an important element for shaping and maintaining the species composition and integrity of many California ecosystems (Syphard et al. 2007, SBFFP 2018). Prior to European settlement, an estimated 1.8 to 4.9 million ha (4.5-12 million ac) burned annually (4-11% of total area of the state), ignited both deliberately by Native Americans and through lightning strikes (Keeley 2005, SBFFP 2018). The impacts of wildland fires on Foothill Yellow-legged Frogs are poorly understood and likely vary significantly across the species' range with differences in climate, vegetation, soils, stream-order, slope, frequency, and severity (Olson and Davis 2009). Mortality from direct scorching is unlikely because Foothill Yellow-legged Frogs are highly aquatic, and most wildfires occur during the dry period of the year when the frogs are most likely to be in or near the water (Pilliod et al. 2003, Bourque 2008). Field observations support this presumption; sightings of post-metamorphic Foothill Yellow-legged Frogs immediately after fires in the northern Sierra Nevada and North Coast indicate they are not very vulnerable to the direct effects of fire (S. Kupferberg and R. Peek pers. comm. 2018). Similarly, Foothill Yellow-legged Frogs were observed two months, and again one year, after a low- to moderate-intensity fire burned an area in the southern Sierra Nevada in 2002, and the populations were extant and breeding as recently as 2017 (Lind et al. 2003b, CNDDB 2019). While water may provide a refuge during the fire, it is also possible for temperatures during a fire, or afterward due to increased solar exposure, to near or exceed a threshold resulting lethal or sublethal harm; this would likely impact embryos and tadpoles with limited dispersal abilities (Pilliod et al. 2003).

Intense fires remove overstory canopy, which provides insulation from extreme heat and cold, and woody debris that increases habitat heterogeneity (Pilliod et al. 2003, Olson and Davis 2009). If this happens frequently enough, it can permanently change the landscape. For example, frequent high-severity burning of crown fire-adapted ecosystems can prevent forest regeneration since seeds require sufficient time between fires to mature, and repeated fires can deplete the seed bank (Stephens et al. 2014). Smoke and ash change water chemistry through increased nutrient and heavy metal inputs that can reach concentrations harmful to aquatic species during the fire and for days, weeks, or years after (Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Erosion rates on granitic soils, which make up a large portion of the Foothill Yellow-legged Frog's range, can be over 60 times greater in burned vs. unburned areas and can increase sedimentation for over 10 years (Megahan et al. 1995, Hayes et al. 2016). Post-fire nutrient inputs into streams could benefit Foothill Yellow-legged Frogs through increased productivity and more rapid growth and development (Pilliod et al. 2003). While the loss of leaf litter that accompanies fire alters the food web, insects are expected to recolonize rapidly, and the lack of cover could increase their vulnerability to predation by Foothill Yellow-legged Frogs (Ibid.).

Low-intensity fires likely have no adverse effect on Foothill Yellow-legged Frogs (Olson and Davis 2009). If they occur in areas with dense canopy, wildfires can improve habitat quality for Foothill Yellow-legged Frogs by reducing riparian cover, providing areas to bask, and increasing habitat heterogeneity, which is likely to outweigh any adverse effects from some fire-induced mortality (Russell et al. 1999, Olson and Davis 2009). In a preliminary analysis of threats to Foothill Yellow-legged Frogs in Oregon, proximity to stand-replacing fires was not associated with absence (Olson and Davis 2009).

Euro-American colonization of California significantly altered the pattern of periodic fires with which California's native flora and fauna evolved through fire exclusion, land use practices, and development (OEHHA 2018). Fire suppression can lead to canopy closure, which reduces habitat quality by limiting thermoregulatory opportunities (Olson and Davis 2009). In addition, fire suppression and its subsequent increase in fuel loads combined with expanding urbanization and rising temperatures have resulted in a greater likelihood of catastrophic stand-replacing fires that can significantly alter riparian systems for decades (Pilliod et al. 2003). Firebreaks, in which vegetation is cleared from a swath of land, can result in similar impacts to roads and road construction (Ibid.). Fire suppression can also include bulldozing within streams to create temporary reservoirs for pumping water, which can cause more damage than the fire itself to Foothill Yellow-legged Frogs in some cases (S. Kupferberg and R. Peek pers. comm. 2018). In addition, fire suppression practices can involve applying hundreds of tons of ammonia-based fire retardants and surfactant-based fire suppressant foams from air tankers and fire engines (Pilliod et al. 2003). Some of these chemicals are highly toxic to some anurans (Little and Calfee 2000).

Fire suppression has evolved into fire management with a greater understanding of its importance in ecosystem health (Keeley and Syphard 2016). Several strategies are employed including prescribed burns, mechanical fuels reduction, and allowing some fires to burn instead of necessarily extinguishing them (Pilliod et al. 2003). Like wildfires themselves, fire management strategies have the potential to benefit or harm Foothill Yellow-legged Frogs. Prescribed fires and mechanical fuels removal lessen the likelihood of catastrophic wildfires, but they can also result in loss of riparian vegetation, excessive sedimentation, and increased water temperatures (Ibid.). Salvage logging after a fire may result in similar impacts to timber harvest but with higher rates of erosion and sedimentation (Ibid.). A balanced approach to wildland fires is likely to have the greatest beneficial impact on species and ecosystem health (Stephens et al. 2012).

Floods and Landslides

As previously described, Foothill Yellow-legged Frog persistence is highly sensitive to early life stage mortality (Kupferberg et al. 2009c). While aseasonal dam releases are a major source of egg mass and tadpole scouring, storm-driven floods are also capable of it (Ashton et al. 1997). Van Wagner (1996) concluded that the high discharge associated with heavy rainfall could account for a significant source of mortality in post-metamorphic Foothill Yellow-legged Frogs as well as eggs and tadpoles; he observed two adult females and several juveniles swept downstream with fatal injuries post-flooding. Severe flooding, specifically two 500-year flood events in early 1969 in Evey Canyon (Los Angeles County), resulted in massive riparian habitat destruction (Sweet 1983). Prior to the floods, Foothill Yellow-legged Frogs were widespread and common, but only four subsequent sightings were documented between 1970 and 1974 and none since (Sweet 1983, Adams 2017b). Sweet (1983) speculates that because Foothill Yellow-legged Frogs overwinter in the streambed in that area, the floods may have reduced the population's abundance below an extinction threshold. Four other herpetologists interviewed about Foothill Yellow-legged Frog extirpations in southern California listed severe flooding as a likely cause (Adams et al. 2017b).

As mentioned above, landslides are a frequent consequence of post-fire rainstorms and can result in lasting impacts to stream morphology, water quality, and Foothill Yellow-legged Frog populations. On the other hand, Olson and Davis (2009) suggest that periodic landslides can have beneficial effects by transporting woody debris into the stream that can increase habitat complexity and by replacing sediments that are typically washed downstream over time. Whether a landslide is detrimental or beneficial is likely heavily influenced by amount of precipitation and the underlying system. As previously described, too little precipitation could lead to prolonged loss of habitat through failure to transport material downstream, and too much precipitation can result in large-scale habitat destruction and direct mortality.

Commented [RAP18]: I think this is an important point…the frequency at which landslides occur in a region or reach is really crucial. If we have a lot of fire in the future, and the odds of having landslides in burned areas goes up, repeated slides in unstable areas could definitely have a significantly negative impact as compared to a large slide that happens infrequently.

Climate Change

Global climate change threatens biodiversity and may lead to increased frequency and severity of drought, wildfires, flooding, and landslides (Williams et al. 2008, Keely and Syphard 2016). Data show a consistent trend of warming temperatures in California and globally; 2014 was the warmest year on record, followed by 2015, 2017, and 2016 (OEHHA 2018). Climate model projections for annual temperature in California in the 21st century range from 1.5 to 4.5°C (2.7-8.1°F) greater than the 1961-1990 mean (Cayan et al. 2008). Precipitation change projections are less consistent than those for temperature, but recent studies indicate increasing variability in precipitation, and increasingly dry conditions in California resulting from increased evaporative water loss primarily due to rising temperatures (Cayan et al. 2005, Williams et al. 2015, OEHHA 2018). Precipitation variability and proportion of dry years were negatively associated with Foothill Yellow-legged Frog presence in a range-wide analysis (Lind 2005). In addition, low precipitation intensified the adverse effects of dams on the species (Ibid.).

California recently experienced the longest drought since the U.S. Drought Monitor began reporting in 2000 (NIDIS 2019). Until March 5, 2019, California experienced drought effects in at least a portion of the state for 376 consecutive weeks; the most intense period occurred during the week of October 28, 2014 when D4 (the most severe drought category) affected 58.4% of California's land area (Figure 23; NIDIS 2019). A recent modeling effort using data on historical droughts, including the Medieval megadrought between 1100 and 1300 CE, indicates the mean state of drought from 2050 to 2099 in California will likely exceed the Medieval-era drought, under both high and moderate greenhouse gas emissions models (Cook et al. 2015). The probability of a multidecadal (35 yr) drought occurring during the late 21st century is greater than 80% in all models used by Cook et al. (2015). If correct, this would represent a climatic shift that not only falls outside of contemporary variability in aridity but would also be unprecedented in the past millennium (Ibid.).

As a result of increasing temperatures, a decreasing proportion of precipitation falls as snow, resulting in more runoff from rainfall during the winter and a shallower snowpack that melts more rapidly (Stewart 2009). A combination of reduced seasonal snow accumulation and earlier streamflow timing significantly reduces surface water storage capacity and increases the risk for winter and spring floods, which may require additional and taller dams and result in alterations to hydroelectric power generation flow regimes (Cayan et al. 2005, Knowles et al. 2006, Stewart 2009). The reduction in snowmelt volume

is expected to impact the northern Sierra (Feather, Yuba, and American River watersheds) to a greater extent than the southern portion (Young et al. 2009). The earlier shift in peak snowmelt timing is predicted to exceed four to six weeks across the entire Sierra Nevada depending on the amount of warming that occurs this century (Ibid.). In addition, the snow water equivalent is predicted to significantly decline by 2070-2099 over the 1961-1990 average in the Trinity, Sacramento, and San Joaquin drainages from -32% to -79%, and effectively no snow is expected to fall below 1000 m (3280 ft) in the high emissions/sensitive model (Cayan et al. 2008).

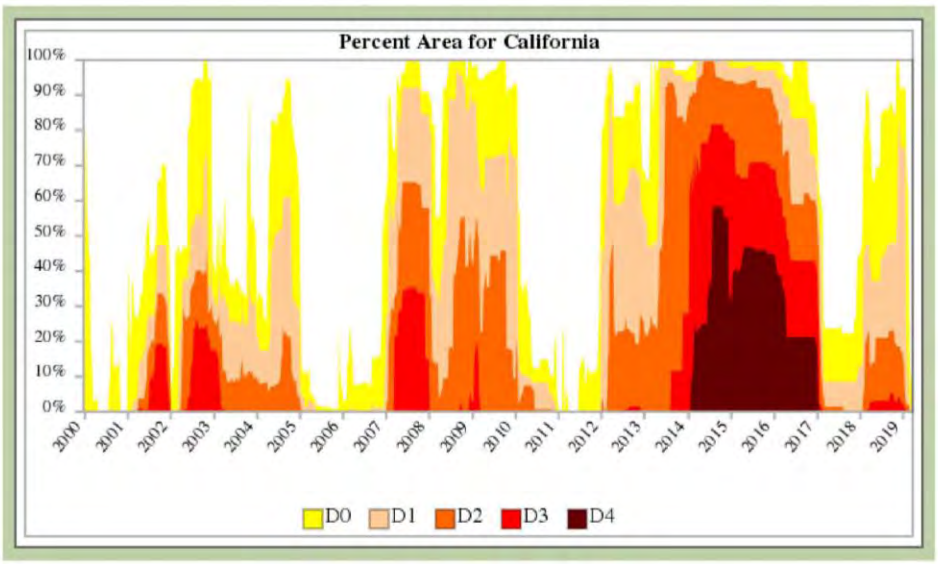

Figure 23. Palmer Hydrological Drought Indices 2000-present (NIDIS)

The earlier shift of snowmelt and lower water content will result in lower summer flows, which will intensify the competition for water among residential, agricultural, industrial, and environmental needs (Field et al. 1999, Cook et al. 2015). In unregulated systems, as long as water is present through late summer, an earlier hydrograph recession that triggers Foothill Yellow-legged Frog breeding could result in a longer time to grow larger prior to metamorphosis, which improves probability of survival (Yarnell et al. 2010, Kupferberg 2011b). However, if duration from peak to base flow shortens, it can result in increased sedimentation and reduced habitat complexity in addition to stranding (Yarnell et al. 2010).

Fire frequency relates to temperature, fuel loads, and fuel moisture (CCSP 2008). Therefore, increasing periods of drought combined with extreme heat and low humidity that stress or kill trees and other vegetation create ideal conditions for wildland fires (Ibid). Not surprisingly, the area burned by wildland fires over the western U.S. increased since 1950 but rose rapidly in the mid-1980s (Westerling et al. 2006, OEHHA 2018). As temperatures warmed and snow melted earlier, large-wildfire frequency and duration increased, and wildfire seasons lengthened (Westerling et al. 2006, OEHHA 2018).

In California, latitude inversely correlates with temperature and annual area burned, but the climate-fire relationship is substantially different across the state, and future wildfire regimes are difficult to predict (Keeley and Syphard 2016). For example, the relationship between spring and summer temperature and area burned in the Sierra Nevada is highly significant but not in southern California (Ibid.). Climate has a greater influence on fire regimes in mesic than arid environments, and the most influential climatological factor (e.g., precipitation, temperature, season, or their interactions) shifts over time (Ibid.). Nine of the 10 largest fires in California since 1932 have occurred in the past 20 years, 4 within the past 2 years (Figure 24; CAL FIRE 2019). However, it is possible this trend will not continue; climate- and wildfire-induced changes in vegetation could reduce wildfire severity in the future (Parks et al. 2016).

Wildfires themselves can accelerate the effects of climate change. Wildfires emit short-lived climate pollutants like black carbon (soot) and methane that are tens to thousands of times greater than carbon dioxide (the main focus of greenhouse gas reduction) in terms of warming effect and are responsible for 40% or more of global warming to date (CNRA 2016). Healthy forests can sequester large amounts of carbon from the atmosphere, but recently carbon emissions from wildfires have exceeded their uptake by vegetation in California (Ackerly et al. 2018).

With increased variability and changes in precipitation type, magnitude, and timing comes more variable and extreme stream flows (Mallakpour et al. 2018). Models for stream flow in California project higher high flows, lower low flows, wetter rainy seasons, and drier dry seasons (Ibid.). The projected water cycle extremes are related to strengthening El Niño and La Niña events, and both severe flooding and intense drought are predicted to increase by at least 50% by the end of the century (Yoon et al. 2015). These changes increase the likelihood of Foothill Yellow-legged Frog egg mass and tadpole scouring and stranding, even in unregulated rivers.

A species' vulnerability to climate change is a function of its sensitivity to climate change effects, its exposure to them, and its ability to adapt its behaviors to survive with them (Dawson et al. 2011). Myriad examples exist of species shifting their geographical distribution toward the poles and to higher elevations and changing their growth and reproduction with increases in temperature over time (Parmesan and Yohe 2003). However, in many places, fragmentation of suitable habitat by anthropogenic barriers (e.g., urbanization, agriculture, and reservoirs) limits a species' ability to shift its range (Pounds et al. 2007). The proportion of sites historically occupied by Foothill Yellow-legged Frogs that are now extirpated increases significantly on a north-to-south latitudinal gradient and at drier sites within California, suggesting climate change may contribute to the spatial pattern of the species' declines (Davidson et al. 2002).

An analysis of the climate change sensitivity of 195 species of plants and animals in northwestern North America revealed that, as a group, amphibians and reptiles were estimated to be the most sensitive (Case et al. 2015). Nevertheless, examples exist of amphibians adjusting their breeding behaviors (e.g., calling and migrating to breeding sites) to occur earlier in the year as global warming increases (Beebee 1995, Gibbs and Breisch 2001). Because of the rapid change in temperature, Beebee (1995) posits these are examples of behavioral and physiological plasticity rather than natural selection. However, for

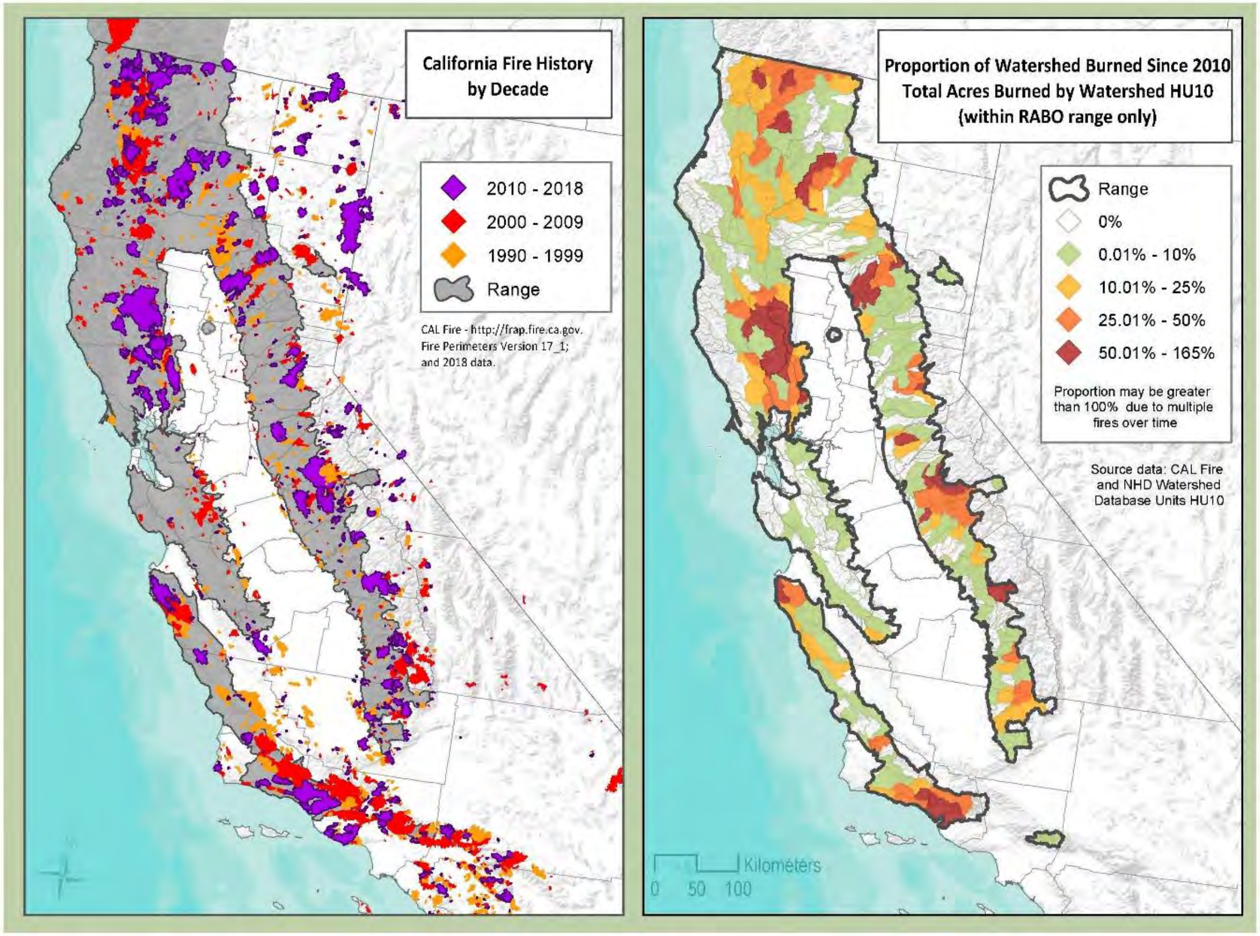

Figure 24. Fire history (1990-2018) and proportion of watershed burned (2010-2018) in California (CAL FIRE, NHD)

species with short generation times or in areas less affected by climate change, populations may be able to undergo evolutionary adaptation to the changing local environmental conditions (Hoffman and Sgrò 2011).

As previously described in the Seasonal Activity and Movements section, Foothill Yellow-legged Frog breeding is closely tied to water temperature, flow, and stage, and the species already adjusts its timing of oviposition by as much as a month or more in the same location during different water years, so the species may have enough inherent flexibility to reduce their vulnerability. The species appears fairly resilient to drought, fire, and flooding, at least in some circumstances. For example, after the 2012-2016 drought, the Loma Fire in late 2016, and severe winter flooding and landslides in 2016 and 2017, Foothill Yellow-legged Frog adults and metamorphs, as well as aquatic insects and rainbow trout, were abundant throughout Upper Llagas Creek in fall of 2017, and the substrate consisted of generally clean gravels and cobbles with only a slight silt coating in some pools (J. Smith pers. comm. 2017). The frogs and fish likely took refuge in a spring-fed pool, and the heavy rains scoured the fine sediments that eroded downstream (Ibid.). These refugia from the effects of climate change reduce the species' exposure, thereby reducing their vulnerability (Case et al. 2015).

Climate change models that evaluate the Foothill Yellow-legged Frog's susceptibility from a species and habitat perspective yield mixed results. An investigation into the possible effects of climate on California's native amphibians and reptiles used ecological niche models, future climate scenarios, and general circulation models to predict species-specific climatic suitability in 2050 (Wright et al. 2013). The results suggested approximately 90-100% of localities currently occupied by Foothill Yellow-legged Frogs are expected to remain climatically suitable in that time, and the proportion of currently suitable localities predicted to change ranges from -20% to 20% (Ibid.). However, a second study using a subset of these models found that 66.4% of currently occupied cells will experience reduced environmental suitability in 2050 (Warren et al. 2014). This analysis included 90 species of native California mammals, birds, reptiles, and amphibians. For context, over half of the taxa were predicted to experience > 80% reductions, a consistent pattern reflected across taxonomic groups (Ibid.).

A third analysis investigated the long-term risk of climate change by modeling the relative environmental stress a vegetative community would undergo in 2099 given different climate and greenhouse gas emission scenarios (Thorne et al. 2016). This model does not incorporate any Foothill Yellow-legged Frog-specific data; it strictly projects climatic stress levels vegetative communities will experience within the species' range boundaries (Ibid.). Unsurprisingly, higher emissions scenarios resulted in a greater proportion of habitat undergoing climatic stress (Figure 25). Perhaps counterintuitively, the warm and wet scenario resulted in a greater amount of stress than the hot and dry scenario. When high emissions and warm and wet changes are combined, a much greater proportion of the vegetation communities will experience "non-analog" conditions, those outside of the range of conditions currently known in California (Ibid.).

Habitat Restoration and Species Surveys

Potential conflicts between managing riverine habitat below dams for both cold-water adapted salmonids and Foothill Yellow-legged Frogs was discussed previously. In addition to problems with temperatures and pulse flows, some stream restoration projects aimed at physically creating or improving salmonid habitat can also adversely affect the species. For example, boulder deflectors were placed in Hurdygurdy Creek (Del Norte County) to create juvenile steelhead rearing habitat; deflectors change broad, shallow, low-velocity reaches into narrower, deeper, faster reaches preferred by the fish (Fuller and Lind 1992). Foothill Yellow-legged Frogs were documented using the restoration reach as breeding habitat annually prior to placement of the boulders, but no breeding was detected in the following three years, suggesting this project eliminated the conditions the frogs require (Ibid.). In addition, a fish ladder to facilitate salmonid migration above the Alameda Creek Diversion Dam was recently constructed on a Foothill Yellow-legged Frog lek site, and the frogs may become trapped in the ladder (M. Grefsrud pers. comm. 2019). Use of rotenone to eradicate non-native fish as part of a habitat restoration project is rare, but if it is applied in streams occupied by Foothill Yellow-legged Frogs, it can kill tadpoles but is unlikely to impact post-metamorphic frogs (Fontenot et al. 1994). Metamorphosing tadpoles may be able to stay close enough to the surface to breathe air and survive but may display lethargy and experience increased susceptibility to predation (Ibid.).

Commonly when riparian vegetation is removed, regulatory agencies require a greater amount to be planted as mitigation to offset the temporal loss of habitat. This practice can have adverse impacts on Foothill Yellow-legged Frogs by reducing habitat suitability. Foothill Yellow-legged Frogs have been observed moving into areas where trees were recently removed, and they are known to avoid heavily shaded areas (Welsh and Hodgson 2011, M. Grefsrud pers. comm. 2019).

Biologists conducting surveys in Foothill Yellow-legged Frog habitat can trample egg masses or larvae if they are not careful. One method for sampling fish is electroshocking, which runs a current through the water that stuns the fish temporarily allowing them to be captured. Post-metamorphic frogs are unlikely to be killed by electroshocking; however, at high frequencies (60 Hz), they may experience some difficulty with muscle coordination for a few days (Allen and Riley 2012). This could increase their risk of predation. At 30 Hz, there were no differences between frogs that were shocked and controls (Ibid.). Tadpoles are more similar to fish in tail muscle and spinal structure and are at higher risk of injuries; however, researchers who reported observing stunned tadpoles noted they appeared to recover completely within several seconds (Ibid.). Adverse effects to Foothill Yellow-legged Frogs from electrofishing may only happen at frequencies higher than those typically used for fish sampling (Ibid.)

Small Population Sizes

Small populations are at greater risk of extirpation, primarily through the disproportionately greater impact of demographic, environmental, and genetic stochasticity on them compared to large populations, so any of the threats previously discussed will likely have an even greater adverse impact on small populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). This risk of extinction from genetic stochasticity is amplified when connectivity between the small populations, and thus gene flow,

is impeded (Fahrig and Merriam 1985, Taylor et al. 1993, Lande and Shannon 1996, Palstra and Ruzzante 2008). Genetic diversity provides capacity to evolve in response to environmental changes, and the "rescue effect" of gene flow is important in minimizing probability of local extinction (Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). However, the rescue effect is diminished in conditions of high local environmental stochasticity of recruitment or survival (Eriksson et al. 2014). In addition, populations living near their physiological limits and lacking adaptive capacity may not be able to evolve in response to rapid changes (Hoffmann and Sgrò 2011). Furthermore, while pathogens or parasites rarely result in host extinction, they can increase its likelihood in small populations by driving the host populations below a critically low threshold beneath which demographic stochasticity can lead to extinction, even if they possess the requisite genetic diversity to adapt to a changed environment (Gomulkiewicz and Holt 1995, Adams et al. 2017b).

A Foothill Yellow-legged Frog PVA revealed that, even with no dam effects considered (e.g., slower growth and increased egg and tadpole mortality), populations with the starting average density of adult females in regulated rivers (4.6/km [2.9/mi]) were four times more likely to go extinct within 30 years than those with the starting average density of adult females from unregulated rivers (32/km [120/mi]) (Kupferberg et al. 2009c). When the density of females in sparse populations was used (2.1/km [1.3/mi], the 30-year risk of extinction increased 13-fold (Ibid.). With dam effects, a number of the risk factors above contribute to the additional probability of local extinction such as living near their lower thermal tolerance and reduced recruitment and survival from scouring and stranding flows, poor food quality, and increased predation and competition (Kupferberg 1997a; Hoffmann and Sgrò 2011; Kupferberg et al. 2011a,b; Kupferberg et al. 2012; Eriksson et al. 2014). These factors act synergistically, contributing in part to the small size, high divergence, and low genetic diversity exhibited by many Foothill Yellow-legged Frog populations located in highly regulated watersheds (Kupferberg et al. 2012, Peek 2018).

EXISTING MANAGEMENT

Land Ownership within the California Range

Using the Department's Foothill Yellow-legged Frog range boundary and the California Protected Areas Database (CPAD), a GIS dataset of lands that are owned in fee title and protected for open space purposes by over 1,000 public agencies or non-profit organizations, the total area of the species' range in California comprises 13,620,447 ha (33,656,857 ac) (CPAD 2019, CWHR 2019). Approximately 37% is owned by federal agencies, 80% of which (4,071,178 ha [10,060,100 ac]) is managed by the Forest Service (Figure 26). Department of Fish and Wildlife-managed lands, State Parks, and other State agency-managed lands constitute around 2.6% of the range. The remainder of the range includes < 1% Tribal lands, 2.3% other conserved lands (e.g., local and regional parks), and 57% private and government-managed lands that are not protected for open space purposes. It is important to note that even if included in the CPAD, a property's management does not necessarily benefit Foothill Yellow-legged Frogs, but in some cases changes in management to conserve the species may be easier to undertake than on private lands or public lands not classified as conserved.

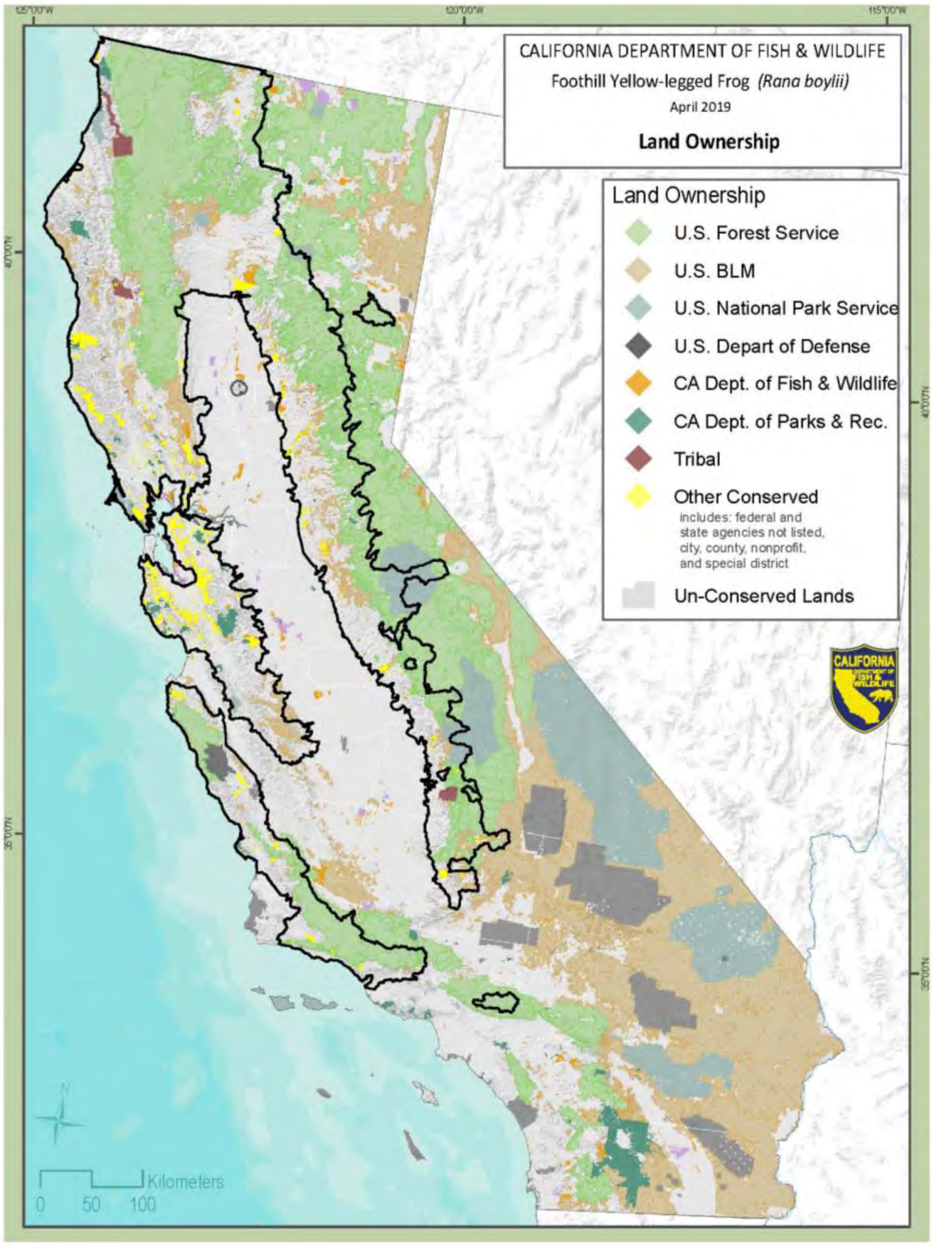

Figure 26. Conserved, Tribal, and other lands (BLM, CMD, CPAD, CWHR, DOD)

Statewide Laws

The laws and regulations governing land management within the Foothill Yellow-legged Frog's range vary by ownership. Several state and federal environmental laws apply to activities undertaken in California that may provide some level of protection for Foothill Yellow-legged Frogs and their habitat. The following is not an exhaustive list.

National Environmental Policy Act and California Environmental Quality Act

Most federal land management actions must undergo National Environmental Policy Act of 1969 (NEPA; 42 U.S.C. § 4321, et seq.) analysis. NEPA requires federal agencies to document, consider alternatives, and disclose to the public the impacts of major federal actions and decisions that may significantly impact the environment. As a BLM and Forest Service Sensitive Species, impacts to Foothill Yellow-legged Legged Frogs are considered during NEPA analysis; however, the law has no requirement to minimize or mitigate adverse effects.

The California Environmental Quality Act (CEQA) is similar to NEPA; it requires state and local agencies to identify, analyze, and consider alternatives, and to publicly disclose environmental impacts from projects over which they have discretionary authority (Pub. Resources Code § 21000 et seq.). CEQA differs substantially from NEPA in requiring mitigation for significant adverse effects to a less than significant level unless overriding considerations are documented. CEQA requires an agency find projects may have a significant effect on the environment if they have the potential to substantially reduce the habitat, decrease the number, or restrict the range of any rare, threatened, or endangered species (Cal. Code Regs., tit. 14, §§ 15065(a)(1), 15380.). CEQA establishes a duty for public agencies to avoid or minimize such significant effects where feasible (Cal. Code regs., tit. 14, § 15021). Impacts to Foothill Yellow-legged Frogs, as an SSC, should be identified, evaluated, disclosed, and mitigated or justified under the Biological Resources section of an environmental document prepared pursuant to CEQA. However, a lead agency is not required to make a mandatory finding of significance conclusion unless it determines on a project-specific basis that the species meets the CEQA criteria for rare, threatened, or endangered.

Clean Water Act and Porter-Cologne Water Quality Control Act

The Clean Water Act originated in 1948 as the Federal Water Pollution Control Act of 1948. It was heavily amended in 1972 and became known as the Clean Water Act (CWA). The purpose of the CWA was to establish regulations for the discharge of pollutants into waters of the United States and establish quality standards for surface waters. Section 404 of the CWA forbids the discharge of dredged or fill material into waters and wetlands without a permit from the ACOE. The CWA also requires an alternatives analysis, and the ACOE is directed to issue their permit for the least environmentally damaging practicable alternative. The definition of waters of the United States has changed substantially over time based on Supreme Court decisions and agency rule changes.

The Porter-Cologne Water Quality Act was established by the State in 1969 and is similar to the CWA in that it establishes water quality standards and regulates discharge of pollutants into state waters, but it

also administers water rights which regulate water diversions and extractions. The SWRCB and nine Regional Water Boards share responsibility for implementation and enforcement of Porter-Cologne as well as the CWA's National Pollutant Discharge Elimination System permitting.

Federal and California Wild and Scenic Rivers Acts

In 1968, the U.S. Congress passed the federal Wild and Scenic Rivers Act (WSRA) (16 U.S.C. § 1271, et seq.) which created the National Wild and Scenic River System. The WSRA requires the federal government to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations. The WSRA prohibits the federal government from building, licensing, funding or otherwise aiding in the building of dams or other project works on rivers or segments of designated rivers. The WSRA does not give the federal government control of private property including development along protected rivers.

California's Wild and Scenic Rivers Act was enacted in 1972 so rivers that "possess extraordinary scenic, recreational, fishery, or wildlife values shall be preserved in their free-flowing state, together with their immediate environments, for the benefit and enjoyment of the people of the state." (Pub. Res. Code, § 5093.50). Designated waterways are codified in Public Resources Code sections 5093.50-5093.70. In 1981, most of California's designated Wild and Scenic Rivers were adopted into the federal system. Currently in California, 3,218 km (1,999.6 mi) of 23 rivers are protected by the WSRA, most of which are located in the northwest. Foothill Yellow-legged Frogs have been observed in 11 of the 17 designated rivers within their range (CNDDB 2019).

Lake and Streambed Alteration Agreements

Fish and Game Code Section 1602 requires entities to notify the Department of activities that "divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake." If the activity may substantially adversely affect an existing fish and wildlife resource, the Department may enter into a lake or streambed alteration agreement with the entity that includes reasonable measures necessary to protect the fish or wildlife resource (Fish & G. Code, §1602, subd. (a)(4)(B)). A lake or stream alteration agreement does not authorize take of species listed as candidates, threatened, or endangered under CESA (see Protection Afforded by Listing for CESA compliance requirements).

Medicinal and Adult-Use Cannabis Regulation and Safety Act

The commercial cannabis cultivation industry is unique in that any entity applying for an annual cannabis cultivation license from California Department of Food and Agriculture (CDFA) must include "a copy of any final lake or streambed alteration agreement…or written verification from the California Department of Fish and Wildlife that a lake or streambed alteration agreement is not required" with their license application (Cal. Code Regs., tit. 3, § 8102, subd. (v)). The SWRCB also enforces the laws related to waste discharge and water diversions associated with cannabis cultivation (Cal. Code Regs., tit. 3, § 8102, subd. (p)).

Forest Practice Act

The Forest Practice Act was originally enacted in 1973 to ensure that logging in California is undertaken in a manner that will also preserve and protect the State's fish, wildlife, forests, and streams. This law and the regulations adopted by the California Board of Forestry and Fire Protection (BOF) pursuant to it are collectively referred to as the Forest Practice Rules. The Forest Practice Rules implement the provisions of the Forest Practice Act in a manner consistent with other laws, including CEQA, Porter-Cologne, CESA, and the Timberland Productivity Act of 1982. The California Department of Forestry and Fire Protection (CAL FIRE) enforces these laws and regulations governing logging on private land.

Federal Power Act

The Federal Power Act and its major amendments are implemented and enforced by FERC and require licenses for dams operated to generate hydroelectric power. One of the major amendments required that these licenses "shall include conditions for the protection, mitigation and enhancement of fish and wildlife including related spawning grounds and habitat" (ECPA 1986). Hydropower licenses granted by FERC are usually valid for 30-50 years. If a licensee wants to renew their license, it must file a Notice of Intent and a pre-application document five years before the license expires to provide time for public scoping, any potentially new studies necessary to analyze project impacts and alternatives, and preparation of environmental documents. The applicant must officially apply for the new license at least two years before the current license expires.

As a federal agency, FERC must comply with federal environmental laws prior to issuing a new license or relicensing an existing hydropower project, which includes NEPA and ESA. As a result of environmental compliance or settlement agreements formed during the relicensing process, some operations have been modified and habitat restored to protect fish and wildlife. For example, the Lewiston Dam relicensing resulted in establishment of the Trinity River Restoration Program, which takes an ecosystem-approach to studying dam effects and protecting and restoring fish and wildlife populations downstream of the dam (Snover and Adams 2016). Similarly, relicensing of the Rock Creek-Cresta Project on the North Fork Feather River resulted in establishment of a multi-stakeholder Ecological Resources Committee (ERC). As a result of the ERC's studies and recommendations, pulse flows for whitewater boating were suspended for several years following declines of Foothill Yellow-legged Frogs, and the ERC is currently working toward augmenting the population in an attempt to increase abundance to a viable level.

Administrative and Regional Plans

Forest Plans

NORTHWEST FOREST PLAN

In 1994, BLM and the Forest Service adopted the Northwest Forest Plan to guide the management of over 97,000 km^2 (37,500 mi^2) of federal lands in portions of northwestern California, Oregon, and Washington. The Northwest Forest Plan created an extensive network of forest reserves including

Riparian Reserves. Riparian Reserves apply to all land designations to protect riparian dependent resources. With the exception of silvicultural activities consistent with Aquatic Conservation Strategy objectives, timber harvest is not permitted within Riparian Reserves, which can vary in width from 30 to 91 m (100-300 ft) on either side of streams, depending on the classification of the stream or waterbody (USFS and BLM 1994). Fuel treatment and fire suppression strategies and practices implemented within these areas are designed to minimize disturbance.

Sierra Nevada Forest Plan

Land and Resource Management Plans for forests in the Sierra Nevada were changed in 2001 by the Sierra Nevada Forest Plan Amendment and subsequently adjusted via a supplemental Environmental Impact Statement and Record of Decision in 2004, referred to as the Sierra Nevada Framework (USFS 2004). This established an Aquatic Management Strategy with Goals including maintenance and restoration of habitat to support viable populations of riparian-dependent species; spatial and temporal connectivity for aquatic and riparian species within and between watersheds to provide physically, chemically, and biologically unobstructed movement for their survival, migration, and reproduction; instream flows sufficient to sustain desired conditions of riparian, aquatic, wetland, and meadow habitats; the physical structure and condition of streambanks and shorelines to minimize erosion and sustain desired habitat diversity; and prevention of new introductions of invasive species and reduction of invasive species impacts that adversely affect the viability of native species. The Sierra Nevada Framework also includes Riparian Conservation Objectives and associated standards and guidelines specific to aquatic-dependent species, including the Foothill Yellow-legged Frog.

Resource Management Plans

Sequoia, Kings Canyon, and Yosemite National Parks fall within the historical range of the Foothill Yellow-legged Frog, but the species has been extirpated from these areas. The guiding principles for managing biological resources on National Park Service lands include maintenance of animal populations native to park ecosystems (Hayes et al. 2016). They also commit the agency to work with other land managers on regional scientific and planning efforts and maintenance or reintroduction of native species to the parks including conserving Foothill Yellow-legged Frogs in the Sierra Nevada (USDI NPS 1999 as cited in Hayes et al. 2016). A Sequoia and Kings Canyon National Parks Resource Management Plan does not include specific management goals for Foothill Yellow-legged Frogs, but it does include a discussion of the factors leading to the species' decline and measures to restore the integrity of aquatic ecosystems (Ibid.). The Yosemite National Park Resource Management Plan includes a goal of restoring Foothill Yellow-legged Frogs to the Upper Tuolumne River below Hetch Hetchy Reservoir (USDI NPS 2003 as cited in Hayes et al. 2016).

FERC Licenses

Dozens of hydropower dams have been relicensed in California since 1999, and several are in the process of relicensing (FERC 2019). In addition to following the Federal Power Act and other applicable federal laws, Porter-Cologne Water Quality Act requires non-federal dam operators to obtain a Water Quality Certification (WQC) from the SWRCB. Before it can issue the WQC, the SWRCB must consult with

the Department regarding the needs of fish and wildlife. Consequently, SWRCB includes conditions in the WQC that seek to minimize adverse effects to native species, and Foothill Yellow-legged Frogs have received some special considerations due to their sensitivity to dam operations during these licensing processes. As discussed above, the typical outcome is formation of an ERC-type group to implement the environmental compliance requirements and recommend changes to flow management to reduce impacts. Foothill Yellow-legged Frog-specific requirements fall into three general categories: data collection, modified flow regimes, and standard best management practices.

Data Collection

When little is known about the impacts of different flows and temperatures on Foothill Yellow-legged Frog occupancy and breeding success, data are collected and analyzed to inform recommendations for future modifications to operations such as temperature trigger thresholds. These surveys include locating egg masses and tadpoles, monitoring temperatures and flows, and recording their fate (e.g., successful development and metamorphosis, displacement, desiccation) during different flow operations and different water years. Examples of licenses with these conditions include the Lassen Lodge Project (FERC 2018), Rock Creek-Cresta Project (FERC 2009a), and El Dorado Project (EID 2007).

Modified Flow Regimes

When enough data exist to understand the effect of different operations on Foothill Yellow-legged Frog occupancy and success, license conditions may include required minimum seasonal instream flows, specific thermal regimes, gradual ramping rates to reduce the likelihood of early life stage scour or stranding, or freshet releases (winter/spring flooding simulation) to maintain riparian processes, and cancellation or prohibition of recreational pulse flows during the breeding season. Examples of licenses with these conditions include the Poe Hydroelectric Project (SWRCB 2017), Upper American Project (FERC 2014), and Pit 3, 4, 5 Project (FERC 2007b).

Best Management Practices

Efforts to reduce the impacts from maintenance activities and indirect operations include selective herbicide and pesticide application, aquatic invasive species monitoring and control, erosion control, and riparian buffers. Examples of licenses with these conditions include the South Feather Project (SWRCB 2018), Spring Gap-Stanislaus Project (FERC 2009b), and Chili Bar Project (FERC 2007a).

Habitat Conservation Plans and Natural Community Conservation Plans

Non-federal entities can obtain authorization for take of federally threatened and endangered species incidental to otherwise lawful activities through development and implementation of a Habitat Conservation Plan (HCP) pursuant to Section 10 of the ESA. The take authorization can extend to species not currently listed under ESA but which may become listed as threatened or endangered over the term of the HCP, which is often 25-75 years. California's companion law, the Natural Community Conservation Planning Act of 1991, takes a broader approach than either CESA or ESA. A Natural Community Conservation Plan (NCCP) identifies and provides for the protection of plants, animals, and their

habitats, while allowing compatible and appropriate economic activity. There are currently four HCPs that include Foothill Yellow-legged Frogs as a covered species, two of which are also NCCPs.

HUMBOLDT REDWOOD (FORMERLY PACIFIC LUMBER) COMPANY

The Humboldt Redwood Company (HRC) HCP covers 85,672 ha (211,700 ac) of private Coast Redwood and Douglas-fir forest in Humboldt County (HRC 2015). It is a 50-year HCP/incidental take permit (ITP) that was executed in 1999, revised in 2015 as part of its adaptive management strategy, and expires on March 1, 2049. The HCP includes an Amphibian and Reptile Conservation Plan and an Aquatics Conservation Plan with measures designed to sustain viable populations of Foothill Yellow-legged Frogs and other covered aquatic herpetofauna. These conservation measures include prohibiting or limiting tree harvest within Riparian Management Zones (RMZ), controlling sediment by maintaining roads and hillsides, restricting controlled burns to spring and fall in areas outside of the RMZ, conducting effectiveness monitoring throughout the life of the HCP, and use the data collected to adapt monitoring and management plans accordingly.

Watershed assessment surveys include observations of Foothill Yellow-legged Frogs and have documented their widespread distribution on HRC lands with a pattern of fewer near the coast in the fog belt and more inland (S. Chinnici pers. comm. 2017). The watersheds within the property are largely unaffected by dam-altered flow regimes or non-native species, so aside from the operations described under Timber Harvest above that are minimized to the extent feasible, the focus on suitable temperatures and denser canopy cover for salmonids may reduce habitat suitability for Foothill Yellow-legged Frogs over time (Ibid.).

SAN JOAQUIN COUNTY MULTI-SPECIES HABITAT CONSERVATION AND OPEN SPACE PLAN

The San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) is a 50-year HCP/ITP that was signed by the USFWS on November 14, 2000 (San Joaquin County 2000). The SJMSCP covers almost all of San Joaquin County except federal lands, a few select projects, and some properties with certain land uses, roughly 364,000 ha (900,000 ac). At the time of execution, approximately 70 ha (172 ac) of habitat within the SJMSCP area in the southwest portion of the county were considered occupied by Foothill Yellow-legged Frogs with another 1,815 ha (4,484 ac) classified as potential habitat, but it appears the species had been considered extirpated before then (Jennings and Hayes 1994, San Joaquin County 2000, Lind 2005). The HCP estimates around 8% of the combined modeled habitat would be converted to other uses over the permit term, but the establishment of riparian preserves with buffers around Corral Hollow Creek, where the species occurred historically, was expected to offset those impacts (San Joaquin County 2000, SJCOG 2018). However, the HCP did not require surveys to determine if Foothill Yellow-legged Frogs are benefiting (M. Grefsrud pers. comm. 2019).

EAST CONTRA COSTA COUNTY HABITAT CONSERVATION PLAN/NATURAL COMMUNITY CONSERVATION PLAN

The East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan (ECCC HCP/NCCP) is a multi-jurisdictional 30-year plan adopted in 2007 that covers over 70,423 ha (174,018 ac) in eastern Contra Costa County (Jones & Stokes 2006). The Foothill Yellow-legged Frog appears to be

extirpated from the ECCC HCP/NCCP area (CNDDB 2019). Nevertheless, suitable habitat was mapped, and impacts were estimated at well under 1% of both breeding and migratory habitat (Jones & Stokes 2006). One of the HCP/NCCP's objectives is acquiring high-quality Foothill Yellow-legged Frog habitat that has been identified along Marsh Creek (Ibid.). In 2017, the Viera North Peak 65 ha (160 ac) property was acquired that possesses suitable habitat for Foothill Yellow-legged Frogs (ECCCHC 2018).

SANTA CLARA VALLEY HABITAT PLAN

The Santa Clara Valley Habitat Plan (SCVHP) is a 50-year HCP/NCCP covering over 210,237 ha (519,506 ac) in Santa Clara County (ICF 2012). As previously mentioned, Foothill Yellow-legged Frogs appear to have been extirpated from lower elevation sites, particularly below reservoirs in this area. Approximately 17% of modeled Foothill Yellow-legged Frog habitat, measured linearly along streams, was already permanently preserved, and the SCVHP seeks to increase that to 32%. The maximum allowable habitat loss is 11 km (7 mi) permanent loss and 3 km (2 mi) temporary loss, while 167 km (104 mi) of modeled habitat is slated for protection. By mid-2018, 8% of impact area had been accrued and 3% of habitat protected (SCVHA 2019).

GREEN DIAMOND AQUATIC HABITAT CONSERVATION PLAN

Green Diamond Resources Company has an Aquatic Habitat Conservation Plan (AHCP) covering 161,875 ha (400,000 ac) of their land that is focused on cold-water adapted species, but many of the conservation measures are expected to benefit Foothill Yellow-legged Frogs as well (K. Hamm pers. comm. 2017). Examples include slope stability and road management measures to reduce stream sedimentation from erosion and landslides, and limiting water drafting during low flow periods with screens over the pumps to avoid entraining animals (Ibid.). Although creating more open canopy areas and warmer water temperatures is not the goal of the AHCP, the areas that are suitable for Foothill Yellow-legged Frog breeding are likely to remain that way because they are wide channels that receive sufficient sunlight (Ibid.).

SUMMARY OF LISTING FACTORS

CESA's implementing regulations identify key factors relevant to the Department's analyses and the Fish and Game Commission's decision on whether to list a species as threatened or endangered. A species will be listed as endangered or threatened if the Commission determines that the species' continued existence is in serious danger or is threatened by any one or any combination of the following factors: (1) present or threatened modification or destruction of its habitat; (2) overexploitation; (3) predation; (4) competition; (5) disease; or (6) other natural occurrences or human-related activities (Cal. Code Regs., tit. 14, § 670.1, subd. (i).

This section provides summaries of information from the foregoing sections of this status review, arranged under each of the factors to be considered by the Commission in determining whether listing is warranted.

Present or Threatened Modification or Destruction of Habitat

Most of the factors affecting ability to survive and reproduce listed above involve destruction or degradation of Foothill Yellow-legged Frog habitat. The most widespread, and potentially most significant, threats are associated with dams and their flow regimes, particularly in areas where they are concentrated and occur in a series along a river. Dams and the way they are operated can have up- and downstream impacts to Foothill Yellow-legged Frogs. They can result in ~~confusing~~ aseasonal or asynchronous ~~natural~~ breeding cues, scouring and stranding of egg masses and tadpoles, reducing quality and quantity of breeding and rearing habitat, reducing tadpole growth rate, impeding gene flow among populations, and establishing and spreading non-native species (Hayes et al. 2016). These impacts appear to be most severe when the dam is operated for the generation of hydropower utilizing hydropeaking and pulse flows (Kupferberg et al. 2009c, Peek 2018). Foothill Yellow-legged Frog abundance below dams is an average of five times lower than in unregulated rivers (Kupferberg et al. 2012). The number, height, and distance upstream of dams in a watershed influenced whether Foothill Yellow-legged Frogs still occurred at sites where they had been present in 1975 in California (Ibid.). Water diversions for agricultural, industrial, and municipal uses also reduce the availability and quality of Foothill Yellow-legged Frog habitat. Dams are concentrated in the Bay Area, Sierra Nevada, and southern California (Figure 17), while hydropower plants are densest in the northern and central Sierra Nevada (Figure 18).

With predicted increases in the human population, ambitious renewable energy targets, higher temperatures, and more extreme and variable precipitation falling increasingly more as rain rather than snow, the need for more and taller dams and water diversions for hydroelectric power generation, flood control, and water storage and delivery is not expected to abate in the future. California voters approved Proposition 1, the Water Quality, Supply and Infrastructure Improvement Act of 2014, which dedicated $2.7 billion to water storage projects (PPIC 2018). In 2018, the California Water Commission approved funding for four new dams in California: expansion of Pacheco Reservoir (Santa Clara County), expansion of Los Vaqueros Reservoir (Contra Costa County), Temperance Flat Dam (new construction) on the San Joaquin River (Fresno County), and the off-stream Sites Reservoir (new construction) diverting the Sacramento River (Colusa County) (CWC 2019). No historical records of Foothill Yellow-legged Frogs from the Los Vaqueros or Sites Reservoir areas exist in the CNDDB, and one historical (1950) collection is documented from the Pacheco Reservoir area (CNDDB 2019). However, the proposed Temperance Flat Dam site is downstream of one of the only known extant populations of Foothill Yellow-legged Frogs in the East/Southern Sierra clade (Ibid.).

The other widespread threat to Foothill Yellow-legged Frog habitat is climate change, although the severity of its impacts is somewhat uncertain. While drought, wildland fires, floods, and landslides are natural and ostensibly necessary disturbance events for preservation of native biodiversity, climate change is expected to result in increased frequency and severity of these events in ways that may exceed species' abilities to adapt (Williams et al. 2008, Hoffmann and Sgrò 2011, Keely and Syphard 2016). These changes can lead to increased competition, predation, and disease transmission as species become concentrated in areas that remain wet into the late summer (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Loss of riparian vegetation from wildland fires can result in increased stream temperatures or concentrations of nutrients and trace heavy metals that inhibit growth and survival (Spencer and Hauer 1991, Megahan et al. 1995, Burton et al. 2016). Stream sedimentation from landslides following fire or excessive precipitation can destroy or degrade breeding and rearing habitat (Harvey and Lisle 1998, Olson and Davis 2009, Kupferberg et al. 2011b). At least some models predict unprecedented dryness in the latter half of the century (Cook et al. 2015). The effects of climate change will be realized across the Foothill Yellow-legged Frog's range, and thetheir severity of these effects will likely differ in ways that are difficult to predict. However, the impacts from extended droughts will likely be greatest in the areas that are naturally more arid, the lower elevations and latitudes of southern California and the foothills surrounding the Central Valley (Figure 21).

While most future urbanization is predicted to occur in areas outside of the Foothill Yellow-legged Frog's range, it has already contributed to the loss and fragmentation of Foothill Yellow-legged Frog habitat in California. In addition, the increased predation, wildland fires, introduced species, road mortality, disease transmission, air and water pollution, and disturbance from recreation that can accompany urbanization expand its impact far beyond its physical footprint (Davidson et al. 2002, Syphard et al. 2007, Cook et al. 2012, Bar-Massada et al. 2014). Within the Foothill Yellow-legged Frog's historical range, these effects appear most significant and extensive in terms of population extirpations in southern California and the San Francisco Bay Area.

Several other activities have the potential to destroy or degrade Foothill Yellow-legged Frog habitat, but they are less common across the range. They also tend to have relatively small areas of impact, although they can be significant in those areas, particularly if populations are already small and declining. These include impacts from mining, cannabis cultivation, vineyard expansion, overgrazing, timber harvest, recreation, and some stream habitat restoration projects (Harvey and Lisle 1998, Belsky et al. 1999, Merelender 2000, Pilliod et al. 2003, Bauer et al. 2015, Kupferberg and Furey 2015).

Overexploitation

Foothill Yellow-legged Frogs are not threatened by overexploitation. There is no known pet trade for Foothill Yellow-legged Frogs (Lind 2005). During the massive frog harvest that accompanied the Gold Rush, some Foothill Yellow-legged Frogs were collected, but because they are relatively small and have irritating skin secretions, there was much less of a market for them (Jennings and Hayes 1985). Within these secretions is a peptide with antimicrobial activity that is particularly potent against *Candida albicans*, a human pathogen that has been developing resistance to traditional antifungal agents (Conlon et al. 2003). However, the peptide's therapeutic potential is limited by its strong hemolytic activity, so further studies will focus on synthesizing analogs that can be used as antifungals, and collection of Foothill Yellow-legged Frogs for lab cultures is unlikely (Ibid.).

Like all native California amphibians, collection of Foothill Yellow-legged Frogs is unlawful without a permit from the Department. They may only be collected for scientific, educational, or propagation reasons through a Scientific Collecting Permit (Fish & G. Code § 1002 et seq.). The Department has the discretion to limit or condition the number of individuals collected or handled to ensure no significant adverse effects. Incidental harm from authorized activities on other aquatic species can be avoided or minimized by the inclusion of special terms and conditions in permits.

Predation

Predation is a likely contributor to Foothill Yellow-legged Frog population declines where the habitat is degraded by one or many other risk factors (Hayes and Jennings 1986). Predation by native gartersnakes can be locally substantial; however, it may only have an appreciable population-level impact if the availability of escape refugia is diminished. For example, when streams dry and only pools remain, Foothill Yellow-legged Frogs are more vulnerable to predation by native and non-native species because they are concentrated in a small area with little aquatic cover.

Several studies have demonstrated the synergistic impacts of predators and other stressors. Foothill Yellow-legged Frogs, primarily as demonstrated through studies on tadpoles, are more susceptible to predation when exposed to some agrochemicals, cold water, high velocities, excess sedimentation, and even the presence of other species of predators (Harvey and Lisle 1998, Adams et al. 2003, Olson and Davis 2009, Kupferberg et al. 2011b, Kerby and Sih 2015, Catenazzi and Kupferberg 2018). Foothill Yellow-legged Frog tadpoles appear to be naïve to chemical cues from some non-native predators; they have not evolved those species-specific predator avoidance behaviors (Paoletti et al. 2011). Furthermore, early life stages are often more sensitive to environmental stressors, making them more vulnerable to predation, and Foothill Yellow-legged Frog population dynamics are highly sensitive to egg and tadpole mortality (Kats and Ferrer, 2003, Kupferberg et al. 2009c). Predation pressure is likely positively associated with proximity to anthropogenic changes in the environment, so in more remote or pristine places, it probably does not have a serious population-level impact.

Competition

Intra- and interspecific competition in Foothill Yellow-legged Frogs has been documented. Intraspecific male-to-male competition for females has been reported (Rombough and Hayes 2007). Observations include physical aggression and a non-random mating pattern in which larger males were more often engaged in breeding (Rombough and Hayes 2007, Wheeler and Welsh 2008). A behavior resembling clutch-piracy, where a satellite male attempts to fertilize already laid eggs, has also been documented (Rombough and Hayes 2007). These acts of competition play a role in population genetics, but they likely do not result in serious physical injury or mortality. Intraspecific competition among Foothill Yellow-legged Frog tadpoles was negligible (Kupferberg 1997a).

Interspecific competition appears to have a greater possibility of resulting in adverse impacts. Kupferberg (1997a) did not observe a significant change in tadpole mortality for Foothill Yellow-legged Frogs raised with Pacific Treefrogs compared to single-species controls. However, when reared together, Foothill Yellow-legged Frog tadpoles lost mass, while Pacific Treefrog tadpoles increased mass (Kerby and Sih 2015). As described previously under Introduced Species, Foothill Yellow-legged Frog tadpoles experienced significantly higher mortality and smaller size at metamorphosis when raised with bullfrog tadpoles (Kupferberg 1997a). The mechanism of these declines appeared to be exploitative competition, as opposed to interference, through the reduction of available algal resources from bullfrog tadpole grazing in the shared enclosures (Ibid.).

The degree to which competition threatens Foothill Yellow-legged Frogs likely depends on the number and density of non-native species in the area rather than intraspecific competition, and co-occurrence of Foothill Yellow-legged Frog and bullfrog tadpoles may be somewhat rare since the latter tends to breed in lentic (still water) environments (M. van Hattem pers. comm. 2019). Interspecific competition with other native species may have some minor adverse consequences on fitness.

Disease

Currently, the only disease known to pose a serious risk to Foothill Yellow-legged Frogs is Bd. Until 2017, the only published studies on the impact of Bd on Foothill Yellow-legged Frog suggested it could reduce growth and body condition but was not lethal (Davidson et al. 2007, Lowe 2009, Adams et al. 2017b). However, two recent mass mortality events caused by chytridiomycosis proved they are susceptible to lethal effects, at least under certain conditions like drought-related concentration and presence of bullfrogs (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Some evidence indicates disease may have played a principal role in the disappearance of the species from southern California (Adams et al. 2017b). Bd is likely present in the environmental throughout the Foothill Yellow-legged Frog's range, and with bullfrogs and treefrogs acting as carriers, it will remain a threat to the species; however, given the dynamics of the two recent die-offs in the San Francisco Bay area, the probability of future outbreaks may be greater in areas where the species is under additional stressors like drought and introduced species (Adams et al. 2017a, Kupferberg and Catenazzi 2019). Therefore, as with predation, Foothill Yellow-legged Frogs are less likely to experience the adverse impacts of diseases in more remote areas with fewer anthropogenic changes to the environment.

Other Natural Events or Human-Related Activities

Agrochemicals, particularly organophosphates that act as endocrine disruptors, can travel substantial distances from the area of application through atmospheric drift and have been implicated in the disappearance and declines of many species of amphibians in California including Foothill Yellow-legged Frogs (LeNoir et al. 1999, Davidson 2004, Lind 2005, Olson and Davis 2009). Foothill Yellow-legged Frogs appear to be significantly more sensitive to the adverse impacts of some pesticides than other native species (Sparling and Fellers 2009, Kerby and Sih 2015). These include smaller body size, slower development rate, increased time to metamorphosis, immunosuppression, and greater vulnerability to predation and malformations (Kiesecker 2002, Hayes et al. 2006, Sparling and Fellers 2009, Kerby and Sih 2015). Some of the most dramatic declines experienced by ranids in California occurred in the Sierra Nevada east of the San Joaquin Valley where over half of the state's total pesticide usage occurs (Sparling et al. 2001).

Many Foothill Yellow-legged Frog populations are small, isolated from other populations, and possess low genetic diversity (McCartney-Melstad et al. 2018, Peek 2018). Genetic diversity is important in providing a population the capacity to evolve in response to environmental changes, and connectivity among populations is important for gene exchange and in minimizing probability of local extinction

(Lande and Shannon 1996, Williams et al. 2008, Eriksson et al. 2014). Small populations are at much greater risk of extirpation primarily through the disproportionate impact of demographic, environmental, and genetic stochasticity than robust populations (Lande and Shannon 1996, Palstra and Ruzzante 2008). Based on a Foothill Yellow-legged Frog PVA, populations in regulated rivers face a 4- to 13-fold greater extinction risk in 30 years than populations in unregulated rivers due to smaller population sizes (Kupferberg et al. 2009c). The threat posed by small population sizes is significant and the general pattern shows increases in severity from north to south; however, many sites, primarily in the northern Sierra Nevada, in watersheds with large hydropower projects are also at high risk.

PROTECTION AFFORDED BY LISTING

It is the policy of the State to conserve, protect, restore and enhance any endangered or threatened species and its habitat (Fish & G. Code, § 2052). The conservation, protection, and enhancement of listed species and their habitat is of statewide concern (Fish & G. Code, § 2051(c)). CESA defines "take" as hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill (Fish & G. Code, § 86). The Fish and Game Code provides the Department with related authority to authorize "take" of species listed as threatened or endangered under certain circumstances (see, e.g., Fish & G. Code, §§ 2081, 2081.1, 2086, & 2835).

If the Foothill Yellow-legged Frog is listed under CESA, impacts of take caused by activities authorized through incidental take permits must be minimized and fully mitigated according to state standards (Fish & G. Code, § 2081, subd. (b)). These standards typically include protection of land in perpetuity with an easement, development and implementation of a species-specific adaptive management plan, and funding through an endowment to pay for long-term monitoring and maintenance to ensure the mitigation land meets performance criteria. Obtaining an incidental take permit is voluntary. The Department cannot force compliance; however, any person violating the take prohibition may be criminally and civilly liable under state law.

Additional protection of Foothill Yellow-legged Frogs following listing would be expected to occur through state and local agency environmental review under CEQA. CEQA requires affected public agencies to analyze and disclose project-related environmental effects, including potentially significant impacts on rare, threatened, and endangered species. In common practice, potential impacts to listed species are examined more closely in CEQA documents than potential impacts to unlisted species. Where significant impacts are identified under CEQA, the Department expects project-specific avoidance, minimization, and mitigation measures to benefit the species. State listing, in this respect, and consultation with the Department during state and local agency environmental review under CEQA, would be expected to benefit the Foothill Yellow-legged Frog in terms of reducing impacts from individual projects, which might otherwise occur absent listing.

For some species, CESA listing may prompt increased interagency coordination and the likelihood that state and federal land and resource management agencies will allocate funds toward protection and recovery actions. In the case of the Foothill Yellow-legged Frog, some multi-agency efforts exist, often associated with FERC license requirements, to improve habitat conditions and augment declining populations. The USFWS is leading an effort to develop regional Foothill Yellow-legged Frog conservation strategies, and CESA listing may result in increased priority for limited conservation funds.

LISTING RECOMMENDATION

CESA directs the Department to prepare this report regarding the status of the Foothill Yellow-legged Frog in California based upon the best scientific information available (Fish & G. Code, § 2074.6). CESA also directs the Department based on its analysis to indicate in the status report whether the petitioned action (i.e., listing as threatened) is warranted (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

Under CESA, an endangered species is defined as "a native species or subspecies…which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish & G. Code, § 2062). A threatened species is defined as "a native species or subspecies…that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]" (Fish and G. Code, § 2067).

The Department includes and makes its recommendation in its status report as submitted to the Commission in an advisory capacity based on the best available science. In consideration of the scientific information contained herein, the Department has determined that listing the Foothill Yellow-legged Frog under CESA by genetic clade is the prudent approach due to the disparate degrees of imperilment among them. In areas of uncertainty, the Department recommends the higher protection status until clade boundaries can be better defined.

NORTHWEST/NORTH COAST: Not warranted at this time.

Clade-level Summary: This is the largest clade with the most robust populations (highest densities) and the greatest genetic diversity. This area is the least densely populated by humans; contains relatively few hydroelectric dams, particularly further north; and has the highest precipitation in the species' California range. The species is still known to occur in most, if not all, historically occupied watersheds; presumed extirpations are mainly concentrated in the southern portion of the clade around the heavily urbanized San Francisco Bay area. The proliferation of cannabis cultivation, particularly illicit grows in and around the Emerald Triangle, the apparent increase in severe wildland fires in the area, and potential climate change effects are cause for concern, so the species should remain a Priority 1 SSC here with continued monitoring for any change in its status.

WEST/CENTRAL COAST: Endangered.

Clade-level Summary: Foothill Yellow-legged Frogs appear to be extirpated from a relatively large proportion of historically occupied sites within this clade, particularly in the heavily urbanized northern portion around the San Francisco Bay. In the northern portion of the clade, nearly all the remaining populations (which may be fewer than a dozen) are located above dams, which line the mountains surrounding the Bay Area, and two are known to have undergone recent disease-associated die-offs. These higher elevation sites are more often intermittent or ephemeral streams than the lower in the watersheds. As a result, the more frequent and extreme droughts that have dried up large areas seem to have contributed to recent declines. Illegal cannabis cultivation, historical mining effects, overgrazing, and recreation likely contributed to declines and may continue to threaten remaining populations.

SOUTHWEST/SOUTH COAST: Endangered.

Clade-level Summary: The most extensive extirpations have occurred in this clade, and only two known extant populations remain. Both are small with apparently low genetic diversity, making them especially vulnerable to extirpation. This is also an area with a large human population, many dams, and naturally arid, fire-prone environments, particularly in the southern portion of the clade. Introduced species are widespread, and cannabis cultivation is rivaling the Emerald Triangle in some areas (e.g., Santa Barbara County). Introduced species, expanded recreation, disease, and flooding appear to have contributed to the widespread extirpations in southern California over 40 years ago.

FEATHER RIVER: Threatened.

Clade-level Summary: This is the smallest clade and has a high density of hydroelectric dams. It also recently experienced one of the largest, most catastrophic wildfires in California history. Despite these threats, Foothill Yellow-legged Frogs appear to continue to be relatively broadly distributed within the clade, although with all the dams in the area, most populations are likely disconnected. The area is more mesic and experienced less of a change in precipitation in the most recent drought than the clades south of it. The clade is remarkable genetically and morphologically as it is the only area where Foothill Yellow-legged Frogs and Sierra Nevada Yellow-legged Frogs overlap and can hybridize. The genetic variation within the clade is greater than the other clades except for the Northwest/North Coast. Most of the area within the clade's boundaries is Forest Service-managed, and little urbanization pressure or known extirpations exist in this area. Recent FERC licenses in this area require Foothill Yellow-legged Frog specific conservation, which to date has included cancelling pulse flows, removing encroaching vegetation, and translocating egg masses and in situ head-starting to augment a population that had recently declined.

NORTHEAST/NORTHERN SIERRA: Threatened.

Clade-level Summary: The Northeast/Northern Sierra clade shares many of the same threats as the Feather River clade (e.g., relatively small area with many hydroelectric dams). The area is also more mesic and experienced less of a change in precipitation during the recent drought than more southern clades. However, this pattern may not continue as some models suggest loss of snowmelt will be greater in the northern Sierra Nevada, and one of the climate change exposure models suggests a comparatively large proportion of the lower elevations will experience climatic conditions not currently known from the area (i.e., non-analog) by the end of the century. Recent surveys suggest the area continues to support several populations of the species, some of which seem to remain robust, with a fairly widespread distribution. However, genetic analyses from several watersheds suggest many of these populations are isolated and diverging, particularly in regulated reaches with hydropeaking flows.

EAST/SOUTHERN SIERRA: Endangered.

Clade-level Summary: Like the Southwest/South Coast clade, widespread extirpations in this area were observed as early as the 1970s. Dams and introduced species were credited as causal factors in these declines in distribution and abundance, and mining and disease may also have contributed. This area is relatively arid, and drought effects appear greater here than in northern areas that exhibit both more precipitation and a smaller difference between drought years and the historical average. There is a relatively high number of hydroelectric power generating dams in series along the major rivers in this clade and at least one new proposed dam near one of the remaining populations. This area is also the most heavily impacted by agrochemicals from the San Joaquin Valley.

Commented [RAP19]: Just realizing the use of hydropower, hydroelectric and hydroelectric power may benefit from one global term. It seems to switch around throughout, and ultimately all means the same…for simplicity I'd recommend using "hydropower" globally.

MANAGEMENT RECOMMENDATIONS

The Department has evaluated existing management recommendations and available literature applicable to the management and conservation of the Foothill Yellow-legged Frog to arrive at the following recommendations. These recommendations, which represent the best available scientific information, are largely derived the from the Foothill Yellow-legged Frog Conservation Assessment, the California Energy Commission's Public Interest Energy Research Reports, the Recovery Plans of West Coast Salmon and Steelhead, and the California Amphibian and Reptile Species of Special Concern (Kupferberg et al. 2009b,c; 2011a; NMFS 2012, 2013, 2014, 2016; Hayes et al. 2016, Thomson et al. 2016).

Conservation Strategies

Maintain current distribution and genetic diversity by protecting existing Foothill Yellow-legged Frog populations and their habitats and providing opportunities for increased connectivity and ~~genetic exchange~~gene flow. Increase abundance to viable levels in populations at risk of extirpation due to small sizes, when appropriate, through in situ or ex situ captive rearing and/or translocations. Use habitat suitability and hydrodynamic habitat models to identify historically occupied sites that may currently support Foothill Yellow-legged Frogs, or they could with minor habitat improvements or modified management. Re-establish extirpated populations in suitable habitat through captive propagation, rearing, and/or translocations. Prioritize areas in the southern portions of the species' range where extirpations and loss of diversity have been the most severe.

If establishing reserves, prioritize areas containing high genetic variation in Foothill Yellow-legged Frogs (and among various native species) and climatic gradients where selection varies over small geographical area. ~~because e~~Environmental heterogeneity can provide a means of maintaining phenotypic variability, which increases the adaptive capacity of populations as conditions change. These reserves should provide connectivity to other occupied areas to facilitate gene flow and allow for ongoing selection to fire, drought, thermal stresses, and changing species interactions.

Commented [RAP20]: Great sentence but should split it up into two parts.

Research and Monitoring

Attempt to rediscover potentially remnant populations in areas where they are considered extirpated, prioritizing the southern portions of the species' range. Collect environmental DNA in addition to conducting visual encounter surveys to improve detectability. Concurrently assess presence of threats and habitat suitability to determine if future reintroductions may be possible. Collect genetic samples from any Foothill Yellow-legged Frogs captured for use in landscape genomics analyses and possible future translocation or captive propagation efforts. Attempt to better clarify clade boundaries where there is uncertainty. Study whether small populations are at risk of inbreeding depression, whether genetic rescue should be attempted, and if so, whether that results in hybrid vigor or outbreeding depression.

Continue to evaluate how water operations affect Foothill Yellow-legged Frog population demographics. Establish more long-term monitoring programs in regulated and unregulated (reference) rivers across the species' range but particularly in areas like the Sierra Nevada where most large hydropower dams in the species' range are concentrated. Assess whether the timing of pulse flows influences population dynamics, particularly whether early releases have a disproportionately large adverse effect by eliminating the reproductive success of the largest, most fecund females, who appear to breed earlier in the season. Investigate survival rates in poorly-understood life stages, such as tadpoles, young of the year, and juveniles. Determine the extent to which pulse flows contribute to displacement and mortality of post-metamorphic life stages.

Collect habitat variables that correlate with healthy populations to develop more site-specific habitat suitability and hydrodynamic models. Study the potential synergistic effect of increased flow velocity and decreased temperature on tadpole fitness. Examine the relationship between changes in flow, breeding and rearing habitat connectivity, and scouring and stranding to develop site-specific benign ramping rates. Incorporate these data and demographic data into future PVAs for use in establishing frog-friendly flow regimes in future FERC relicensing or license amendment efforts and habitat restoration projects. Ensure long-term funding for post-license or restoration monitoring to evaluate attainment of expected results and for use in adapting management strategies accordingly.

Evaluate the distribution of other threats such as cannabis cultivation, vineyard expansion, livestock grazing, mining, timber harvest, and urbanization and roads in the Foothill Yellow-legged Frog's range. Study the short- and long-term effects of wildland fires and fire management strategies. Assess the extent to which these potential threats pose a risk to Foothill Yellow-legged Frog persistence in both regulated and unregulated systems.

Investigate how reach-level or short-distance habitat suitability and hydrodynamic models can be extrapolated to a watershed level. Study habitat connectivity needs such as the proximity of breeding sites and other suitable habitats along a waterway necessary to maintain gene flow and functioning meta-population dynamics.

Habitat Restoration and Watershed Management

Remove or update physical barriers like dams and poorly constructed culverts and bridges to improve connectivity and natural stream processes. Remove anthropogenic features that support introduced predators and competitors such as abandoned mine tailing ponds that support bullfrog breeding. Conduct active eradication and management efforts to decrease the abundance of bullfrogs, non-native fish, and crayfish (where they are non-native). In managed rivers, manipulate stream flows to negatively affect non-native species not adapted to a winter flood/summer drought flow regime.

Adopt a multi-species approach to channel restoration projects and managed flow regimes (thermal, velocity, timing) and mimic the natural hydrograph to the greatest extent possible. When this is impractical or infeasible, focus on minimizing adverse impacts by gradually ramping discharge up and down, creating and maintaining gently sloping and sun-lit gravel bars and warm calm edgewater habitats for tadpole rearing, and mixing hypolimnetic water (from the lower colder stratum in a reservoir) with warmer surface water before release if necessary to ensure appropriate thermal conditions for successful metamorphosis. Promote restoration and maintenance of habitat heterogeneity (different depths, velocities, substrates, etc.) and connectivity to support all life stages and gene flow. Avoid damaging Foothill Yellow-legged Frog breeding habitat when restoring habitat for other focal species like anadromous salmonids.

Regulatory Considerations and Best Management Practices

Develop range-wide minimum summer baseflow requirements that protect Foothill Yellow-legged Frogs and their habitat with appropriate provisions to address regional differences using new more ecologically-meaningful approaches such as modified percent-of-flow strategies for watersheds (e.g., Mierau et al. 2018). Limit water diversions during the dry season and construction of new dams by focusing on off-stream water storage strategies.

Ensure and improve protection of riparian systems. Require maintenance of appropriate riparian buffers and canopy coverage (i.e., partly shaded) around occupied habitat or habitat that has been identified for potential future reintroductions. Restrict instream work to dry periods where possible. Prohibit fording in and around breeding habitat. Avoid working near streams after the first major rains in the fall when Foothill Yellow-legged Frogs may be moving upslope toward tributaries and overwintering sites. Use a 3 mm (0.125 in) mesh screen on water diversion pumps and limit the rate and amount of water diverted such that depth and flow remain sufficient to support Foothill Yellow-legged Frogs of all life stages occupying the immediate area and downstream. Install exclusion fencing where appropriate, and if Foothill Yellow-legged Frog relocation is required, conduct it early in the season because moving egg masses is easier than moving tadpoles.

Reduce habitat degradation from sedimentation, pesticides, herbicides, and other non-point source waste discharges from adjacent land uses including along tributaries of rivers and streams. Limit mining to parts of rivers not used for oviposition, such as deeper pools or reaches with few tributaries, and at times of year when frogs are more common in tributaries (i.e., fall and winter). Manage recreational activities in or adjacent to Foothill Yellow-legged Frog habitat (e.g., OHV and hiking trails, camp sites, boating ingress/egress, flows, and speeds) in a way that minimizes adverse impacts. Siting cannabis grows in areas with better access to roads, gentler slopes, and ample water resources could significantly reduce threats to the environment. Determine which, when, and where agrochemicals should be restricted to reduce harm to Foothill Yellow-legged Frogs and other species. Ensure all new road crossings and upgrades to existing crossings (bridges, culverts, fills, and other crossings) accommodate at least 100-year flood flows and associated bedload and debris.

Partnerships and Coordination

Establish collaborative partnerships with agencies, universities, and non-governmental organizations working on salmon and steelhead recovery and stream restoration. Anadromous salmonids share many of the same threats as Foothill Yellow-legged Frogs, and recovery actions such as barrier removal, restoration of natural sediment transport processes, reduction in pollution, and eradication of non-native predators would benefit frogs as well. Ensure Integrated Regional Water Management Plans and fisheries restoration programs take Foothill Yellow-legged Frog conservation into consideration during design, implementation, and maintenance.

Encourage local governments to place conditions on new developments to minimize negative impacts on riparian systems. Promote and implement initiatives and programs that improve water conservation use efficiency, reduce greenhouse gas emissions, promote sustainable agriculture and smart urban growth, and protect and restore riparian ecosystems. Shift reliance from on-stream storage to off-stream storage, resolve frost protection issues (water withdrawals), and ensure necessary flows for all life stages in all water years.

Establish a Department-coordinated staff and citizen scientist program to systematically monitor occupied stream reaches across the species' range.

Education and Enforcement

Support programs to provide educational outreach and local involvement in restoration and watershed stewardship, such as Project Wild, Adopt a Watershed, school district environmental camps, and other programs teaching the effects of human land and water use on Foothill Yellow-legged Frog survival.

Provide additional funding for increased law enforcement to reduce ecologically harmful stream alterations and water pollution and to ensure adequate protection for Foothill Yellow-legged Frogs at pumps and diversions. Identify and address illegal water diverters and out-of-compliance diverters, seasons of diversion, off-stream reservoirs, well pumping, and bypass flows to protect Foothill Yellow-legged Frogs. Prosecute violators accordingly.

ECONOMIC CONSIDERATIONS

The Department is charged in an advisory capacity in the present context to provide a written report and a related recommendation to the Commission based on the best scientific information available regarding the status of Foothill Yellow-legged Frog in California. The Department is not required to prepare an analysis of economic impacts (See Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

California Fish and Game Commission

Staff Report on Staff Time Allocation and Activities

September 30, 2019

Commission staff time is a tangible and invaluable asset. Especially since the Commission's staff is so small, where and how staff members spend their time is important. This report identifies where Commission staff allocated time to general activity categories (see table; sample tasks for each general category begin on the next page) and to specific activities during August and September 2019.

The general allocation table summarizes time across all staff classifications, though some classifications require a greater emphasis on certain task categories than others. For example, advisors can spend 30% or more of their time on special projects due to committee project assignments, while regulatory analysts spend up to 70% of their time on regulatory program tasks. Of note during this reporting period, staff increased its allocation under special projects and administration. For special projects, this represents staff time for specific staff to work on the California Coastal Fishing Communities Project. An increase in the administration category is the result of recruitment and hiring actions for two vacant positions.

General Allocation

Task Category	August Staff Time	September Staff Time
Regulatory Program	15%	15%
Non-Regulatory Program	3%	3%
Commission/Committee Meetings	22%	20%
Legal Matters	3%	5%
External Affairs	5%	7%
Special Projects	8%	11%
Administration	20%	23%
Leave Time	19%	14%
Unfilled Positions	6%	6%
Total Staff Time[1]	101%	104%

[1] *Total staff time is greater than 100% due to overtime*

Activities for August 2019

- Prepared for and conducted two publicly noticed meetings (August 7-8 Fish and Game Commission, August 8 Water Resiliency Listening Session)
- Began preparations for two publicly noticed meetings (September 3 Commission teleconference, September 10 Wildlife Resources Committee)

- Prepared for and conducted bullfrog environmental/animal welfare stakeholder meeting
- Completed service-based budgeting data collection and participated in gap analysis review
- Conducted executive director recruitment
- Conducted joint regulations coordination meeting with California Department of Fish and Wildlife (DFW) Regulations Unit
- Participated in chronic wasting disease task force meeting
- Participated in MPA Statewide Leadership Team *Other Uses Subgroup* meeting
- Participated in DFW Regulations Unit Quarterly Coordination meeting

Activities for September 2019

- Finalized preparations for and conducted two publicly noticed meetings (September 3 Commission teleconference, September 10 Wildlife Resources Committee)
- Began preparations for one two publicly noticed meetings (October 8 Tribal Committee, October 9-10 Commission)
- Prepared for and conducted public outreach activities at 2019 California Native American Day
- Conducted interviews and completed hiring process for seasonal clerk and completed hiring process for executive director
- Prepared for and conducted Tribal Committee workgroup meeting
- Prepared for and conducted stakeholder discussion about draft delta fisheries management policy and potential revisions to Commission Striped Bass Policy
- Prepared for and conducted bullfrog environmental/animal welfare stakeholder meeting
- Participated in the California Natural Resources Agency Directors Convening
- Participated in climate-ready fisheries training
- Participated in fishing research with California Collaborative Fisheries Research Program
- Participated in Red Abalone Fishery Management Plan Project Team and Administrative Team meetings
- Participated in MPA Statewide Leadership Team *Other Uses Subgroup* meetings
- Participated in conference on the ocean's role in sustainable food production
- Participated in DFW Joint Leadership Team meeting

General Allocation Categories with Sample Tasks

Regulatory Program

- Coordination meetings with DFW to develop timetables and notices
- Prepare and file notices, re-notices, and initial/final statements of reasons
- Prepare administrative records
- Track and respond to public comments
- Consult, research and respond to inquiries from the Office of Administrative Law

Non-Regulatory Program

- DFW partnership, including joint development of management plans and concepts
- Process and analyze non-regulatory requests
- Develop, review and amend Commission policies
- Research and review adaptive management practices
- Review and process California Endangered Species Act petitions

Commission/Committee Meetings and Support

- Research and compile subject-specific information
- Review and develop policies
- Develop and distribute meeting agendas and materials
- Agenda and debrief meetings
- Prepare meeting summaries, audio files and voting records
- Research and secure meeting venues
- Develop and distribute after-meeting memos/letters
- Make travel arrangements for staff and commissioners
- Conduct onsite meeting management
- Process submitted meeting materials
- Provide commissioner support (expense claims, office hours, etc.)
- Process and analyze regulatory petitions

Legal Matters

- Public Records Act requests
- Process appeals and accusations
- Process requests for permit transfers
- Process kelp and state water bottom leases
- Litigation
- Prepare administrative records

External Affairs

- Engage and educate legislators, monitor legislation
- Maintain state, federal and tribal government relations
- Correspondence
- Respond to public inquiries
- Website maintenance

Special Projects

- Coastal Fishing Communities
- Fisheries Bycatch Workgroup
- Streamline routine regulatory actions
- Strategic planning
- Aquaculture best management practices
- Website transition
- Service Based Budgeting Initiative

Administration

- Staff training and development
- Purchases and payments
- Contract management
- Personnel management
- Budget development and tracking
- Health and safety oversight
- Internal processes and procedures
- Document archival

Leave Time

- Holidays
- Sick leave
- Vacation or annual leave
- Jury duty
- Bereavement

Unfilled

- Deputy executive director
- Seasonal clerk

Department of Fish & Wildlife Legislative Report

September 2019

(as of September 30, 2019 at 9:00 a.m.)

AB 44 (**Friedman** D) **Fur products: prohibition.**
Introduced: 12/3/2018
Last Amend: 9/6/2019
Status: 9/20/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/20/2019-A. ENROLLED
Summary: Would make it unlawful to sell, offer for sale, display for sale, trade, or otherwise distribute for monetary or nonmonetary consideration a fur product, as defined, in the state. The bill would also make it unlawful to manufacture a fur product in the state for sale. The bill would exempt from these prohibitions used fur products, as defined, fur products used for specified purposes, and any activity expressly authorized by federal law. The bill would require a person that sells or trades any fur product exempt from this prohibition to maintain records of each sale or trade of an exempt fur product for at least one year, except as provided.

AB 202 (**Mathis** R) **Endangered species: conservation: California State Safe Harbor Agreement Program Act.**
Introduced: 1/14/2019
Last Amend: 2/26/2019
Status: 7/10/2019-Failed Deadline pursuant to Rule 61(a)(10). (Last location was N.R. & W. on 4/24/2019)(May be acted upon Jan 2020)
Location: 7/10/2019-S. 2 YEAR
Summary: Would delete the January 1, 2020, repeal date of the California State Safe Harbor Agreement Program Act, thereby extending the operation of the act indefinitely. Because submission of false, inaccurate, or misleading information on an application for a state safe harbor agreement under the act would be a crime, this bill would extend the application of a crime, thus imposing a state-mandated local program.

AB 231 (**Mathis** R) **California Environmental Quality Act: exemption: recycled water.**
Introduced: 1/17/2019
Status: 5/9/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was NAT. RES. on 2/7/2019)(May be acted upon Jan 2020)(Recorded 4/26/2019)
Location: 2/7/2019-A. 2 YEAR
Summary: Would exempt from CEQA a project to construct or expand a recycled water pipeline for the purpose of mitigating drought conditions for which a state of emergency was proclaimed by the Governor if the project meets specified criteria. Because a lead agency would be required to determine if a project qualifies for this exemption, this bill would impose a state-mandated local program. The bill would also exempt from CEQA the development and approval of building standards by state agencies for recycled water systems.

AB 243 (**Kamlager-Dove** D) **Implicit bias training: peace officers.**
Introduced: 1/18/2019
Last Amend: 4/22/2019
Status: 8/30/2019-Failed Deadline pursuant to Rule 61(a)(12). (Last location was APPR. SUSPENSE FILE on 8/12/2019)(May be acted upon Jan 2020)

Location: 8/30/2019-S. 2 YEAR
Summary: Current law requires every peace officer to participate in expanded training prescribed by the Commission on Peace Officer Standards and Training that includes and examines evidence-based patterns, practices, and protocols that make up racial and identity profiling, including implicit bias. Once basic training is completed, current law requires specified peace officers to complete a refresher course on racial and identity profiling at least every 5 years. This bill would require those peace officers currently required to take the refresher course every 5 years, and additional peace officers, as specified, to instead take refresher training on racial and identity profiling, including the understanding of implicit bias and the promotion of bias-reducing strategies, at least every 2 years.

AB 255 **(Limón D) Coastal resources: oil spills: grants.**
Introduced: 1/23/2019
Status: 7/12/2019-Approved by the Governor. Chaptered by Secretary of State - Chapter 84, Statutes of 2019.
Location: 7/12/2019-A. CHAPTERED
Summary: The Lempert-Keene-Seastrand Oil Spill Prevention and Response Act authorizes the administrator for oil spill response to offer grants to a local government with jurisdiction over or directly adjacent to waters of the state to provide oil spill response equipment to be deployed by a certified local spill response manager, as provided.This bill would provide that Native American tribes and other public entities are also eligible to receive those grants.

AB 256 **(Aguiar-Curry D) Wildlife: California Winter Rice Habitat Incentive Program.**
Introduced: 1/23/2019
Last Amend: 9/3/2019
Status: 9/24/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/24/2019-A. ENROLLED
Summary: Current law requires the lessees of the rice lands to have the owners of record execute the contracts and defines "productive agricultural rice lands that are winter-flooded" for these purposes. Current law requires each contract to include, among other things, an agreement by the owner and any lessee to restore, enhance, and protect the waterfowl habitat character of the described land. This bill would no longer require the lessees of the rice lands to have the owners of record execute the contracts and would revise the definition of "productive agricultural rice lands that are winter-flooded." The bill would revise that agreement to instead require an agreement by the owner or the lessee to restore, enhance, and protect the waterfowl habitat character of an established number of acres of described land that may be annually rotated provided that the minimum contracted acreage amount is achieved for each of the contracted winter flooding seasons.

AB 273 **(Gonzalez D) Fur-bearing and nongame mammals: recreational and commercial fur trapping: prohibition.**
Introduced: 1/24/2019
Last Amend: 3/5/2019
Status: 9/4/2019-Approved by the Governor. Chaptered by Secretary of State - Chapter 216, Statutes of 2019.
Location: 9/4/2019-A. CHAPTERED
Summary: Would prohibit the trapping of any fur-bearing mammal or nongame mammal for purposes of recreation or commerce in fur and would prohibit the sale of the raw fur of any fur-bearing mammal or nongame mammal otherwise lawfully taken pursuant to the Fish and Game Code or regulations adopted pursuant to that code. Because a violation of these provisions would be a crime, this bill would impose a state-mandated local program. The bill would also make other conforming changes.

AB 284 **(Frazier D) Junior hunting licenses: eligibility: age requirement.**
Introduced: 1/28/2019
Status: 5/17/2019-Failed Deadline pursuant to Rule 61(a)(5). (Last location was APPR. SUSPENSE FILE on 4/3/2019)(May be acted upon Jan 2020)

Location: 5/17/2019-A. 2 YEAR
Summary: Current law requires the Department of Fish and Wildlife to issue various types of hunting licenses, including a discounted hunting license known as a junior hunting license, upon payment of a certain fee from an eligible applicant. Current law, until July 1, 2020, expands the eligibility for a junior hunting license from persons who are under 16 years of age on July 1 of the licensing year to persons who are under 18 years of age on July 1 of the licensing year, as specified, and makes conforming changes related to that expanded eligibility. This bill would extend, this expanded eligibility, for a junior hunting license indefinitely.

AB 286 **(Bonta D) Taxation: cannabis.**
Introduced: 1/28/2019
Last Amend: 4/3/2019
Status: 5/16/2019-In committee: Held under submission.
Location: 5/1/2019-A. APPR. SUSPENSE FILE
Summary: The Control, Regulate and Tax Adult Use of Marijuana Act imposes duties on the Bureau of Cannabis Control in the Department of Consumer Affairs, the Department of Food and Agriculture, and the State Department of Public Health with respect to the creation, issuance, denial, suspension and revocation of commercial cannabis licenses, and imposes an excise tax commencing January 1, 2018, on the purchase of cannabis and cannabis products at the rate of 15% of the average market price of any retail sale by a cannabis retailer. Commencing January 1, 2018, AUMA also imposes a cultivation tax upon all cultivators on all harvested cannabis that enters the commercial market, at specified rates per dry-weight ounce of cannabis flowers and leaves. This bill would reduce that excise tax rate to 11% on and after the operative date of this bill until July 1, 2022, at which time the excise tax rate would revert back to 15%.

AB 298 **(Mathis R) Housing: home purchase assistance program: first responders: Legislative Analyst: study and report.**
Introduced: 1/28/2019
Status: 5/3/2019-Failed Deadline pursuant to Rule 61(a)(3). (Last location was H. & C.D. on 2/15/2019)(May be acted upon Jan 2020)
Location: 5/3/2019-A. 2 YEAR
Summary: Would require the Legislative Analyst to conduct a study, and present the findings thereof to the Legislature, to inform the creation of a low-interest loan program for first responders. The bill would require the report to be submitted on or before January 1, 2024. The bill would require the report to include a recommendation as to which state department is best suited to administer the program, an estimation of the amount of funding that would be necessary to conduct the program, and recommendations for qualifications for participation in the program.

AB 312 **(Cooley D) State government: administrative regulations: review.**
Introduced: 1/29/2019
Status: 5/17/2019-Failed Deadline pursuant to Rule 61(a)(5). (Last location was APPR. SUSPENSE FILE on 4/3/2019)(May be acted upon Jan 2020)
Location: 5/17/2019-A. 2 YEAR
Summary: Would require each state agency to, on or before January 1, 2022, review its regulations, identify any regulations that are duplicative, overlapping, inconsistent, or out of date, revise those identified regulations, as provided, and report its findings and actions taken to the Legislature and Governor, as specified. The bill would repeal these provisions on January 1, 2023.

AB 352 **(Garcia, Eduardo D) Wildfire Prevention, Safe Drinking Water, Drought Preparation, and Flood Protection Bond Act of 2020.**
Introduced: 2/4/2019
Last Amend: 8/14/2019
Status: 8/14/2019-From committee chair, with author's amendments: Amend, and re-refer to committee. Read second time, amended, and re-referred to Com. on EQ.

Location: 8/14/2019-S. E.Q.
Summary: Would enact the Wildfire Prevention, Safe Drinking Water, Drought Preparation, and Flood Protection Bond Act of 2020, which, if approved by the voters, would authorize the issuance of bonds in the amount of $3,920,000,000 pursuant to the State General Obligation Bond Law to finance a wildlife prevention, safe drinking water, drought preparation, and flood protection program.The bill would provide for the submission of these provisions to the voters at the November 3, 2020, statewide general election.The bill would provide that its provisions are severable.

AB 392 (Weber D) **Peace officers: deadly force.**
Introduced: 2/6/2019
Last Amend: 5/23/2019
Status: 8/19/2019-Approved by the Governor. Chaptered by Secretary of State - Chapter 170, Statutes of 2019.
Location: 8/19/2019-A. CHAPTERED
Summary: Would redefine the circumstances under which a homicide by a peace officer is deemed justifiable to include when the officer reasonably believes, based on the totality of the circumstances, that deadly force is necessary to defend against an imminent threat of death or serious bodily injury to the officer or to another person, or to apprehend a fleeing person for a felony that threatened or resulted in death or serious bodily injury, if the officer reasonably believes that the person will cause death or serious bodily injury to another unless the person is immediately apprehended.

AB 394 (Obernolte R) **California Environmental Quality Act: exemption: egress route projects: fire safety.**
Introduced: 2/6/2019
Last Amend: 9/6/2019
Status: 9/23/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/23/2019-A. ENROLLED
Summary: Would, until January 1, 2025, exempt from CEQA egress route projects undertaken by a public agency that are specifically recommended by the State Board of Forestry and Fire Protection that improve the fire safety of an existing subdivision if certain conditions are met. The bill would require the lead agency to hold a noticed public meeting to hear and respond to public comments before determining that a project is exempt. The bill would require the lead agency, if it determines that a project is not subject to CEQA and approves or carries out that project, to file a notice of exemption with the Office of Planning and Research and with the clerk of the county in which the project will be located.

AB 430 (Gallagher R) **Housing development: Camp Fire Housing Assistance Act of 2019.**
Introduced: 2/7/2019
Last Amend: 8/27/2019
Status: 9/11/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/11/2019-A. ENROLLED
Summary: Current law authorizes a development proponent to submit an application for a development permit that is subject to a streamlined, ministerial approval process and not subject to a conditional use permit if the development satisfies specified objective planning standards, including that the development is a multifamily housing development that contains 2 or more residential units. This bill would authorize a development proponent to submit an application for a residential development, or mixed-use development that includes residential units with a specified percentage of space designated for residential use, within the territorial boundaries or a specialized residential planning area identified in the general plan of, and adjacent to existing urban development within, specified cities that is subject to a similar streamlined, ministerial approval process and not subject to a conditional use permit if the development satisfies specified objective planning standards.

AB 431 **(Gallagher R) California Environmental Quality Act: exemptions: projects in Town of Paradise and Butte County.**
Introduced: 2/7/2019
Last Amend: 3/19/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was NAT. RES. on 2/15/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-A. 2 YEAR
Summary: Would exempt from CEQA projects or activities related to the provision of sewer treatment or water service to the Town of Paradise or related to the improvement of evacuation routes in the Town of Paradise. The bill would also exempt from CEQA projects or activities undertaken by the Paradise Irrigation District related to the provision of water service.

AB 441 **(Eggman D) Water: underground storage.**
Introduced: 2/11/2019
Last Amend: 3/27/2019
Status: 5/17/2019-Failed Deadline pursuant to Rule 61(a)(5). (Last location was APPR. SUSPENSE FILE on 4/24/2019)(May be acted upon Jan 2020)
Location: 5/17/2019-A. 2 YEAR
Summary: Under current law, the right to water or to the use of water is limited to that amount of water that may be reasonably required for the beneficial use to be served. Current law provides for the reversion of water rights to which a person is entitled when the person fails to beneficially use the water for a period of 5 years. Current law declares that the storing of water underground, and related diversions for that purpose, constitute a beneficial use of water if the stored water is thereafter applied to the beneficial purposes for which the appropriation for storage was made. This bill would instead provide that any diversion of water to underground storage constitutes a diversion of water for beneficial use for which an appropriation may be made if the diverted water is put to beneficial use, as specified.

AB 448 **(Garcia, Eduardo D) Water rights: stockponds.**
Introduced: 2/11/2019
Last Amend: 4/3/2019
Status: 5/17/2019-Failed Deadline pursuant to Rule 61(a)(5). (Last location was APPR. SUSPENSE FILE on 4/24/2019)(May be acted upon Jan 2020)
Location: 5/17/2019-A. 2 YEAR
Summary: Would provide that the owner of a stockpond built prior to January 1, 2019, that does not have a capacity greater than 10 acre-feet may obtain a right to appropriate water for the principal purpose of watering livestock if that person files a claim for a water right with the State Water Resources Control Board accompanied by a fee not later than December 31, 2021, with certain exceptions. Upon the issuance of a certificate by the board for an appropriation of water obtained under the bill's provisions, the bill would require the board to provide in writing conditions to which the appropriation is subject.

AB 454 **(Kalra D) Migratory birds: California Migratory Bird Protection Act.**
Introduced: 2/11/2019
Last Amend: 5/16/2019
Status: 9/27/2019-Signed by the Governor
Location: 9/27/2019-A. CHAPTERED
Summary: The California Migratory Bird Protection Act, would instead, until January 20, 2025, make unlawful the taking or possession of any migratory nongame bird designated in the federal act before January 1, 2017, any additional migratory nongame bird that may be designated in the federal act after that date, or any part of those migratory nongame birds, except as provided by rules and regulations adopted by the United States Secretary of the Interior under the federal act before January 1, 2017, or subsequent rules or regulations adopted pursuant to the federal act, unless those rules or regulations are

inconsistent with the Fish and Game Code. This bill contains other related provisions and other existing laws.

AB 467 (**Boerner Horvath** D) **Competitions on state property: prize compensation: gender equity.**
Introduced: 2/11/2019
Last Amend: 6/14/2019
Status: 9/9/2019-Approved by the Governor. Chaptered by Secretary of State - Chapter 276, Statutes of 2019.
Location: 9/9/2019-A. CHAPTERED
Summary: Would require the Department of Parks and Recreation, the State Lands Commission and the California Coastal Commission to include in permit or lease conditions, for a competition event to be held on land under the jurisdiction of the entity, as described, and that awards prize compensation, as defined, to competitors in gendered categories, a requirement that the prize compensation be identical between the gendered categories at each participant level.

AB 527 (**Voepel** R) **Importation, possession, or sale of endangered wildlife.**
Introduced: 2/13/2019
Last Amend: 4/22/2019
Status: 6/4/2019-Failed Deadline pursuant to Rule 61(a)(8). (Last location was APPR. on 4/23/2019)
Location: 6/4/2019-A. 2 YEAR
Summary: Would delay the commencement of the prohibition on importing into the state for commercial purposes, possessing with intent to sell, or selling within the state, the dead body, or a part or product thereof, of a crocodile or alligator until January 1, 2030. The bill would also require a specified disclosure on all products sold in the state prior to January 1, 2030, failure to do so being punishable as a misdemeanor. By creating a new crime, this bill would impose a state-mandated local program.

AB 559 (**Arambula** D) **Millerton Lake State Recreation Area: acquisition of land.**
Introduced: 2/13/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was W.,P. & W. on 2/25/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-A. 2 YEAR
Summary: Would require the Department of Parks and Recreation to effectively manage lands currently within its jurisdiction in the Millerton Lake State Recreation Area adjacent to the San Joaquin River, and would authorize the department to enter into an agreement with the conservancy to manage lands acquired by the conservancy adjacent to the state recreation area, as specified.

AB 584 (**Gallagher** R) **Sport fishing licenses.**
Introduced: 2/14/2019
Status: 5/3/2019-Failed Deadline pursuant to Rule 61(a)(3). (Last location was PRINT on 2/14/2019)(May be acted upon Jan 2020)
Location: 5/3/2019-A. 2 YEAR
Summary: Current law requires every person 16 years of age or older who takes any fish, reptile, or amphibian for any purpose other than profit to first obtain a sport fishing license for that purpose, with specified exceptions, and to have that license on their person or in their immediate possession when engaged in carrying out any activity authorized by the license. This bill would make nonsubstantive changes to this provision.

AB 658 (**Arambula** D) **Water rights: water management.**
Introduced: 2/15/2019
Last Amend: 7/11/2019
Status: 9/24/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/24/2019-A. ENROLLED

Summary: Would authorize a groundwater sustainability agency or local agency to apply for, and the State Water Resources Control Board to issue, a conditional temporary permit for diversion of surface water to underground storage for beneficial use that advances the sustainability goal of a groundwater basin, as specified. This bill contains other related provisions and other existing laws.

AB 719 **(Rubio, Blanca D) Endangered wildlife: crocodiles and alligators.**
Introduced: 2/19/2019
Last Amend: 8/13/2019
Status: 8/30/2019-Failed Deadline pursuant to Rule 61(a)(12). (Last location was APPR. SUSPENSE FILE on 8/19/2019)(May be acted upon Jan 2020)
Location: 8/30/2019-S. 2 YEAR
Summary: Current law makes it a misdemeanor to import into the state for commercial purposes, to possess with intent to sell, or to sell within the state, the dead body, or a part or product thereof, of a polar bear, leopard, ocelot, tiger, cheetah, jaguar, sable antelope, wolf, zebra, whale, cobra, python, sea turtle, colobus monkey, kangaroo, vicuna, sea otter, free-roaming feral horse, dolphin, porpoise, Spanish lynx, or elephant. This bill would require manufacturers of products that use the hides of crocodiles or alligators, after consultation with the Department of Fish and Wildlife, to submit to the Director of Fish and Wildlife proposals for technologies or processes that allow for the tracking or tracing of the source of origin of crocodile or alligator hides used to manufacture products sold in this state and require humane treatment of farmed crocodiles and alligators, as well as humane slaughtering techniques. The bill would require the director, on or before March 30, 2021, to approve technologies or processes that meet those requirements.

AB 782 **(Berman D) California Environmental Quality Act: exemption: public agencies: land transfers.**
Introduced: 2/19/2019
Last Amend: 5/28/2019
Status: 8/30/2019-Approved by the Governor. Chaptered by Secretary of State - Chapter 181, Statutes of 2019.
Location: 8/30/2019-A. CHAPTERED
Summary: CEQA requires a lead agency to prepare a mitigated negative declaration for a project that may have a significant effect on the environment if revisions in the project would avoid or mitigate that effect and there is no substantial evidence that the project, as revised, would have a significant effect on the environment. This bill ould exempt from CEQA the acquisition, sale, or other transfer of interest in land by a public agency for certain purposes, or the granting or acceptance of funding by a public agency for those purposes.

AB 834 **(Quirk D) Freshwater and Estuarine Harmful Algal Bloom Program.**
Introduced: 2/20/2019
Last Amend: 8/30/2019
Status: 9/27/2019-Signed by the Governor
Location: 9/27/2019-A. CHAPTERED
Summary: Would require the State Water Resources Control Board to establish a Freshwater and Estuarine Harmful Algal Bloom Program to protect water quality and public health from harmful algal blooms. The bill would require the state board, in consultation with specified entities, among other things, to coordinate immediate and long-term algal bloom event incident response, as provided, and conduct and support algal bloom field assessment and ambient monitoring at the state, regional, watershed, and site-specific waterbody scales.

AB 855 **(McCarty D) Department of Justice: law enforcement policies on the use of deadly force.**
Introduced: 2/20/2019
Last Amend: 3/19/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was PUB. S. on 3/18/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-A. 2 YEAR

Summary: Would require the Attorney General to convene a task force, as specified, to study the use of deadly force by law enforcement officers and to develop recommendations, including a model written policy, for law enforcement agencies.

AB 883 **(Dahle R) Fish and wildlife: catastrophic wildfires: report.**
Introduced: 2/20/2019
Status: 5/17/2019-Failed Deadline pursuant to Rule 61(a)(5). (Last location was APPR. SUSPENSE FILE on 4/24/2019)(May be acted upon Jan 2020)
Location: 5/17/2019-A. 2 YEAR
Summary: Would require the Department of Fish and Wildlife, in consultation with the Department of Forestry and Fire Protection, on or before December 31, 2020, and by December 31 each year thereafter, to study, investigate, and report to the Legislature on the impacts on wildlife and wildlife habitat resulting from any catastrophic wildfire, as defined, that occurred during that calendar year, including specified information on a catastrophic wildfire's impact on ecosystems, biodiversity, and protected species in the state.

AB 889 **(Maienschein D) Animal research.**
Introduced: 2/20/2019
Last Amend: 4/1/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was HEALTH on 3/4/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-A. 2 YEAR
Summary: Current law prohibits the keeping or use of animals for diagnostic purposes, education, or research without approval by the State Department of Public Health. Current law authorizes the department to prescribe rules under which persons who wish to keep or use animals for those purposes may obtain approval from the department, and to promulgate regulations governing the use of animals for those purposes. Current law exempts certain persons from those requirements, including persons who use or keep animals for animal training and animal cosmetics, among other things. This bill would define "animal" for purposes of these provisions as any live vertebrate nonhuman animal used for diagnostic purposes, education, or research, as specified.

AB 935 **(Rivas, Robert D) Oil and gas: facilities and operations: monitoring and reporting.**
Introduced: 2/20/2019
Last Amend: 3/21/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was NAT. RES. on 3/21/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-A. 2 YEAR
Summary: Under current law, the Division of Oil, Gas, and Geothermal Resources in the Department of Conservation regulates the drilling, operation, maintenance, and abandonment of oil and gas wells in the state. Current law defines various terms for those purposes, including "production facility. This bill "Would define the term "sensitive production facility" for those purposes to mean a production facility that is located within certain areas, including, among others, an area containing a building intended for human occupancy that is located within 2,500 feet of the production facility.

AB 936 **(Rivas, Robert D) Oil spills: response and contingency planning.**
Introduced: 2/20/2019
Last Amend: 9/6/2019
Status: 9/19/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/19/2019-A. ENROLLED
Summary: Would define "nonfloating oil" for purposes of the Lempert-Keene-Seastrand Oil Spill Prevention and Response Act. The bill would require the administrator to hold, on or before January 1, 2022, a technology workshop that shall include the topic of technology for addressing nonfloating oil spills, and, in fulfilling specified duties, to consider information gained from technology workshops, as well as available scientific and technical literature concerning nonfloating oil spill response technology.

The bill would require the administrator to include in the revision to the California oil spill contingency plan due on or before January 1, 2023, provisions addressing nonfloating oil.

AB 948 **(Kalra D) Coyote Valley Conservation Program.**
Introduced: 2/20/2019
Last Amend: 8/12/2019
Status: 9/27/2019-Signed by the Governor
Location: 9/27/2019-A. CHAPTERED
Summary: Would authorize the authority to establish and administer the Coyote Valley Conservation Program to address resource and recreational goals of the Coyote Valley, as defined. The bill would authorize the authority to collaborate with state, regional, and local partners to help achieve specified goals of the program. The bill would authorize the authority to, among other things, acquire and dispose of interests and options in real property. The bill would require a proponent or party to a certain proposed development project within Coyote Valley to provide notice to the authority of the proposed project, and would authorize the authority to provide analysis of the environmental values and potential impacts of the proposed project. The bill would require Coyote Valley to be acknowledged as an area of statewide significance in local planning documents developed or updated on or after January 1, 2020, affecting land use within Coyote Valley. To the extent that this bill would impose new duties on local entities, it would impose a state-mandated local program. This bill contains other related provisions and other existing laws.

AB 1013 **(Obernolte R) State agencies: grant applications.**
Introduced: 2/21/2019
Last Amend: 8/20/2019
Status: 9/11/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/11/2019-A. ENROLLED
Summary: Current law authorizes various state agencies to award grant money for various purposes.This bill would prohibit a state agency from permitting an evaluator to review a discretionary grant application submitted by an organization or a person for which the evaluator was a representative, voting member, or staff member within the 2-year period preceding receipt of that application.

AB 1040 **(Muratsuchi D) Protection of cetaceans: unlawful activities.**
Introduced: 2/21/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was W.,P. & W. on 3/7/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-A. 2 YEAR
Summary: Current law makes it unlawful to hold in captivity an orca, whether wild caught or captive bred, for any purpose, including for display, performance, or entertainment purposes; to breed or impregnate an orca held in captivity; to export, collect, or import the semen, other gametes, or embryos of an orca held in captivity for the purpose of artificial insemination; or to export, transport, move, or sell an orca located in the state to another state or country. Current law creates certain exceptions to these provisions, including an exception that authorizes an orca located in the state on January 1, 2017, to continue to be held in captivity for its current purpose and, after June 1, 2017, to continue to be used for educational presentations. This bill would expand these provisions to include cetaceans, which the bill would define to mean a whale, dolphin, and porpoise in the order Cetacea.

AB 1117 **(Grayson D) Peace officers: peer support.**
Introduced: 2/21/2019
Last Amend: 9/6/2019
Status: 9/23/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/23/2019-A. ENROLLED
Summary: The California Emergency Services Act also authorizes the governing body of a city, county, city and county, or an official designated by ordinance adopted by that governing body, to proclaim a local emergency, as defined. This bill would enact the Law Enforcement Peer Support and

Crisis Referral Services Program. The bill would authorize a local or regional law enforcement agency to establish a peer support and crisis referral program to provide an agencywide network of peer representatives available to aid fellow employees on emotional or professional issues. The bill would, for purposes of the act, define a "peer support team" as a team composed of law enforcement personnel, as defined, who have completed a peer support training course, as specified.

AB 1149 **(Fong R) California Environmental Quality Act: record of proceedings.**
Introduced: 2/21/2019
Last Amend: 4/23/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was NAT. RES. on 3/25/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-A. 2 YEAR
Summary: CEQA requires a lead agency to prepare a mitigated negative declaration for a project that may have a significant effect on the environment if revisions in the project would avoid or mitigate that effect and there is no substantial evidence that the project, as revised, would have a significant effect on the environment. In an action or proceeding alleging the lead agency violated the act, the act requires the lead agency to prepare and certify the record of proceedings and requires the parties to pay any reasonable costs or fees imposed for the preparation of the record of proceedings, as specified.

AB 1160 **(Dahle R) Forestry: timber operations: sustained yield plans.**
Introduced: 2/21/2019
Last Amend: 4/11/2019
Status: 7/12/2019-Approved by the Governor. Chaptered by Secretary of State - Chapter 108, Statutes of 2019.
Location: 7/12/2019-A. CHAPTERED
Summary: The Z'berg-Nejedly Forest Practice Act of 1973 prohibits a person from conducting timber operations, as defined, unless a timber harvesting plan prepared by a registered professional forester has been submitted to, and approved by, the Department of Forestry and Fire Protection. The act requires the State Board of Forestry and Fire Protection to adopt district forest practice rules and regulations, as provided, and requires a sustained yield plan that is prepared and approved in accordance with these rules and regulations to be effective for a period of no more than 10 years.This bill would instead require the sustained yield plan to be effective for a period of no more than 20 years.

AB 1184 **(Gloria D) Public records: writing transmitted by electronic mail: retention.**
Introduced: 2/21/2019
Last Amend: 8/30/2019
Status: 9/19/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/19/2019-A. ENROLLED
Summary: Would, unless a longer retention period is required by statute or regulation, or established by the Secretary of State pursuant to the State Records Management Act, require a public agency, for purposes of the California Public Records Act, to retain and preserve for at least 2 years every public record, as defined, that is transmitted by electronic mail.

AB 1190 **(Irwin D) Unmanned aircraft: state and local regulation: limitations.**
Introduced: 2/21/2019
Last Amend: 5/1/2019
Status: 6/19/2019-Referred to Com. on RLS.
Location: 5/24/2019-S. RLS.
Summary: Would, among other things, prohibit a state or local agency from adopting any law or regulation that bans the operation of an unmanned aircraft system. The bill would also authorize a local agency to adopt regulations to enforce FAA regulations regarding the operation of unmanned aircraft systems and would authorize local agencies to regulate the operation of unmanned aircraft and unmanned aircraft systems within their jurisdictions, as specified. The bill would also authorize a local

agency to require an unmanned aircraft operator to provide proof of federal, state, or local registration to licensing or enforcement officials.

AB 1197 **(Santiago D) California Environmental Quality Act: exemption: City of Los Angeles: supportive housing and emergency shelters.**
Introduced: 2/21/2019
Last Amend: 9/6/2019
Status: 9/26/2019-Chaptered by Secretary of State- Chapter 340, Statutes of 2019
Location: 9/26/2019-A. CHAPTERED
Summary: The California Environmental Quality Act (CEQA) requires a lead agency, as defined, to prepare, or cause to be prepared, and certify the completion of an environmental impact report on a project that it proposes to carry out or approve that may have a significant effect on the environment or to adopt a negative declaration if it finds that the project will not have that effect. CEQA also requires a lead agency to prepare a mitigated negative declaration for a project that may have a significant effect on the environment if revisions in the project would avoid or mitigate that effect and there is no substantial evidence that the project, as revised, would have a significant effect on the environment. This bill would, until January 1, 2025, exempt from the requirements of CEQA certain activities approved or carried out by the City of Los Angeles and other eligible public agencies, as defined, related to supportive housing and emergency shelters, as defined.

AB 1237 **(Aguiar-Curry D) Greenhouse Gas Reduction Fund: guidelines.**
Introduced: 2/21/2019
Last Amend: 8/13/2019
Status: 9/27/2019-Signed by the Governor
Location: 9/27/2019-A. CHAPTERED
Summary: Current law requires the Department of Finance to annually submit a report to the appropriate committees of the Legislature on the status of the projects funded with moneys from the Greenhouse Gas Reduction Fund. This bill, no later than January 1, 2021, would require an agency that receives an appropriation from the Greenhouse Gas Reduction Fund to post on the internet website of the agency's program from which moneys from the fund are being allocated the guidelines, as specified, for how moneys from the fund are allocated for competitive financing programs, as specified.

AB 1244 **(Fong R) Environmental quality: judicial review: housing projects.**
Introduced: 2/21/2019
Status: 5/3/2019-Failed Deadline pursuant to Rule 61(a)(3). (Last location was NAT. RES. on 3/11/2019)(May be acted upon Jan 2020)
Location: 5/3/2019-A. 2 YEAR
Summary: Would, in an action or proceeding seeking judicial review under the California Environmental Quality Act, prohibit a court from staying or enjoining a housing project for which an environmental impact report has been certified, unless the court makes specified findings.

AB 1254 **(Kamlager-Dove D) Bobcats: take prohibition: hunting season: management plan.**
Introduced: 2/21/2019
Last Amend: 9/5/2019
Status: 9/19/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/19/2019-A. ENROLLED
Summary: Current law authorizes nongame mammals, among other specified species, that are found to be injuring growing crops or other property to be taken at any time or in any manner by specified persons in accordance with the Fish and Game Code and regulations adopted pursuant to that code. Current law authorizes the department to enter into cooperative agreements with any state or federal agency for the purpose of controlling harmful nongame mammals. Current law also authorizes the department to enter into cooperative contracts with the United States Fish and Wildlife Service for the control of nongame mammals. This bill would make it unlawful to hunt, trap, or otherwise take a

bobcat, except under specified circumstances, including under a depredation permit. The bill, upon appropriation of funds by the Legislature for this purpose, commencing January 1, 2025, would authorize the commission to open a bobcat hunting season in any area determined by the commission to require a hunt, as specified.

AB 1260 **(Maienschein D) Endangered wildlife.**
Introduced: 2/21/2019
Last Amend: 4/11/2019
Status: 9/11/2019-Enrolled and presented to the Governor at 3:30 p.m.
Location: 9/11/2019-A. ENROLLED
Summary: Would, commencing January 1, 2022, make it a misdemeanor to import into the state for commercial purposes, to possess with intent to sell, or to sell within the state, the dead body or other part or product of an iguana, skink, caiman, hippopotamus, or a Teju, Ring, or Nile lizard. By creating a new crime, the bill would impose a state-mandated local program.

AB 1305 **(Obernolte R) Junior hunting licenses: eligibility: age requirement.**
Introduced: 2/22/2019
Last Amend: 6/18/2019
Status: 6/19/2019-Withdrawn from committee. Re-referred to Com. on RLS.
Location: 6/19/2019-S. RLS.
Summary: Current law requires the Department of Fish and Wildlife to issue various types of hunting licenses, including a discounted hunting license known as a junior hunting license, upon payment of a certain fee from an eligible applicant. Current law provides that, until July 1, 2020, a person is eligible for a junior hunting license if the person is under 18 years of age on July 1 of the licensing year. Existing law provides that, on and after July 1, 2020, a person is eligible for a junior hunting license if the person is under 16 years of age on July 1 of the licensing year. Current law makes conforming changes to certain other types of hunting licenses as a result of the age change for a junior hunting license. This bill would extend the eligibility for a junior hunting license to a person who is under 18 years of age on July 1 of the licensing year until July 1, 2021.

AB 1387 **(Wood D) Sport fishing licenses: 12-consecutive-month licenses.**
Introduced: 2/22/2019
Last Amend: 5/20/2019
Status: 7/10/2019-Failed Deadline pursuant to Rule 61(a)(10). (Last location was N.R. & W. on 6/12/2019)(May be acted upon Jan 2020)
Location: 7/10/2019-S. 2 YEAR
Summary: Current law requires a resident or a nonresident, 16 years of age or older, upon payment of a specified fee, to be issued a sport fishing license for the period of a calendar year, or, if issued after the beginning of the year, for the remainder thereof. Existing law also requires the issuance of shorter term licenses upon payment of a specified lesser fee. This bill, in addition to sport fishing licenses for the periods specified above, would require a sport fishing license to be issued to a resident or nonresident for the period of 12 consecutive months, upon payment of a fee that is equal to 130% of the fees for issuance of resident or nonresident calendar-year sport fishing licenses, as applicable.

AB 1472 **(Stone, Mark D) California Dungeness Crab Commission.**
Introduced: 2/22/2019
Last Amend: 6/19/2019
Status: 9/15/2019-Failed Deadline pursuant to Rule 61(a)(15). (Last location was INACTIVE FILE on 9/12/2019)(May be acted upon Jan 2020)
Location: 9/15/2019-A. 2 YEAR
Summary: Would create the California Dungeness Crab Commission. The bill would specify the membership, powers, duties, and responsibilities of the commission. The commission would be authorized to approve the payment of a stipend to commission members, as specified. The commission also would be authorized to carry out programs of education, public information, promotion,

marketing, and research relating to Dungeness crab. The bill would authorize the commission to levy an assessment, as specified, on Dungeness crab fishers, as defined, and would authorize the expenditure of those moneys for the purposes of carrying out the commission's powers, duties, and responsibilities, thereby making an appropriation.

AB 1549 (**O'Donnell** D) **Wildlife: deer: Santa Catalina Island: report.**
Introduced: 2/22/2019
Last Amend: 3/21/2019
Status: 5/17/2019-Failed Deadline pursuant to Rule 61(a)(5). (Last location was APPR. SUSPENSE FILE on 4/24/2019)(May be acted upon Jan 2020)
Location: 5/17/2019-A. 2 YEAR
Summary: Would require the Department of Fish and Wildlife to develop, by January 1, 2022, a report, in consultation with other relevant state agencies, local governments, federal agencies, nongovernmental organizations, landowners, and scientific entities, to inform and coordinate management decisions regarding deer on Santa Catalina Island that includes, among other things, estimates of the historic, current, and future deer population on the island and an assessment of the overall health of the deer population on the island.

AB 1561 (**Rubio, Blanca** D) **Endangered wildlife: crocodiles and alligators.**
Introduced: 2/22/2019
Last Amend: 9/6/2019
Status: 9/9/2019-Read second time. Ordered to third reading. Re-referred to Com. on RLS. pursuant to Senate Rule 29.10(c).
Location: 9/9/2019-S. RLS.
Summary: Would delay the commencement of the prohibition on importing into the state for commercial purposes, possessing with intent to sell, or selling within the state, the dead body, or a part or product thereof, of a crocodile or alligator until January 1, 2021.This bill contains other related provisions.

AB 1612 (**Quirk** D) **Department of Fish and Wildlife: Invasive Species Response Fund.**
Introduced: 2/22/2019
Last Amend: 3/28/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was W.,P. & W. on 3/28/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-A. 2 YEAR
Summary: Would establish the Invasive Species Response Fund in the State Treasury and would continuously appropriate money deposited in the fund to the Department of Fish and Wildlife to respond to nonnative vertebrate species invasions in coordination with other relevant government agencies. The bill would require any money received by the department from the federal government for the purpose of controlling and eradicating nonnative vertebrate species to be deposited in the fund.

AB 1657 (**Garcia, Eduardo** D) **Salton Sea: Office of the Salton Sea: Salton Sea Oversight Committee.**
Introduced: 2/22/2019
Status: 7/10/2019-Failed Deadline pursuant to Rule 61(a)(10). (Last location was N.R. & W. on 6/12/2019)(May be acted upon Jan 2020)
Location: 7/10/2019-S. 2 YEAR
Summary: The Salton Sea Restoration Act requires the Secretary of the Natural Resources Agency, in consultation and coordination with the Salton Sea Authority, to lead Salton Sea restoration efforts.This bill would establish an Office of the Salton Sea within the Natural Resources Agency. The bill would require the secretary to establish a Salton Sea Oversight Committee.

AB 1788 (**Bloom** D) **Pesticides: use of anticoagulants.**
Introduced: 2/22/2019
Last Amend: 6/24/2019

Status: 8/30/2019-Failed Deadline pursuant to Rule 61(a)(12). (Last location was APPR. on 7/9/2019)(May be acted upon Jan 2020)
Location: 8/30/2019-S. 2 YEAR
Summary: Current law prohibits the use of any pesticide that contains one or more of specified anticoagulants in wildlife habitat areas, as defined. Current law exempts from this prohibition the use of these pesticides for agricultural activities, as defined. Existing law requires the director, and each county agricultural commissioner under the direction and supervision of the director, to enforce the provisions regulating the use of pesticides. This bill would create the California Ecosystems Protection Act of 2019 and expand this prohibition against the use of a pesticide containing specified anticoagulants in wildlife habitat areas to the entire state.

AB 1798 **(Levine D) California Racial Justice Act: death penalty.**
Introduced: 2/22/2019
Last Amend: 3/21/2019
Status: 5/17/2019-Failed Deadline pursuant to Rule 61(a)(5). (Last location was APPR. SUSPENSE FILE on 5/1/2019)(May be acted upon Jan 2020)
Location: 5/17/2019-A. 2 YEAR
Summary: Would prohibit a person from being executed pursuant to a judgment that was either sought or obtained on the basis of race if the court makes a finding that race was a significant factor in seeking or imposing the death penalty. The bill would provide that a finding that race was a significant factor would include statistical evidence or other evidence that death sentences were sought or imposed significantly more frequently upon persons of one race than upon persons of another race or that race was a significant factor in decisions to exercise preemptory challenges during jury selection.

SB 1 **(Atkins D) California Environmental, Public Health, and Workers Defense Act of 2019.**
Introduced: 12/3/2018
Last Amend: 9/10/2019
Status: 9/27/2019-Vetoed by the Governor. In Senate. Consideration of Governor's veto pending.
Location: 9/27/2019-S. VETOED
Summary: Current state law regulates the discharge of air pollutants into the atmosphere. The Porter-Cologne Water Quality Control Act regulates the discharge of pollutants into the waters of the state. The California Safe Drinking Water Act establishes standards for drinking water and regulates drinking water systems. The California Endangered Species Act requires the Fish and Game Commission to establish a list of endangered species and a list of threatened species, and generally prohibits the taking of those species. This bill would, until January 20, 2025, require specified agencies to take prescribed actions regarding certain federal requirements and standards pertaining to air, water, and protected species, as specified. By imposing new duties on local agencies, this bill would impose a state-mandated local program.

SB 4 **(McGuire D) Housing.**
Introduced: 12/3/2018
Last Amend: 4/10/2019
Status: 4/26/2019-Failed Deadline pursuant to Rule 61(a)(2). (Last location was GOV. & F. on 4/2/2019)(May be acted upon Jan 2020)
Location: 4/26/2019-S. 2 YEAR
Summary: Would authorize a development proponent of a neighborhood multifamily project or eligible transit-oriented development (TOD) project located on an eligible parcel to submit an application for a streamlined, ministerial approval process that is not subject to a conditional use permit. The bill would define a “neighborhood multifamily project” to mean a project to construct a multifamily unit of up to 2 residential dwelling units in a nonurban community, as defined, or up to 4 residential dwelling units in an urban community, as defined, that meets local height, setback, and lot coverage zoning requirements as they existed on July 1, 2019.

SB 19 **(Dodd D) Water resources: stream gages.**
Introduced: 12/3/2018
Last Amend: 6/11/2019
Status: 9/27/2019-Signed by the Governor
Location: 9/27/2019-S. CHAPTERED
Summary: Would require the Department of Water Resources and the State Water Resources Control Board, upon an appropriation of funds by the Legislature, to develop a plan to deploy a network of stream gages that includes a determination of funding needs and opportunities for modernizing and reactivating existing gages and deploying new gages, as specified. The bill would require the department and the board, in consultation with the Department of Fish and Wildlife, the Department of Conservation, the Central Valley Flood Protection Board, interested stakeholders, and, to the extent they wish to consult, local agencies, to develop the plan to address significant gaps in information necessary for water management and the conservation of freshwater species.

SB 34 **(Wiener D) Cannabis: donations.**
Introduced: 12/3/2018
Last Amend: 9/6/2019
Status: 9/18/2019-Enrolled and presented to the Governor at 4 p.m.
Location: 9/18/2019-S. ENROLLED
Summary: Current administrative law prohibits a cannibis retailer licensee from providing free cannabis goods to any person or allowing individuals who are not employed by the retailer to provide free cannabis goods to any person on the licensed premises. Current administrative law provides an exception to this prohibition for specified medicinal retailer and microbusiness licensees to provide access to medicinal cannabis patients who have difficulty accessing medicinal cannabis goods, as specified. This bill, the Dennis Peron and Brownie Mary Act, would similarly authorize, on and after a specified date, licensees that are authorized to make retail sales to provide free cannabis or cannabis products to a medicinal cannabis patient or the patient's primary caregiver if specified requirements are met, including that the cannabis or cannabis products otherwise meet specified requirements of MAUCRSA.

SB 45 **(Allen D) Wildfire Prevention, Safe Drinking Water, Drought Preparation, and Flood Protection Bond Act of 2020.**
Introduced: 12/3/2018
Last Amend: 9/10/2019
Status: 9/10/2019-Senate Rule 29.3(b) suspended. (Ayes 29. Noes 8.) From committee with author's amendments. Read second time and amended. Re-referred to Com. on APPR.
Location: 4/25/2019-S. APPR.
Summary: Would enact the Wildfire Prevention, Safe Drinking Water, Drought Preparation, and Flood Protection Bond Act of 2020, which, if approved by the voters, would authorize the issuance of bonds in the amount of $4,189,000,000 pursuant to the State General Obligation Bond Law to finance projects for a wildfire prevention, safe drinking water, drought preparation, and flood protection program.

SB 50 **(Wiener D) Planning and zoning: housing development: streamlined approval: incentives.**
Introduced: 12/3/2018
Last Amend: 6/4/2019
Status: 6/4/2019-Failed Deadline pursuant to Rule 61(a)(5). (Last location was APPR. SUSPENSE FILE on 5/13/2019)(May be acted upon Jan 2020)
Location: 6/4/2019-S. 2 YEAR
Summary: Would authorize a development proponent of a neighborhood multifamily project located on an eligible parcel to submit an application for a streamlined, ministerial approval process that is not subject to a conditional use permit. The bill would define a "neighborhood multifamily project" to mean a project to construct a multifamily structure on vacant land, or to convert an existing structure that does not require substantial exterior alteration into a multifamily structure, consisting of up to 4

residential dwelling units and that meets local height, setback, and lot coverage zoning requirements as they existed on July 1, 2019.

SB 62 **(Dodd D) Endangered species: accidental take associated with routine and ongoing agricultural activities: state safe harbor agreements.**
Introduced: 1/3/2019
Last Amend: 4/3/2019
Status: 7/30/2019-Approved by the Governor. Chaptered by Secretary of State. Chapter 137, Statutes of 2019.
Location: 7/30/2019-S. CHAPTERED
Summary: The California Endangered Species Act requires the Department of Fish and Wildlife to adopt regulations for the issuance of incidental take permits. The act also provides, until January 1, 2020, that the accidental take of candidate, threatened, or endangered species resulting from an act that occurs on a farm or a ranch in the course of otherwise lawful routine and ongoing agricultural activities is not prohibited by the act. This bill would extend this exception to January 1, 2024, and would limit this exception to an act by a person acting as a farmer or rancher, a bona fide employee of a farmer or rancher, or an individual otherwise contracted by a farmer or rancher.

SB 69 **(Wiener D) Ocean Resiliency Act of 2019.**
Introduced: 1/9/2019
Last Amend: 7/11/2019
Status: 8/30/2019-Failed Deadline pursuant to Rule 61(a)(12). (Last location was APPR. SUSPENSE FILE on 8/21/2019)(May be acted upon Jan 2020)
Location: 8/30/2019-A. 2 YEAR
Summary: Current law requires the Fish and Game Commission to establish fish hatcheries for the purposes of stocking the waters of California with fish, and requires the Department of Fish and Wildlife to maintain and operate those hatcheries. This bill would require the department to develop and implement a plan, in collaboration with specified scientists, experts, and representatives, as part of its fish hatchery operations for the improvement of the survival of hatchery-produced salmon, and the increased contribution of the hatchery program to commercial and recreational salmon fisheries.

SB 85 **(Committee on Budget and Fiscal Review) Public resources: omnibus trailer bill.**
Introduced: 1/10/2019
Last Amend: 6/11/2019
Status: 6/27/2019-Approved by the Governor. Chaptered by Secretary of State. Chapter 31, Statutes of 2019.
Location: 6/27/2019-S. CHAPTERED
Summary: Would require the Controller to continue to annually transfer $30,000,000 from the General Fund, less any amount transferred to the Habitat Conservation Fund from specified accounts and funds, to the Habitat Conservation Fund until June 30, 2030, and would continuously appropriate that amount on an annual basis in the same proportions to the specified entities until July 1, 2030. The bill would also make conforming and nonsubstantive changes.

SB 183 **(Borgeas R) Property: wild animals.**
Introduced: 1/29/2019
Status: 2/6/2019-Referred to Com. on RLS.
Location: 1/29/2019-S. RLS.
Summary: Current law provides that animals that are wild by nature may be the subject of ownership while those animals are living only in specified circumstances.This bill would make nonsubstantive changes to that provision of law.

SB 195 **(Nielsen R) Sierra Nevada Conservancy.**
Introduced: 1/31/2019
Status: 2/13/2019-Referred to Com. on RLS.

Location: 1/31/2019-S. RLS.
Summary: Current law establishes the Sierra Nevada Conservancy and prescribes the functions and duties of the conservancy with regard to the preservation of specified lands in the Sierra Nevada Region, as defined. Current law makes specified findings and declarations relating to the importance and significance of the Sierra Nevada Region and the need to protect, conserve, restore, and enhance lands within the region.This bill would make nonsubstantive changes in those findings and declarations.

SB 198 (**Bates** **R**) **California Environmental Quality Act: historical resources.**
Introduced: 1/31/2019
Status: 2/13/2019-Referred to Com. on RLS.
Location: 1/31/2019-S. RLS.
Summary: CEQA provides that a project may have a significant effect on the environment if the project may cause a substantial adverse change in the significance of a historical resource. This bill would make nonsubstantive changes in the provision relating to historical resources.

SB 226 (**Nielsen** **R**) **Watershed restoration: wildfires: grant program.**
Introduced: 2/7/2019
Last Amend: 7/3/2019
Status: 8/30/2019-Failed Deadline pursuant to Rule 61(a)(12). (Last location was APPR. SUSPENSE FILE on 8/14/2019)(May be acted upon Jan 2020)
Location: 8/30/2019-A. 2 YEAR
Summary: Would, upon appropriation by the Legislature, require the National Resources Agency to develop and implement a watershed restoration grant program, as provided, for purposes of awarding grants to eligible counties, as defined, to assist them with watershed restoration on watersheds that have been affected by wildfire, as specified. The bill would require the agency to develop guidelines for the grant program, as provided. The bill would require an eligible county receiving funds pursuant to the grant program to submit annually to the agency a report regarding projects funded by the grant program, as provided.

SB 230 (**Caballero** **D**) **Law enforcement: use of deadly force: training: policies.**
Introduced: 2/7/2019
Last Amend: 9/3/2019
Status: 9/13/2019-Chaptered by Secretary of State. Chapter 285, Statutes of 2019.
Location: 9/12/2019-S. CHAPTERED
Summary: Would, by no later than January 1, 2021, require each law enforcement agency to maintain a policy that provides guidelines on the use of force, utilizing deescalation techniques and other alternatives to force when feasible, specific guidelines for the application of deadly force, and factors for evaluating and reviewing all use of force incidents, among other things. The bill would require each agency to make their use of force policy accessible to the public. By imposing additional duties on local agencies, this bill would create a state-mandated local program.

SB 243 (**Borgeas** **R**) **San Joaquin River Conservancy.**
Introduced: 2/11/2019
Status: 2/21/2019-Referred to Com. on RLS.
Location: 2/11/2019-S. RLS.
Summary: Current law establishes the San Joaquin River Conservancy and prescribes the functions and responsibilities of the conservancy with regard to the protection and conservation of public lands in the San Joaquin River Parkway, as described. Current law requires the conservancy to administer any funds appropriated to it and any revenue generated by member agencies of the conservancy for the parkway and contributed to the conservancy, and authorizes the conservancy to expend those funds for capital improvements, land acquisitions, or support of the conservancy's operations. This bill would make a nonsubstantive change in that provision requiring the conservancy to administer those funds.

SB 247 **(Dodd D) Wildland fire prevention: vegetation management.**
Introduced: 2/11/2019
Last Amend: 9/3/2019
Status: 9/18/2019-Enrolled and presented to the Governor at 4 p.m.
Location: 9/18/2019-S. ENROLLED
