Subject: Resource Assessment at Big Bear Lake, Plumas County

Big Bear Lake (Lake ID: 12247), Plumas County, is an easily accessible day-use lake located within the popular Lakes Basin Recreation Area (Figure 1). It was last surveyed in 2013 and brook trout (*Salvelinus fontinalis;* BK) and speckled dace (*Rhinichthys osculus;* SD) were found to be present (Mussulman 2015).

On September 24, 2019 at 7:46 pm, two California Department of Fish and Wildlife (CDFW) Scientific Aids set a gill net along the northern reaches of the lake. The purpose of the survey is to determine the species and relative densities of fish present in the lake. The gill net was pulled the following morning, September 25, 2019, at 7:15 am for a total effort of 11.5 hours. The catch consisted of four BK and two DC (Figure 2, Table 1).

The Scientific Aids then performed a Visual Encounter Survey (VES) of the entire lake. The purpose of the VES is to determine if special status herpetofauna species are present at Big Bear Lake. The survey began at 9:19 am during clear skies, light wind, an air temperature of 15 degrees C, and a water temperature of 14 degrees C. The survey continued until 10:05 am for a total survey effort of 88 minutes. Both the inlet and outlet were dry. One Sierra garter snake (*Thamnophis couchii*; THCO) was observed during the survey.

Big Bear Lake was last planted with BK in 1992. The continued presence of BK suggests the population is self-sustaining and survived the extreme drought from 2014 to 2016. However, BK densities are very low and natural reproduction may not be successful annually. Therefore, the BK are probably not sufficiently abundant to provide a fishery, and the population may be

Figure 1: Big Bear Lake, Plumas County, represented by the red pin, situated north west of Lake Tahoe and south west of Graeagle, CA (retrieved from Google Maps, Oct 2019).

susceptible to future extirpation. Fish were in good condition indicating ample food supply. Both sexes were present, but the two females exhibited early egg stage in late September. This suggests spawn timing may be much later at Big Bear Lake than other high elevations BK populations in the Sierra Nevada. Alternatively, late egg development may be due to above average snowpack and late ice-out of 2019. Regardless, this could result in spawning interference if female BK consistently produce eggs late in the year.

The data are not adequate to determine if BK are sufficiently abundant to provide a fishery. It should be noted that movement of fish by entities other than

CDFW could also account for the presence of BK at Big Bear Lake. Recruitment of BK into Big Bear Lake could also be immigration from Silver Lake, Cub Lake, Little Bear Lake, and Round Lake during seasonal drainage.

Additionally, 7,000 fingerling rainbow trout (*Oncorhynchus mykiss*; RT) were air planted in 2018. The absence of these fish in the gill net survey may indicate low winter survival of fish in the lake.

Alternatively, the lake could be considered for native species management. The tributaries dry up in late summer, and therefore limit BK distribution and in-stream fall spawning. Gill net surveys indicate the BK population is very small and would be easy to eradicate. However, Big Bear Lake is downstream of four fish-bearing waters, Silver Lake, Cub Lake, Little Bear Lake, and Round Lake, which would have to be included in a native species management schema. It is not within the scope of this report to analyze management of those waters.

Figure 2: Photograph of BK catch from a gill net survey at Big Bear Lake, Plumas Co, on September 25, 2019. Two fish on the left are males, while the two fish on the right are females.

Table 1: Total length, weight, sex, and egg stage of fish captured during a gill net survey at Big Bear Lake, Plumas County, on September 25, 2019.
