In response to public comments received during the 15-day comment period, modifications to the proposed regulations were made to the express terms of the regulations. These regulatory text modifications pertain only to sections 830.1, 830.4, 830.5, and 830.6. No changes were made to the other accompanying sections related to Definitions, and Oil Spill Contingency Plans filed concurrently.

Additionally, in response to comments requesting re-evaluation of the economic impacts, OSPR has made modifications to the Economic Impact Assessment within this document, consistent with the Second Revised Economic and Fiscal Impact Statement (form STD 399). This Second Addendum to the Initial Statement of Reasons (ISOR) provides statements of necessity for new regulatory provisions and other clarifying statements only for those changes made after the 15-day comment period (from January 16, 2021 to February 1, 2021).

Pursuant to Government Code section 11347.1, OSPR is providing public notice of this Second Addendum to the ISOR and Second Revised Economic and Fiscal Impact Statement (STD 399), for an additional 15 calendar days.

Revisions to Section 830.1 – Purpose, Scope, and Applicability

Subsection (a)(4)

The word “planning” is inserted to clarify that these regulations establish planning standards.

Revisions to Section 830.4 – On-Scene Requirements

Subsections (a)(1)(A)1., (a)(2)(A)1., and (a)(3)(A)1. establish the time frames by which initial response personnel must be capable of arriving on scene, while subsections
(a)(1)(B)1., (a)(2)(B)1., and (a)(3)(B)1. establish these time frames for cascading response personnel. The original express terms of the regulatory text specified these time frames as within “eight hours of being notified of a spill” and “24 hours of being notified of a spill” for initial and cascading response personnel, respectively. The language describing the origin time from which these time frames are measured is amended from being “notified of a spill” to being “activated” in each of the subsections listed above. This description is more precise than the original language because spill management personnel may be notified of an incident without being requested to mobilize by a plan holder, qualified individual, or an incident commander or unified command. This change is also consistent with language used in the regulatory definition of Qualified Individual (Title 14, California Code of Regulations section 790), whose duties include “activating and engaging…certified spill management teams.”

Revisions to Section 830.5 – Training and Experience Requirements

Subsection (e)(3)

This subsection is amended to specify that spill management teams drawing upon a larger number of initial response personnel than required by subsections 830.4(a)(1)(A), (a)(2)(A), and (a)(3)(A) must only ensure that the minimum number of personnel perform their incident command system position(s) at a spill or exercise in California at least every three years. This amendment is consistent with the analogous provision in 830.5(i)(5) describing the requirements for cascading response personnel to perform their positions in California.

Subsections (f)(3), (g)(3), and (h)(5)

These subsections are removed because existing laws require incident commanders assuming control of operations to stop and contain an oil spill to have the training specified in these subsections. Because initial response personnel are required to include an incident commander, this training is addressed by subsection 830.5(d), which requires spill management personnel to have all health and safety training required by law according to their position, function, and exposure.

Section 830.6 – Exercise Objectives Required for Full Certification

Subsection (a)(2)(D)

“Form ICS 201” was adjusted to “ICS Form 201” for consistency with other OSPR regulations.

Subsections (b)(1), (b)(2), and (b)(3)

Subsections 830.6(b)(1), (b)(2), and (b)(3) were updated to state that spill management teams must be able to meet objectives within 10, 16, and 24 hours of being “activated for” a spill or exercise. These adjustments were made to conform with changes made in section 830.4 specifying that on-scene arrival time frames originate from the time that spill management personnel are activated.
Subsection (c)(1)(A)

The examples of supporting documents included in a credit request for a spill or exercises were updated to better reflect the work products associated with the objectives for which the documentation should provide support.

Subsection (c)(2)(A)

The reference to supporting documentation for credit requests is adjusted to more precisely cite to the provision describing the documentation.

Economic Impact Assessment

[Gov. C. section 11346.2(b)(2)(A),(5); 11346.3(a)]

In response to comments received during the first 15-day comment period (January 16, 2021 to February 1, 2021), OSPR has re-evaluated certain aspects of the economic impacts of these regulations and consequently has made modifications to this Economic Impact Assessment beginning on page 11, consistent with the Second Revised Economic and Fiscal Impact Statement (STD 399). These changes are illustrated with single underline for additions and single strikethrough for deletions.

The proposed regulations add new sections 830.1 through 830.11, and make conforming amendments as detailed above. The regulations implement, interpret, and add specificity to the provisions of Government Code sections 8670.29 and 8670.32.

(a) What is the evidence supporting a finding of No Significant Statewide Adverse Economic Impact directly affecting business, including the ability of California businesses to compete with businesses in other states?

These regulations will not have a significant statewide adverse economic impact. Less than 1,100 companies are subject to these requirements, primarily oil producers and certain transporters or handlers of oil, but also a few firms that provide spill management team services. For all combined), the total expected costs are estimated to be $14.234 million per year.

These are not considered “major regulations” because the economic impact assessment concludes that the impacts, summing both costs and benefits, will be less than $50 million dollars annually.

Costs

These regulations establish a certification process for Spill Management Teams (SMTs). SMTs may be external companies under contract, in-house staff, staff affiliated with plan holder companies, or any combination thereof. Certifications are voluntary in that external SMTs may offer their services regardless of whether they are certified. However, owners and operators that are required to have contingency plans must specify a certified SMT in their contingency plans. Hiring a certified external SMT and/or providing training for in-house staff are potential costs to a plan holder.

For the purposes of evaluating private sector cost impacts, we focus on new costs associated with training requirements, because the SMTs should already have experience participating in exercises for contingency plan holders under OSPR’s current
drills and exercise regulations (Title 14 California Code of Regulations sections 820.01 and 820.02). Note that most plan holders already have SMTs, whether internal or external (contracted), as part of their oil spill contingency plan and most of these SMTs already have some level of training and experience. This proposed regulation would require all SMTs listed in contingency plans to become certified, which is accomplished primarily through training and exercise participation, if they will be listed in the contingency plans of plan holders.

External (contracted) firms that provide SMT services will initially bear the cost of meeting the certification requirements in order to be listed in the contingency plans of existing clients. Attaining certification is also an investment on their part because it will create business opportunities. Additionally, some out-of-state SMTs may hire additional staff in California to meet the increased demand from plan holders wanting to maintain compliance with the regulations. The results from the SMT survey conducted by OSPR approximate the annual cost of additional training to be in the range of $40,000 – $50,000. SMTs that choose to hire new personnel could face additional annual costs of approximately $150,000. These costs will then be passed on as increased retainer fees to their clients who are the plan holders, which OSPR approximates as a $2,000 per year increase.

As of 2019, approximately 101 facility SMTs and 18 vessel SMTs operate in California. These SMTs were contacted by the Office of Spill Prevention and Response (OSPR) as part of a survey to ascertain their expected costs from these proposed regulatory requirements. In total, two external (contracted) spill management teams and three plan holders with internal SMTs responded to OSPR’s inquiry. Based on discussions with industry representatives in 2018, the cost of maintaining an SMT contract for a contingency plan holder is approximately $5,000 per year.

Plan holders with internal SMTs are directly impacted by the costs associated with the requirements for personnel and for additional training. Based upon the survey results OSPR received from plan holders in the tier classification with the most intensive personnel and training requirements, we expect the additional annual costs to internal SMTs to be approximately $160,000 for hiring additional personnel to meet the staffing requirements and $250,000 to meet the training requirements of these regulations, for a total of $410,000 in additional annual costs. These projected costs represent an upper limit, since they reflect the most robust training and personnel requirements included in the proposed regulations, and personnel must only take the required incident command system courses once. We do not have analogous cost estimates from plan holders in lower tiers that require fewer trained personnel, but we presume that they will be less.

The impacted plan holders are involved in the production, transport, and distribution of crude oil and refined products, as well as commercial shipping in proximity of state waters. California receives about two-thirds of its oil from out of state (mostly via tankers coming from Alaska or overseas), and a third of its oil from domestic production within California. Most of the domestic production is from inland facilities. Nearly all of the oil consumed in California is refined in the state and then distributed for sale throughout the state. Using the consolidated definition of small business, there are a total of 33 plan holders that qualify as small businesses (i.e., those that are independently owned, not dominant in their field, and have fewer than 100 employees) impacted by these
regulations. Eight of these are oil producers, and 25 are involved in the marine terminal and mobile transfer unit (MTU) business.

In general, businesses from outside of California do not compete with California refineries or transporters (although facilities within California may be owned by a larger corporation based outside of California). Producers do compete on the global market with all oil producers worldwide; however, because they are located locally, they have a strong economic advantage over out-of-state competitors due to minimal transportation costs. All domestic California oil production is consumed within California.

For context, the increased costs incurred by oil production companies associated with the 2018 statewide regulations that required inland facilities meeting applicability requirements to have contingency plans, conduct drills and exercises, and demonstrate financial responsibility (Title 14 California Code of Regulations sections 817.04; 820.02; 791 through 798, respectively) did little to affect their ability to compete with businesses from outside the state. While OSPR does not have data at the individual company level, we can examine the impact across the oil production industry. Annual California crude oil production was approximately 170 million barrels in 2018 (U.S. Energy Information Administration, Annual Crude Oil Production 2018). Assuming a market value of $66.77 per barrel based on the average 2018 value for a barrel of California Midway-Sunset (U.S. Energy Information Administration, California Midway-Sunset Price Data), the value of this annual production was approximately $11.35 billion. The estimated total cost of complying with the 2018 regulations, across all facilities and companies, was $4,090,297 for initial implementation and $2,045,417 per year thereafter.

Assuming the costs of initial implementation were all incurred in the first year, this was 0.036% of the total revenues of oil production in 2018. The ongoing annual cost of $2.045 million would represent about 0.018% of the total revenues of oil production in 2018. If applied to the cost of production, these costs would add $0.024 (about two cents) to the price of a barrel of oil in the first year and $0.012 (about a penny) to the price of a barrel of oil thereafter. Given the normal variability in the price of oil, and the transport price advantage that producers in California have over their overseas competitors (several dollars per barrel), the cost of implementing the 2018 regulations was unlikely to affect their ability to compete with other producers from out of state.

Using a similar analysis for the implementation of these proposed SMT certification regulations, we anticipate that the cost of implementation will be passed along from external SMTs to the plan holders. Our analysis examines the contrast between the potential costs of these regulations to oil producing plan holders with their expected revenues based upon oil production and pricing data and estimates the impact of these costs as a percentage of the producers' revenues. The process of contrasting the projected costs with estimated revenues is repeated for those plan holders who do not produce oil, such as railroads, pipelines, MTUs, marine facilities, and vessel operators.

Tables 1 and 2 below present the 79 on-shore oil-producing companies whose California production exceeded 10,000 barrels in 2018, categorized by volume produced. Because OSPR's contingency planning requirements only apply to facilities that may impact state waters, only 23 of these companies hold contingency plans for oil production facilities in California. The remaining 56 companies either do not have facilities within proximity of state waters or have received an exemption from OSPR. In
order to provide a conservative upper limit for the potential costs imposed by these regulations, our analysis includes all 79 companies whose 2018 production exceeded 10,000 barrels of oil, overestimating the number of impacted production companies by a factor of three. Although 18 of these production plan holders are in the lowest SMT tier and only four are in the highest tier, we performed the analysis using cost estimates for the highest tier classification, which includes 50% more personnel than the lowest tier, as well as more intensive training requirements. As a result of these means of overestimation, our analysis should be considered a robust ceiling for the potential impacts of the estimated cost increase.

Categorizing oil producers by volume produced allows for more accurate cost estimation for larger producers who have designated in-house SMTs, while the smaller firms are expected to retain external (contracted) SMTs as a cost saving measure to avoid the increased expenses for hiring additional SMT staff and providing the required training. Since a vast majority of oil producing plan holders produce over 9,000 barrels a year, the smallest category begins at 10,000 barrels a year, while the largest category is over 10 million barrels a year. Revenues are calculated using a price of $40 per barrel based on the most recent forecast for the 2021 per barrel value of California Midway-Sunset in order to account for the economic downturn caused by the coronavirus pandemic (U.S. Energy Information Administration, Short-Term Energy Outlook). It is important to note that this estimate is lower than the forecasted price of oil for 2022, which the U.S. Energy Information Administration estimates will rise to approximately $50 per barrel in its Short-Term Energy Outlook.

The figures presented in Table 2 are based on the limited feedback OSPR received from industry in the 2019 survey described above. The figures reflect estimated cost increases that production plan holders may incur from training their own staff to meet SMT certification requirements (top production category), retaining an SMT for the first time (second and third categories), or increased SMT retainer fees (bottom three production categories). The cost of an SMT retainer includes compensation for the added training that external SMTs must undergo, as well as the costs to participate in required exercises. Costs are expected to be higher for the top production category as the companies either have in-house SMTs or a combination of in-house and external SMT personnel to meet the requirements of a Tier I certification, and thus are directly paying for labor costs for trained SMT staff. The smaller producers are most likely to have Tier III plans, which require fewer personnel and are more easily covered by a contracted SMT. As mentioned previously, we expect the annual costs to be up to $160,000 for plan holders hiring additional personnel to meet staffing requirements, and $250,000 to meet the training requirements, for a total of $410,000 in annual costs for maintaining an in-house SMT based upon the survey results OSPR received. As noted above, only 23 of the 79 companies included in Tables 1 and 2 are plan holders, so these costs are conservatively overestimated.

</table>
For the purpose of this analysis, based upon the 2019 survey results, we assume that external SMTs will pass on to their clients the increased staffing and training costs they incur to meet the proposed SMT certification requirements by increasing their retainer rates from $5,000 per year to $7,000 per year. Larger production plan holders that maintain their own SMTs may see increased costs associated with additional staffing to meet minimum personnel requirements, or for contracting with external SMTs to compensate for personnel shortfalls. Some production plan holder with an annual production above 500,000 barrels but less than 10 million barrels may elect to contract with an SMT for the first time to meet the requirements and would pay the full retainer cost of $7,000 rather than just the $2,000 increase. The average estimated cost increases for each production category are used to calculate an estimated $1.069 million in total costs for the industry.

While we have no information on the costs of production, we can estimate gross revenues by multiplying the annual production of crude oil by the price of crude oil. We then assumed that all of the costs of the regulations are borne by each company and not passed on to consumers. We compared those costs to the estimated annual revenues to provide a measure of the economic burden of complying with the regulations (Table 2).

For all but the smallest producers (those producing 10,000 barrels to 50,000 barrels of oil per year), the impact of the estimated cost increase of compliance with these regulations is less than 0.1% of their average revenues. The smallest producers would experience a cost increase of 0.21% of their average revenue. The additional cost for most producers, regardless of size, is probably less than that described here, as this analysis assumes only high-end cost estimates. Additionally, producers with in-house SMTs may decide to reduce their costs by hiring external SMTs instead, which eliminates the need to maintain a certified SMT and thus eliminates the associated labor costs.

We also compared these cost increases to the natural volatility in the market that oil producers experience. For all producers, the effect of a $1 per barrel change in the price of crude oil (e.g., from $40 per barrel to $39 per barrel) would have a greater impact than the total maximum estimate of the costs of regulatory compliance (Table 2). To calculate the impact on producers, we divided the cost increases in Table 2 by the average production in Table 1 to calculate the per barrel effect. For producers in the top five production categories the cost of regulatory compliance is equal to or smaller than the impact of a $0.03 drop in the price of a barrel of crude oil, while producers in the lowest category would potentially face an impact similar to an $0.08 drop in the price of a barrel of crude oil. This is well within the daily average variability in the price of crude oil and thus unlikely to affect business decisions.

Other plan holders, such as pipeline operators, railroads, MTUs, marine facilities, and vessels would incur similar cost increases associated with in-house SMT training and personnel requirements or from increased SMT retainer costs. As mentioned above, the cost for an SMT retainer includes compensation for the training that an SMT must undergo, as well as the cost for participating in required exercises. Larger companies which maintain in-house SMTs, such as class I railroads, marine facilities with Tier I plans, and large pipelines, are expected to have costs similar to the those for larger oil producers with in-house SMTs, as they must meet the same training and must hire the
appropriate personnel to meet the staff requirements for their SMTs. Vessels typically
contract with one or two SMTs to cover their fleets. No vessel plans currently retain
more than two SMTs, but in order to capture a conservative upper estimate, we used
the cost increase for maintaining three SMT retainers to generate the estimate in Table
3. It is expected that MTUs will behave as companies contracting with an SMT for
the first time and would thus pay $7,000 annually to retain a new contracted SMT. Marine
facilities that are not in the Tier I category are expected to pay the estimated retainer
increase of $2,000 for their contracted SMT. Class III railroads are expected to pay the
retainer fee increase of $2,000 as well. As with Table 2, the expected cost for
maintaining in-house SMT staff or retaining a contracted SMT are based on the results
of OSPR’s 2019 survey of existing SMTs.

As most of the companies with contingency plans for pipelines, railroads, MTUs, marine
facilities, and vessels are large and have revenues comparable to, if not higher than
those of inland producers, it is reasonable to assume that the economic impacts of the
increased costs to comply with these regulations would be similarly miniscule. An
estimation of the cost increases and impact of those costs on revenues is presented in
Table 3.

</table>
As seen in Table 3, the impact of the expected costs on average revenues is not expected to exceed 0.05% for any operator type. The total expected cost to all rail, pipeline, MTUs, marine facilities, and vessel operators is $13.165 million. Combined with the total expected cost of $1.069 million to oil producers (Table 2), the total expected costs across all impacted plan holders are estimated to be $14.234 million.

Assuming that production plan holders decide to pass the cost of complying with the proposed regulations on to the consumer, the likely outcome would be an increase in gasoline prices, which would primarily impact automobile drivers — but quite insignificantly. To apply this total to the annual cost of driving a car, we assume that the average vehicle is driven 12,000 miles per year, gets 17.5 miles per gallon, and thus requires 686 gallons of gasoline per year. The annual crude production in California was estimated at 170 million barrels in 2018 (U.S. Energy Information Administration, Annual Crude Oil Production 2018). Applying the total cost of compliance for oil producers to the estimated production of 170 million barrels yields a per barrel increase of $0.08 per barrel (8 cents a barrel). A price increase of $0.08 per barrel translates to $0.002 per gallon (1 barrel = 42 gallons). Applied to the 686 gallons needed to drive for a year, this would add $1.37 to the annual gas budget per vehicle.

The total cost to oil producers to adjust their in-house SMT personnel or incur increased contracted SMT retainer fees is expected to be around $1.069 million annually (Table 2). The total cost to railroads, pipelines, mobile transfer units (MTUs), marine facilities, and vessel operators is expected to be around $13.165 million (Table 3). Combined, the total expected costs are estimated to be $14.234 million.

In terms of the size of the businesses impacted, 33 plan holders qualify as small businesses (i.e., those that are independently owned, not dominant in their field, and have fewer than 100 employees) based in California. Eight of these plan holders are producers, five are marine facilities, and 20 are MTUs. Class III railroads and small pipeline operators are excluded due to their nature of having relative monopolies over the infrastructure they provide and often being owned by holding companies, which make them dominant in their fields and not independently owned. This leaves 1,037 “typical” businesses out of the 1,071 total estimated impacted businesses (Table 4).

The eight producers are expected to pay the $2,000 retainer fee increase, for a total expected cost of $16,000. Only one marine facility operator that qualifies as a small business is expected to have a Tier I plan and would be expected to switch to an external SMT for a cost of $7,000, while the four lower tiered marine facility operators that qualify as small businesses are expected to pay the $2,000 retainer increase, for a total expected cost of $15,000. The 20 MTUs that qualify as small businesses are expected to pay the full cost of $7,000 to retain a new external SMT, for a total expected cost of $140,000. Across all industries the total expected cost for small businesses is estimated to be $171,000, with the total expected cost of $14.234 million per year borne by all industry members.

Table 4 presents the total estimated cost increases across all impacted industries and shows each industry’s share of the cost increase. Multiple industries are involved in the production and distribution of oil within California, including production facilities, railroads, vessels, pipeline operators, and MTUs. All of these industries must comply with California regulations for contingency planning. Our analysis assumes that external
SMTs pass along the increased cost associated with complying with these proposed regulations by increasing the retainer fees charged to contingency plan holders, and that plan holders with in-house SMTs will incur increased personnel costs to meet the requirements of the proposed regulations.

The total cost across all industries is expected to be $14.234 million. Despite making up approximately 86% of the firms impacted, vessel owners only bear 38.7% of the total cost to industry. The impact of these costs on an average firm’s revenue can be seen in Tables 2 and 3 within the analysis in section A. Summarizing those results, oil producers would experience cost impacts of less than 0.026% of their average revenues, while operators of railroads, pipelines, MTUs, marine facilities, and vessels would experience cost impacts of less than 0.0009% of their average revenues.

**Benefits**

These regulations will provide benefits to the health and welfare of California residents by ensuring a minimum level of skills and competence to manage a spill in California’s waterways. Training and exercise requirements prepare and test the ability of SMTs to respond to and effectively manage an oil spill. These regulations will benefit the state’s environment and communities by ensuring that oil spill responses are efficiently and competently managed.

We use the large, well-documented 2015 Refugio spill that occurred near the Santa Barbara coast to estimate the benefits using the cost of cleaning up the spill, the potential reduction in the volume spilled (represented as a range of a 1% to 10% reduction), and the annual probability of a large marine spill. For the sake of the analysis, we assume that a 1% reduction in the volume spilled corresponds to a 1% reduction in the costs of the spill.

\[
\text{Benefits per year} = (\text{cost of Refugio spill multiplied by the potential reduction in spill volume from using an SMT}) \times \text{probability of a large marine spill per year.}
\]
There have been two large marine spills above 1,000 barrels since OSPR began collecting spill data in 2008. Thus, the annual probability of a large marine spill occurring between 2008 and 2019, which is the range for the data used in this analysis, is 0.167. The costs for Refugio included $64.5 million in cleanup and response costs (California Oil Spill Response Cost Study, November 2019). It should be noted that these costs do not include figures for third-party claims and the natural resource damage assessment settlement, and thus are a conservative representation of the actual costs associated with the Refugio spill. Using the formula above, we can estimate the annual benefit from a 1% reduction of oil spilled: \( \text{($64,500,000 \times 0.01) \times 0.167 = $107,715 \text{ per year}} \).

Similarly, we can estimate the benefit of a 10% reduction in the volume spilled: \( \text{($64,500,000 \times 0.1) \times 0.38 = $1,077,150 \text{ per year}} \).

Taking the mean of both estimates gives us an average annual benefit of $592,432.50.

We take a similar approach with estimating the benefits from the reduction in the volume of oil spilled during a large inland spill (greater than 1,000 barrels) to water. For the sake of this analysis, we assume the probability based on the six largest (over 1,000 barrels) inland spills to water that were documented by OSPR from 2008 to 2019. This is an annual probability of 0.5. As with the marine spills, we assume that a 1% reduction in the volume spilled corresponds to a 1% reduction in the response costs for the spill. For this analysis, we multiplied response costs by potential spill volume reductions to derive estimated benefits, unlike the case study approach used above, which used cleanup costs for a specific spill for which total cleanup costs are known.

The mean spill size for a large spill over 1,000 barrels during this period was 2,017.94 barrels. OSPR’s certificate of financial responsibility regulations establish inland facilities’ financial responsibility for spill cleanup as a function of a facility’s reasonable worst-case spill volume (RWCS), applying a per barrel amount contingent on the facility’s proximity to state waters designated as either ephemeral, intermittent, or perennial in the National Hydrography Dataset (14 CCR Section 791.7). Facilities potentially impacting intermittent or ephemeral inland waters must demonstrate financial responsibility equating to their reasonable worst-case spill volume times $6,000; and facilities that may impact perennial waters must demonstrate financial responsibility equating to their reasonable worst-case spill volume times $10,000. Based on these figures, an average response cost of $8,000 per barrel is used for our estimation since our analysis does not distinguish among impacts to perennial, intermittent, or ephemeral waters. To derive the average cost of a large inland oil spill we use the following equation:

\[
\text{Benefits per year} = (\text{average large spill volume} \times \text{the potential reduction in spill volume from using an SMT} \times \text{the per barrel response cost of an inland spill}) \times \text{the probability of a large inland spill per year.}
\]

We can estimate a 1% reduction as: \( (2,017.94 \text{ barrels} \times $8,000 \text{ per barrel} \times 0.01) \times 0.5 = $80,717.60 \text{ per year}. \) A 10% reduction can be estimated as: \( (2,017.94 \text{ barrels} \times $8,000 \text{ per barrel} \times 0.1) \times 0.5 = $807,176 \text{ per year}. \) Taking the mean gives us an average benefit of $443,946.80 per year.
Finally, we apply this approach to small (greater than one barrel and less than 1,000 barrels) inland and marine spills, which happen at a much greater frequency. We use the following generalized equation to derive the benefit from the potential reduction in the volume of oil spilled during one of these small spill events:

\[
\text{Benefits per year} = (\text{average small inland or marine spill volume multiplied by the potential reduction in spill volume from using an SMT multiplied by the per barrel response cost of an inland or marine spill}) \times \text{multiplied by the annual average number of small inland or marine spills to water.}
\]

We again utilize the cleanup cost of $12,500 per barrel for marine spills and $8,000 per barrel for inland spills based on OSPR’s current per barrel financial responsibility requirements. We used OSPR’s spill data going back to 2008 to calculate the average number of marine and inland spills greater than 1 barrel and less than 1,000 barrels to derive the annual probability of a small spill occurring, as well the average volume spilled for small marine and inland spills. Between 2008 and 2019 there was an annual average of 88 inland spills to water in the range of 1 – 1,000 barrels, with an average spill volume of 512.82 barrels. During this same period there was an annual average of 32 marine spills to water, with an average spill volume of 244.72 barrels.

Using this information, we can estimate the benefit from a 1% reduction in small inland spill volumes as:

\[
(512.82 \text{ barrels multiplied by 0.01 multiplied by $8,000 per barrel}) \times 88 = $3,610,252.80.
\]

The benefit of a 10% reduction in volume can be estimated as:

\[
(512.82 \text{ barrels multiplied by 0.1 multiplied by $8,000 per barrel}) \times 88 = $36,102,528.00.
\]

Taking the mean yields an estimated benefit of $19,856,390.40.

For marine spills, the estimated benefit from a 1% reduction in small spill volumes is expressed as:

\[
(244.72 \text{ barrels multiplied by 0.01 multiplied by $12,500 per barrel}) \times 32 = $978,880.
\]

The benefit from a 10% reduction to the volume spilled during small marine spills can be estimated as:

\[
(244.72 \text{ barrels multiplied by 0.1 multiplied by $12,500 per barrel}) \times 32 = $9,788,800.
\]

Taking the mean yields an estimated benefit of $5,383,840.

Table 5: Total Estimated Annual Statewide Benefits from Potential Spill Reduction

A 1% reduction in the total annual volume spilled from all spill types listed in Table 5 from the use of certified SMTs would result in a total potential annual benefit of about
$4.78 million. A 10% reduction in the annual volume spilled would result in a potential annual benefit of about $47.78 million. The mean total potential annual benefit from these regulations is about $26.28 million.

OSPR is required by statute to establish regulations certifying that SMTs have the skills and training to effectively manage a response to an oil spill for the benefit of California residents and the environment. These regulations will ensure that all plan holders will have a certified SMT that meets minimum standards for training and qualifications, ability to arrive on-scene, and the number of personnel available. Prior to these regulations, it was both allowable and common for a plan holder to list only two or three personnel with no specific qualifications as their SMT. Although it is difficult to quantify the benefits of having a certified SMT listed in each contingency plan, we expect that these regulations will result in plan holders promptly activating their certified SMTs in the event of a spill, leading to timely and effective spill responses of lesser duration and with minimal impacts to natural resources, the health and welfare of the public, and businesses.

Our analysis assumes that a more efficiently managed oil spill response would lead to modest reductions in the per barrel response and cleanup costs, as these costs tend to grow larger as the duration of the spill response increases. We generalize this approach using the following formula, and adjust the reduction to the per barrel response and cleanup costs for each spill type by 0.1%, 0.5%, and 1% to generate a range of possible outcomes:

Benefits per year = (average spill volume multiplied by the spill's per barrel response cost multiplied by the potential reduction in per barrel response cost from using an SMT) multiplied by the annual probability of a spill event.

We begin by analyzing the benefit to a reduction in the per barrel response and cleanup costs for a large marine spill with a volume greater than 1,000 barrels. There have been two large marine spills above 1,000 barrels since OSPR began collecting spill data in 2008, with an average volume of 1,735.88 barrels. The responsible parties for both of these spills were OSPR plan holders who will be required to have a certified SMT under these regulations. Thus, the annual probability of a large marine spill occurring from 2008 through 2019, which is the range for the data used in this analysis, was 0.167. We utilize a maximum per barrel cleanup and response cost of $12,500 for marine spills, as established in OSPR’s regulations for obtaining a certificate of financial responsibility (14 CCR 791.7). Using the formula above, we can estimate the annual benefit from a 0.1% reduction in the response and cleanup costs: (1,735.88 barrels multiplied by $12,500 per barrel multiplied by 0.001) multiplied by 0.167 per year = $3,623.65 per year.

Similarly, we can estimate the annual benefit of a 0.5% and 1% reduction in the per barrel response and cleanup costs by plugging in 0.005 and 0.01 in place of 0.001 in the previous equation. Doing so yields corresponding annual benefits of $18,118.25 and $36,236.50, respectively.

We take a similar approach with estimating the benefits from the reduction in the response and cleanup costs for a large inland spill (greater than 1,000 barrels) to water. For the sake of this analysis, we assume the probability based on the six largest (over
1,000 barrels) inland spills to water that were documented by OSPR from 2008 to 2019. Only three of those spills had responsible parties with an OSPR contingency plan that would be affected by the proposed SMT regulations, giving us an annual probability of 0.25. As with the marine spills, we assume a range of .01%, 0.5%, and 1% reductions in the response and cleanup costs for the spill.

The mean spill size for a large inland spill over 1,000 barrels with a responsible party regulated by OSPR during this period was 2,353.33 barrels. OSPR’s certificate of financial responsibility regulations establish inland facilities’ financial responsibility for spill cleanup as a function of a facility’s reasonable worst-case spill volume (RWCS), applying a per barrel amount contingent on the facility’s proximity to state waters designated as either ephemeral, intermittent, or perennial in the National Hydrography Dataset (14 CCR 791.7). Inland facilities potentially impacting intermittent or ephemeral inland waters must demonstrate financial responsibility equating to their reasonable worst-case spill volume times $6,000; and facilities that may impact perennial waters must demonstrate financial responsibility equating to their reasonable worst-case spill volume times $10,000. Based on these figures, an average response cost of $8,000 per barrel is used for our estimation since our analysis does not distinguish among impacts to perennial, intermittent, or ephemeral waters.

Utilizing the same generalized annual benefit equation as before, we can estimate a 0.1% reduction in the per barrel response and cleanup costs for large inland spills to water as: $(2,353.33 \text{ barrels multiplied by } $8,000 \text{ per barrel multiplied by } 0.001) \times 0.25 = $4,706.66 \text{ per year.}$ As with the large marine spills, we can plug in 0.005 and 0.01 in the place of 0.001 to get the annual benefits from 0.5% and 1% reductions in cleanup and response costs. Doing so yields annual benefits of $23,533.30 and $47,066.60, respectively.

Finally, we apply this approach to small (greater than one barrel and less than 1,000 barrels) inland and marine spills, which happen at a much greater frequency. We again utilize the cleanup cost of $12,500 per barrel for marine spills and an average response cost of $8,000 per barrel for inland spills based on OSPR’s current per barrel financial responsibility requirements. We used OSPR’s spill data going back to 2008 to calculate the average number of marine and inland spills greater than 1 barrel and less than 1,000 barrels to derive the annual probability of a small spill occurring, as well the average volume spilled for small marine and inland spills. Between 2008 and 2019 there was an annual average of 32 marine spills to water in the range of 1 – 1,000 barrels, with an average spill volume of 244.72 barrels. Of the marine spills for which a responsible party was identified, 33.66% of the responsible parties were OSPR plan holders and therefore would be affected by these regulations, giving us approximately 11 spills per year that would potentially be impacted. During this same period there was an annual average of 88 inland spills to water, with an average spill volume of 512.82 barrels. Of the inland spills to water for which a responsible party was identified, 34.63% of the responsible parties were OSPR plan holders and therefore would be affected by the proposed SMT regulations, giving us approximately 30 spills per year that would potentially be impacted.

Using this information, we can estimate the annual benefit from a 0.1% reduction in the per barrel response and cleanup costs for small marine spills as: $(244.72 \text{ barrels multiplied by } $12,500 \text{ per barrel multiplied by } 0.001) \times 11 = $33,649.$
Plugging in 0.005 and 0.01 in place of 0.001 yields annual benefits of $168,245 and $336,490 for 0.5% and 1% reductions in the per barrel response and cleanup costs.

For small inland spills, the estimated annual benefit from a 0.1% reduction in the per barrel response costs is expressed as: \((512.82 \text{ barrels} \times 8,000 \text{ per barrel} \times 0.001) \times 30 = $123,076.80\). As before, we can estimate the annual benefits for 0.5% and 1% reductions in the per barrel response and cleanup costs by plugging in 0.005 and 0.01 in place of 0.001 in the equation. Doing so yields annual benefits of $615,384 and $1,230,768, respectively.

**Table 5: Total Estimated Annual Statewide Benefits from Potential Spill Reduction in Response and Cleanup Costs**

</tbody>
</table>

A 0.1% reduction in the annual per barrel response and cleanup costs for all spill types listed in Table 5 from the use of certified SMTs would result in a total potential annual benefit of about $165,056.11. Likewise, a 0.5% reduction in the annual per barrel response and cleanup costs would yield a potential annual benefit of $825,280.55, and a 1% reduction in the annual per barrel response and cleanup costs would yield a potential annual benefit of about $1.651 million.

(b) **Will there be any effects of the regulation on the creation or elimination of jobs within the State?**

By creating a certification program for spill management teams, OSPR is creating a stable market opportunity in which companies may participate and provide a service defined and approved by OSPR. This will likely lead to more spill management teams and more associated jobs than without the regulations.

(c) **Will there be any effects of the regulation on the creation of new businesses or the elimination of existing businesses within the State?**

See the answer above. By creating a spill management team certification program, implementing the provisions of Assembly Bill 1197, OSPR is defining a service that businesses may provide and likely lead to the creation of more business than would otherwise exist without the regulations.

(d) **Will there be any effects of the regulation on the expansion of businesses currently doing business within the State?**
Plan holders with in-house spill management teams may hire more personnel to fill certain staff requirements. External (contracted) spill management teams may hire additional staff to meet increased demand.

(e) Will there be any benefits to the health and welfare of California residents, worker safety, and the State’s environment?

OSPR anticipates benefits to the health and welfare of California residents and the State’s environment by ensuring strategies for effective and efficient management of spill response, thus benefiting the communities affected by a spill, enhancing worker safety, and better protecting the environment. Training and exercise requirements prepare and test the ability of SMTs to respond to and effectively manage an oil spill. These regulations will benefit the state’s environment and communities by ensuring that oil spill responses are efficiently and competently managed.

(f) Will there be any other benefits of the regulations?

This regulation will help move oil spill response towards the best achievable protection of the State’s natural resources through advancing spill response preparedness by ensuring improved and standardized levels of training, resources, and staffing of spill management teams.

Studies, Reports, or Documents Relied Upon [Government Code section 11346.2(b)(3)]

The following technical, theoretical, and/or empirical studies, reports, or documents relied upon are added to the rulemaking file. All documents are available from OSPR upon request.
