In addition to piscivorous fishes, non-native invertebrates and amphibians have also been introduced and spread across the Southern SH/RT range. American bullfrogs (*Lithobates catesbeianus*) have become widely established and can prey upon rearing juvenile steelhead (COMB 2022; Cucherousset and Olden 2011; Dagit et al. 2019; Stillwater Sciences 2019). Non-native Red Swamp Crayfish (*Procambarus clarkia*) populations have also increased in some Southern SH/RT waters (Garcia et al. 2015; Dagit et al. 2019). Direct observations of YOY Southern SH/RT being attacked by crayfish in shallow riffle-run habitat suggest that predation poses a threat to the survival of juvenile steelhead (Dagit et al. 2019).

6.5.2 Predation in Marine Environments

Marine predation influences on Southern SH/RT are not well documented or understood. Primary predators of salmonids in the marine environment are pinnipeds, such as harbor seals (*Phoca vitulina*) and California sea lions (*Zalophus californianus*) (Cooper and Johnson 1992; Spence et al. 1996). Although fish are a major dietary component of marine pinnepeds, their predation on Southern SH/RT may be minimal at present, given the very low relative abundances of Southern SH/RT.

6.6 Competition

Competition is the interaction between individuals of the same or different species that compete for a limited supply of a common resource (Holomuzki et al. 2010). The extent to which competition impacts the distribution, abundance, and productivity of Southern SH/RT populations is not well understood. Pacific steelhead typically compete with other salmonid species like Coho and Chinook salmon in freshwater; however, unlike northern populations of steelhead that typically co-occur with other salmonid species, Southern SH/RT are the only salmonids that occur in their range. While inter-specific competition with other salmonids is unlikely to occur, intraspecific competition among Southern SH/RT may be prevalent in southern California watersheds, especially those that are highly degraded. Poor and degrading habitat conditions can contribute to increased competition, which, in turn, can adversely affect fish during the juvenile life-history stage and lead to reduced recruitment and reproductive performance over the entire life cycle (Chilcote et al. 2011; Tatara et al. 2012). Limited habitat space, coupled with high juvenile densities, is associated with reduced growth, premature emigration, increased competition for food, decreased feeding territory sizes, and increased mortality (Kostow 2009).

Juvenile steelhead are habitat generalists, occupying a variety of microhabitat types in streams depending on the size and age of individuals (Spina et al. 2005). Non-native fish species can competitively restrict the spatial distribution of juvenile steelhead to suboptimal habitats such as shallower, higher-velocity rifles, where the energetic cost to forage is higher (Rosenfeld and Boss 2001). Non-native fish species may also exclude juvenile steelhead from areas of suitable habitat. For example, recent watershed-wide surveys in Sespe Creek, a large and unregulated tributary to the Santa Clara River, documented the absence of Southern SH/RT in several stream reaches with suitable steelhead habitat (i.e., cool water with deep pools) that were dominated by multiple species of non-native juvenile fishes (Stillwater Sciences 2019). According to Krug et al. (2012), Arroyo Chub may also compete with Southern SH/RT juveniles for food resources. Like juvenile steelhead, Arroyo Chub are opportunistic feeders and consume benthic and drift invertebrates, sometimes switching preferences depending on food abundance. Southern SH/RT and Arroyo Chub are frequently part of the same native southern California fish assemblages and generally habitat partition, with juvenile steelhead mostly feeding on drift invertebrates while chub have a more benthic diet. However, periods of diet overlap may lead to strong interspecific competition between the two species. While other native fishes may impose some level of competitive threat to Southern SH/RT, it remains likely that non-native competitors pose the greater threat, especially with these species continued expansion and proliferation (O'Brien and Barabe 2022).

6.7 Genetic Diversity

West coast steelhead have considerable genetic diversity, both within and across populations, including variation in traits linked to anadromy, morphology, fecundity, spawning, and run timing, as well as age at smolting and maturation (McElhany et al. 2000). While some traits are entirely genetically based, the expression of most traits usually varies, due to a combination of both genetic and environmental factors. Species with high genetic diversity typically occupy a wider range of habitats than those with lower diversity and are more resilient to both short-and long-term spatial-temporal fluctuations in the environment such as ecological disturbances (i.e., wildfires, floods, and landslides) and human-caused impacts. Generally, populations need to be large enough to maintain long-term genetic diversity and avoid genetic problems, such as loss of variation, inbreeding depression, bottlenecks, and the accumulation of deleterious mutations, all of which occur more frequently in smaller populations.

A range-wide genetic analysis demonstrated that populations in the southernmost portions of the Southern SH/RT range are dominated by hatchery ancestry, indicating genetic introgression of native lineages with hatchery strains (Jacobsen et al. 2014; Abadia-Cardoso et al. 2016). Most of these hybridized wild populations occur above barriers in the upper reaches of the Los Angeles, San Gabriel, Santa Ana, San Juan, San Diego, and Sweetwater rivers. It is unclear whether introgression will decrease the viability of these southern populations, since the introduction of small amounts of novel genetic material, even from hatchery stocks, can lead to increased diversity and the phenomenon known as "hybrid vigor," conferring adaptive resilience to changing environments and the negative impacts of inbreeding. This study also confirmed that the northernmost populations of Southern SH/RT within the species range, including all watersheds in the Monte Arido Highlands BPG, contain native steelhead ancestry and generally higher genetic diversity than more southern populations (Clemento et al. 2009; Abadia-Cardoso et al. 2016).

As with other salmonids, natural straying and the resultant gene flow between populations maintain the genetic diversity of Southern SH/RT. A recent study, which examined the otoliths of seven adult steelhead from a small basin on the Big Sur coast of California, revealed that all adults were strays, coming from at least six different source populations, including neighboring ones on the Big Sur coast as well as distant populations such as the Klamath River (Donohoe et al. 2021). As is the case for many coastal steelhead populations, the genetic diversity of Southern SH/RT has been compromised by human impacts on their habitats, such as the blocking of migration corridors by artificial dams and widespread reductions in streamflow, at least partially due to locally and regionally intensive water diversions for municipal, agricultural, and other human consumptive uses (NMFS 2012a).

Measures of genetic diversity, such as heterozygosity and allelic richness, indicate that Southern SH/RT populations have lower diversity than northern coastal populations. Within the range of Southern SH/RT, the northernmost populations in the Santa Maria, Santa Ynez, Ventura, and Santa Clara rivers have higher genetic diversity than the southernmost populations (Abadia-Cardoso et al. 2016). Previous genetic studies have revealed that populations occurring downstream of modern artificial barriers are genetically more similar to above-barrier populations in the same basin than they are to populations below barriers in neighboring basins (Clemento et al. 2009). While above- and below-barrier populations within the same drainage are usually each other's closest relatives, they appear divergent in respect to the frequencies of the anadromous (A) and resident (R) haplotypes found in each subpopulation (see Section 4.7). The A haplotype is more common below dams, while the R haplotype is found more frequently above dams. This evidence of genetic drift is likely a product of artificial dams or other barriers blocking anadromous adults from returning to these upstream areas to reproduce and provide A haplotype genetic influx to the above-barrier population (Pearse et al. 2014; Pearse et al. 2019). Apgar et al. (2017) found that the frequency of the A haplotype in above-barrier populations is strongly associated with several factors, including the extent of migration barriers present, barrier type (complete, partial, artificial, or natural), barrier age (recent or longstanding), and migration distance.

Because migratory phenotypes are primarily genetically based, variation in the reproductive success of anadromous and resident individuals can influence the tendency of populations to produce anadromous offspring, corresponding to changes in the frequency of the A haplotype. Moreover, environmental factors, such as intra-and inter-annual climate variation, food availability, and water temperature, also influence the expression of anadromy in Southern SH/RT populations (Satterthwaite et al. 2009; Ohms et al. 2014; Kendall et al. 2015). Furthermore, climate change projections for Southern SH/RT range predict an intensification of climate patterns, such as more intense cyclic storms, droughts, and extreme heat (NMFS 2012a). These projections suggest that Southern SH/RT will likely experience more frequent periods of adverse conditions and continued selection pressure against the anadromous life-history form.

6.8 Habitat Conditions

The decline of Southern SH/RT can be attributed to a wide variety of human activities, including, but not limited to, urbanization, agriculture, and water development. These activities have degraded range-wide aquatic habitat conditions, particularly in the lower and middle reaches of most watersheds in the Southern SH/RT range (NMFS 2012a). Southern California is home to over 20 million people and 1.8 million acres of metropolitan, urban, and suburban areas (DWR 2021) which has resulted in highly urbanized watersheds that are impacted by surface and groundwater diversions and associated agricultural, residential, and industrial uses. Major rim dams, instream diversion dams, and other water conveyance infrastructure have significantly reduced or eliminated access to the majority of historical upstream rearing and spawning habitat for southern steelhead. While some of these human activities have been reduced, eliminated, or mitigated, the cumulative impacts of these activities remain throughout most of the Southern SH/RT range, particularly in larger systems such as the Santa Maria, Santa Ynez, Ventura, Santa Clara, Los Angeles, San Gabriel, Santa Ana, and Santa Margarita watersheds, as well as in smaller coastal systems such as Malibu Creek.

6.8.1 Roads

High human population densities in southern California have led to the development of an extensive network of transportation corridors throughout the range of Southern SH/RT. The extensive road and highway networks across much of the Southern SH/RT range, especially in areas proximate to rivers and streams, are attributed to increases in a number of negative habitat impacts. Among these are: non-point pollution (e.g., oil, grease, and copper from braking systems); sedimentation; channel incision due to bankside erosion; substrate embeddedness; floodplain encroachment and loss of floodplain connectivity; loss of channel heterogeneity (e.g., filling of pool habitats); and higher frequencies of flood flows (NMFS 2012a). Additionally, extensive road and highway networks require many road crossings (e.g., culverts and bridges) that are often improperly designed for the volitional passage of aquatic organisms (CalTrans 2007; NMFS 2012a).

NMFS (2012) assessed the impacts of roads and transportation corridors on Southern SH/RT using roads per square mile of watershed and the density of roads within 300 feet of streams per square mile of watershed as metrics. The results of their analysis demonstrated that roads and associated passage barriers have the highest impact on rivers and streams in the Santa Monica Mountains and Conception Coast BPG regions: 60% of watersheds in the Conception Coast BPG ranked “very high” or “high” in severity for roads as a stressor, while 100% of the watersheds that drain the Santa Monica Mountains received the same ranking. Highway 101 and the Union Pacific Railroad cross the mainstem of each watershed along the Conception

Coast BPG region (as well as the Monte Arido Highlands BPG region) near their river mouths. At each major transportation crossing, culverts were constructed to allow stream flows to pass through to the Pacific Ocean, but they were not necessarily engineered to allow upstream fish passage. For example, the Highway 101 culvert on Rincon Creek serves as a total barrier to upstream migration, preventing Southern SH/RT from reaching any of its historical habitats upstream of the barrier. Road development, bridges, and other transportation corridors are also partly responsible for the significant (70-90%) reduction of estuarine habitat across all BPGs (Hunt and Associates 2008).

The Mojave Rim and Santa Catalina Gulf Coast BPG regions are home to the highest urban densities across the Southern SH/RT range, and both BPGs are impacted by high road densities. For example, in the Santa Catalina Gulf Coast BPG region, the Rancho Viejo Bridge, Interstate-5 Bridge array, and the Metrolink drop structure are all recognized as total fish passage barriers on Arroyo Trabuco Creek, a tributary to San Juan Creek. On the Santa Margarita River, an outdated box culvert at the Sandia Creek Bridge serves as a significant fish passage barrier on the river (Dudek 2001). Recently, efforts have been undertaken to repair and modify these barriers to provide upstream steelhead passage and again allow access to many miles of historical habitat in these watersheds (see Chapter 6: Influence of Existing Management Efforts).

6.8.2 Dams, Diversions, and Artificial Barriers

A number of anthropogenic impacts, including water diversions, dams, and other artificial barriers, influence stream flows in most Southern SH/RT-supporting watersheds. Surface water diversions can lead to reduced downstream flows, as well as changes to the natural flow regime (e.g., magnitude, timing, and duration of flow events), stream hydrodynamics (e.g., velocity, water depth), and degradation of both habitat quality and quantity needed to support Southern SH/RT (NMFS 2012a; Yarnell et al. 2015). Changes to the natural flow regime can result in elevated downstream water temperatures, reduced water quality, shifts in fish community composition and structure, increased travel times for migrating fish, increased susceptibility of native aquatic organisms to predation, and reduced gravel recruitment from upstream areas of watersheds to the lower reaches of rivers (NMFS 1996b; Axness and Clarkin 2013; Kondolf 1997). Dams physically separate fish populations into upstream and downstream components, leading to population and habitat fragmentation, along with potential changes to population spatial and genetic structure over time (NMFS 2012a). Large dams often trap upstream sediments, which naturally would be transported downstream and deposited, augmenting substrates and improving spawning habitats for salmonids and other fish. It is common for rivers and streams with large dams to exhibit more scouring and streambed degradation downstream of the impoundment (Kondolf 1997; Yarnell et al. 2015). Stream flow reductions also interfere with the downstream transport and influx of freshwater to estuaries. The consequences of reduced inflows to estuaries include wetland and edge habitat loss, changes to the amount and location(s) of suitable habitat for aquatic organisms and accelerated coastal erosion (Nixon et al. 2004).

Many types of artificial stream barriers exist throughout the range of Southern SH/RT, including dams, concrete channels for flood control, gravel and borrow pits, roads and utility crossings, fish passage facilities, and other non-structural features such as velocity barriers. In the South Coast hydrologic region, a total of 164 known total migration barriers were identified as part of a larger effort to inventory fish passage barriers across California's coastal watersheds (California Coastal Conservancy 2004). Of the 164 total barriers, 11 were identified as requiring modification or removal to improve fish passage. Dams were identified as the most numerous barrier type, followed by stream crossings and non-structural barriers. The Santa Maria River, San Antonio Creek, Cuyama River, Santa Ynez River, and Santa Barbara coastal watersheds, which all belong to the Central Coast hydrologic region, also contain hundreds of known barriers scattered throughout the area, with the highest number found along the Santa Barbara coastal area (California Coastal Conservancy 2004).

Artificial barriers act as physical impediments but may also contribute to, or enhance, non-structural barriers to steelhead spawning migrations. For example, the three major watersheds of the Los Angeles basin have channelized concrete aqueducts in their lower reaches, with some extending from their mouths upstream for miles. As a result, adult Southern SH/RT can no longer access the lower reaches of these three major regional rivers (Titus et al. 2010). Furthermore, if Southern SH/RT were to successfully enter into the channelized reaches of these rivers, migration success would be limited because individuals would encounter non-structural velocity barriers that would require greater swimming speeds than could be sustained (Castro-Santos 2004). Other non-structural barriers may exist in the form of low flows, disconnected wetted habitat, and poor or lethal water quality in these largely metropolitan lower river aqueduct reaches.

Most of the large rivers in the Monte Arido Highlands BPG region contain multiple large, impassable dams. Twitchell Dam on the Cuyama River is primarily managed for groundwater recharge in the Santa Maria Valley. Operations of Twitchell Dam limit downstream surface flows into the mainstem Santa Maria River (NMFS 2012a). Cachuma, Gibraltar, and Juncal dams on the mainstem Santa Ynez River prevent upstream migratory access to approximately 70% of historical spawning and rearing habitat in the watershed (NMFS 2012a). In the Ventura River watershed, Matilija and Casitas dams on Matilija Creek and Coyote Creek, respectively, block access to 90% of historical Southern SH/RT spawning and rearing habitat. However, the recent Matilija Dam Ecosystem Restoration Project is aimed at restoring over 20 miles of perennial

Southern SH/RT habitat in the Matilija Creek watershed through the removal of Matilija Dam. Santa Felicia Dam and Pyramid Dam on Piru Creek, as well as Castaic Dam on Castaic Creek, block access to historical habitat in the tributaries of the mainstream Santa Clara River. Several of these large dams are operated along with smaller downstream diversion dams: primarily the Robles Diversion Dam on the Ventura River and the Vern Freeman Diversion Dam on the Santa Clara River. The Robles Diversion Dam diverts water from the upper Ventura River into storage at Lake Casitas, while the Vern Freeman Diversion diverts water for groundwater recharge purposes in the Santa Clara Valley.

Two major dams impair habitat connectivity and hydrologic function in the Malibu Creek watershed: Rindge Dam and Malibu Lake Dam. Both dams have created favorable habitat conditions for non-native species, including crayfish, snails, fish, and bullfrogs. As a result, invasive aquatic species have been documented in high abundance in Malibu Creek (NMFS 2012a). Rindge Dam is located only 2 miles upstream of the mouth and is no longer functional, so it is targeted for future removal. The removal of this dam alone would allow Southern SH/RT access to 18 miles of high-quality spawning and rearing habitat in the Malibu Creek watershed.

Dams are ranked “high” or “very high” as a threat in 88% of the component watersheds that comprise the Mojave Rim BPG region (NMFS 2012a). There are also at least 20 jurisdictional-sized dams (i.e., a dam under the regulatory powers of the State of California) within each of the three major watersheds of the Los Angeles basin, owned by federal, state, local, and/or private entities and operated for multiple purposes, including: irrigation, flood control, storm water management, and recreation. The principal impoundments in the San Gabriel River watershed are Whittier Narrows, Santa Fe, Morris, San Gabriel, and Cogswell dams. Sepulveda Dam on the Los Angeles River is operated as a flood control structure approximately 8 miles downstream from the river’s source. Prado Dam on the Santa Ana River is also primarily operated as a flood risk management project. These dams alter the physical, hydrological, and habitat characteristics of the lower and middle reaches of the mainstem rivers in this BPG. They also create favorable habitat for non-native species such as crayfish, largemouth bass, and bullfrogs, which have all been documented in the Los Angeles, San Gabriel, and Santa Ana rivers. Periodic removal of sediments accumulated behind dams on the San Gabriel River also degrades downstream riparian and instream habitat conditions (Hunt and Associates 2008).

In the Santa Catalina Gulf Coast BPG, dams also ranked “high” or “very high” as a threat in 90% of constituent watersheds. At least 20 major dams and diversions without fish passage facilities occur throughout the BPG’s distribution. Prominent dams in this BPG include Agua Tibia, Henshaw, and Eagles Nest dams in the San Luis Rey watershed; and the O’Neill Diversion and Vail dams in the Santa Margarita River watershed. Dams in this BPG are generally not operated with fish passage as a consideration in flow release schedules, and many of these facilities lack fish passage provisions (NMFS 2012a).

Municipalities and agricultural beneficial uses comprise the majority of water demand in the South Coast region (Mount and Hanak 2019). Approximately 1.57 million acre-feet of groundwater are used on an annual basis in southern California to meet both urban and agricultural water demands (DWR 2021). Reservoir releases are typically increased during the summer and fall months for the purposes of recharging groundwater for future diversions. Unsustainable water diversions have led to the depletion of several large groundwater aquifers in the region. Recently, the Sustainable Groundwater Management Act priority process identified several groundwater basins across the South Coast hydrologic region as either critically over drafted (i.e., Santa Clara River Valley, Cuyama River Valley, and Pleasant Valley) or medium-to-high priority basins for water conservation (e.g., the Coastal Plain of Orange County) based on several metrics such as population growth rates, the total number of wells, and the number of irrigated acres (DWR 2020). Groundwater sustainability agencies overseeing critically overdrafted and medium-to-high priority basins are responsible for developing and realizing groundwater sustainability plans (GSPs) to achieve basin sustainability within a 20-year implementation horizon.

6.8.3 Estuarine Habitat

The estuaries of many coastal watersheds in southern California form freshwater lagoons that are seasonally closed to the ocean. Lagoons form when low summer baseflows are unable to displace sand deposition at the mouth of the estuary, which results in the formation of a sandbar that blocks connectivity with the ocean. This closure creates an environment characterized by warmer and slower-moving (i.e., longer residence times) freshwater that is relatively deep (Bond et al. 2008). These habitat characteristics provide important, high-quality nursery conditions for rearing juveniles and transition areas for smolts acclimating to the ocean environment. Adult steelhead also acclimate in these areas prior to upstream migration during the winter months when the estuary is fully open (NMFS 2012a). The importance of such habitats was demonstrated by the observed doubling of growth in juvenile *O. mykiss,* which reared throughout the summer in a typical northern California coastal watershed (Bond et al. 2008). The same study examined scales from returning adult steelhead and found that estuary-reared individuals dominated adult returns, despite comprising only a small part of the annual outmigrating population. Another study conducted in the same watershed also reported higher growth rates for estuary-reared juvenile steelhead than for their cohorts reared in the upper watershed (Hayes et al. 2011). Hayes et al. (2011) also found that the lagoon environment provided warmer water temperatures and a diverse abundance of invertebrate prey resources for rearing juvenile *O. mykiss* to consume. Trade-offs between accelerated growth and survival likely exist in lagoon habitats because they represent a relatively high-risk yet high-reward environment in which accelerated growth may come at the cost of increased metabolic demand and potentially increased predation risk (Osterback et al. 2013; Satterthwaite et al. 2012).

The southern California Bight, which encompasses the entire southern California coastline, from Point Conception to San Diego, historically supported around 20,000 hectares of estuary habitat (Stein et al. 2014). Over half of all historical estuaries were found in San Diego County (e.g., Mission Bay and San Diego Bay), while Los Angeles and Orange counties contained about 15% each of the total estimated historical area. Estimates of the amount of estuarine habitat loss from historical levels, based on wetland acreage, range from 48-75% (Brophy et al. 2019; NMFS 2012a; Stein et al. 2014). The magnitude of the loss varies depending on the watershed. For example, the estuaries of the Santa Maria and Santa Ynez rivers in the northern portion of the Southern SH/RT range remain almost entirely intact, while the estuaries of the Los Angeles, San Gabriel, and Santa Ana rivers have been reduced to 0-2% of their historical extent (NMFS 2012a). Overall, estuary habitat loss in southern California is likely underestimated because early landscape modifications (e.g., housing and transportation development and associated filling of wetlands with sediment) had substantially altered the landscape before attempts were made to quantify the extent of historical habitat (Brophy et al. 2019).

The primary cause of estuarine loss in southern California is the conversion of habitat to other land use practices such as agriculture, grazing, and urban development activities, which require the construction of infrastructure and the subsequent filling, diking, and draining of coastal wetlands (NMFS 2012a). Currently, estuary habitats in the range of Southern SH/RT remain highly degraded and prone to further degradation by urban impacts such as point and nonpoint source pollution, coastal development, and dams. These environmental stressors can cause declines in water quality and the proliferation of harmful algal blooms that can lead to the rapid die-off of both aquatic and terrestrial organisms (Lewitus et al. 2012; Smith et al. 2020). Artificial breaching of estuaries also poses a mortality risk to Southern SH/RT. Seven moribund juvenile steelhead were observed in the lagoon at the mouth of the Santa Clara River shortly after the sandbar was artificially breached in 2010 (Swift et al. 2018). The authors of this study noted that the Santa Clara River, upstream of the lagoon, was dry during this time and that the observed fish were relatively large and in robust condition, indicating that favorable rearing conditions existed prior to the artificial breaching.

6.8.4 Water Quality and Temperature

Contaminants and pollutants are well-documented to alter water quality parameters that affect the growth and survival of Pacific salmonids in both freshwater and estuarine environments (Arkoosh et al. 1998; Baldwin et al. 2009; Laetz et al. 2008; Sommer et al. 2007; Sullivan et al. 2000). Both are generally introduced into southern California rivers and streams by urban runoff, agricultural and industrial discharges, wastewater treatment effluent, and other anthropogenic activities. Recent monitoring conducted by the USGS measured between 20 and 22 current-use pesticides in samples collected from urban sites at Salt Creek and the Sweetwater River in Orange and San Diego counties (Sanders et al. 2018). Diminished water quality conditions, including contaminants and associated toxicity, elevated nutrients, low dissolved oxygen, increased temperature, and increased turbidity, can all adversely affect Southern SH/RT as well as other native fish and aquatic organisms. The effects of individual pollutants and combinations thereof can impact populations by altering growth, reproduction, and mortality rates of individual fish (Sommer et al. 2007). These impacts can ultimately manifest in direct mortality due to acute and long-term physiological stress or may act through indirect pathways such as changes to food webs, ecosystem dynamics, increased susceptibility to disease and predation, and more frequent occurrences of harmful algal blooms. Aquatic stressors that impair water quality can also interact with each other in an additive or synergistic fashion, such that they are generally interdependent and can greatly amplify negative impacts on aquatic ecosystems (Sommer et al. 2007). Dissolved oxygen concentrations, turbidity, and water temperatures are all parameters directly influenced by flow management. Lower flows can lead to warmer water temperatures that hold less dissolved oxygen than cold water. Higher water temperatures also increase the metabolic and oxygen consumption rates of aquatic organisms, making these conditions particularly stressful for aquatic life (Myrick and Cech 2000). See Section 6.2.1 in this Status Review for a full description of air and water temperature influences and trends.

Many watersheds that support Southern SH/RT are listed under Section 303(d) of the Federal Clean Water Act (CWA). Section 303(d) requires states to maintain a list of waters that do not meet prescribed water quality standards. For waters on this list, states are required to develop TMDLs that account for all sources (i.e., point and non-point sources) of the pollutants that caused the water to be listed as impaired under the CWA. Approved TMDLs and their implementing regulations are incorporated into water quality control plans required by the Porter-Cologne Act of 1969. In southern California, there are many impaired water bodies and pollutant combinations listed under Section 303(d). While contaminant and discharge sources have changed over the years and there have been significant improvements in controlling many of these sources, many 303(d)-listed waters do not yet have approved TMDLs (SWRCB 2020). All four of the major rivers in the Monte Arido Highlands BPG region are listed as 303(d)-

impaired, and each system contains over five sources of pollutants. Seven Southern SH/RT-supporting watersheds in the Conception Coast BPG region and three in the Santa Monica Mountains BPG region are 303 (d) listed, including Jalama, Gaviota, Mission, Carpinteria, Rincon, Big Sycamore Canyon, Malibu, and Topanga creeks. All three of the major watersheds in the Mojave Rim BPG region, as well as eight out of ten in the Santa Catalina Gulf Coast BPG region, are 303(d)-listed, including the Los Angeles, San Gabriel, Santa Ana, Santa Margarita, San Diego, and Sweetwater rivers and the San Juan, San Mateo, San Luis Rey, and San Dieguito creeks. Essentially, all rivers and streams supporting Southern SH/RT that are 303(d)-listed are impaired by multiple pollutants, including water temperature, benthic community effects, indicator bacteria, trash, toxicity, and invasive species. Furthermore, southern California's coastal and bay shorelines, estuary environments, and tidal wetlands are also frequently 303(d)-listed as impaired. As examples, the estuaries of Malibu, Aliso, San Juan, and Los Penasquitos creeks; the entirety of Santa Monica Bay; and the estuaries of the Los Angeles, Santa Clara, Santa Margarita, and Tijuana rivers are all listed as 303(d)-impaired waterbodies.

6.8.5 Agricultural Impacts

The impacts of agricultural development have lessened over time as farm and pasturelands continue to be converted to urban development in southern California (NMFS 2012a). Historically, the loss of riparian and floodplain habitat was due first to conversion for livestock ranching, followed by irrigated row-crop agriculture, and then urban development. For example, interior portions of the Santa Clara River floodplain were originally converted to agriculture but are now dominated by urban growth and major human population centers, such as the cities of Santa Paula and Fillmore. Today, the South Coast hydrologic region supports approximately 159,000 acres of agricultural land, with avocados, citrus, truck crops, and strawberries comprising the highest agricultural production by acreage (DWR 2021). Approximately 530,000 acre-feet of groundwater are annually pumped from underlying basins to support agricultural production in southern California (DWR 2021). Agricultural activities produce wastewater effluent containing nutrients that can either directly or indirectly be introduced into the rivers, streams, and estuaries that support Southern SH/RT, particularly when agricultural best management practices and water quality objectives have not been established. Agricultural production is prevalent in several watersheds, including the lower Santa Maria and Santa Ynez rivers; many of the smaller coastal watersheds along the Santa Barbara coast, such as the Goleta Slough complex and Rincon Creek; the upper Ventura River and the Ojai basin; and portions of the San Mateo Creek, San Luis Rey, and San Dieguito River tributaries in the southernmost portion of the range. Statewide, the counties of Ventura, Santa Barbara, and San Diego are each ranked in the top fifteen for total value of agricultural production (CDFA 2021).

While the impacts of agricultural development on Southern SH/RT and their habitats have decreased over time due to land use conversion, both activities have resulted in considerable cumulative regional habitat loss and degradation. These changes have led to greatly reduced habitat complexity and connectivity in the lower and middle reaches of many southern California watersheds. Currently, agricultural impacts on Southern SH/RT are most evident during the summer dry season, when agricultural and residential water demands are the highest. This period coincides with the juvenile *O. mykiss* rearing life-history stage, which is dependent on adequate summer base flows to maintain suitable habitat conditions for growth and survival (Grantham et al. 2012). Agricultural groundwater diversions can lead to rapid stream drying by depleting aquifer groundwater that contributes to stream base flows, which limits the extent of summer rearing habitat for fish (Moyle et al. 2017). Naturally occurring surface waters supported only by groundwater recharge can be rapidly dewatered due to excessive groundwater pumping or diversions. These areas have been shown to provide adequate depth, surface area, and habitat for steelhead in streams lacking cold-water refuges (Tobias 2006).

6.8.6 Invasive Species

Invasive and non-native species are abundant and widely distributed in many watersheds that support Southern SH/RT. Non-native species frequently occur in both anadromous and non-anadromous waters that have been extensively stocked by a variety of public and private entities (NMFS 2012a). Most reservoirs contain non-native species, such as largemouth and smallmouth bass, carp, sunfish, bullfrogs, and bullhead catfish, that can all establish reproducing populations in the river and stream reaches above and below the dams. Range-wide habitat alteration has also facilitated the widespread distribution and increased abundance of non-native fish species, which typically favor slower-moving, warmer-water habitats with lower dissolved oxygen concentrations and higher sediment loads (Moyle et al. 2017). While the introduction of non-native game species has historically been viewed as a fishery enhancement, these species can have negative impacts on Southern SH/RT due to predation, competition, disease, habitat displacement and alteration, as well as behavior modifications (Cucherousset and Olden 2011).

Invasive species have recently been documented in high densities in Sespe Creek, an unregulated tributary to the Santa Clara River and a Department-designated Wild Tout Water (Stillwater Sciences 2019). High abundances of invasive species are due to the historic and ongoing stocking of non-native fish in the Rose Valley Lakes on Howard Creek, a tributary to Sespe Creek. In both Malibu and Topanga creeks, red swamp crayfish abundances have increased with recent warmer stream temperatures and lower flow conditions despite regular removal efforts (Dagit et al. 2019). High densities of crayfish likely have a direct (predation) and indirect (competition) effect on Southern SH/RT in both creeks. A variety of warm-water, non-native fish species are frequently observed in the lower Santa Ynez River, including multiple species of sunfish and catfish, carp, and largemouth bass, all of which are known predators of Southern SH/RT early life stages. In the lower Ventura River, annual monitoring efforts have consistently detected higher numbers of non-native fish species than Southern SH/RT in recent years (CMWD 2021).

Non-native plant and amphibian species also occur in several watersheds that support Southern SH/RT. Invasive plants such as giant reed and tamarisk have displaced extensive areas of native riparian vegetation in major drainages, such as the Santa Clara and San Luis Rey rivers (NMFS 2012a). These water-intensive plant species both reduce instream flows through groundwater uptake and severely reduce the extent of riparian cover and shading. These habitat changes often affect stream flow and thermal regimes, potentially increasing susceptibility of Southern SH/RT to predation, disease, and competitive exclusion. Other non-native plant species, such as water primrose and hyacinth, both of which form dense, sprawling mats on the water's surface, can alter the structure and function of aquatic ecosystems by outcompeting native aquatic plants, reducing the amount of open water habitat, altering the composition of invertebrate communities, physically blocking fish movement, and inducing anoxic conditions detrimental to fish (Khanna et al. 2018). In the Santa Clara River watershed, bullfrogs and African clawed frogs are abundant and widespread throughout the mainstem reaches, from the estuary upstream to Fillmore, including tributaries such as Santa Paula Creek and Hopper Canyon Creek (NMFS 2012a). Both species represent a threat to native aquatic communities because they opportunistically consume a variety of native prey, and eradication of either species is unlikely (Wishtoyo Foundation 2008).

6.8.7 Cannabis Cultivation

The cultivation, manufacturing, and distribution of cannabis products have increased since recreational use became legal in California in 2016 (Butsic et al. 2018). Threats and stressors on aquatic ecosystems associated with the cultivation of cannabis include stream flow and bank modifications, water pollution, habitat degradation, and species invasions (CDFW 2018b). Cannabis is a water-and nutrient-intensive crop that requires an average of up to 6 gallons of water per day, per plant, during the growing season, which usually spans a total of 150 days from June to October (Zheng et al. 2021). Water diversions can lead to changes in flow regimes, the creation of fish passage barriers, the loss of suitable spawning and foraging habitat, and the rerouting and dewatering of streams, especially during drought years or during the dry season (CDFW 2018b; see Section 6.8.2).

A number of local and state agencies, including counties, cities, the State Water Resource Control Board (SWRCB), the Department of Cannabis Control, the Department of Pesticide Regulation, and the Department, regulate the legal cannabis cultivation industry in southern California. These entities issue permits and licenses related to cultivation practices, discharge requirements, diversion rules, and environmental protections. The SRWCB, which issues water rights permits to cannabis cultivators, prohibits the diversion of surface water during the dry season from April 1 through October 1 each calendar year. Surface water diversions to off-stream storage are allowed for collection during the wet season and are later used during the dry season. Many Southern SH/RT-bearing streams are regulated by numerical instream flow requirements that must be met in order for cultivation diversions to occur. For example, instream flow requirements for the Santa Ynez River near Lompoc, California, range between 61.1 and 310 cubic feet per second (cfs) from November to March (SWRCB 2020). These wet-season requirements were developed to address the life history needs of threatened and endangered anadromous salmonids, including maintaining the natural abundance and availability of spawning habitat, minimizing adult exposure, stress, predation, and migration delay during the adult spawning season, and sustaining high-quality and abundant juvenile salmonid winter-rearing habitat.

Illegal cannabis cultivation operations are still prevalent on public lands in southern California, despite the now legal status of recreational use of cannabis in the state. The impacts of illegal cultivation sites are similar to those described for legal operations; however, the severity is likely higher due to the illicit nature of illegal cultivation sites, the higher likelihood of point-source pollution and unregulated diversions, along with the use of illegal and/or unauthorized pesticides, which are all common practices observed at illegal grow sites. As of January 2020, the Department’s South Coast Regional Cannabis Unit has inspected 143 illegal cultivation sites and identified threats to 303(d)-listed water bodies and Regional Water Quality Control Board priority water systems (Covellone et al. 2020). According to Wengert et al. (2021), illegal cannabis cultivation sites in Northern California typically occur at low to mid-elevations (800 m to 1600 m) in forested areas with moderate slopes. If the same distribution patterns hold true in areas of southern California, illegal grow operations within these elevation ranges could overlap with the upper reaches of watersheds on national forest lands that currently support headwater populations of Southern SH/RT. The impact of these illegal grows could have significant adverse impacts on above-barrier resident populations, which have been shown to retain native steelhead genetics important to conserving the genetic diversity of Southern SH/RT. These isolated headwater populations may offer important conservation tools via native genetic stock that can be utilized to re-establish and support the fluvial-anadromous and lagoon-anadromous life history strategies in restored areas no longer occupied by Southern SH/RT (NMFS 2012a; Clemento et al. 2009).

6.9 Fishing and Illegal Harvest

Southern SH/RT traditionally supported important recreational fisheries for both winter adults and summer juveniles in coastal streams. Angling-related mortality may have contributed to the decline of some small populations but is generally not considered a leading cause of the decline of the Southern California Steelhead DPS as a whole (Good et al. 2005; Busby et al. 1996; NMFS 1996b). After the southern California steelhead DPS was federally listed as endangered in 1997, Department fishing regulation modifications led to the closure of recreational fisheries for Southern SH/RT in marine and anadromous waters with few exceptions. That closure continues, and there is currently no legal recreational fishery for Southern SH/RT (CDFW 2023).

Southern SH/RT take is primarily from poaching rather than legal commercial and recreational fishing. While illegal harvest rates appear to be very low, the removal of even a few individuals in some years could be a threat to the population because of such low adult abundance in most populations (Moyle et al. 2017). Southern SH/RT are especially vulnerable to poaching due to their high visibility in shallow streams. Estimates of fishing effort from self-report cards for 1993–2014 suggest extremely low levels of angling effort for Southern SH/RT, primarily due to the statewide prohibition of angling in anadromous waters starting in 1998 (NMFS 2016; Jackson 2007). Historic commercial driftnet fisheries may have contributed slightly to localized declines; however, Southern SH/RT are targeted in commercial fisheries, and reports of incidental catch are rare. Commercial fisheries are not believed to be a leading cause of the widespread declines of Southern SH/RT over the past several decades (NMFS 2012a).

7. INFLUENCE OF EXISTING MANAGEMENT EFFORTS

7.1 Federal and State Laws and Regulations

Several state and federal environmental laws apply to activities undertaken in California that may provide some level of protection for Southern SH/RT and their habitat. There are also restoration, recovery, and management plans, along with management measures specific to habitat restoration, recreational fishing, research, and monitoring that may benefit Southern SH/RT. The following list of existing management measures is not exhaustive.

7.1.1 National Environmental Policy Act and California Environmental Quality Act

The National Environmental Policy Act (NEPA) was enacted in 1970 to evaluate the environmental impacts of proposed federal actions. The NEPA process begins when a federal agency proposes a major federal action. The process involves three levels of analysis: 1) Categorical Exclusion determination (CATEX); 2) Environmental Assessment (EA) or Finding of No Significant Impact (FONSI); and 3) Environmental Impact Statement (EIS). A CATEX applies when the proposed federal action is categorically excluded from an environmental analysis because it is not deemed to have a significant impact on the environment. If a CATEX does not apply, the lead federal agency for the proposed action will prepare an EA, which concludes whether the action will result in significant environmental impacts. A lead agency will issue a FONSI document if significant impacts are not expected. Alternatively, if the action is determined to have a potentially significant effect on the environment, an EIS containing an explanation of the purpose and need for the proposed action, a reasonable range of alternatives that can achieve the same purpose and need, a description of the affected environment, and a discussion of environmental consequences of the proposed action is required (EPA 2017). The United States Environmental Protection Agency is responsible for reviewing all EIS documents from other federal agencies and must provide NEPA documentation for its own proposed actions. Because the Southern California DPS is listed as endangered under the federal ESA, proposed actions that may impact the species are evaluated as biological resources in the project area concurrently and interdependently with the federal ESA Section 7 consultation process.

The California Environmental Quality Act (CEQA) is similar to NEPA in that it requires environmental review of discretionary projects proposed by state and local public agencies unless an exemption applies (Pub. Resources Code, § 21080). Under CEQA, the lead agency is responsible for determining whether an EIR, Negative Declaration, or Mitigated Negative Declaration is required for a project (Cal. Code Regs., tit. 14, § 15051). When there is substantial evidence that a project may have a significant effect on the environment and adverse impacts cannot be mitigated to a point where no significant effects would occur, an EIR must be prepared that identifies and analyzes environmental impacts and alternatives (Pub. Resources Code, § 21082.2, subds. (a) & (d)). Significant effects for a proposed project may occur if project activities have the potential to substantially reduce the habitat, decrease the number, or restrict the range of any rare, threatened, or endangered species (Cal. Code Regs., tit. 14, §§ 15065, subd. (a)(1) & 15380). CEQA requires public agencies to avoid or minimize significant effects where feasible (Cal. Code Regs., tit. 14, § 15021); NEPA does not include this requirement. Further, CEQA requires that when a lead agency approves a project which will result in significant effects which are identified in the final EIR but are not avoided or substantially lessened, the agency shall make a statement of overriding considerations in which the agency states in writing the specific reasons to support its action based on the final EIR and/or other information in the record (Cal. Code Regs., tit. 14, § 15093).

7.1.2 Federal Endangered Species Act

The ESA was established in 1973 to conserve and protect fish, wildlife, and plants that are listed as threatened or endangered. The ESA provides a mechanism to add or remove federally listed species, cooperate with states for financial assistance, and develop and implement species recovery. The ESA also provides a framework for interagency coordination to avoid take of listed species and for issuing permits for otherwise prohibited activities. The lead federal agencies for implementing the ESA are the USFWS and NMFS. Federal agencies are required to consult with either the USFWS or NMFS to ensure that actions they undertake, fund, or authorize are not likely to jeopardize the continued existence of any listed species or their designated critical habitat. The federal ESA prohibits the take, import, export, or trade in interstate or foreign commerce of ESA-listed species.

NMFS listed the Southern California Steelhead DPS as endangered under the federal ESA in 1997 as part of the South-Central/Southern California Coast recovery domain and designated critical habitat for that DPS in 2005 (NMFS 2012a). The scope of the DPS is naturally spawned anadromous steelhead originating below natural and manmade impassable barriers from the Santa Maria River to the U.S.-Mexico border. NMFS's West Coast Region manages recovery planning and implementation for this domain, and in 2012 the region adopted a Recovery Plan for the Southern California Steelhead DPS, which provides the foundation for recovering populations to healthy levels. The listing of the DPS afforded the DPS ESA protections through the consultation provisions of ESA Section 7(a)(2); habitat protection and enhancement provisions of ESA Section 4 and 5; take prohibitions through ESA Sections 4(d) and 9; cooperation with the State of California through ESA Section 6; and research, enhancement, and species conservation by non-federal actions through ESA Section 10.

Section 7(a)(2) of the ESA requires federal agencies to ensure their actions are not likely to jeopardize the continued existence of the species or adversely modify designated critical habitat. The agency requesting consultation will typically produce and submit a biological assessment that documents potential effects on listed species or their habitats to either the USFWS or NMFS. USFWS or NMFS then produces and submits a Biological Opinion to the requesting agency that contains conservation recommendations and actions to minimize any harmful effects of the proposed action. Currently, NMFS spends a significant amount of its resources and time fulfilling Section 7 consultation requirements for federal actions that may impact the Southern California Steelhead DPS (NMFS 2012a). This includes working with agencies to avoid and minimize the potential impacts of proposed actions and to ensure project activities do not jeopardize the species or destroy critical habitat. NMFS has issued Biological Opinions for several large federally owned and operated projects, including the Santa Felicia Hydroelectric Project on Piru Creek (2008), USBR's operation and maintenance of the Cachuma Project on the Santa Ynez River (2000), USBR's construction and operation of the Robles Diversion Fish Passage Facility on the Ventura River (2003), the U.S Army Corp of Engineer's (USACE) Matilija Dam Removal and Ecosystem Restoration Project on Matilija Creek (2007), USACE's Santa Paula Creek Flood Control Project (2013). However, the application of Section

7(a)(2) is limited in scope because it applies only to federal actions and areas under federal ownership, and without a related federal action it does not apply to the significant areas of public and private ownership in southern California (NMFS 2012a).

7.1.3 Clean Water Act and Porter-Cologne Water Quality Act

The CWA was established in 1972 to regulate the discharge of pollutants into the waters of the United States and create surface water quality standards. Section 401 of the CWA requires any party applying for a federal permit or license for a project that may result in the discharge of pollutants into the waters of the United States to obtain a state water quality certification. This certification affirms that the project adheres to all applicable water quality standards and other appropriate requirements of state law. Section 404 of the CWA prohibits the discharge of dredged or fill material into the waters of the United States without a permit from the USACE. Activities regulated under this program include fill for development, water resource projects, infrastructure development, and mining projects. Applicants for a 404 permit must demonstrate that all steps have been taken to avoid impacts to wetlands, streams, and aquatic resources and that compensation is provided for unavoidable impacts prior to permit issuance from the USACE.

Since 1969, the Porter-Cologne Water Quality Act (Porter-Cologne Act) has been the principal law governing water quality in California. The Porter-Cologne Act includes goals and objectives that align with those of the federal CWA, such as water quality standards and discharge regulations. The SWRCB and nine regional water quality control boards share responsibility for the implementation and enforcement of the Porter-Cologne Act. These entities are required to formulate and adopt water quality control plans that describe beneficial uses, water quality objectives, and a program of implementation that includes actions necessary to achieve objectives, a time schedule for the actions to be taken, and monitoring to determine compliance with water quality objectives and the protection of beneficial uses of water.

Under Section 401 of the CWA, a federal agency may not issue a permit or license to conduct any activity that may result in any discharge into waters of the United States unless a Section 401 water quality certification is issued or certification is waived. The SWRCB and the regional water quality control boards administer Section 401 water quality certifications in California.

In accordance with Section 303(d) of the CWA, the U.S. Environmental Protection Agency (EPA) assists the SWRCB and the regional water boards in listing impaired waters and developing TMDLs for waterbodies within the state. TMDLs establish the maximum concentration of pollutants allowed in a waterbody and serve as the starting point for restoring water quality. The primary purpose of the TMDL program is to assure that beneficial uses of water, such as cold freshwater and estuarine habitat, are protected from detrimental increases in sediment, water temperature, and other pollutants defined in Section 502 of the CWA. TMDLs are developed by either the regional water quality control boards or the EPA. TMDLs developed by the regional water quality control boards are included as water quality control plan amendments and include implementation provisions, while those developed by the EPA contain the total load and load allocations required by Section 303(d) but do not contain comprehensive implementation provisions. The EPA is required to review and approve the list of impaired waters and each TMDL. If the EPA cannot approve the list or a TMDL, it is required to develop its own. There can be multiple TMDLs on a particular waterbody, or there can be one TMDL that addresses numerous pollutants. TMDLs must consider and include allocations to both point and non-point sources of the listed pollutants.

Waters within the range of the Southern SH/RT are under the jurisdiction of the Central, Los Angeles, Santa Ana, and San Diego regional water quality control boards. There are many 303(d)-listed impaired waterbodies within the jurisdiction of each of these regional boards, and most waterbodies have more than one pollutant that exceeds water quality standards designed to protect beneficial uses of water, water quality criteria, or objectives. More information on 303(d) listed waters in southern California can be found at: https://www.waterboards.ca.gov/water_issues/programs/water_quality_assessment/2018_integrated_report.html

The National Pollution Discharge Elimination System (NPDES) delegated implementation responsibility for the regulation of wastewater discharges to the State of California through the SWRCB and the regional water quality control boards. In southern California, tertiary wastewater treatment plants commonly discharge treated water into the rivers, streams, and estuaries that support Southern SH/RT. For example, the Tapia Water Reclamation Facility discharges tertiary treated effluent into Malibu, Las Virgenes, and Arroyo Calabasas creeks. While wastewater effluent is often the primary source of streamflow for southern California rivers and streams during the summer months, the potential impacts of wastewater effluent on adult and juvenile life stages are not well understood (NMFS 2012a). The review, assessment, and potential modification of NPDES wastewater discharge permits is a key recovery action in the federal recovery plan for the Southern California DPS to address the threat of urban effluents (NMFS 2016).

7.1.4 Federal and California Wild and Scenic Rivers Act

In 1968, Congress enacted the National Wild and Scenic Rivers Act (WSRA) to preserve certain rivers with outstanding natural, cultural, and recreational values in a free-flowing state. Under the National Wild and Scenic Rivers System, rivers are classified as either wild, scenic, or recreational. Designation neither prohibits development nor gives the government control over private property; recreation, agricultural practices, residential development, and other land uses may continue. However, the WSRA does prevent the federal government from licensing, funding, or otherwise assisting in dam construction or other projects on designated rivers or river segments. Designation does not impact existing water rights or the existing jurisdiction of states and the federal government over waters. In California, approximately 2,000 miles of river are designated as wild and scenic, which comprises about one percent of the state's total river miles. The California Wild and Scenic Rivers Act was passed by the California Legislature in 1972. The state act mandates that "certain rivers which possess extraordinary scenic, recreational, fishery, or wildlife values shall be preserved in their free-flowing state, together with their immediate environments, for the benefit and enjoyment of the people of the state." (Pub. Res. Code, § 5093.50). Designated waterways are codified in Public Resources Code Sections 5093.50-5093.70.

The designated state and federal wild and scenic rivers within the range of Southern SH/RT are the Sisquoc River, Piru Creek, and Sespe Creek. The Sisquoc River, which is a tributary of the Santa Maria River, contains 33 miles of designated water from its origin in the Sierra Madre Mountains downstream to the Los Padres National Forest boundary. Piru and Sespe creeks are both tributaries of the Santa Clara River and encompass a combined 38 miles of designated waters. The downstream end of Pyramid Dam and the boundary between Los Angeles and Ventura counties constitute the start and end points of the designated reach for Piru Creek. The designated reach for Sespe Creek is the main stem from its confluence with Rock Creek and Howard Creek downstream, near its confluence with Tar Creek. Both Sespe Creek and the Sisquoc River have comprehensive river management plans that address resource protection, development of lands and facilities, user capacities, and other management practices necessary or desirable to achieve the purposes of the WSRA (USDA 2003a; USDA 2003b).

7.1.5 Lake and Stream Bed Alteration Agreements

Fish and Game Code Section 1602 requires entities to notify the Department prior to beginning any activity that may "divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake." The requirement applies to both intermittent and perennial waterbodies. If an activity will adversely affect an existing fish and wildlife resource, the Department's Lake and Streambed Alteration Program is responsible for issuing a Lake or Streambed Alteration (LSA) Agreement that includes reasonable measures necessary to protect the resource (Fish & G. Code, §1602, subd. (a)(4)(B)). There are several types of LSA agreements that entities can request from the Department, including standard; general cannabis; gravel, sand, or rock extraction; routine maintenance; timber harvest; and master.

Recently, severe storms during the winter of 2023 in southern California caused flooding, landslides, and mudslides within the watersheds that Southern SH/RT occupy. As a result, multiple emergency actions were conducted to protect life and property. In these circumstances, Fish and Game Code Section 1610 exempts entities that conduct certain emergency work from notification requirements prior to the start of any work activity and instead allows them to notify in writing within fourteen days after the work begins.

In the South Coast Region, legal cannabis cultivation is currently focused in Santa Barbara County, with a concentration of the larger notifications in the Santa Ynez River watershed. The Santa Ynez River and its tributaries are a high priority wildlife resource that supports *O. mykiss*, the Southern California Steelhead DPS listed as endangered under the federal ESA; southwestern willow flycatcher, which is listed as endangered under both the federal ESA and CESA; least Bell's vireo, which is listed as endangered under both the federal ESA and CESA; and California red-legged frog, which is listed as threatened under the federal ESA. There are currently about 453 acres of permitted cannabis in the Santa Ynez watershed. Project water use adjacent to the Santa Ynez River can have significant individual and/or cumulative impacts on Southern SH/RT and other species along this reach and adjacent up- and downstream areas. The predominant water source for these large grows along the Santa Ynez River and within the region are well diversions that can be located within or immediately adjacent to the stream. These diversions have the potential to substantially affect surface flows, hydrology, and vegetation within the Santa Ynez River. Where this situation occurs along the Santa Ynez River, Department staff have included appropriate measures to report on water use in any agreements that have been issued. Such measures include having an established protocol for monitoring and reporting water use throughout the season. Permittees must also abide by the SWRCB forbearance period for diversion of surface water during the dry season, from April 1 through October 1 of each calendar year.

7.1.6 Medicinal and Adult-Use Cannabis Regulation and Safety Act

Regulation of the commercial cannabis cultivation industry under the Medicinal and Adult-Use Cannabis Regulation and Safety Act requires that any entity applying for an annual cannabis cultivation license from the California Department of Food and Agriculture include "a copy of any final lake or streambed alteration agreement… or written verification from the California Department of Fish and Wildlife that a lake or streambed alteration agreement is not required" with their license application (Cal. Code Regs., tit. 3, § 8102, subd. (w)). Waste discharge and water diversions associated with cannabis cultivation are regulated by the SWRCB (Cal. Code Reg., tit. 3, § 8102, subd. (p)).

7.1.7 Federal Power Act

The Federal Energy Regulatory Commission (FERC) implements and enforces the Federal Power Act. FERC has the exclusive authority to license most non-federal hydropower projects that are located on navigable waterways, federal lands, or are connected to the interstate electric grid. The term for a hydropower license granted by FERC is typically 30-50 years. FERC must comply with federal environmental laws prior to issuing a new license or relicensing an existing hydropower project, including NEPA and ESA. Section 10(a) of the Federal Power Act instructs FERC to solicit recommendations from resource agencies and tribes (when applicable) on ways to make a project more consistent with federal or state comprehensive plans. Section 10(j) allows NMFS, USFWS, and the Department to submit recommendations to protect, mitigate damage to, and enhance fish and wildlife resources affected by a proposed project. FERC is not required to incorporate these recommendations into a hydropower license if it determines the recommendations are outside the scope of Section 10(j) or inconsistent with the Federal Power Act or any other applicable law.

Pursuant to Section 401 of the CWA, FERC may not issue a FERC license to a project unless a Section 401 water quality certification is issued to that project or that certification is waived. The SWRCB administers 401 water quality certifications for projects that involve a FERC license.

UWCD owns and operates Santa Felicia Dam, which is the main component of the Santa Felicia Project *(FERC Project Number 2153)*. The project is located on Piru Creek, a tributary of the Santa Clara River, in Ventura County. Santa Felicia Dam, which is located five miles north of the town of Piru, impounds Piru Creek to form Lake Piru Reservoir. Lake Piru has a usable storage capacity of 67,997 acre-feet, and the spillway of the Santa Felicia Dam has a capacity of 145,000 cfs. A small powerhouse located on the west embankment of the dam is capable of producing up to 1,420 kilowatts of energy. UWCD owns two appropriative water rights for the project for the purposes of power, domestic, industrial, municipal, irrigation, and recreational uses. The project currently operates under a 2014 water quality certification that contains provisions to protect fish and wildlife beneficial uses in lower Piru Creek, including a reservoir release schedule to protect Southern SH/RT migration flows each year from January 1 through May 31 (see https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/santafelicia_ferc2153.html for more information).

7.1.8 Sustainable Groundwater Management Act

In September 2014, the Governor signed legislation to strengthen the management and monitoring of groundwater basins. These laws, known collectively as the Sustainable Groundwater Management Act (SGMA), established a timeline and process for forming local

GSAs in designated groundwater basins. GSAs are responsible for developing and implementing GSPs to achieve basin sustainability within a 20-year implementation horizon. DWR is the agency responsible for reviewing and approving individual GSPs, while the SWRCB serves as the regulatory backstop for groundwater basins found to be out of compliance with SGMA. Since 2014, the Department's Groundwater Program has developed multiple documents to assist GSAs in developing and implementing effective GSPs, including a groundwater consideration planning document and a habitat-specific document for wetlands (CDFW 2019). These documents highlight scientific, management, legal, regulatory, and policy considerations that should be accounted for during GSP development. DWR is currently in the process of reviewing GSP plans for critically overdrafted and medium-to-high priority basins. Within the range of Southern SH/RT, there are over fifteen GSPs that are currently being reviewed by DWR. SGMA requires GSAs to submit annual reports to DWR each April 1 following the adoption of a GSP. Annual reports provide information on groundwater conditions and the implementation of the GSP for the prior water year (see https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management/Groundwater-Sustainability-Plans for more information).

7.1.9 State Water Resources Control Board Water Rights Administration

Water rights are a legal entitlement authorizing water to be diverted from a specified source and put to a beneficial, non-wasteful use. Riparian water rights are based on ownership of land bordering a waterway, while appropriative water rights are issued without regard to the relationship of land to water but rather the priority in which the water was first put to beneficial use. The exercise of most water rights (i.e., appropriative water rights) requires a permit or license from the SWRCB. The goal of the SWRCB in making water rights-related decisions is to develop water resources in an orderly manner, prevent waste and unreasonable use of water, and protect the environment. The SWRCB has several other major water rights - related duties, including but not limited to: participating in water rights adjudications; enhancing instream uses for fish and wildlife beneficial uses; approving temporary water transfers; investigating possible illegal, wasteful, or unreasonable uses of water; and revoking or terminating water rights. SWRCB-issued water right permits contain public trust provisions for the protection of instream aquatic resources. While these provisions (i.e., maximum diversion amounts and diversion seasons) are meant to protect aquatic resources, they do not have an explicit regulatory mechanism to implement protections required in other state statutes, such as Fish and Game Code 5937 (see Section 7.1.10 below). Furthermore, prior to recent advancements in groundwater management, the SWRCB generally lacked the authority to regulate groundwater diversions and development. Overlying landowners may extract percolating groundwater without approval from the SWRCB as long as the extracted water is put to beneficial uses and the region in which the groundwater diversion occurs has not been formally adjudicated.

7.1.10 Fish and Game Code Section 5937

Fish and Game Code Section 5937 states "the owner of any dam shall allow sufficient water at all times to pass through a fishway, or in the absence of a fishway, allow sufficient water to pass over, around, or through the dam, to keep in good condition any fish that may be planted or exist below the dam."

7.2 Species Recovery Plans and Regional Management Plans

7.2.1 Southern California Steelhead Recovery Plan

The Southern California Steelhead Recovery Plan (Recovery Plan) was adopted in 2012 following the listing of the Southern California Steelhead DPS in 1997. The goal of the Recovery Plan is to prevent the extinction of the species in the wild; ensure the long-term persistence of viable, self-sustaining populations of steelhead distributed across the DPS; and establish a sustainable sport fishery (NMFS 2012a). Generally, recovery of the DPS, which consists of naturally spawned anadromous steelhead originating below natural and manmade impassable barriers from the Santa Maria River to the U.S.-Mexico Border, entails the protection, restoration, and maintenance of a range of habitats in the DPS to allow all life-history forms of the species to be fully expressed (e.g., anadromous and resident). The Recovery Plan outlines key objectives that address factors limiting the species' ability to survive and naturally reproduce, including preventing extinction by protecting populations and habitats, maintaining the current distribution of steelhead and restoring distribution to historically occupied areas, increasing abundance, conserving existing genetic diversity, and maintaining and restoring habitat conditions to support all life-history stages of the species. NMFS defines a viable population as a population that has a less than 5% risk of extinction due to threats from demographic variation, non-catastrophic environmental variation, and genetic diversity changes over a 100-year time frame (NMFS 2012a).

The Recovery Plan organizes the recovery plan area into five BPGs: Monte Arido Highlands, Conception Coast, Santa Monica Mountains, Mojave Rim, and Santa Catalina Gulf Coast. The BPGs were initially divided based on whether individual watersheds within them are ocean-facing systems subject to marine-based climate inversion and orographic precipitation from ocean weather patterns. Secondarily, population groups were then organized based on similarity in physical geography and hydrology. The rationale for this approach is that steelhead populations utilizing unique individual watersheds have different life histories and genetic adaptations that enable the species to persist in a diversity of different habitat types represented by the BPGs. The Recovery Plan's strategy emphasizes larger watersheds in each BPG that are more capable of sustaining larger and more viable populations than smaller watersheds. Core 1 populations are identified as having the highest priority based on their intrinsic potential for meeting viable salmonid population criteria, the severity of the threats facing the populations, and the capacity of the watershed and population to respond to recovery actions (NMFS 2012a).

Like all federal recovery plans, the Recovery Plan for the Southern California Steelhead DPS contains recovery criteria, recovery actions, and estimates of the time and costs to achieve recovery goals. Recovery criteria are objective, measurable criteria that, when met, would result in a determination that the species be delisted. Recovery criteria for the Southern California Steelhead DPS Recovery are based on both DPS-level and population-level criteria. At the population level, criteria include characteristics such as mean annual run-size, spawner density, and anadromous fraction, while the DPS-level criteria are informed by the minimum number of populations that must be restored in each BPG. Recovery actions are site-specific management actions necessary to achieve species recovery. Actions for the Southern California DPS are organized based on the BPG and core population approaches. High-priority recovery actions include, but are not limited to, physically modifying passage barriers such as dams to allow natural rates of migration to upstream spawning and rearing habitats, enhancing protection of natural in-channel and riparian habitats, reducing water pollutants, and conducting research to better understand the relationship between resident and anadromous forms of the species (NMFS 2012a).

7.2.2. Forest Plans

Land Management, or Forest Plans, were developed by the United States Department of Agriculture for the southern California National Forests (the Angeles, Cleveland, Los Padres, and San Bernadino National Forests) in 2006 to provide a framework for guiding ongoing land and resource management operations. The southern California Forest Plans contain various protections for Southern SH/RT that occur within national forests. These include, but are not limited to, mitigating the effects of visitor use within watersheds occupied by steelhead, working collaboratively with federal and state agencies and water management entities to restore steelhead trout access to upstream habitat, reducing risks from wildland fires to maintain water quality, and eliminating and limiting the further spread of invasive nonnative species (USDA 2005). For example, in 2014, the Cleveland National Forest initiated an effort to restore Southern SH/RT migratory corridors in the San Juan and Santiago watersheds by removing numerous small, outdated, and non-functional dams constructed by Orange County (Donnell et al. 2017). Thus far, up to 81 small check dams on Silverado, Holy Jim, Trabuco, and San Juan creeks have been removed. Forest Plans are required to be updated every 10 to 15 years. In recent years, several amendments to the Southern California National Forest Plans have been adopted in response to monitoring and evaluation, new information, and changes in conditions.

7.2.3 Habitat Conservation Plans and Natural Community Conservation Plans

A Habitat Conservation Plan (HCPs) is a planning document that authorizes the incidental take of a federally listed species when it occurs due to an otherwise lawful activity. HCPs are designed to accommodate both economic development and the permanent protection and management of habitat for species covered under the plan. At minimum, HCPs must include an assessment of the impacts likely to result from the proposed taking of one or more federally listed species, the measures that the permit applicant will undertake to monitor, minimize, and mitigate such impacts, the funding available to implement such measures, procedures to deal with unforeseen or extraordinary circumstances, alternative actions to the taking that the applicant analyzed, and the reasons why the applicant did not adopt such alternatives (USFWS 2021).

The Natural Community Conservation Planning Act authorized the Department to develop Natural Community Conservation Plans (NCCPs). NCCPs identify and provide for the regional protection of plants, animals, and their habitats, while allowing compatible and appropriate economic activity. The development of a NCCP by a local agency requires significant collaboration and coordination with landowners, environmental organizations, and state and federal agencies. Most approved HCP/NCCP documents are joint documents that fulfill the requirements of both Section 10 of the ESA and the Natural Community Conservation Planning Act.

Within the range of the Southern SH/RT, there are at least nine HCP or NCCPs that are either in the implementation phase or the planning phase. The majority of HCP and NCCP plans are for the southern portion of the species range and include multiple plan subareas. For example, the San Diego County Multiple Species Conservation Program contains six subareas, including the City of San Diego, Poway, Santee, La Mesa, Chula Vista, and South San Diego County. Generally, rivers, streams, and riparian vegetation communities in HCP and NCCP plan areas are considered ecologically important areas that are targeted for conservation. HCP/NCCP plans typically contain provisions to conserve fish and wildlife habitat, including fire management, invasive species control, fencing, trash removal, and annual monitoring.

7.2.4 Other Management and Restoration Plans

The Steelhead Restoration and Management Plan for California is a Department-statewide steelhead management plan that provides guidelines for steelhead restoration and management that can be incorporated into stream-specific project planning (McEwan and Jackson 1996).

https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=3490

7.3 Habitat Restoration and Watershed Management

7.3.1 Fisheries Restoration Grant Program

The goal of the Department's Fisheries Restoration Grant Program (FRGP) is to recover and conserve salmon and steelhead trout populations through restoration activities that reestablish natural ecosystem functions. The FRGP annually funds projects and activities that provide a demonstrable and measurable benefit to anadromous salmonids and their habitat; restoration projects that address factors limiting productivity as specified in approved, interim, or proposed recovery plans; effectiveness monitoring of habitat restoration projects at the watershed or regional scales for anadromous salmonids; and other projects such as outreach, coordination, research, monitoring, and assessment projects that support the goal of the program. Uniquely, the FRGP provides CWA Section 401 certification and CWA Section 404 coverage for all eligible projects funded through the program. In recent years, several FRGP proposals have been funded to support conservation efforts for Southern SH/RT, including the Upper Gaviota Fish Passage Project (2022), Life Cycle Monitoring on Topanga Creek and the Ventura River (2021), Fish Passage Barrier Removal on San Jose Creek, Gaviota Creek, and Maria Ygnacio Creek (2021), and the South Coast Steelhead Coalition (2021) (see https://wildlife.ca.gov/Grants/FRGP for more information.)

7.3.2 Wildlife Conservation Board, Proposition 68 and Proposition 1

The Water Quality, Supply, and Infrastructure Improvement Act of 2014 (Proposition 1) and the California Drought, Water, Parks, Climate, Coastal Protection, and Outdoor Access for All Act of 2018 (Proposition 68) authorized both the Wildlife Conservation Board and the Department to award significant grant funding to restoration projects that are intended to benefit Southern SH/RT. Both entities distribute Proposition 68 and Proposition 1 funds on a competitive basis to projects that specifically address river and stream restoration (Proposition 68; Proposition 1), Southern SH/RT habitat restoration (Proposition 68), fish and wildlife habitat restoration (Proposition 68; Proposition 1), or stream flow enhancements (Proposition 1). Proposition 68 funded projects that benefit Southern SH/RT and their habitat include the Harvey Diversion Fish Passage Restoration Project on Santa Paula Creek, the Matilija Dam Ecosystem Restoration Project on Matilija Creek, and the Santa Margarita River Fish Passage Project and Bridge Replacement. Proposition 1 funded projects include, but are not limited to, *Arundo donax* removal at the Sespe Cienega on the Santa Clara River, the Santa Clara River Riparian

Improvement, and the Integrated Water Strategies Project for Flow Enhancement in the Ventura River Watershed (WCB 2021).

7.3.3 Other Habitat Restoration Funding Sources

In addition to funding provided by the Department, Wildlife Conservation Board and FRGP, Southern SH/RT conservation projects are also supported by numerous other funding sources. These sources include local, state, and federal sources such as the California Coastal Conservancy, Pacific Coastal Salmon Recovery Fund, the National Fish and Wildlife Foundation, the NOAA Restoration Center, the California Department of Water Resources Integrated Regional Water Management Plan grant program (Proposition 50), the California Natural Resources Agencies Parkways Program (Proposition 40), the CalTrans Environmental Enhancement and Mitigation Program, the Santa Barbara County Coastal Resource Enhancement Fund, and the San Diego Association of County Government TransNet Environmental Mitigation Program (NMFS 2016).

7.3.4 California Steelhead Report and Restoration Card

The California Steelhead Report and Restoration Card program has funded various types of conservation projects since 1993, including instream habitat improvement, species monitoring, outreach and education, and watershed assessment and planning. However, no restoration projects within the Southern SH/RT range were funded between 2015 and 2019, as most funds were granted to projects in more northern watersheds (CDFW 2021c).

7.3.5 Non-Governmental Organization (NGOs) Efforts

Several NGOs contribute funding and staff time to implement restoration projects for the benefit of Southern SH/RT, often with the support of federal, state, or local grants. For example, the South Coast Steelhead Coalition under the guidance of California Trout, has received grant funding from the Department's FRGP to implement several restoration projects that benefit Southern SH/RT, including the Harvey Diversion Fish Passage Project on Santa Paula Creek; the Interstate 5 Trabuco Fish Passage Project on San Juan Creek in Orange County, the Santa Margarita River Fish Passage Project on Sandia Creek in San Diego County; the Rose Valley Restoration Project on Sespe Creek; invasive vegetation removal in the Santa Clara River floodplain; and *O. mykiss* protection in the upper Santa Margarita River, West Fork San Luis Rey River, and upper tributaries to the Santa Clara and Ventura rivers (NMFS 2016). Other NGOs that promote funding and implementation of steelhead recovery actions include the Santa Clara River Steelhead Coalition under the direction of California Trout, the Tri-Counties Fish Team, the Environmental Defense Center, the San Gabriel and Lower Los Angeles Rivers Mountain Conservancy, the West Fork San Gabriel River Conservancy, and the Council for

Watershed Health (San Gabriel and Los Angeles rivers). Additionally, there are many other groups or agencies that are also involved in Southern SH/RT conservation efforts: Concerned Resource and Environmental Workers; Heal the Ocean; Santa Barbara ChannelKeeper; Matilija Coalition; Ojai Valley Land Conservancy; Friends of the Ventura River; Friends of the Santa Clara River; Friends of the Los Angeles River; Friends of the Santa Monica Mountains; Heal the Bay; Friends of the Santa Margarita River; San Dieguito River Valley Conservancy; and the Endangered Habitat League (NMFS 2016).

7.3.6 Other Regional and Local Public Institution Efforts

The Southern California Wetlands Recovery Project (SCWRP) consists of directors and staff from 18 public agencies, which collectively coordinate to protect, restore, and enhance coastal wetlands and watersheds between Point Conception and the Mexican Border. The SCWRP, which was founded in 1997, is chaired by the California Natural Resources Agency with support from the California State Coastal Conservancy. The mission of the SCWRP is to expand, restore, and protect wetlands in southern California. The SCWRP is guided by long-term goals, specific implementation strategies, and quantitative objectives articulated in its 2018 regional strategy report (SCWRP 2018).

The Southern California Coastal Water Research Project (SCCWRP) is a public research and development agency whose mission is to enhance the scientific foundation for management of southern California's ocean and coastal watersheds. Since its creation in 1969, the focus of the SCCWRP has been to develop strategies, tools, and technologies to improve water quality management for the betterment of the ecological health of the region's coastal ocean and watersheds. SCCWRP research projects are guided by comprehensive annual plans for major research areas, including ecohydrology, climate change, eutrophication, microbial water quality, and stormwater best management practices (SCCWRP 2022). Currently, the SCCWRP, in cooperation with other local and state agencies, is leading the Los Angeles River Environmental Flows Project. The project's goals are to quantify the relationship between flow and aquatic life, account for flow reduction allowances to the river from multiple wastewater reclamation plants during the summer months and develop flow criteria for the Los Angeles River using the California Environmental Flows Framework.

The City of Santa Barbara supports a Creeks Restoration and Water Quality Improvement Division (Creeks Division), whose mission is to improve creek and ocean water quality and restore natural creek systems through storm water and urban runoff pollution reduction, creek restoration, and community education programs. The Creeks Division's goal for restoration includes increasing riparian vegetation and wildlife habitat, removing invasive plants, and improving water quality through shading, bank stabilization, and erosion control. The Division has completed several restoration projects in Santa Barbara County, including the Mission Creek Fish Passage project, the Arroyo Burro Estuary and Mesa Creek restoration project, and the upper Las Positas Creek restoration project. The Creeks Division also conducts removal efforts of invasive giant reed from the Arroyo Burro, Mission, and Sycamore Creek watersheds and participates in water quality improvement projects, creek and beach cleanups, and education outreach efforts throughout Santa Barbara County.

The California Conservation Corps Fisheries Program gives U.S. military veterans opportunities to develop skills and work experience by restoring habitat for endangered salmon and steelhead and conducting fisheries research and monitoring. The program, which is a partnership between the California Conservation Corps, NMFS, and the Department, trains participants on a variety of fisheries monitoring techniques, including riparian restoration, dual-frequency identification sonar (DIDSON) techniques, adult and juvenile fish identification, downstream migrant trapping, and instream flow and habitat surveys.

7.4 Commercial and Recreational Fishing

California freshwater sport fishing regulations prohibits fishing in virtually all anadromous coastal rivers and streams in southern California that are accessible to adult steelhead. However, recreational angling for *O. mykiss* above impassable barriers is permitted in many coastal rivers and streams (CDFW 2023a). The Department has expanded its use of sterile “triploid” fish to prevent interbreeding of hatchery fish with native Southern SH/RT (NMFS 2016). The freshwater exploitation rates of Southern SH/RT are likely very low given the Department’s prohibition of angling within the geographic range of the Southern California Steelhead DPS listed under the federal ESA (NMFS 2016). Additionally, sport and commercial harvest of Southern SH/RT greater than 16 inches in length in the Department’s Southern Recreational Fishing Management Zone is prohibited (CDFW 2023b). All incidentally captured steelhead in the ocean must be released unharmed and should not be removed from the water.

7.5 Research and Monitoring Programs

7.5.1 California Coastal Monitoring Program

The purpose of the CMP is to gather statistically sound and biologically meaningful data on the status of California’s coastal salmonid populations to inform salmon and steelhead recovery, conservation, and management activities. The CMP framework is based on four viable salmonid population metrics: abundance, productivity, spatial structure, and diversity (Adams et al. 2011; McElhany et al. 2000). Boughton et al. (2022b) updated the CMP approach for the southern coastal region to address the scientific uncertainty on Southern SH/RT ecology due to lower abundances and a more arid climate compared to more northern populations, for which the original CMP framework was designed.

Currently, the Department leads monitoring efforts in the southern coastal region, with most efforts focused on obtaining abundance estimates for anadromous adults in Core 1 and Core 2 populations (NMFS 2016). As of March 2023, Department CMP staff operate fixed-point counting stations and conduct summer-low flow juvenile surveys, redd surveys, and PIT tagging arrays on the Ventura River, Topanga Creek, and Carpinteria Creek, including the various tributaries to these watersheds. Fixed-point counting stations for anadromous adults are also operated on the Santa Ynez River and its primary tributary, Salsipuedes Creek. Redd surveys and juvenile low-flow surveys also occur in coastal watersheds of the Santa Monica Mountains, such as Big Sycamore Creek, Malibu Creek, Arroyo Sequit Creek, and Solstice Creek. Additionally, the Department conducts spawning surveys in the many watersheds of the Conception Coast, including Jalama, Gaviota, Glenn Annie, San Pedro, Maria Ygnacio, and Mission creeks. Department CMP staff anticipate expanding the number of southern coastal watersheds monitored as landowner agreements and available funding increase (K. Evans, CDFW, personal communication).

7.5.2 Other Monitoring Programs

Several special districts or local governments monitor Southern SH/RT on an annual basis in watersheds that contain federally owned or operated infrastructure. Such monitoring is often required for compliance with monitoring and reporting measures set forth in federal ESA Section 7 Biological Opinions. Although the level of monitoring effort and protocol methods vary between monitoring programs, the data produced by these special districts or local governments are often the longest time-series data available for Southern SH/RT.

COMB has conducted monitoring within the Lower Santa Ynez River and its tributaries since 1994 as part of the assessment and compliance measures required in the Cachuma Project Biological Opinion. Redd and adult spawner surveys typically occur throughout the winter months, while juvenile snorkel surveys are conducted in the spring, summer, and fall months. Estuary monitoring is also periodically conducted to complement upstream trapping during the migration seasons.

Since 2005, the CMWD has monitored fish migration at the Robles Fish Passage facility (14 miles upstream from the ocean) on the Ventura River using a VAKI Riverwatcher remote fish monitoring system. CMWD also conducts reach-specific spawner and redd surveys and snorkel surveys at index sites throughout the Ventura River watershed from the winter through late spring (Dagit et al. 2020).

UWCD monitors both upstream and downstream migration at the Vern Freeman Diversion Dam (approximately 10 miles upstream from the ocean) using both video-based and motion detection surveillance systems. Monitoring occurs from January to June when streamflow in the Santa Clara River is high enough to maintain water levels at the passage facility (Booth 2016).

The RCDSMM has monitored Arroyo Sequit, Malibu, and Topanga creeks since the early 2000s. Monitoring typically occurs from January through May and includes snorkel surveys, spawning and rearing surveys, instream habitat surveys, and periodic lagoon surveys (Dagit et al. 2019). Since 2016, the South Coast Steelhead Coalition, under the direction of California Trout, has conducted post-rain reconnaissance surveys in San Juan Creek, San Mateo Creek, the Santa Margarita River, and the San Luis Rey River (Dagit et al. 2020).

8. SUMMARY OF LISTING FACTORS

The Commission's CESA implementing regulations identify key factors relevant to the Department's analyses and the Commission's decision on whether to list a species as endangered or threatened. A species will be listed as endangered or threatened if the Commission determines that the species' continued existence is in serious danger or is threatened by any one or any combination of the following factors: (1) present or threatened modification or destruction of its habitat; (2) overexploitation; (3) predation; (4) competition; (5) disease; or (6) other natural occurrences or human-related activities (Cal. Code Regs., tit. 14, § 670.1, subd. (i)). This section provides summaries of information from the preceding sections of this Status Review, arranged under each of the factors to be considered by the Commission in determining whether listing is warranted.

8.1 Present or Threatened Modification or Destruction of Habitat

The decline of Southern SH/RT can be attributed to a wide variety of human activities, including, but not limited to, urbanization, agriculture, and water development. These activities have degraded range-wide aquatic habitat conditions, particularly in the lower and middle reaches of individual watersheds (See Section 6.8). Southern California is home to over 20 million people and 1.8 million acres of urban area (DWR 2021). As a result, the majority of watersheds, currently occupied by Southern SH/RT, are highly urbanized and impacted by surface and groundwater diversions and associated agricultural, residential, and industrial uses.

Although some deleterious activities have been eliminated or mitigated, habitat conditions for Southern SH/RT have continued to deteriorate over time due to numerous stressors associated with human population growth and climate change impacts. Water diversions, storage, and conveyance for agriculture, flood control, and domestic uses have significantly reduced much of the species' historical spawning and rearing habitat. Changes to the natural flow regime of southern California rivers and streams have resulted in lower and less variable stream flows, increased water temperatures, shifts in aquatic community composition, and reduced recruitment of gravel and sediments. High road densities and the presence of many in-stream artificial barriers have reduced habitat connectivity by impeding and restricting volitional fish passage in many watersheds, especially in the lower reaches. Development activities associated with agriculture, urbanization, flood control, and recreation have also substantially altered Southern SH/RT habitat quantity and quality by increasing ambient water temperatures, increasing nutrient and pollutant loading, degrading water quality, eliminating riparian habitat, and creating favorable conditions for non-native species. Range-wide and coastal estuarine habitat conditions are highly degraded and are at risk of loss and further degradation. Legal cannabis cultivation is a relatively new yet potentially serious threat to Southern SH/RT watersheds if best management practices, instream flow requirements, and diversion season regulations are not complied with. Our review of habitat conditions in southern California supports the conclusions of other review efforts, which conclude that populations continue to be at risk of extinction unless significant restoration and recovery measures are implemented (Moyle et al. 2017; NMFS 2012a).

The Department considers present or threatened modification or destruction of habitat to be a significant threat to the continued existence of Southern SH/RT.

8.2 Overexploitation

Exploitation rates of Southern SH/RT are relatively low across its range (See Section 6.9). While angling-related mortality may have historically contributed to the decline of some small populations, it is generally not considered a leading cause of the decline of the Southern California Steelhead DPS as a whole (Good et al. 2005; Busby et al. 1996; NMFS 1996b). After southern California steelhead was first listed as endangered under the federal ESA as an ESU in 1997, the Commission closed recreational fisheries for Southern SH/RT in California marine and anadromous waters with few exceptions. The closure continues, and there is currently no recreational fishery for Southern SH/RT (CDFW 2023a; CDFW 2023b).

Marine commercial driftnet fisheries in the past may have contributed slightly to localized declines; however, Southern SH/RT are not targeted in commercial fisheries and reports of incidental catch are rare. Commercial fisheries are not believed to be a leading cause of the widespread declines over the past several decades (NMFS 2012a).

Illegal harvest is likely the leading source of exploitation. Southern SH/RT are especially vulnerable to poaching due to their visibility in shallow streams. Estimates of fishing effort from self-report cards for 1993-2014 suggest extremely low levels of angling effort for Southern SH/RT (NMFS 2016; Jackson 2007). Though illegal harvest rates appear to be very low, because of low adult abundance, the removal of even a few individuals in some years could be a threat to the population (Moyle et al. 2017).

The Department does not consider overexploitation to be a substantial threat to the continued existence of Southern SH/RT, but further directed study is warranted to confirm this threat level.

8.3 Predation

Southern SH/RT experience predation in both the freshwater and marine environments, but specific predation rates, particularly in marine environments, are not well understood (See Section 6.5). While Southern SH/RT have evolved to cope with a variety of natural predators, a suite of non-native predators has also become established within its watersheds (Busby et al. 1996; NMFS 2016; Stillwater Sciences 2019; Dagit et al. 2019; COMB 2022). Established populations of non-native fishes, amphibians, and aquatic invertebrates combined with anthropogenic habitat alterations that provide favorable conditions for the persistence of these non-native species have led to increased predation rates in much of its range (NMFS 1996b). Habitat modification and degradation has also likely increased predation rates from terrestrial and avian predators (Grossman 2016; Osterback et al. 2013).

The Department considers predation to be a moderate threat to the continued existence of Southern SH/RT based on the available data. Further directed study is warranted to confirm the level of impact of these predation threats on Southern SH/RT.

8.4 Competition

Southern SH/RT populations are subject to competitive forces across their range (See Section 6.6). The extent to which competition impacts the distribution, abundance, and productivity of Southern SH/RT populations is not well understood. Southern SH/RT are the only species of salmonid that occur in their range. Therefore, the potential for inter-specific competition with other salmonids is unlikely to occur. Interspecific competition with other non-salmonid fishes occurs to varying degrees across the Southern SH/RT range. In addition to competing with juvenile steelhead for food resources, juvenile non-native fish species can limit the distribution and abundance of juvenile steelhead. Non-native fish species can competitively exclude and confine the spatial distribution of juvenile steelhead to habitats such as shallower, higher velocity riffles, where the energetic cost to forage is higher (Rosenfeld and Boss 2001).

The Department considers competition with nonnative fish species to be a moderate threat to the continued existence of Southern SH/RT. Further directed study is warranted to confirm the level of impact from competition.

8.5 Disease

Southern SH/RT survival is impacted by a variety of factors including infectious disease (See Section 6.3). A myriad of diseases caused by bacterial, protozoan, viral, and parasitic organisms can infect *O. mykiss* in both the juvenile and adult life stages (NMFS 2012a). Degraded water quality and chemistry in much of the Southern SH/RT range is likely to increase infection rates and severity (Belchik et al. 2004; Stocking and Bartholomew 2004; Crozier et al. 2008). There is very little current information available to quantify present infection and mortality rates in Southern SH/RT.

The Department does not consider disease to currently be a significant threat to the continued existence of Southern SH/RT, however further directed study is warranted to confirm the level of current and potential future impact.

8.6 Other Natural Occurrences or Human-related Activities

Southern SH/RT populations have evolved notably plastic and opportunistic survival strategies and are uniquely adapted to wide-ranging natural environmental variability, characterized by challenging and dynamic habitat conditions (Moyle et al. 2017). However, combined anthropogenic and climate change-driven impacts may ultimately outpace Southern SH/RT's capacity to adapt and persist, potentially leading to extirpation within the next 25–50-year time frame (Moyle et al. 2017; See Section 6.2). This prediction is underscored by the fact that Southern SH/RT already encounters water temperatures that approach and may, at times, exceed the upper limit of salmonid thermal tolerances, across portions of its current distribution (Moyle et al. 2017). Southern SH/RT has, therefore, been characterized as having potential for severe climate change impacts (Moyle et al. 2017). With increasing exposure to periods of higher water temperatures and flow variability, along with extended droughts, more frequent and intense wildfires, catastrophic flooding and associated sediment movement, sea level rise, and ever-increasing human demands for natural resources, the combined impacts to Southern SH/RT will be interdependent, synergistic, and are expected to intensify without intensive and timely human intervention (NMFS 2012b; Hall et al. 2018; OEHHA 2022).

Human-related activities are considered by the Department to be significant threats to the continued existence of Southern SH/RT.

9. SUMMARY OF KEY FINDINGS

Southern California steelhead (*Oncorhynchus mykiss*) inhabit coastal streams from the Santa Maria River system south to the U.S.-Mexico border. Non-anadromous resident *O. mykiss*, familiar to most as Rainbow Trout, reside in many of these same streams and interbreed with anadromous adults, contributing to the overall abundance and resilience of the species. Southern California steelhead as defined in the Petition include both anadromous (ocean-going) and resident (stream-dwelling) forms of *O. mykiss* below complete migration barriers in these streams.

Less than half of the watersheds historically occupied by Southern SH/RT remain occupied, most commonly with individuals able to express only a freshwater-resident life-history strategy (NMFS et al. 2012). Adult steelhead runs have declined to precariously low levels, particularly over the past five to seven years, with declines in adult returns of 90% or more on major watersheds that historically supported the largest anadromous populations (e.g., the Santa Maria, Santa Ynez, Ventura, and Santa Clara rivers). Additionally, our analysis of resident populations indicates a sharp decline over this same time period.

While recent genetic findings suggest that the anadromous life-history form can be sustained and reconstituted from resident individuals residing in orographic drought refugia, in southern California, nearly all drought refugia habitats are currently above impassable barriers. Therefore, the anadromous phenotype is at an increasingly high risk of being entirely lost from the species within its southern California range, in large part due to the lack of migration corridors between drought refugia and the ocean, and the inability of resident progeny to successfully migrate downstream in years with sufficient rainfall and streamflow.

Southern SH/RT continues to be most at risk from habitat degradation, fragmentation, and destruction resulting from human-related activities. Specifically, dams, surface water diversions, and groundwater extraction activities restrict access to most historical spawning and rearing habitats and alter the natural flow regime of rivers and streams that sustain ecological, geomorphic, and biogeochemical functions and support the specific life history and habitat needs of Southern SH/RT. Agricultural and urban development negatively affect nearby rivers and streams through increased pollution and surface runoff, which degrade water quality and habitat conditions. Furthermore, the rapid rate of climate change and the increasing presence of non-native species present another challenge to the persistence of Southern SH/RT.

Based on the best scientific information available at the time of the preparation of this review, the Department concludes that the Southern SH/RT is in danger of extinction throughout all of its range. Intensive and timely human intervention, such as ecological restoration, dam removal, fish passage improvement projects, invasive species removal, and groundwater management, are required to prevent the further decline of the species. The extinction of Southern SH/RT would represent an insurmountable loss to the *O. mykiss* diversity component in California due to their unique adaptations, life histories, and genetics, which have allowed them to persist at the extreme southern end of the species' West Coast range.

10. RECOMMENDATION FOR THE COMMISSION

CESA requires the Department to prepare this report regarding the status of Southern SH/RT in California based upon the best scientific information available to the Department (Fish & G. Code, § 2074.6). CESA also requires the Department to indicate in this Status Review whether the petitioned action (i.e., listing as endangered) is warranted (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)).

Under CESA, an endangered species is defined as “a native species or subspecies…which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease” (Fish & G. Code, § 2062). A threatened species is defined as “a native species or subspecies…that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]” (Fish and G. Code, § 2067).

Based on the criteria described above, the best scientific information available to the Department indicates that Southern SH/RT is in serious danger of becoming extinct in all or a significant portion of its range due to one or more causes including: 1. present or threatened modification or destruction of habitat; and 2. other natural occurrences or human-related activities. The Department recommends that the Commission find the petitioned action to list Southern SH/RT as an endangered species to be warranted.

11. PROTECTION AFFORDED BY LISTING

It is the policy of the State to conserve, protect, restore, and enhance any endangered or threatened species and its habitat (Fish & G. Code, § 2052). The conservation, protection, and enhancement of listed species and their habitat is of statewide concern (Fish & G. Code, § 2051, subd. (c)). If listed, unauthorized take of Southern SH/RT would be prohibited under state law. CESA defines “take” as hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill (Fish & G. Code, § 86). Any person violating the take prohibition would be punishable under state law. The Fish and Game Code provides the Department with related authority to authorize “take” of species listed as threatened or endangered under certain circumstances (see, e.g., Fish & G. Code, §§ 2081, 2081.1, 2086, & 2835). If Southern SH/RT is listed under CESA, take resulting from activities authorized through incidental take permits must be minimized and fully mitigated according to state standards (Fish & G. Code, § 2081, subd. (b)). Take of Southern SH/RT for scientific, educational, or management purposes could be authorized through permits or memorandums of understanding pursuant to Fish and Game Code Section 2081(a).

Additional protection of Southern SH/RT following listing would also occur during required state and local agency environmental review under CEQA. CEQA requires affected public agencies to analyze and disclose project-related environmental effects, including potentially significant impacts on endangered, threatened, and rare special status species. Under CEQA's "substantive mandate," state and local agencies in California must avoid or substantially lessen significant environmental effects to the extent feasible. With that mandate, and the Department's regulatory jurisdiction generally, the Department expects related CEQA review will likely result in increased information regarding the status of Southern SH/RT in California as a result of pre-project biological surveys. Where significant impacts are identified under CEQA, the Department expects project-specific required avoidance, minimization, and mitigation measures will also benefit the species. While CEQA may require analysis of potential impacts to Southern SH/RT regardless of its listing status under CESA, the act contains specific requirements for analyzing and mitigating impacts to listed species. In common practice, potential impacts to listed species are scrutinized more in CEQA documents than are potential impacts to unlisted species. State listing, in this respect, and required consultation with the Department during state and local agency environmental review under CEQA, is expected to benefit the species by reducing impacts from individual projects to a greater degree than may occur absent listing.

CESA listing may prompt increased interagency coordination specific to Southern SH/RT conservation and protection. Listing may also increase the likelihood that state and federal land and resource management agencies will allocate additional funds toward protection and recovery actions.

12. MANAGEMENT RECOMMENDATIONS AND RECOVERY MEASURES

CESA directs the Department to include in its Status Review recommended management activities and other recommendations for recovery of Southern SH/RT (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f).). Department staff generated the following list of recommended management actions and recovery measures.

1. Implement comprehensive monitoring in all streams with extant Southern SH/RT populations and produce statistically robust population estimates. Fully implement the CMP and integrate the updated south coastal region monitoring strategy (Boughton et al. 2022b) to resolve the various ecological and methodological factors that currently impede monitoring. The main features of this updated strategy are:

- Estimates of average density for each BPG;
- Research on the location and extent of drought refugia in each BPG;

- Adult steelhead abundance estimates in selected populations that are robust enough to evaluate species' resilience to catastrophic events and the ability to adapt over time to long-term environmental changes;
- Adult *O. mykiss* abundance estimates that are sufficient to develop an estimate for total abundance in the region;
- Routine genetic monitoring to track the *Omy 5* A haplotype and AA genotype as indicators for viability; and
- Greater emphasis on monitoring methods that are unbiased or can be corrected for bias (NMFS 2016).

2. Support and participate in the development of watershed-specific plans to effectively maintain and restore Southern SH/RT habitat by focusing on the combination of factors currently limiting their distribution and abundance, such as dams, agriculture, and water extraction. This includes continuing to coordinate and collaborate with NMFS, NGOs, state and local governments, landowners, and other interested entities to implement recovery actions identified in the 2012 Recovery Plan for the southern California Steelhead DPS and other management and conservation strategies. High priority actions include (NMFS 2012a):

- Remove manmade passage barriers in all population watersheds and re-establish access to upper watersheds in both small coastal streams and the larger interior rivers within each BPG identified in the Recovery Plan;
- Complete planning and removal of Matilija Dam on Matilija Creek and Rindge Dam on Malibu Creek;
- Provide ecologically meaningful flows below major dams and diversions in all population watersheds by re-establishing adequate flow regimes in both small coastal streams and large interior rivers;
- Reevaluate the efficacy of existing fish passage structures at instream surface water diversions, dams, culverts, weirs, canals, and other infrastructure in all watersheds historically and currently occupied by Southern SH/RT; and
- Minimize the adverse effects of exotic and non-native plant and animal species on aquatic ecosystems occupied by Southern SH/RT through direct removal and control efforts.

3. Improve and expand suitable and preferred habitat used by Southern SH/RT for summer holding, spawning, and juvenile rearing. Prioritize habitat restoration, protection, and enhancement in Southern SH/RT holding, spawning, and rearing areas. Habitat projects should focus on improving habitat complexity, riparian cover, fish passage, and sediment transport, as well as enhancing essential deep, cold-water habitats for holding adults. Restoration should also be considered in potential habitats not currently occupied by Southern SH/RT.

4. Continue research on *Omy5* haplotypes and other relevant genomic regions to better understand: the mechanism for anadromy in Southern SH/RT, the impact of migration barriers on the frequency of the “A” haplotype in individuals, and the risk of progressively losing the genetic basis for anadromy over time in above-barrier populations despite the current presence of the “A” haplotype.

5. Continue to investigate the population structure and ancestry of Southern SH/RT at the extreme southern end of the species distribution in southern California, including further research on identifying genetically introgressed populations and the potential benefit of these populations for maintaining the persistence of viable networks of Southern SH/RT, given recent findings of limited native ancestry in the region and the importance of variation in adaptation.

6. Initiate research into Southern SH/RT ecology identified in the Southern California Steelhead Recovery Plan (NMFS 2012a). Important research topics include:

- Environmental factors that influence anadromy;
- The relationship between migration corridor reliability and anadromous fraction;
- Identification of nursery habitat types that promote juvenile growth and survival;
- The role of seasonal lagoons and estuaries in the life history of Southern SH/RT and the extent to which these areas are used by juveniles prior to emigration;
- Investigation on the role that mainstem habitats play in the life history of steelhead, including identification of the ecological factors that contribute to mainstem habitat quality;
- The role of naturally intermittent creeks and stream reaches;
- Determining whether spawner density is a reliable indicator of a viable population;
- Determining the frequency of return adult spawners;
- Recolonization rates of extirpated watersheds by source populations;
- Dispersal rates between watersheds, including interactions among and between populations through straying;
- Intra-and interannual variation in diet composition and growth rate; and
- Partial migration and life-history crossovers.

7. Formalize minimization and avoidance measures on a Department-wide basis to minimize incidental take of the CESA-listed species due to otherwise lawful activities resulting from construction, research, management, and enhancement activities. This includes working with federal agencies to coordinate and develop efficient permitting processes for incidental take authorization for actions that contribute to the recovery of Southern SH/RT.

8. Explore other means of conserving individual populations of *O. mykiss* that may face the risk of extirpation due to catastrophic events, such as wildfires, droughts, and oil spills (e.g.,

conservation translocations to other existing facilities at academic institutions or museums, or natural refugia habitats). This includes ensuring that translocations of Southern SH/RT conducted by the Department for conservation purposes significantly contribute to species and ecosystem conservation and are planned, executed, and supported in a manner consistent with best scientific practices and the Department's Policy and Procedures for Conservation Translocations of Animals and Plants (CDFW 2017).

9. Strengthen law enforcement in areas occupied by Southern SH/RT to reduce threats of poaching, illegal water diversions, and instream work used for cannabis cultivation.

10. Evaluate current fishing regulations to determine any potential changes that could be implemented for further protection of Southern SH/RT, and update regulations, using clear and transparent communication, in response to restoration actions, such as dam removal projects, that could change the sport fishing regulation boundary (e.g., inland anadromous waters).

11. Conduct a robust outreach and education program that works to engage with tribes and interested parties, including federal, state, local, NGOs, landowners, underserved communities, and interested individuals, to promote and implement conservation actions. This includes developing outreach and educational materials to increase public awareness and knowledge of the ecological and societal benefits that can be gained by recovering Southern SH/RT.

ACKNOWLEDGEMENTS

This Status Review was prepared by Robin Shin in the Department's Fisheries Branch and Vanessa Gusman in the Department's Water Branch, with contributions from Max Fish, Claire Ingel, Jeff Weaver, and Chechen Shen in the Department's Fisheries Branch.

The Department would like to thank [peer reviewer names] for providing scientific peer review for this Status Review.

Table 2. Comments from External Peer Reviewers on the Draft Southern California Steelhead Status Review Report

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
1-193	all	Camm Swift	Overall the case for an endangered listing under the CESA is very well jusified and supported by this draft. It has been heartening to see effort to protect this highly impacted fish come closer to fruition and finally have the genetic justifications for protecting the remnant populations. For a long time the decline and its causes were well known, but it was conjectural the degree to which native vs introduced fish were present, and how resident and anadromous populations were related. Conclusions about these issues are now firmly established with detailed genetic informaion much less subject to alternative explanations. Most, if not all. of my comments to follow will mostly address clarity, mistakes and additions that do not seriously affect the very strongly supported conclusions and recommendation put forward. Some of these address the potential audiences for this document. This reviewer had been steeped in this subject for a long time and understands the issues put forward but a more naive reader may have more difficulty with some issues. These are noted below. The Literature cited or references were not all checked against the text but obvious mistakes are noted.	Comment noted.
1	all	David Boughton	Overall this is a thorough and careful status review. Nicely done. Overall, I find the body of available information supports the Department's recommendation to list southern Steelhead and Rainbow Trout as endangered under the California Endangered Species Act. However, this proposed listing omits the Rainbow Trout subpopulations in southern California that are currently isolated above impassable barriers, many of which in my view are at risk due to climate change and its various knock-on effects (increased drought, intensified wildfire regimes, bigger storms driving mudslide potential, warmer temperatures), combined with inability to be recolonized by Steelhead Rainbow Trout due to impassable barriers. I should note that my own agency (NMFS) has never assessed risk for these subpopulations due to lack of jurisdiction.	Additional information about the proposed listing unit was added to Section 3.2.
1-145	all	Alan Byrne	Good luck. This is a unique population of steelhead occupying the southern end of the range of O. mykiss. As such, there will be unique traits and adaptations in this DPS. From an ecological viewpoint it is important to recover this DPS. However, given the effects of climate change and urban development in southern California, policy choices outside the realm of CDFW are needed. If these populations can not regain access to headwater areas the future is not bright. I would focus on key rivers that have a chance to retain anadromy.	Comment noted.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
9	248	Matthew Sloat	I have reviewed the draft status assessment and my view is that the body of available information supports the Department's listing recommendation. The draft assessment is well written and thorough. I really don't have any substantive recommendations. I found the information well presented and agree that the conclusions are well supported by the best available science presented in this draft. My other comments are very nit picky corrections to a few inaccuracies I noticed in the general description of the species.	Comment noted.
9	255-258	Camm Swift	Essential habitat for the continued existence of the "species" but really mean the later identified Southern California SH/RT which is a subdivision of the subspecies *O. m. irideus* as discussed later, p. 12, line 346	The term "species", used in reference to the Petitioner's listing definition, was changed to "Southern SH/RT" throughout the document to reduce confusion.
12	329	Camm Swift	A native species or subspecies under CESA; only much later do you add that it can be a subpopulation like the Southern California SH/RT and as noted below someone used to thinking species and subspecies always have scientific names this might be confusing.	See Department response for page number 9, line number 255-258.
12	329	Camm Swift	"in California species range," technically the Tijuana River goes in and out of California into Baja California so the Southern California SH/RT could be interpreted as living (or having lived!) slightly in Mexico.	Comment noted.
12	338-345	Camm Swift	The unit being discussed is a species again here	See Department response for page number 9, line number 255-258.
12	353	Camm Swift	Here the allowance for subsets of species to be protected is detailed in the law and compared with the long federally listed entity. This explanation should come earlier to avoid confusion to my mind.	Comment noted.
13	357	Devon Pearse	Here and elsewhere, the issue of how to consider the anadromous and resident life-history forms, and all of the additional variation in migratory life-history patterns within those categories, is challenging. While the language used in the Status Review is slightly different from that in the Petition, both focus on protection of all O. mykiss within a given below-barrier habitat unit. This reflects the interconnected relationships among individuals with different life-histories, as well as the greater need of the anadromous ecotype to have intact migratory corridors and sufficient flows to connect upstream habitats with the ocean. Thus, maintaining habitats that supports viable numbers of anadromous adults will also protect resident individuals. See comment on line 620.	Comment noted.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
13	364	Camm Swift	Part of summary of adverse effects might include priorities of DFGW rumored in "the old days" to have concentrated scarce resources towards northern California and tacitly made southern a lower priority.	Comment noted.
14	413-416	David Boughton	This statement is not quite correct, or at least it refers to the version of the ESU policy that was changed by the referenced FR notice (NMFS 2006). You can fix it by changing "ESU" to "DPS" in this sentence. The NMFS DPS policy as applied to steelhead is confusing and even within NMFS many people misinterpret it in my view. ESU is a scientific concept (Waples 1991) but the ESU policy is to equate DPS (a legal concept) to ESU. Scientifically this means southern California resident adults (Rainbow Trout) must be considered in the same ESU as steelhead. NMFS considers the ESU policy (as opposed to the ESU scientific concept) to be an "extension" of the joint NMFS-USFWS DPS policy suitable for the specific life-history of Pacific salmon, but for steelhead fell back to the more general approach of the joint DPS policy, for two reasons: 1) "Use of the ESU policy--originally intended for Pacific salmon--should not continue to be extended to O. mykiss, a type of salmonid with characteristics not typically exhibited by Pacific salmon" (NMFS 2006, page 834, middle column, bottom), and 2) NMFS considered "that within a discrete group of O. mykiss populations, the resident and anadromous life forms of O. mykiss remain 'markedly separated' as a consequence of physical, physiological, ecological, and behavioral factors, and may therefore warrant delineation as separate DPSs" (NMFS 2006, page 835, middle column). That is, the anadromous form is markedly distinct in terms of phenotype even though it interbreeds with rainbow trout. In my view, we can still talk about O. mykiss ESUs as a scientific concept, and the listed steelhead DPS is the anadromous component of the ESU. This is subtly different from the way you all are implementing the DPS policy. Your implementation explicitly includes rainbow trout in anadromous waters, whereas the NMFS version includes those fish only insofar as they are indistinguishable from anadromous O. mykiss (e.g juveniles whose life history is not yet determined). Confused? Join the crowd.	Changed "ESU" to DPS in the referenced sentence. The Department acknowledges and is aware of the different applications of the DPS Policy used here in the Status Review and in other technical documents by NMFS.
14	416	Camm Swift	It could be more explicitly explained that the anadromous jurisdiction lies with NOAA vs the resident one with the USFWS and both populations of fish are included in this proposed state listing.	Comment noted.
14	419	Matthew Sloat	O mykiss doesn't have the largest range. That distinction belongs to chum salmon.	Edited line 419.
14	419-420	Camm Swift	Range of *O. mykiss* extends to the western Pacific into Russia where *mykiss* was described from	Expanded range to include the western Pacific.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
15	444	David Boughton	Table 1 is adapted from a similar table in our monitoring update, but parts have been omitted and it has been changed a bit. As a scientist, I like your definition of "Steelhead Rainbow Trout" as an ESU, but then you should probably include the definition of ESU itself as well. The ESU concept has an aspect of common descent, meaning that the above-barrier O. mykiss would be included in the ESU; but you don't include them in your DPS, even though your interpretation of DPS (unlike the NMFS version), includes adult rainbow trout. This might cause some confusion, particularly since the above-barrier O. mykiss probably have the capacity to express the anadromous life history and are therefore useful for recovery. In addition, they themselves are threatened by the loss of migration connectivity, because disturbances such as droughts and wildfires might extirpate individual above-barrier populations, and they will not get recolonized due to the dams; or, disturbances may cause bottlenecks that reduce genetic diversity, and gene flow via anadromous migrants is also blocked by the dams.	Removed the term ESU from the definition of Steelhead Rainbow Trout in Table 1. Steelhead Rainbow Trout are populations that contain both steelhead and Rainbow Trout individuals.
16	456	David Boughton	I would say "smolting the primary ***physiological*** characteristic that distinguishes…", because migration to the ocean is the primary characteristic	Suggested edit was made to line 456.
16	460	Devon Pearse	Suggest editing to: "Juvenile >O. mykiss< that do not smolt and remain in freshwater generally lose their parr marks as they grow and develop into adult >Rainbow Trout<"	Suggest edit was made to line 460.
16	462	Devon Pearse	Suggest deleting 'Upon reentering freshwater rivers and streams to spawn,", since the timing of maturation relative to freshwater entry is variable and not relevant to the rest of the paragraph.	Suggested edit was made to line 462.
17	501	David Boughton	monophyly means something a little more restrictive than the definition here; it means the whole set of species descended from a common ancestor.	The definition of monophyly in line 509-510 was edited to improve clarity.
17-18	477-518	Camm Swift	This is a nice informative summary but perhaps too extensive for the purposes of this draft?	Comment noted.
18	513-516	Camm Swift	Does historical range count, this wording implies current range which could differ from historical range.	Comment noted. This sentence defines "range" and "distribution" for the purposes of the status review. These definitions apply to both current and historical descriptions.
18	519	Matthew Sloat	The only native O. mykiss populations in Asia are on the Kamchatka Peninsula and Shantar Islands.	Edited line 519.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
18	527	Matthew Sloat	A more recent and accurate phylogeny is available in: Crete-Lafreniere, A., Weir, L.K. and Bernatchez, L., 2012. Framing the Salmonidae family phylogenetic portrait: a more complete picture from increased taxon sampling.	Added Crete-Lafreniere et al. (2012) as a citation to line 530.
21	620	Devon Pearse	The high fecundity of female steelhead relative to female rainbow trout, combined with the female sex-bias in expression of anadromy (Kendall et al. 2015; Pearse et al. 2019), leads to anadromous females providing a disproportionately large contribution to the total egg and juvenile production below barriers in most systems. This is a consequence of their ability to access marine resources, bringing these nutrients and energy back into freshwater systems. This is stated on page 28, but cannot be overemphasized, and highlights the dependence of O. mykiss populations on the maintenance of diverse interrelated life-history forms.	Comment noted.
21	639	David Boughton	At the beginning of the sentence, add "Further north,"	Suggested edit was made to line 639.
23-34	687-991	Camm Swift	Section 2.5, this seems very well written and is central to much of the core argument for listing as scientific substantiation of many of the claims of endangerment. You need a good genetically proficient reviewer to also assess this section.	Comment noted.
23	699-701	Alan Byrne	The sentence about adaptive markers is based on genome wide association studies and most of the time the function of the gene is inferred. The key (and important) word is "putative".	Comment noted.
23	698-706	Alan Byrne	Move to Section 4.7. Focus on fish and their life histories.	Comment noted. Sections were left in place based on other comments received (page 23-34, lines 687-991)
25	721	Devon Pearse	The peer-reviewed publication Garza et al. 2014 TAFS, represents the same study and should replace Garza et al. 2004 throughout	Comment noted. Figures from Garza et al. 2004 are preferred to represent the information.
26	775-780	Alan Byrne	Information that supports the importance of 'straying' in these populations. This is important point to make. If only a handful of rivers have access to the sea in the winter it makes sense that adults in the ocean will go into those rivers regardless of their origin. It also represents a 'safety net' where rivers can be re-populated with anadromous individuals if there was a prolonged drought that caused the river to be disconnected from the ocean.	Comment noted.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
26-29	786 - 852	Alan Byrne	The Omy5 discussion in Section 2.5.5 should be folded into the haplotype discussion in Section 4.7 except I would retain lines 835-852 (it would be a good introduction to Section 2.5.6). I'd rather see a more high level discussion as presented in section 4.7 than all the detail provided in 2.5.5. Although this is an interesting topic, it's the life history variations that are important--genetics may help explain. Some of the info in this section is not necessary (lines 812-813, 823-825, 826-834)	Comment noted.
27	805	Devon Pearse	Rundio et al. 2012 not an appropriate citation here, delete.	Suggest edit was made to line 805.
28	817	Devon Pearse	The cited papers (Leitwein et al. 2016; Pearse et al. 2014) did not have data to directly support the statement that 'populations with a high frequency of the 'A' Omy05 variant also had higher proportions of individuals phenotypically expressing anadromy', although the data in those papers is consistent with this and statements in the rest of the paragraph. Suggest reversing the sentence and editing to Populations with higher potential to support anadromous or migratory individuals typically have a higher population-wide frequency of the anadromous variant of Omy5 than populations that have a higher frequency of the resident rainbow trout, such as those above waterfall barriers.	Suggest edit was made to line 817.
28	835	Devon Pearse	While accurate regarding the population genetic and evolutionary relationships among populations within versus among watersheds, this paragraph should more strongly enough state that resident and anadromous individuals within a given population or watershed are not just closely related in a population genetic sense, but interbreed, and that close relatives including full siblings may express these alternative phenotypes (or other life-history variation, e.g. adfluvial or lagoon migration).	More information as added to line 854.
28-29	835-852	Alan Byrne	Important point--retain this PP, see comment above.	Comment noted.
29	859	David Boughton	I'm not sure "monophyletic clade" is the right term here, it's usually used for species relationships. Safer to say "more closely related"	Suggested edit was made to line 859.
31	895	David Boughton	Insert "in the downstream direction" after "over barriers"	Suggested edit as made to line 895
31	904	Devon Pearse	Data in Pearse et al. 2014 is also very relevant to this statement, including for So Cal steelhead the Santa Clara and Santa Ynez Rivers.	Added suggested reference to line 904.
31	907	David Boughton	Add sentence: "However, a reservoir environment imposes different selective pressures than migration to the northern Pacific Ocean and therefore we would expect the anadromous genotype to be changed over time and eventually lose its ability to express a successful anadromous phenotype."	Suggested edit was made to line 907.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
31	893-907	Alan Byrne	Most of the points in this PP are made in lines 877-892 except for the last sentence.	Comment noted.
32	945-947	David Boughton	There is an important distinction to be made here between continual vs past or occasional stocking. Past stocking introduced many new genes, many of which were selected against (outbreeding depression), but a few of which may have been selected for, increasing fitness as noted. But for the erosion of native lineage in a way that reduces fitness, you would likely need ongoing stocking so that natural selection is swamped by geneflow from the hatchery stock	Redundant language was removed. See Department response for line 33, page 956.
33	956	Devon Pearse	The CDFW report, Jacobson et al. 2014, presents the same samples and data as Abadia-Cardoso et al. 2016, which was published following additional analyses and peer review. Given that, this paragraph is somewhat redundant with much of the preceding paragraph. Suggest reworking.	Redundant language was removed from Section 2.5 of the report.
33	962	David Boughton	Suggest changing to "Many more southerly populations…" since all the populations are southern.	Suggested edit was made to line 962.
36	1076	Devon Pearse	The statement "The anadromous life history of Southern SH/RT is not markedly separate from the non-anadromous life history of Southern SH/RT" seems incongruous with the rest of this paragraph, but it's meaning becomes clear when reading the next section. Suggest deleting or moving this sentence.	Comment noted.
36	1075-1077	David Boughton	This is the opposite of the NMFS DPS policy, which states that the anadromous form is markedly separate from the non-anadromous form (in terms of physical, physiological, ecological, and behavioral factors), even though the two forms interbreed. So you are applying the DPS policy in a way that is different from the way NMFS applied it. Of course the State of California is free to do what they want, but this may cause confusion. But also, if you are going to apply the DPS policy this way, it seems strange to exclude the above-barrier populations, which are also threatened by the loss of migration access due to the dams (commented on above), and also provide a genetic resource that could aid in the recovery of the below-barrier populations.	Additional information about the proposed listing unit was added to Section 3.2.
36	1077-1081	David Boughton	See above comment	Comment noted.
37	1086-1094	David Boughton	See above comment	Comment noted.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
37	1096-1107	David Boughton	See above comment. There are three kinds of "markedly separate" being lumped here: the geographic separation (which both NMFS and CDFW treat identically), the "marked" separation of anadromous vs resident forms below barriers but within the same geographic area (which NMFS recognizes but CDFW doesn't), and the separation of above-barrier and below-barrier rainbow trout (CDFW treats as one being threatened, the other not; neither are considered threatened by USFWS (who has Federal jurisdiction), and NMFS does not have an approach because the adult rainbow trout are outside their Federal jurisdiction).	Comment noted. The Department acknowledges and is aware of the similarities and differences in the application of the DPS Policy metrics (i.e., markedly separate) used here in the Status Review and in other technical documents by NMFS.
37-38	1116, 1146, 1150	Alan Byrne	I don't know what this is or why its included. If it is referring to ESU criteria on pages 35-36 please be specific.	Comment noted. See section 3.1 (DPS and ESU criteria) for more information.
37	1106	Camm Swift	Southern California SH/RT are distinct from the rest of the species	Comment noted. See Department response for page number 9, line number 255-258.
37	1114	Camm Swift	Southern California SH/RT are distinct from the rest of the populations; it is unclear if these three all mean the same thing [apparently], and the wording needs to be standardized somehow. To me the use of these terms as well as the words species and subspecies outside the zoological taxonomic sense is confusing. Suggest earlier after a concise discussion of the CESA and ESA listings criteria, make some kind of summary statement such as, "The proposed Southern California SH/RT is defined under the CESA as an ecologically, geographically, genetically, and legally distinct (and/or discreet) subdivision of [the subspecies?] *Oncorhynchus mykiss irideus."* And from there on avoid the use of the terms species, subspecies, and taxon in favor of Southern California SH/RT.	Comment noted. See Department response for page number 9, line number 255-258.
37	1118	Camm Swift	The range of Southern California SH/RT is at the southern most of its taxon. True if the taxon is *O. m. irideus* but not if *O. mykiss* that goes into Mexico as *O. m. nelsoni*.	Edited line 1118 to improve clarity of the statement.
38	1130	David Boughton	But what about the Bay Area, which also has steelhead-rainbow trout cohabiting with millions of people?	Edited line 1130 to improve clarity of the statement.
38	1147	Camm Swift	which taxon again	Comment noted.
39	1174-1175	Camm Swift	Southern California SH/RT is a DPS and a subspecies, despite earlier comments about the CESA allowing for designation of species, subspecies, and/or lesser distinct subgroups deemed deserving of protection.	Comment noted. See Department response for page number 9, line number 255-258.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
41	1255	Camm Swift	Becker and Reining (2008) cited here and often later but in list of references has a title restricting it to the Eel River.	Fixed incorrect reference in the Literature Cited section for Becker and Reining (2008).
41-60	1248-1771	Alan Byrne	The loss of habitat depicted in the maps for each BPG is the major reason for the decline of SH in this DPS. Although one can get the sense that a lot of habitat is now inaccessible I recommend that for each BPG you include a table that for each river shown in the BPG maps, list the historical anadromous distribution, the current anadromous distribution, and the percentage of habitat lost and if available the total historical habitat available for the entire BPG, current available for the BPG, and % lost for the BPG. Express habitat/distribution as drainage area or stream length? Make the point that loss of habitat by itself puts SH/RT in serious danger of becoming extinct in this DPS.	Comment noted. Information regarding the extent of current and anadromous habitat for the Ventura and Santa Ynez Rivers can be found in Section 6.8.2. Additional information regarding the range-wide presence and absence of Southern SH/RT in watersheds historically occupied can be found in Chapter 9.
43	1274	Camm Swift	Not sure why San Antonio Creek left out? San Antonio, a short distance north of the Santa Ynez, certainly suspected historically even if on size alone.	Comment noted. *O. mykiss* were determined to be "absent" from the drainage in 2002 based on surveys as part of a steelhead distribution study (Becker and Reining 2008).
44	1290-95	Camm Swift	Newspaper, Lompoc Record, vol. 16, No. 8, May 10, `1890, party of persons to the Sisquoc, creeks alive with mtn trout, No. 9, May 17, 1890, Sisquoc party report 2 persons/2 hrs, 450 fish. Well before stocking up in that area.	Additional information on the historical distribution and abundance of *O. Mykiss* in the Santa Maria River watershed was added to lines 1290-1295.
45	1336-1337	Camm Swift	The earliest years of the Lompoc Record in the Lompoc library from 1875,76 have notes of many one pound trout in San Miguelito creek entering the river from the south in the town of Lompoc, perhaps noted in Algona et al. 2012.	See line 1325-1326.
46	1383	David Boughton	Robles is not impassable, or at least, it depends on how they operate it.	Edited line 1435.
48	1435	David Boughton	I think you mean Santa Clara River, not Santa Maria River	Fixed incorrect river.
49	1470	David Boughton	I'm not sure where you got "eight" from. There are a much larger number of small creeks along this stretch of coast that have had O. mykiss.	Edited line 1470.
50-51	1502-1508	Camm Swift	Jalama Creek had juveniles in May of 1970, specimens at LACM (Natural History Museum of Los Angeles County, Section of Fishes)	Added reference to Jalama Creek in section 4.3.2.3.
51	1509	Camm Swift	Some explanation as to why Calleguas Creek not in Monte Arido or Santa Monica Mtns, another that size alone would predict expectation of steelhead in the past	Comment noted.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
53	1556	Camm Swift	Accessible mileage for Topanga should be much less than Malibu or explain that the upstream barrier is natural in Topanga and artificial in Malibu, the latter at least has more mileage if barrier removal takes place	Suggested edit was made to line 1556.
54	1594-1595	Camm Swift	Figure could include other significant dams? San Gabriel and Cogswell dams on the San Gabriel, Seven Oaks dam on the Santa Ana, and two on Santiago Creek, trib to the Santa Ana, and in text that follows. Some of these are noted much later.	Comment noted.
55	1606	Camm Swift	LACM has records from Fish Canyon for rainbow trout being abundant on 02 July 1986, 15 February 1998 and 16 June 2000. Fish were said to be common or abundant each time below and up into Forest service property. Camm Swift field notes and/or specimens.	Comment noted.
55	1617	Camm Swift	Boughton et al. (2006, Technical Memorandum 394, NMFS-SWFC) noted late 1850s historical accounts of abundant trout in the upper Santa Ana river, City Creek, and Cucamonga Creek of the Santa Ana drainage.	Added information in Boughton et al. 2006.
56	1634	Camm Swift	Should consider Big Tujunga Wash, trib to L. A. River, only place in current L. A. River drainage where native sucker, chub, and dace still occur and supported trout fishery in 1940s with controlled release from Big Tujunga dam.	Added Big Tujunga Creek as a tributary to the Los Angeles River.
56	1654	David Boughton	intermittency also results from groundwater depletion caused by pumping for water extraction. I suspect many dry creeks and rivers stem from groundwater depletion, and it would be good to highlight this problem more throughout this status review. Dams of course are a big part of the problem but so is lowered water tables because aquifers are used as another summertime water storage facility.	Noted groundwater depletion as a cause for stream intermittency.
57	1666	Camm Swift	San Mateo creek, map shows Cristianitos creek, a major northern tributary that is largely ephemeral but does not show upper Devils Canyon where steelhead actually spawned 1998-2000 (Hovey 2004).	Comment noted.
57	1670	David Boughton	If there's an impassable barrier, then shouldn't the sentence say rainbow trout rather than steelhead?	Edited line 1670.
58	1687	David Boughton	This is a bit confusing because Hovey used genetic data to argue that the creek had been colonized by steelhead after the Nehlsen et al paper; suggest rewrite to reflect that the San Mateo/Devil Canyon fish are believed to be descendants of this steelhead colonization event	Restructured lines 1675-1680.
60	1773	Camm Swift	As per earlier comments instead of "…of the candidate species…" use "...of Southern California SH/RT…"	See Department response for page number 9, line number 225-258.
60	1777-1778	Camm Swift	as above, reword to avoid using the word species	See Department response for page number 9, line number 255-258.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
61	1790-1792	David Boughton	The definition of core populations was those receiving highest priority for recovery actions, which is not quite the same as the definition here. For example, a well-protected and healthy population might not be core because it is already protected and thus not a priority.	Edited line 1790-1792 to improve clarity of the sentences.
61-71	1803-2003	Alan Byrne	Section 4.4.1. This is depressing and is all you need to have in the report to arrive at the conclusion that SH in this DPS are in serious danger of becoming extinct	Comment noted.
63	1848	David Boughton	How do redd surveys produce O. mykiss estimates?	Corrected mistake in line 1848.
65	1872	David Boughton	Thus, the observed steelhead were entering sink habitat? Might want to point this out--this situation creates an ecological trap.	Comment noted.
67	1920	David Boughton	According to the equation in line 1896, if any entry is zero, the geometric mean will be zero. How did you get these numbers, which are mostly not zero, even though the three Tables 2 indicate they should be zero? Something seems wrong here.	Added more information to Section 4.4.2.
66-68	1899 - 1946	Alan Byrne	You presented some estimates of steelhead run sizes in Section 4.3.1 for the Santa Ynez, Ventura, and Santa Clara rivers. Can you also show those estimates in this section in Table 3?	Comment noted.
71 - 74	2005 - 2073	Alan Byrne	You are probably required to do a trend analysis but with such low abundance's it does not add much. A population of 2 that goes to 4 is still in a world of hurt. Make that point.	Comment noted.
74	2068-2073	David Boughton	Clarify that you're talking about steelhead specifically here, not O. mykiss, since there are often extant O. mykiss populations in the headwaters	Comment noted.
74 - 77	2075 - 2122	Alan Byrne	You are probably required to do a productivity analysis but with such low abundances it does not add much. You need fish. Same point I made for trend applies here.	Comment noted.
75	2089	David Boughton	Apparently some typos in this equation. The "t+t4" should be "t+4" I think, and should be subscripted, as should the second "t". Also, this CRR estimator completely disregards age structure (not all adult steelhead return at age 4, and there is probably an important role for kelts). These simplifications should be noted. Also, productivity is defined differently in Fish Bulletin 182.	Fixed typo and edited the definition of productivity to align with Fish Bulletin 182.
71-77	2005-2122	Alan Byrne	The most important VSP parameter is abundance. You can not have meaningful positive trend, productivity, diversity metrics at population sizes (especially the anadromous component) as low as those presented in the abundance section	Comment noted.
78	2162-2163	David Boughton	Not necessarily - see Moore, M. R. (1980). Factors influencing the survival of juvenile steelhead rainbow trout (Salmo gairdneri gairdneri) in the Ventura River, California. M.S., Humboldt State University. Also, for the Carmel River a little bit to the north, but very similar in a lot of ways: Arriaza, J. L., D. A. Boughton, K.	Edited line 2162-2163 based on Moore (1980). Reference and citation added.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
			Urquhart and M. Mangel (2017). "Size-conditional smolting and the response of Carmel River steelhead to two decades of conservation efforts." Plos One 12(11). There could be a lot of improvement to these habitats to help spawning and rearing, in my view	
78	2144-2161	Camm Swift	Dams were also built often where the larger downstream reaches began to level out and probably provided considerable spawning sites in larger flows than in the higher tributaries with more bedrock and boulders with much lower flows. Thus they may well have been more than just corridors for migration.	See Department response for page number 78, line 2162-2163.
78	2145	David Boughton	Here is another place where it would be good to include groundwater depletion among the many ills impacting southern steelhead-rainbow trout	Added groundwater extraction to line 2145.
78	2171	David Boughton	This last sentence makes no sense. I think you mean the reverse?	Removed confusing sentence.
79	2186	David Boughton	But there were drought refugia in the mountains, where resident trout could regenerate anadromous fish when conditions were suitable	Added information on drought refugia to line 2186.
79	2188	David Boughton	Diversity - the extended phenotype - includes life-history diversity but potentially other phenotypic traits as well.	Edited line 2188.
79	2203	David Boughton	Comma after "range"	Added comma.
80	2217	David Boughton	Invasive species are also a big problem in many southern lagoons	Added invasive species to line 2217.
80	2220-2223	Camm Swift	While lagoon anadromous are rare or absent in the south, angling for "sundowners," in coastal lagoons like San Mateo creek was common in the 1930s and the Department had specific angling regulations for them (Swift et al. 1993). Given the epemeral nature of some southern California streams, the integrity of the lagoons may have been more important in the south relative to streams (Swift, Mulder et al. 2018; Swift, Holland et al. 2018,).	Comment noted. Added Swift et al. (1993) citation to line 3540.
80	2233	David Boughton	Hyphenate "above-barrier"	Added hyphen.
80	2234	David Boughton	"restricted fish passage to" can be read in two contradictory ways	Revised line 2234 to improve clarity of the sentence.
80-81	2224-2255	Alan Byrne	This is where I would move the Omy5 discussion (at a very high level) that is now in Section 2.5.5.	Comment noted.
81	2225-2227	Alan Byrne	Statement is true for females but "AR" males expressed more resident life history.	Comment noted.
81	2249-2251	Alan Byrne	...."it is unclear whether the resident component can reliably sustain the anadromous component in the long term...." -- I rather think of the resident component as having the ability to produce anadromous fish after prolonged unfavorable conditions (not needing to sustain the "A" life history). The returning anadromous fish can then sustain the "A" life history.	Revised lines 2249-2251 based on suggested revision.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
81	2278	Alan Byrne	another instance of "believe"--please re-write	Revised line 2278.
82	2299	David Boughton	Add "to" after "prior" and commas after "2012"	Suggested edits were made to line 2299.
82	2303	David Boughton	Poor sentence structure	Fixed poor sentence structure in line 2303.
82	2302-2307	Alan Byrne	This is worth repeating in the ES. Also, I find that not listing population's upstream of dams/artificial barriers problematic as, in my view, the only possible way for this DPS to persist is to gain access to their historical range. It's worth explaining the logic of excluding upstream areas somewhere in the report.	Added lines 2302-2307 to the Executive Summary.
83	2323	David Boughton	Change "necessary" to "necessarily"	Changed to neccesarily.
83-91	2346-2606	Alan Byrne	All this info is factual however it could be shortened if it was focused on the Southern SH/RT habitat requirements. Since you cite Bjornn and Reiser, Moyle, and NMFS a lot, I don't think its necessary to cite other studies that confirm what they stated (for example lines 2513 - 2522). As most of these rivers become de-watered all the habitat requirements listed are a moot point. I would make the lack of water the major habitat problem in this section. Fish need water. And it should be cool and clean.	Comment noted.
84	2361-2363	Camm Swift	For surmouning vertical barriers, the 25% pool depth figure applies to relatively low barriers and must be much more for the fish to clear higher barriers.	Comment noted.
86	2426-2430	Camm Swift	While Arroyo Chub may provide food for Southern California SH/RT they also can compete with small individuals in streams (Richards and Soltz 1986, cited in Swift et al. 1993) and are considered introduced in Topanga Creek and many other streams north of Malibu Creek (Swift et al. 1993). Through much of the range non-native species both compete with and prey upon Southern California SH/RT.	Added that Arroyo Chub are considered introduced in Topanga Creek.
87	2479	Devon Pearse	Another reference relevant to adaptation of Southern SH/RT to cite here and elsewhere in the Status Report: Dressler et al. 2023. Thermal tolerance and vulnerability to warming differ between populations of wild Oncorhynchus mykiss near the species' southern range limit. Scientific Reports 13:145338. https://doi.org/10.1038/s41598-023-41173-7	Added Dressler et al. (2023) as a citation to line 2479 and elswhere in the report where appropriate.
89-90	2555-2571	Camm Swift	Text implies lagoons that do not open to the ocean are in poor condition but lagoons otherwise not impacted can remain in good condition through the fall or even for multiple years during extremely dry years. Even if surface flows do not exist upstream, lagoon are also often fed by groundwater.	Comment noted. Text revised to remove implication that closed lagoons are in poor condition.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
91-92	2609-2658	Alan Byrne	I'm not opposed to keeping this section however it is not focused on the Southern SH. And it has no effect/little on the resident forms. The CCE indicators are close to shore but steelhead don't spend much time there (compared to chinook) as they head to sea after entering the ocean. I would delete line 2632 beginning with ....For the CCE region to 2658 and Figure 15.	Suggested edit was made.
93-102	2659-2940	Alan Byrne	This is a very important Section. I didn't get the sense of its importance when I read the full document. The points in Section 6.2 should be forcefully repeated in a concluding section and the ES. Climate effects should be elevated so that the reader understands that expected changes in climate is a serious threat to the species survival and could ultimately drive it to extinction.	Comment noted.
97	2788	Devon Pearse	Also appropriate to cite new (2023) NMFS status review?	Added NMFS (2023) citation.
100	2866-2875	Camm Swift	In southern California among estuarine types, only lagoons serve as salmonid nursery areas and the much more tidal and saline "created" estuaries apparently do not function as such. The brackish estuaries noted are a phenomenon of systems farther north where larger volume of freshwater inputs much of the year sustain brackish estuarine conditions.	Comment noted.
103	2989	David Boughton	Would be good to write a comment on the above-barrier populations' conservation value, which has been talked about elsewhere.	Comment noted. Conservation value of above-barrier populations discussed in Section 2.5.7.
103	2995	David Boughton	Could cite Clemento et al paper for populations retaining high degree of native ancestry	Added Clemento et al. (2008) citation.
103-105	3000-3048	Camm Swift	Include striped bass, both freshwater estuarine, and marine (Boughton, 2020, Calif. Fish and Wildlife, 106(3):226-257). Also Redeye bass (*Micropterus coosae*) in the prime Southern California SH/RT habitat in the Santa Margarita River gorge	Added information about Redeye bass. Reference provided concludes striped bass are rare in southern California.
104	3024-3033	Alan Byrne	delete everything after …....Bonar, et al.2005).	Suggested edit was made to lines 3024-3033.
104	3040	Alan Byrne	are crayfish native to these streams?? If yes, so what. It's a stretch to conclude that crayfish pose a threat to the survival of juvenile steelhead from 1 study. Predation effects should be assessed at the population scale not individuals.	Red Swamp Crayfish are non-native to southern California waters.
105-106	3074-3083	Camm Swift	Arroyo chub competition noted above, originally very little competition/predation outside L. A. basin since north and south only two or three other species in freshwater like stickleback, prickly sculpin and lampreys.	Comment noted.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
106	3104-3108	Alan Byrne	highlight this.	Comment noted.
107	3134	Devon Pearse	Delete "…in above-barrier populations…", since the statement applies to a comparative analysis among many populations below and above partial and complete barriers to migration.	Suggested edit was made to line 3134.
107	3119-3136	Alan Byrne	not a surprising result given the low population size.	Comment noted.
107	3136	David Boughton	Add a sentence that the above-barrier diversity is an important repository of genetic material, serving a similar function as conservation hatcheries do in other parts of the species range.	Added suggested sentence after line 3136.
107	3137-3139	Alan Byrne	A strong statement. See my earlier comments about Omy5. I don't think this sentence is needed. The previous PP covers the points about A/R haplotypes.	Comment noted.
107	3147	David Boughton	Although the very wet years may select for the anadromous form!	Comment noted.
106-110 or 11		Camm Swift	This seems to repeat much of what was described earlier but is perhaps necessary to expand on it with more detail.	Comment noted.
111	3277	Camm Swift	Mention Big Tujunga dam, which as noted above supported a trout fishery in the 1940s and the stream is the only habitat in the Los Angeles River basin to still support three native Los Angeles basin fishes noted above.	Added Big Tunjunga dam.
112	3297	David Boughton	In my view there should be an expanded section - perhaps a couple paragraphs - on aquifer draw-down, groundwater depletion, and its links to dewatering of surface flows, especially in summer. This tends to get lumped in with dam effects on flows, but it deserves more attention as an important factor in its own right. Many of the dewatered stream channels in southern California may have one been perennial or mostly perennial but are very sensitive to groundwater depletion	Added more information regarding impacts of groundwater depletion.
112	3303	David Boughton	Most groundwater sustainability plans focus on water storage not the restoration of surface flows. See, for example, Ulibarri, N., N. E. Garcia, R. L. Nelson, A. E. Cravens and R. J. McCarty (2021). "Assessing the Feasibility of Managed Aquifer Recharge in California." Water Resources Research 57(3). They found that the goal of protecting surface water was only 1/8th as common as the goal of increasing groundwater storage, and 1/10th as common as the goal of raising the water table, even though all three are explicit intents of the act	Added more information based on Ulibarri et al. (2021) to line 3303.
112	3306	David Boughton	Again, GSPs don't necessarily address surface water - see above comment. One important CESA goal for southern steelhead-rainbow trout might be to get water agencies to include surface water restoration into their GSPs	Comment noted.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
112	3313	Camm Swift	Not sure what deep means in Bond's paper but under natural conditions many coastal lagoons were broad and flat and relatively shallow in relation to their depth. Restriction and channelization has caused deepening of many.	Comment noted.
113	3329	David Boughton	Other risks are poor water quality, stratification (which can cause low DO and fish kills) and episodic breaching by beachgoing humans, etc.	Added these other risks to line 3329.
115	3413-3414	Camm Swift	Habitat was converted "by" livestock rather than for livestock with the well-known loosing of cattle and horses onto the open ranges of southern California by the early Spanish colonists beginning in the late 1700s and subsequently land owners were allowed to own additional land holdings reclaimed from margins of estuaries and wetlands.	Suggested edit was made to line 3413-3414.
116	3446	Camm Swift	Most of the Los Angeles Basin was known as an artesian area with widespread springs and marshes that would have supported salmonids (Mendenhall, W. C. 1907. Ground waters and irrigation enterprises in the foothill belt, Southern California. USGS Water supply Paper 219.	Comment noted. Added information to lines 1591-1592.
116	3462	David Boughton	fix typo for "Trout"	Fixed typo.
117	3486-87	Camm Swift	Clawed frogs originated in the Santa Clara system upstream in Agua Dulce canyon above Santa Clarita in the earliest 1970s.	Comment noted.
117-118	3492-3538.	Alan Byrne	Why does cannabis have more lines than agriculture?? I would retain lines 3492 - 3501 but move it into the Agriculture section. You can delete 3502 - 3538.	Suggested edits were made to the Cannabis Cultivation section.
119	3539-3541	Camm Swift	Southern California SH/RT known as sundowners in coastal lagoons etc. as noted above and quoting retired DFG biologist Richard Croker in Swift, et al. 1993, p. 113.	Added Swift et al. (1993) citation to line 3540.
119-136	3560-4139	Alan Byrne	An exhaustive list of regulations, plans, and programs without any discussion on whether any of these actions are having an effect to prevent the Southern SH/RT from going extinct. Is all this detail needed?? Or can you just list each with short sentence of its intent? Can all these programs be implemented? is there funding to continue them? Programs already in place did not prevent the Southern SH/RT populations from an "endangered" listing.	Comment noted.
126	3802-3815	David Boughton	it’s a little odd that this dam is described in detail, but other important dams aren't.	Comment noted.
129	3810	Camm Swift	Add integration with USFWS recovery plans for federally endangered Unarmored threespine stickleback (Los Angeles Basin and Santa Clara River), (now) northern and southern tidewater goby (many coastal lagoons), and federally threatened Santa Ana sucker (Los Angeles Basin). DFGW now reviewing status of Santa Ana speckled dace as well. And Arroyo chub is California species of special concern.	Comment noted.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
129	3924-25	Camm Swift	Many of these check dams originated as concrete barriers buried in stream sediments to force ground water to the surface and subsequent high flows scoured out the downstream sides making them appear as dams and creating barriers where none were present intitially.	Added reviewer information to lines 3924-3925
135	4119	David Boughton	Spell out COMB in parentheses or something, for the uninitiated	Suggested edit was made to line 4119.
135	4125	David Boughton	Likewise for CMWD	Suggested edit was made to line 4125.
136	4130	David Boughton	Likewise for UWCD	Suggested edit was made to line 4130.
136	4134	David Boughton	Likewise for RCDSMM	Suggested edit was made to line 4134.
136-137	4163-4164	Camm Swift	I thought urbanization made streams more flashy and variable in extremes of flow rather than less variable? Namely from high, rapid runoff from increasing amounts of impervious surfaces.	Revised lines 4163-4164.
137-138	4195-4200	Camm Swift	"Locals" often know fish can be found below impassable barriers like Rindge Dam on Malibu Creek just after large rain events which, as noted, can allow a few anglers to have strong effects.	Comment noted.
138	4204-4218	Alan Byrne	With the SH/RT populations at such low abundances I don't see a compelling argument for whether Predation or Competition are or are not a threat so I would re-assess you're conclusion of "moderate threat". I'd be more comfortable stating something like…adequate data/studies specific to the Southern SH/RT DPS is lacking.	Re-assessed and revised the Department's conclusion for predation and competition.
138	4204-4217	Camm Swift	My opinion is that the effects of predation are usually (or probably) under estimated, partially because little hard data is available for local fish. Its hard to imagine the channel catfish, largemouth bass, striped bass and other do not significantly impact the younger stages of Southern California SH/RT in streams and lagoons. Thus, I would grade them as more than a moderate threat. Particularly since west coast salmonids evolved free of many of these predators and thus would be expected to have have few avoidance behaviors related to them. It may also be unrealistic to expect to rid streams of these popular sport fishes or somehow keep them separated from Southern California SH/RT habitats in many cases, but perhaps not all.	Comment noted. See Department response for page number 138, line number 4204-4218.
138	4221-4222	Camm Swift	Brown trout Is a salmonid with self-sustaining populations within these areas, namely Bear Creek, trib to Santa Ana river and Ice Houses Canyon, trib to San	Comment noted. Brown trout are covered by the non-native category.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
			Antonio Creek, trib to Santa Ana River. Perhaps Brown trout are covered by the non-native category.	
140	4266	David Boughton	To match what you have said elsewhere, you should call them "southern California steelhead-rainbow trout", not southern California steelhead	Suggested edit was made to line 4266.
140	4268	David Boughton	As said elsewhere, this is different from how the Feds define the DPS. I myself have no quibbles with this from a scientific perspective, but it will likely cause even more confusion then there is presently. Also, it seems odd to include rainbow trout below the barriers, but not above the barriers, since they share common descent and could provide important genetic materials for the recovery of the below-barrier steelhead-rainbow-trout. Arguably, the loss of connectivity to the above-barrier rainbow trout endangers them as well, since they can no longer get gene flow (via steelhead) from other stream systems, and also cannot get recolonized if a fire or something extirpates a given population. Why don't you include them in the DPS as well?	Additional information about the proposed listing unit was added to Section 3.2.
140	4269	David Boughton	I think you should clarify this statement that it does not include the above-barrier rainbow trout, which are still present in many systems that have lost O. mykiss from below-barrier parts of the system	Added clarification to line 4269.
140	4292-4299	Camm Swift	given the recommendations above the wording here is excellent sticking with Southern California SH/RT rather than species, subspecies, taxon, etc.	Comment noted.
141	4318	Camm Swift	Thus change this line to "….to list Southern California SH/RT as endangered to be warranted." since this unit was defined earlier and avoiding calling it a species or subspecies. In the explanation leading up to this last sentence it might be optional to add the additional wording from the law about species, subspecies, or subdivisions of these as discussed before.	Suggested edit was made to line 4318. See Department response for page 9, line 255-258.
142-145	4356-4465	Alan Byrne	No major disagreement, however it is likely that many will be difficult and very costly to implement given the current population abundances in most of these rivers. I would recommend selecting priority streams that could serve to retain anadromy and provide "strays" into other rivers when conditions are favorable. Other streams could be assessed on an alternating basis.	Comment noted.
143	4373	Devon Pearse	Genetic monitoring of *Omy 5* variation would not necessarily be informative with respect to viability. Suggest deleting this bullet point, since evaluation of Omy5 is described under action 4.	Suggested edit was made to line 4373.
143	4386	David Boughton	Do you mean the Federal Recovery Plan? If so, you should probably say "Federal," since if this listing goes through there will presumably be a state recovery plan. I would also encourage you to explicitly say that fishways or assisted migration should be established at passage barriers that cannot be removed, at least in the near term.	Added clarification to line 4386.

Page Number	Line Number	Reviewer	Reviewer Comment	Department Response
143	4391	David Boughton	and also restore aquifers in dewatered areas to sustain surface flows during the dry season whenever possible.	Added suggested recovery measure to line 4391.
143	4392	David Boughton	and establish fish passage at barriers that currently lack it, or where it exists but is ineffective!!! Don't just re-evaluate it! Create it! Create fish passage, especially for above-barrier populations that still have a lot of native ancestry.	Added suggested recovery measure to line 4392.
144	4404-4413	David Boughton	Although the genetic work is very interesting, for recovery it is not nearly as important in my view as establishing passage, improving habitat and streamflows, and the items in paragraph 6.	Comment noted.
144	4437	Camm Swift	Implies a broadening of an effort to the whole species from Russia to Baja California buy using *O. mykiss?*	Revised language in line 4437 to remove the implication.
145	4462	Camm Swift	Literature Cited: citations were not checked against their appearance in the text and in this list. Not being sure of the style for this draft some inconsistencies are pointed out in the following entries. Particularly the multi-authored papers seem to be alphabetized by first author and then chronologically by date regardless of subsequently listed co-authors. Most books and journals alphabetize these by second, or even third or more authors if present and then by date (year). Possibly you have a style manual to standardize citations/references.	Comment noted. Citations were organized chronologically by date of publication, not by second author, consistent with citation styles used in previous status reviews.
145	4464-5644	David Boughton	Some of the references are NOT in alphabetical order, so check them.	See Department response for page number 145, line 4462.
146	4492-4493	Camm Swift	No title to item	Fixed.
147	4516	Camm Swift	No journal indicated	Fixed.
149	4586-4591	Camm Swift	Boughton papers rearranged if alphabetized by second and other authors including additional paper noted above	See Department response for page number 145, line 4462.
153	4695, 4698	Camm Swift	Chapman, B. B. should precede Chapman, D. W.	Fixed
156	4790-4802	Camm Swift	rearrange by 2nd author	Comment noted.
157	4828-4830	Camm Swift	add California Department of Fish and Game, Fish Bulletin 178 (this was before change to Fish and Wildlife)	Comment noted. Citation written as recommended in the article.
161-162	4954-4962	Camm Swift	re-alphabetize	See Department response for page number 145, line 4462.
162	4978-4983	Camm Swift	re-alphabetize, elaborate what G3-2 and G3.5 indicate	Fixed.

Status Review for Southern California Steelhead

Oncorhynchus mykiss

Presentation to the California Fish and Game Commission

April18 | Robin Shin

Fisheries Branch

Presentation Overview

- Listing Description
- Species Overview
- Information Received
- Abundance and Population Trends
- Threats
- Department Recommendation
- Management and Recovery Measures

Listing Description

- Southern California steelhead means all *O. mykiss*, including <u>anadromous</u> and <u>resident</u> life histories, below manmade and natural complete barriers to anadromy from and including the Santa Maria River to the U.S.-Mexico Border.

- Federal listing includes only naturally spawned anadromous adults

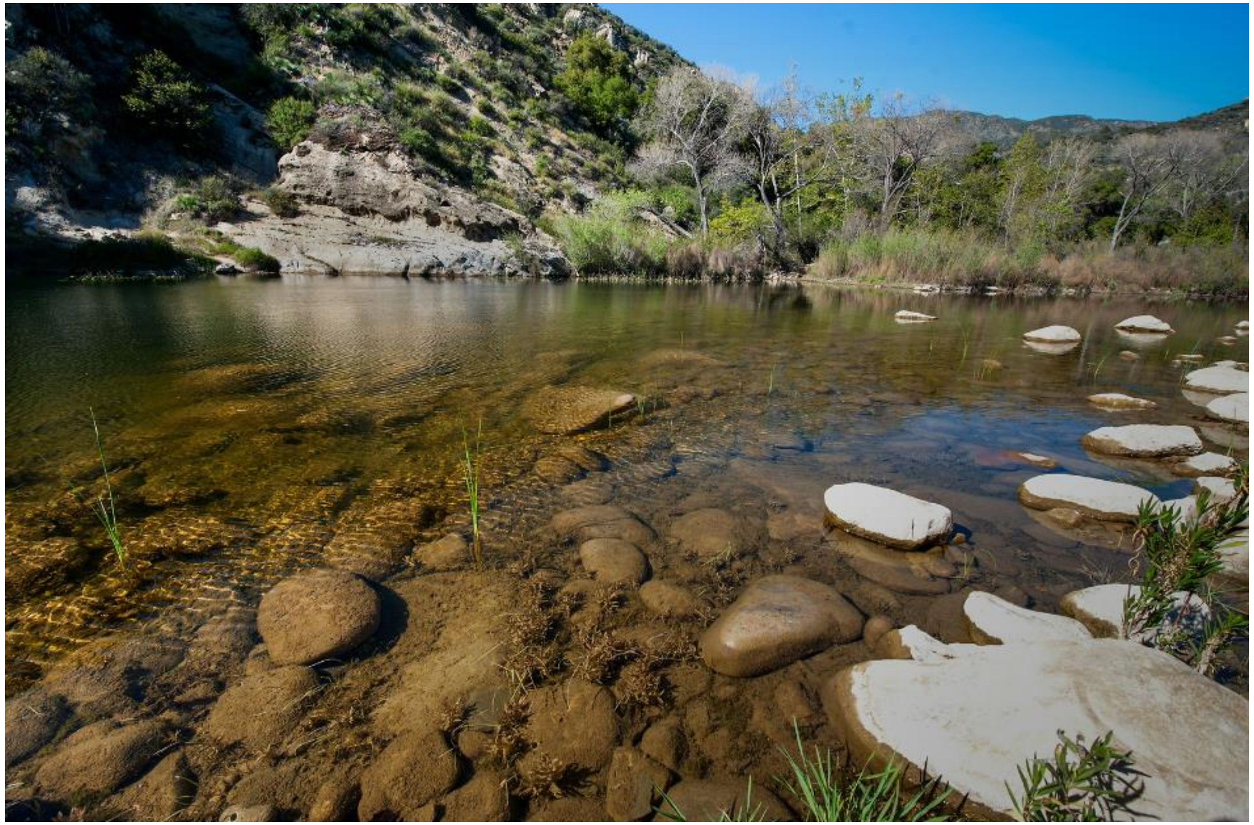
- Department determination that Southern California steelhead is a Distinct Population Segment (DPS) and hence a subspecies for CESA listing purposes.

Species Overview: Life History

- Exhibit an anadromous life-history
- Born and reared in freshwater and mature in saltwater before returning to their natal waters to reproduce
- Variation in the time and location spent at each life-history:
  - Anadromous (freshwater to saltwater migration)
  - Freshwater Resident (remain in freshwater)
  - Lagoon-anadromous (migration to and from brackish lagoons)

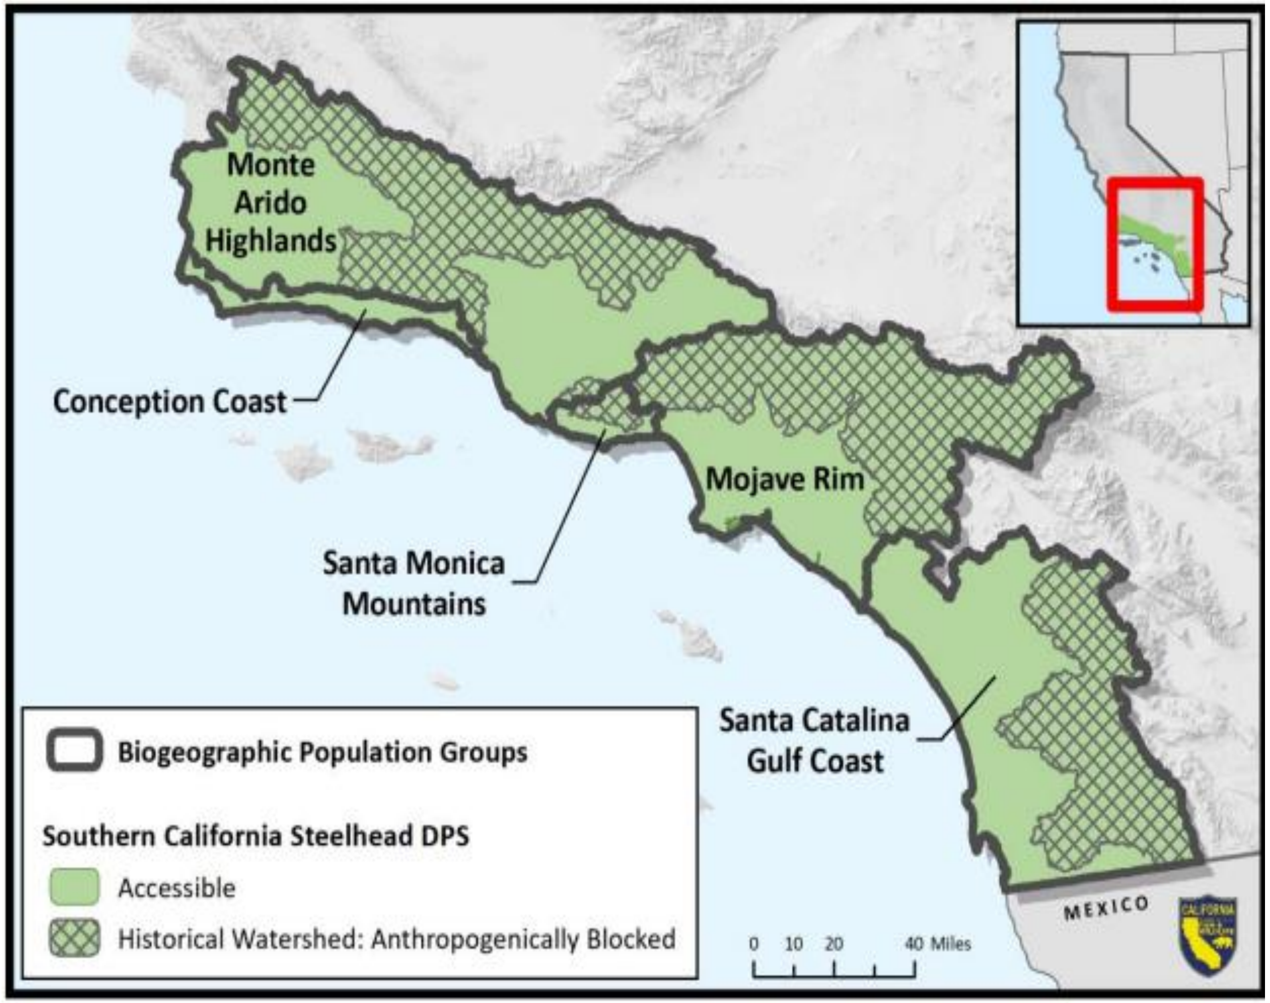
Species Overview: Habitat

- Spawning
  - Clean loose gravel
  - Adequate depth and velocity
- Freshwater Residency
  - Sufficient flow
  - Cool water temperatures
  - Cover habitat
  - Availability of prey items
- Estuarine Rearing
  - Sand berm formation
  - Low degradation



Species Overview: Range and Distribution

- Santa Maria River (San Luis Obispo and Santa Barbara counties)to the U.S.-Mexico Border
- Encompasses 5 biogeographic population groups of *O. mykiss*
- Less than half of 46 watersheds known to support historical populations are still occupied



Map by Janet Brewster, CDFW

Information Received

- During data solicitation period [April 2022 to January 2023]:
  - 17 comments from Tribes
  - 480 emails received
  - 12 submissions of information
- After Status Review delivered to Commission [January 2024]:
  - 39 references
  - Draft technical memo for southern California steelhead life cycle model and graphic user interface

Abundance/Population Trends

Anadromous Adults

- Critically low range-wide abundances
- Counts have not been greater than ten for any watershed examined
- Most streams have observed no adult returns in past 10 years

Population	Years	Trend (%/year)	Minimum Abundance (12-year)	Maximum Abundance (12-year)
Santa Ynez River	1995-2021	-2.24	0	9
Ventura River	2006-2021	**-7.54**	0	1
Santa Clara River	1994-2018	-2.29	0	3
Topanga Creek	2001-2019	-1.7	0	5
Malibu Creek	2004-2019	-1.41	0	2

CALIFORNIA DEPARTMENT OF FISH & WILDLIFE

Abundance/Population Trends

Resident *O.mykiss*

- Measurable declines in population trend and abundances for all populations examined.

Population	Years	Trend (%/year)	Minimum Abundance (12-year)	Maximum Abundance (12-year)
Santa Ynez River	1995-2021	**-8.81**	5	484
Ventura River	2006-2021	**-19.39**	0	640
Santa Clara River	1994-2018	-6.09	1	170
Malibu Creek	2004-2019	**-25.56**	0	2,245
Topanga Creek	2001-2019	-1.41	34	316

Major Threats

- Dams, Diversions, and Artificial Barriers
- Urbanization
- Estuarine Habitat Loss
- Invasive Species
- Wildfires
- Drought
- Climate change

Rindge Dam, Malibu Creek

Department Recommendation

The Department recommends that the Commission find the petitioned action to list Southern California steelhead as an endangered species to be warranted.

Management and Recovery Measures

- Implement comprehensive monitoring

- Remove manmade passage barriers and re-establish access to upper watersheds

- Habitat and streamflow restoration

Questions ◈ Thank You

California Fish and Game Commission
P.O. Box 944209
Sacramento, California 94244-2090

RE: California Trout, Inc.'s Petition to list Southern California Steelhead (*Oncorhynchus mykiss*) as Endangered Office - Administrative Law's Notice ID #Z2021-0702-02 and Z2022-0426-01—*Support*

President Murray and Commissioners:

Endangered Habitats League (EHL) fully supports designating the Southern California steelhead as endangered under California's Endangered Species Act. For your reference, EHL is Southern California regional conservation group dedicated to ecosystem protection and sustainable land use.

Returning Southern steelhead to our coastal streams is a longstanding goal of conservationists. Yet, the species is at the brink of extinction. Your Commission should act immediately to prevent the total and irreversible loss of this species.

Recent research tells us that Southern steelhead populations are in danger of extinction within the next 25 to 50 years if current trends persist. Since their listing as endangered under the federal Endangered Species Act in 1997, Southern steelhead numbers have *continued to decline* to dangerously low levels. This is the result of continued urbanization, agriculture, and water development. These activities have compromised and drastically reduced their essential required habitat. The legacy of degradation will only be exacerbated by climate crisis projections of intensified floods, droughts, and extreme heat.

The rivers and streams in Southern California once saw Southern steelhead adults return in the tens of thousands. In the past 25 years, only 177 adult Southern steelhead were documented in their native range. Allowing this species to disappear is not acceptable.

CalTrout's petition, reaffirmed in State Courts as containing sufficient information to warrant a decision, and California Department of Fish and Wildlife's (CDFW) peer-reviewed species status report present you with the best available science and a clear mandate to make the decision to fully list this species immediately.

These fish play a key role in our ecosystems on which we all depend. They are a crucial part of the integrity of watersheds in which they swim. Their continued survival and recovery will reflect the resilience of our communities in the face of growing climate crisis challenges. We can look to them for clues on how California must work to address bigger problems in our Southern California rivers, streams, watersheds, and coastlines. These aquatic ecosystems, extending from summits to the seabed, provide countless environmental, social, and economic benefits for the entire state. We believe that we prosper, now and in the future, when Southern steelhead are thriving in our rivers.

For all these reasons, EHL strongly support listing Southern steelhead as endangered in all waters within historic range below natural or man-made barriers.[1]

Yours truly,

Dan Silver
Executive Director

---

[1] Please note that, consistent with section 10.5(c) of the Tejon Agreement, EHL is not advocating that state listing of Southern steelhead requires changes to any Tejon Ranch project or project approval. In addition, we wish to confirm that in light of the benefits to important biological resources realized through the Agreement, EHL does not oppose the developments currently proposed on Tejon Ranch.

CALIFORNIA FISH AND GAME COMMISSION
RECEIVED 03/20/2024

To: California Fish and Game Commission
P.O. Box 944209
Sacramento, CA 94244-2090

From: Stephen L. Kanne

President Silva and Commissioners:

As a concerned California resident, I write to you today to express my full support for designating the Southern California steelhead as endangered under California's Endangered Species Act.

Southern steelhead are an iconic native species, but without further protections we risk losing them forever. That's not a California I want to live in. Do you? You must act immediately to put in place all precautions to prevent this species from total loss.

Recent research tells us that Southern steelhead populations are in danger of extinction within the next 25 to 50 years, if current trends persist. Since their listing as an endangered species in 1997 under the federal Endangered Species Act, Southern steelhead numbers have continued to decline to precariously low levels. In the past 25 years, only 177 adult Southern steelhead were documented in their native range! Allowing this species to disappear is not acceptable, and more protections are essential.

These fish play a key role in our ecosystems, and they can give us crucial information about the greater health of the watersheds they swim in (and that our communities rely upon). We can look to them for clues on how California must work to address bigger problems in our southern rivers and streams, watersheds that provide countless societal and economic benefits for the entire state. I believe that we prosper when rivers and waterways in key locations are thriving, and in many of these places there is work to be done.

These fish may also play a role in providing resiliency for ecosystems further north along the coast. Southern steelhead are uniquely adapted to Southern California's warmer Mediterranean climate. As climate change continues to increase water temperatures and alter flow regimes along the entire West Coast, Southern steelhead could be critical to the long-term resiliency of their northern relatives.

For all these reasons, I wholeheartedly support California Trout's recommendation that Southern California steelhead be listed as endangered in all waterways within historic range below natural or man-made barriers. CalTrout chose this delineation thoughtfully, so that fishing and continued management for rainbow trout, the freshwater form of this amazing species, would still be possible above these barriers.

It's not too late to save the Southern California steelhead species from blinking out – but if you don't act urgently, we may very well miss our chance. Please make protection of these amazing and important fish a conservation priority by listing them as endangered under the state's Endangered Species Act.

Sincerely,

Stephen J. Hanna

CACHUMA CONSERVATION RELEASE BOARD

March 21, 2024

Submitted via Email

Melissa Miller-Henson
Executive Director
California Fish and Game Commission
715 P Street, 16th Floor
Sacramento, California 95814

Request for a Southern California Location for the Commission's Hearing to Consider Listing Southern California Steelhead as an Endangered Species

Dear Ms. Miller-Henson:

On behalf of the Cachuma Conservation Release Board (CCRB), I am writing to respectfully request that the California Fish and Game Commission's hearing on final consideration of listing Southern California steelhead as an endangered species be held in Southern California, rather than in San Jose.

CCRB is a joint powers agency consisting of the City of Santa Barbara, the Goleta Water District and the Montecito Water District. We have a long history of effective efforts on behalf of steelhead in the Lower Santa Ynez River watershed in Santa Barbara County. In response to the petition, we have submitted timely comments on the proposed listing.

We appreciate that internet access is available for the Commission's hearings. However, we hope the Commission will consider holding this hearing closer to the habitat and natural range of Southern California steelhead and closer to the local and regional agencies working for steelhead, such as CCRB, which would be most affected by such a listing.

Thank you for your kind attention to our request.

Sincerely yours,

Lauren Hanson
Board President

Re: Comments on CDFW's Use of COMB data related to Fish Abundance - Status Review Report (January 2024) for Listing of the Southern California Steelhead Under the California Endangered Species Act

Dear Ms. Miller-Hensen and Ms. Bacon,

On behalf of the Cachuma Operation and Maintenance Board (COMB), we appreciate the opportunity to provide comments on the Status Review report (Report) for listing of the Southern California Steelhead (Southern SH/RT) under the California Endangered Species Act (CESA). We applaud the efforts of the California Department of Fish and Wildlife (CDFW) in compiling this extensive and comprehensive Report related to the listing of the Southern SH/RT as endangered under CESA. We respectfully submit the following comments regarding your use of COMB's data.

The Fisheries Division (FD) staff at COMB has been monitoring Southern SH/RT within the Santa Ynez River watershed since the mid-1990s. Considering the importance of the CDFW Report and our contribution of data to a portion of its content, we respectfully submit the following comments and recommended changes based on our scientific observations of the data.

COMB's Senior Resources Scientist, Timothy Robinson, PhD, has been managing the FD staff and all related 2000 Biological Opinion requirements and activities for the Cachuma Project and Lower Santa Ynez River system since 2005. Dr. Robinson and our team of Senior Biologists have been deeply involved with data gathering, data analyses and all levels of reporting including those COMB-FD materials which were used in the CDFW Report's analyses. After careful review of the Report, COMB would like to provide the following observations and recommended changes:

- Appendix C (Page 189) provides the base data used in many of the analyses in the Report. For the Ventura River, snorkel survey data were used whereas for the Santa Ynez and Santa Clara rivers, migrant trapping data were used. Based on our scientific expertise, using two separate types of data for the same analysis leads to inaccurate comparison and analysis because migrant trapping data represents a subset of abundance results, where snorkel survey data are more representative of actual abundance.

- The upstream/downstream migrant trapping data for the Lower Santa Ynez River (LSYR, downstream of Bradbury Dam) basin provides a view of the Southern SH/RT abundance which is limited in several ways. First, it only captures movement of fish within the basin and does not represent in any way the total abundance within the basin, which was the objective of the Report's trend analysis and supporting dataset. We recommend using snorkel data that would be more representative of the LSYR basin-wide Southern SH/RT abundance, as was used for the Ventura River over a limited area. Second, the enforcement by the National Marine Fisheries Service (NMFS) of the 2000 Cachuma Project Biological Opinion Incidental Take Statement (ITS) numbers for juveniles and adults started in 2014 and greatly skewed the capture numbers, particularly in 2021 and onward, when the trapping season ended early due to reaching the take limit. This regulatory monitoring limitation for the Santa Ynez River can easily be seen in Appendix C (Page 189) in the presented data from 2014 to 2021 compared to 2001 to 2012. Third, box fyke traps used for monitoring fish migration must be removed during moderate to high flow events to safeguard the fishery, equipment, and staff, resulting in a capture number most likely less than what migrated through that location. Even deployment of a Dual-Frequency Identification Sonar (DIDSON) camera struggles with this limitation. Standardization of the data in the form of catch per unit effort or catch per day would address some of these limitations. These types of metrics are provided in COMB's Annual Monitoring Summaries.

- We highly recommend using snorkel survey data (spring surveys which generally had the highest observations) to represent Southern SH/RT abundance within the LSYR basin and the standing crop of the fishery. By using these data for trend analyses, the result from the beginning of the data record through the prolonged drought period (2001-2016) out to 2021 and beyond exhibit an even stronger recovery from the drought, particularly when adding two more years of data for 2022 and 2023 (Table 1 and Figure 1). Adding a simple linear trendline to the snorkel data results in a flat trajectory through 2021 and a slightly positive sloped line when including 2022 and 2023 data. Our provided analysis indicates that the LSYR basin is sustaining a population and does not follow the same downward trend as other populations within the geographic range of Southern SH/RT. Also, snorkel survey data can underestimate the actual number of fish per habitat. We will be addressing this issue this summer by conducting calibration surveys for our routine snorkel surveys.

Table 1: Migrant trapping and snorkel survey data from 2001 to 2023 for the LSYR basin.

Year	Santa Ynez River	
	Migrant Trapping	Snorkel Surveys (Spring)
2001	266	1595
2002	116	1016
2003	196	647
2004	238	532
2005	117	1719
2006	653	3262
2007	665	1879
2008	561	3407
2009	610	982
2010	367	2373
2011	484	1803
2012	199	3152
2013		1416
2014	137	429
2015	134	141
2016	103	58
2017	5	42
2018	27	29
2019	39	2479
2020	147	1556
2021	205	4064
2022	182	2110
2023	52	2190

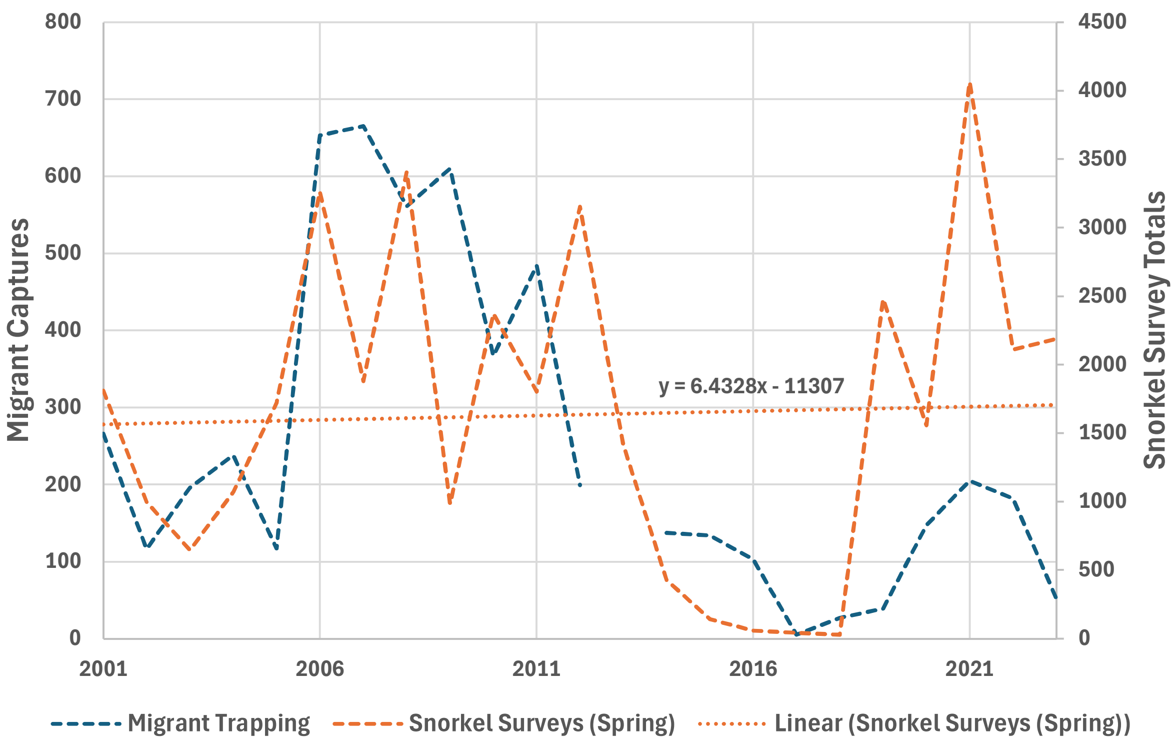

Figure 1: Migrant trapping and snorkel survey data from 2001 to 2023 for the LSYR basin showing a trendline for the snorkel survey data.

- Although no anadromous LSYR fish have been observed during migrant trapping in the LSYR basin since 2011 (partly due to the prolonged drought when the sandbar at the LSYR Lagoon was closed to the ocean), we have documented anadromous redds (identified by size) in 2021 (LSYR mainstem downstream of a beaver dam near the Salsipuedes Creek confluence) and 2023 in El Jaro Creek. Redds were not used in the analyses, but spawner surveys are a means of identifying the presence of anadromous fish and could be used as a surrogate.

- There was no mention of beaver dams possibly inhibiting migration within the LSYR basin. During high flow years, beaver dams are not an issue for fish passage. However, during moderate to low years, they can limit migration considering there can be well over 50 dams (range from 2010 to 2023 is 45 to 132 dams) within the LSYR mainstem of varying sizes to navigate, and often double-digit dams in the tributaries.

- Section 4.3.1.2: Santa Cota Creek, the correct name is Zanja de Cota Creek.

- 4.3.1.2 Page 46: We request the paragraph discussing recent modification in the operation of Bradbury Dam for increased releases be modified for accuracy. For example, the 2000 Biological Opinion contains provisions for dam releases to benefit the downstream fishery both in the LSYR mainstem and Hilton Creek during dry and wet years. The recent Water Rights Order 2019-0148 tiered off those provisions and required higher releases during wet years (determined by inflow to the lake) to benefit the downstream fishery during the year of and year after that determined wet year. The higher releases are referred to as Table 2 flows that have the purpose of supporting migration, spawning, and rearing in the LSYR.

Thank you for considering our observations, comments, and suggestions. Please contact our General Manager, Janet Gingras, at 805 / 687-4011 ext. 201 if you have questions or need additional information.

Sincerely,

Polly Holcombe

From: Pasadena Casting Club

Subject: CESA listing for Southern Steelhead

Dear President Murray and Commissioners:

Pasadena Casting Club is a group of fly fishing enthusiasts dedicated to the art of angling and casting, conservation, and education. The club was founded in 1947 and has over 350 members. We participate in conservation activities to maintain healthy streams and fisheries, run programs to introduce veterans, women, and young people to fly fishing, and serve our community by raising awareness of California's fisheries and the habitat that supports them. I am writing on behalf of our Board of Directors and our club to support designating Southern California steelhead as endangered under California's Endangered Species Act.

We appreciate the extensive research performed by California Trout and the work completed to submit the petition for listing in 2021. And we applaud the unanimous decision that the California Fish and Game Commission made in April 2022 that stated listing under CESA "may be warranted". Now that the species status review has been completed by the California Department of Fish and Wildlife, and supports the findings of the petition, we request that the Commission act quickly to save this amazing fish.

Southern steelhead are an iconic native species in our region, and our members have witnessed first-hand the loss of habitat and decline of the species in Southern California. These fish are not just valued for their beauty and incredible toughness, but as an indicator of the state of our watersheds. Although remarkably resilient, continued impacts on our stream systems could result in the complete loss of this species unless they are protected. We believe that protection for the fish will also provide water quality, watershed health, recreation, and other benefits to all Californians.

For these reasons, Pasadena Casting Club supports California Trout's recommendation that Southern steelhead be listed as endangered in all waterways within their historic range below natural or man-made barriers. California Trout chose this delineation thoughtfully, so that fishing and continued management for rainbow trout, the freshwater form of this species, will still be possible above these barriers.

Please act now to make protection of these amazing fish a conservation priority by listing them as endangered under the state's Endangered Species Act.

Sincerely,
Pasadena Casting Club

Edward E. Wallace

Subject: United Water Conservation District Comments on the California Department of Fish and Wildlife California Endangered Species Act Status Review of Southern California Steelhead (*Oncorhynchus mykiss*)

Dear Commissioners and Fisheries Branch Staff:

United Water Conservation District (United) submits the following comments to the California Fish and Game Commission (Commission) and California Department of Fish and Wildlife (CDFW) in response to the Status Review of southern California steelhead (*Oncorhynchus mykiss*) (Status Review) prepared by CDFW (2024). In their Status Review, and pursuant to Fish and Game Code (FGC) § 2074.3 and 2074.6, CDFW is required to evaluate the breadth of available scientific literature and develop a summary of the status of southern California steelhead as well as a recommendation to the Commission for listing under the California Endangered Species Act (CESA). United has completed a thorough review of the Status Review and it is clear that CDFW has based key findings on partial sets of data, which in large part is only relevant to the anadromous component of the proposed listing unit of southern California steelhead rainbow trout ("Southern SH/RT"). The comments from United include relevant context regarding the analysis and findings of the Status Review and should inform the Commission's decision at this stage in the listing process. Past comments from United to the Commission and CDFW are included as an attachment to this submittal as they remain applicable and provide useful background regarding the information relied upon through the previous stage of the listing process. Ultimately, the Status Review does not provide an analysis of the status of the species based on the best available science and the recommendation from CDFW to list Southern SH/RT under CESA is premature. The Commission should find that the listing is not warranted at this time and should rather delay the listing decision until after additional data collection to accurately characterize the resident and anadromous life-history variants in the proposed listing unit.

Population Abundance and Trend

The population trend analysis in the Status Review is flawed

Regarding the methods to monitor fish in a given study, CDFW's steelhead monitoring protocol (Fish Bulletin 182) states "The methods likely involve different inherent biases in their estimates; and thus, once a deployment decision is made, a given method should be used consistently for a given population, to support valid trend estimation." In short, the sources of information that CDFW utilized in their analysis of population abundance and trend do not provide consistent and comparable results as these monitoring programs are not designed to support such an assessment. The results included in the Status Review do not meet CDFW's own standards and are, therefore, invalid.

In the Status Review, CDFW completed an analysis of abundance and trends with "annual abundance data compiled from a variety of sources." The sources used include monitoring programs in the Santa Ynez River (COMB 2022), Santa Clara River (Booth 2016), and Ventura River (CMWD 2005-2021 and Dagit et al. 2020) and was limited to data from trapping efforts associated with past and ongoing monitoring in these three watersheds, the populations within which are designated as Core 1 under the federal ESA listing (NMFS 2012). This is problematic for multiple reasons:

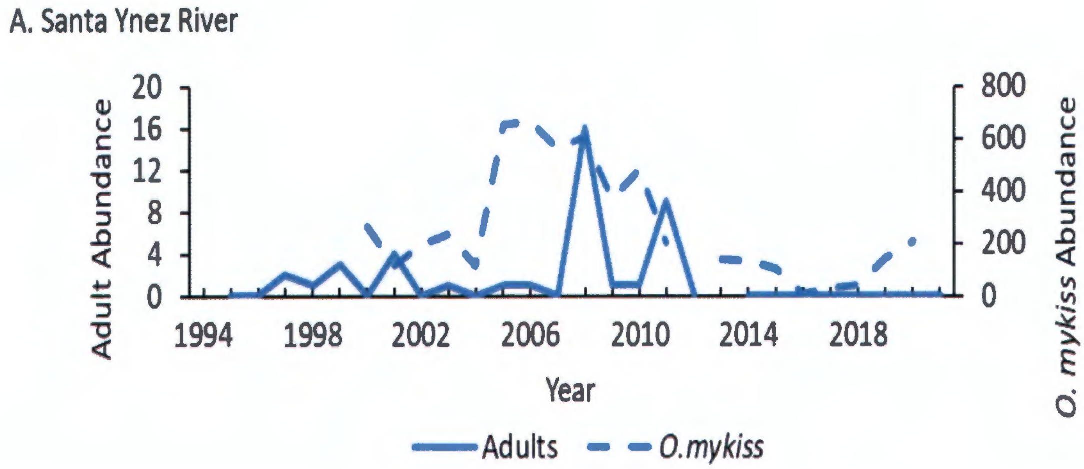
1) Monitoring data accounts for those individuals that are biologically motivated to move within the watershed (e.g., based on resource availability) or to migrate, but does not account for *O. mykiss* residents within the watershed. A detailed example of this shortcoming is provided in the 'Proper accounting for resident *O. mykiss* yields different conclusions' section below.
2) Monitoring efforts have changed within the period of analysis, so these results are not directly comparable. Monitoring of adult migration conducted by United at the Freeman Diversion fish ladder has consisted of trapping from 1994-1997 (prior to the federal ESA listing), incidental observation during facility dewatering from 1998-2002, false weir and passive video-based surveillance system (video cameras/ infrared scanner) from 2002-2010, updated computer-based surveillance system (network cameras) in 2010 with additional cameras added between 2011-2014, and further upgrades to the camera systems in 2016 and 2023 to current generation equipment. The current system is triggered to record video footage by an infrared scanning beam and camera–based motion detection. This system is thought to potentially undercount adult steelhead based on collection of several downstream migrating kelts observed in the facility's downstream migrant trap through 2014 that did not match observed upstream migrants. The 2016 upgrades are thought to have addressed these shortcomings, though only one (possibly a second, though not confirmed) adult upstream migrating steelhead has been detected by the surveillance system since 2012 (in 2020). Monitoring efforts at the Freeman Diversion were not consistent over the range of years evaluated by CDFW. Due to permitting restrictions, the downstream migrant trap at the Freeman Diversion was not operated after 2015, a fact the Status Review fails to acknowledge (4.4.1.1, Figure 12.C.) and downstream migrant trapping efficiency has never been assessed. Overall, monitoring data from the Freeman Diversion on the Santa Clara River does not provide the level of detail and consistency necessary to support the analysis completed in the Status Review.

In another example, regarding monitoring data from the Santa Ynez River, the Status Review notes that no data was collected in 2013 and that "Biological Opinion Incidental Take provisions have been required since 2014" (4.4.1.1, Figure 12.A.). However, the Status Review fails to acknowledge that the Biological Opinion Incidental Take provision required a reduced trapping effort (i.e., fewer trapping days) after 2014 compared to previous years, even though the COMB (2022) reference clearly states the reduced trapping efforts from 2014 through 2022. Therefore, monitoring results are not comparable across years. Overall, the data utilized by CDFW in the Status Review to evaluate the abundance and trends of the proposed listing unit does not provide the level of rigor necessary for this analysis and does not meet CDFW's own standards outlined in Fish Bulletin 182.

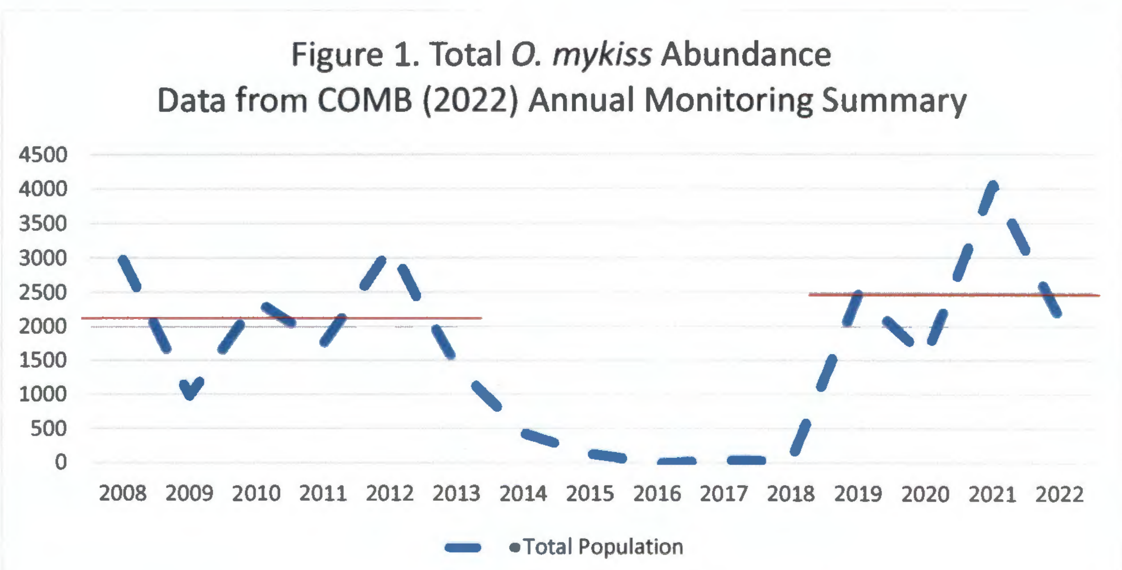
3) Trapping is limited to periods when flows allow for installation and operation of fish traps (i.e., high flows may preclude trap operation) and/ or based on other facility or flow conditions. As an example, the downstream migrant trap at the Freeman Diversion only operated when United was actively diverting water and only as a conservation tool to rescue fish (and subsequently relocate them to suitable habitat) that would otherwise be discharged downstream to poor river conditions. During high flows, the trap was not operating because United was not diverting water or downstream river conditions were suitable for fish and trapping/ relocating fish was not necessary. Also, notably the downstream migrant trap only sampled a small proportion of the total river discharge at high flows (i.e., the proportion being diverted), the remainder of which was flowing downstream past the diversion facility.
4) Trap data alone is not representative of even the migrating portion of *O. mykiss* without a trap efficiency study. Further, the Status Review failed to include available information from other monitoring studies (e.g., snorkel surveys) conducted as part of these same monitoring efforts, which more accurately characterizes the overall *O. mykiss* population. CDFW failed to use the best available science in their analysis, and therefore, the conclusions drawn are not sufficiently supported. Please see the detailed example of this issue in the 'Proper accounting for resident *O. mykiss* yields different conclusions' section below.

Proper accounting for resident *O. mykiss* yields different conclusions

In the Status Review, CDFW omits survey data for resident *O. mykiss,* which in one example below, contradicts the stated conclusions regarding the abundance and trends of the proposed listing unit. The information presented in the Status Review for the Santa Ynez River regarding the abundance of *O. mykiss* is displayed on Figure 12 (A. Santa Ynez River), and is reproduced here for ease of reference:



The Status Review figure above indicates that *O. mykiss* abundance never increased above approximately 700 individuals during the period of analysis. However, a review of the monitoring reports referenced by CDFW (COMB 2022) found a total *O. mykiss* abundance within the surveyed reaches varying with the antecedent conditions (i.e., wet/ dry water year cycles), from a low of <100 individuals at the height of the recent drought to a maximum of over 4,000 individuals following drought. It should be noted that these totals represent only the numbers within the surveyed portions of the river, which cover only a small fraction of the overall Santa Ynez River watershed. The totals, therefore, do not represent a characterization of the total population within the watershed. Clearly, the abundance numbers in the Status Review do not account for the full reported values and it is unclear why CDFW omitted a portion of the available data. These totals include all *O. mykiss* surveys (i.e., trapping and snorkel surveys), which more appropriately represents the petitioned listing unit. A closer review of this data finds that the "pre-drought" population from roughly 2008-2013 averaged 2,100 individuals while the "post-drought" population from roughly 2018-2022 averaged 2,500 individuals (Figure 1).



In the Status Review, CDFW does not properly account for resident *O. mykiss*, and the resulting interpretation of the species status mischaracterizes the overall abundance and trends, as demonstrated by the example on the Santa Ynez River detailed above. The monitoring results on the Santa Ynez do illustrate the species response to drought conditions, with an observed reduction in observations during the historic 2012-2017 drought experienced in the region, presumably due to limitations in available suitable habitat, food resources, etc., which may provide an indication of the overall trends within the watershed. However, the data also shows the expected response post-drought, with a significant population increase following the onset of average to above average precipitation in ensuing water years. This example was selected since the Santa Ynez River has the most complete dataset of the overall *O. mykiss* population within the watersheds analyzed in the Status Review. Further, data from United's Freeman Diversion used in the Status Review is not comparable to data collected in the Santa Ynez River as the Freeman Diversion is located in the lower Santa Calara River, approximately 10 miles from the river mouth, in a reach that has been considered a migration corridor, and not spawning or rearing habitat for *O. mykiss*. More broadly within the region, the available data does not provide a consistent and accurate representation of the *O. mykiss* population, and therefore, the abundance and trends cannot be reliably calculated. Taken together, the abundance and trends analysis in the Status Review is a foundational component of the listing recommendation upon which the Commission is likely to base their decision. However, CDFW's analysis is flawed and not supported by the best available science.

Information relevant to resident *O. mykiss* is lacking or omitted

As United has commented on in the past, the original petition submitted by CalTrout did not address resident *O. mykiss* sufficiently. CDFW's previous petition evaluation report similarly failed to address resident *O. mykiss* sufficiently to accurately characterize the petitioned listing unit, which was defined in CDFW's evaluation report as:

> "All *Oncorhynchus mykiss,* including anadromous and resident life histories, below manmade and natural complete barriers to anadromy from the Santa Maria River, San Luis Obispo County (inclusive) to the U.S.-Mexico Border with the understanding that anadromous (adult southern steelhead) arise from anadromous and resident naturally spawning adults."

The definition of the proposed listing unit in the Status Review is largely similar to the previous definition, with the primary exception being the removal of the language regarding "anadromous (adult southern steelhead) arise from anadromous and resident naturally spawning adults":

> "all *O. mykiss* below manmade and natural complete barriers to anadromy, including anadromous and resident life histories, from and including the Santa Maria River (San Luis Obispo and Santa Barbara counties) to the U.S.-Mexico Border."

To account for the life history variability, CDFW used the term "southern California steelhead rainbow trout (Southern SH/RT)" to define the proposed listing unit. However, in multiple instances, the Status Review fails to account for resident *O. mykiss* both in the presentation of data as well as in the development of conclusions. For example, in the Historical and Current Distribution Section (4.3), the Status Review states:

> "In general, estimates of historical population abundance are based on sparse data and assumptions that are plausible but have yet to be adequately verified or tested. While the following

historical estimates are likely biased either upward or downward, the examination of historical records of adult run size in southern California show consistent patterns of abundance that are at least two or three orders of magnitude greater in size than in recent years."

The quoted language above mentions the "adult run size," presumably referring to the anadromous portion of the proposed listing unit. However, the resident component is not mentioned, which is concerning given CDFW's ongoing Heritage and Wild Trout Program and/or the Coastal Salmonid Monitoring Program. These Department programs complete surveys on *O. mykiss* in multiple watersheds within the region A separate example of omission of resident *O. mykiss* is in the Trends Analysis section (4.4.3.3) of the Status Review, which states "many populations occurring south of the Santa Monica Mountains are considered severely reduced and, in many instances, extirpated." However, David Boughton, an *O. mykiss* researcher with the National Oceanic and Atmospheric Administration Southwest Fisheries Science Center (NOAA SWFSC) selected by CDFW to peer review the draft Status Review commented that CDFW "clarify that you're talking about steelhead specifically here, not *O. mykiss*, since there are often extant *O. mykiss* populations in the headwaters." CDFW failed to add clarification in the final Status Review, but rather changed the preceding language from "steelhead" to "Southern SH/RT," which contradicts the peer reviewer's comment.

In the original listing of southern California steelhead Environmentally Sensitive Unit (ESU) under the federal ESA and reiterated in the designation of the southern California steelhead Distinct Population Segment (DPS), the U.S. Fish and Wildlife Service (USFWS) disagreed with NMFS' proposal to include resident *O. mykiss* in the listing unit. The 2006 DPS listing (71 FR 833) states that "FWS, the agency with ESA jurisdiction over resident *O. mykiss*, disagreed that resident fish should be included in the steelhead ESUs and advised that the resident fish not be listed". The position of the USFWS was based on the absence of evidence that resident *O. mykiss* needed protection under the federal ESA (62 FR 43937). The information provided in the Status Review is focused on the anadromous component of the proposed listing unit and the lack of evidence regarding the status of residents persists. As United has commented on in the past[1], the available evidence shows that a resilient population of resident *O. mykiss* persist in many watersheds both above and below barriers, and these systems are capable of supporting robust populations that provide a substantial and well documented contribution to the overall species.

NMFS population viability model does not include the resident component

The CalTrout petition included multiple references to National Oceanic and Atmospheric Administration National Marine Fisheries Service (NOAA-NMFS) assessments of the anadromous component of the overall *O. mykiss* population. In the evaluation of the petition completed by CDFW in November 2021, CDFW referred to the NMFS population viability threshold of 4,150 anadromous spawners per year on average within an individual watershed, which was developed by the NMFS Southwest Fisheries Science Center (Boughton et al. 2007) and included in the NMFS Recovery Plan (NMFS 2012). The Status Review similarly refers to the NMFS viability threshold in the conclusions under the Abundance and Trends section (4.8.1), stating that "the results of our analyses demonstrate that no population is near the criteria necessary to provide resilience from extinction."

Again, the Status Review fails to account for the resident component of *O. mykiss* in key findings and conclusions. The viability criteria developed by NMFS accounts for only the anadromous component of

[1] See attached comment letters and information submittals from United to the Commission and CDFW dated August 17, 2021, December 2, 2021, February 1, 2022, and September 20, 2022

O. mykiss. In Boughton et al. (2007), the authors state the importance of the interchange between resident and anadromous *O. mykiss*; however, the conclusions of their assessment are limited to the anadromous component, stating that "100% of the spawners must be anadromous". In 2023, NMFS released a 5-year review of southern California steelhead (NMFS 2023), which further examines the interchange between resident and anadromous *O. mykiss* and suggests a new population density criterion of 0.3 fish/m^2 to account of residents as an "appropriate provisional population density viability criterion". Ultimately, the NMFS 5-year review does not change the population viability criteria under the federal listing but CDFW does not refer to this information in their Status Review. The statement in the Status Review that "no population is near the criteria necessary to provide resilience from extinction" is therefore, misleading as it is based on information relevant solely to the anadromous component of the listing unit.

New southern California steelhead life-cycle model includes resident life-history

United and other agencies have commented in the earlier stages of the CESA listing process that information presented in the CalTrout petition and evaluated by CDFW in the petition evaluation regarding the population trend of southern California steelhead presented only the anadromous component of the proposed listing unit – not the resident component – including numbers of returning anadromous adults and declines in numbers compared to historic population estimates. In the petition evaluation report, CDFW noted that information on population abundance and trends of resident *O. mykiss* is limited. United disagrees, as information that contributes to the best available science is readily available and would allow for reasonable inference regarding the status of residents as it relates to the proposed listing. United provided information to CDFW at the outset of the Status Review process relevant to the abundance of resident *O. mykiss* in several watersheds within the proposed listing unit boundaries. However, this information was largely ignored and information presented by CDFW in the Status Review regarding resident *O. mykiss* was not utilized in the development of key findings, including the status of the species abundance and population trends over time.

A group of agencies led by the Association of California Water Agencies (ACWA) anticipated that this key information gap would persist through the development of the Status Review. In an effort to fill this gap and demonstrate the complex life-history dynamics contributing to the persistence of *O. mykiss* and inform the listing process ACWA contracted Cramer Fish Sciences (Cramer) to develop a life-cycle model that incorporates the resident and anadromous life-history types. During the petition process through the start of CDFW's status review, the water agencies, including United, provided substantial comments and background references highlighting the available science on the interplay of the resident and anadromous life-history types on the persistence of the species. Notably, the June 2021 CalTrout petition agrees with this, stating in their assessment that "[f]ish that express the resident freshwater life-history strategy play a central role to the continued existence of southern steelhead." This statement is well supported by the available literature; however, a thorough evaluation incorporating the multiple *O. mykiss* life-history strategies and viability metric was not available, and therefore, the development of a life-cycle model is seen as providing new information for consideration by CDFW and the Commission. The Status Review supports the development of such a tool to consider existing information related to the interplay of resident and anadromous *O. mykiss,* stating in section 2.5.5 that "the close genetic relationships between sympatric populations of steelhead and Rainbow Trout suggest that the populations interbreed and that close relatives, including full siblings, may express alternative ecotypes (or other life-history variation, e.g., adfluvial or lagoon migration). Therefore, managing individual fish with different life histories separately is biologically unjustified, and the two life history variants should be considered a single population when found coexisting in streams."

The life-cycle model in its current iteration is intended to inform CDFW and the Commission of the overall trajectory of the proposed listing unit with appropriate consideration of the life-history types, including resident and anadromous O. mykiss. The scope of the life-cycle model is appropriately broad at this stage, encompassing general assumptions based on the available literature about the species within the proposed listing unit, applying local information and reasonable assumptions to parameterize the model and allow for the evaluation of a wide range of scenarios to test those assumptions. As described by Cramer (2023), the life-cycle model parameters are based on the known life-history variability of *O. mykiss* in the proposed listing unit. The model uses empirical data, when available, from the scientific literature to set parameter values, with flexibility to change parameter values as additional data becomes available as well as based on professional judgement. As commented on above, population trends are a key component of the Status Review, and the findings and conclusions are based on incomplete data. The life-cycle model provides a valuable tool, with incorporation of all available information on anadromous and resident *O. mykiss* within the proposed listing unit, to examine the long-term responses to a range of scenarios and reevaluate the conclusions in the Status Review. Integration of the model in the Status Review would allow for the exploration of population dynamics, and the extent to which these dynamics are affected by individual parameters and their values. Cramer (2023) highlights a key advancement provided by the model, noting that "the core dynamics demonstrate that concepts like connectivity and life history variants can have large impacts on a population's trajectories, and that omitting them may not fully capture the population's capabilities." This is one example of the utility of the model, but there are others, including the assessment of other biological variables (e.g., anadromous fraction) and environmental variables (e.g., future climate scenarios) as they contribute to the status of the species.

The life-cycle model was presented to CDFW prior to the submission of the Status Review. On December 12, 2023, a meeting was held to introduce the life-cycle model to CDFW staff, including those working on the Status Review, with an overview on the model development background, methodology used, literature reviewed as the basis for the model parameterization, and initial model outputs. The meeting was also intended to initiate a dialogue between the biologists working for the regulated stakeholders, third-party technical experts (Cramer), and CDFW regarding the information needed to make sound management decisions in the proposed listing unit. ACWA members were represented by biologists Randall McInvale (United), Sarah Mulder (Ventura Water), and Scott Lewis (Casitas Municipal Water District), Environmental Services Manager Marissa Caringella (United), Executive Director of Planning and Natural Resources Lisa Haney (Orange County Water District), and State Relations Advocate Stephen Pang (ACWA). CDFW was represented by Kyle Evans, Chenchen Shen, and Robyn Bilski. Cramer was represented by Kai Ross, PhD and Joe Merz, PhD.

Following the submission of the Status Review, ACWA United and independent scientists have continued to bring the life-cycle model to the attention of CDFW and the Commission. On January 22, 2024, ACWA sent CDFW a link to the life-cycle model giving CDFW full access to use the model. On February 7, 2024, ACWA sent CDFW a copy of Cramer's draft memorandum detailing the model's background and function. And, on February 13, 2024, United and its legal representative met with the Commission's attorney—Supervising Deputy Attorney General Eric Katz. During that meeting, United presented the life-cycle model, demonstrated how the model worked and explained how the model represented an advancement in the scientific tools available to evaluate the long-term survival of *O. mykiss.*

Considering the lack of data in the Status Review to properly characterize the proposed listing unit, and without incorporation of the life-cycle model in the evaluation, CDFW has not demonstrated that they have utilized the best scientific information currently available in developing their conclusions and recommendations. The listing decision should not move forward until there is a more thorough evaluation of the available scientific information, including the life-cycle model, to ensure that the management decisions appropriately characterize the population proposed for listing.

Recommendations for management of the proposed listing unit

United appreciates the opportunity to provide comments on the Status Review. The information summarized herein demonstrates the need for a more transparent analysis of the data available on *O. mykiss* in the proposed listing unit, as well as the need for future data collection using standardized methods to accurately characterize the proposed listing unit population. The decision by the Commission at this stage must be scientifically sound and, as noted in our comments, the analysis completed in the Status Review, and the data used to complete these analyses, raises fundamental questions regarding the validity of the conclusions upon which the recommendations are based. We understand that the Commission must make a decision based on the available information, but as demonstrated in our comments, key questions have yet to be sufficiently addressed. With availability of the new life-cycle model developed for southern California steelhead and provided to CDFW, the conclusions in the Status Review should be reevaluated. As of now, fundamental questions regarding the status of the species remain unanswered and it is evident that the data currently available does not begin to fill the information gap needed to properly evaluate the proposed listing unit. United implores the Commission to find that the listing is not warranted at this time.

Respectfully,

Mauricio E. Guardado, Jr.
General Manager

Subject: CalTrout petition to list Southern California Steelhead as endangered under the California Endangered Species Act (CESA)

Dear Ms. Gusman:

United Water Conservation District (United) submits the following information in response to the CalTrout petition to list southern California Steelhead as an endangered species under the California Endangered Species Act (CESA) (CalTrout petition). As a California Special District with a vested interest in the conservation of southern California steelhead (*Oncorhynchus mykiss irideus*) (steelhead; *O. mykiss*), United has a well-documented history of monitoring southern California steelhead in the Santa Clara River watershed. The work of United, along with a handful of others in the region, comprises the majority of the monitoring conducted on the species in southern California. Through this monitoring and data analysis, United has developed an understanding of *O. mykiss* in the watershed that has been leveraged in extensive consultations with the regulatory agencies over the years. An information gap regarding *O. mykiss* ecology exists in the region and key research questions remain unanswered, as the information presented below demonstrates. That history and knowledge gap compels the conclusion that the California Department of Fish and Wildlife (CDFW) should study this species – not list it based on the limited information provided in the CalTrout petition.

To aid CDFW's review, United provides additional information and references, formatted to primarily address inaccuracies, or in some cases correct information, presented in the CalTrout petition, followed by a discussion and references to specific documents for consideration in the evaluation of the petition. Specific references included in this submittal are largely focused on steelhead in the Santa Clara River watershed, though reference to the greater geographic region and steelhead population is included as appropriate.

1701 Lombard Street, Suite 200, Oxnard CA 93030 Tel: (805)525-4431 www.unitedwater.org

The CalTrout Petition Misrepresents United's Freeman Diversion.[1]

The CalTrout petition states that United's Freeman Diversion facility has not been remediated. This statement fails to recognize that (1) the existing facility[2] continues to provide passage for steelhead, with two confirmed upstream migrating steelhead observations as recently as 2020, (2) United is continuing to prepare a Habitat Conservation Plan (HCP) pursuant to Section 10 of the federal Endangered Species Act (ESA) associated with the rehabilitation of the fish passage facility at the Freeman Diversion and an updated bypass flow program intended to balance the needs of species and water resources in the region, (3) physical modeling of alternative fish passage designs by the United States Bureau of Reclamation (BOR) is currently underway, and (4) United continues to consult with National Marine Fisheries Service (NMFS) and CDFW on all of the above. The rehabilitated fish passage facility will represent a significant improvement over the existing condition and will provide improved fish passage conditions for steelhead as well as Pacific lamprey (*Entosphenus tridentatus*), design criteria for which is a primary component in the 10+ year alternative fish passage design process underway with NMFS and CDFW's involvement.

The adult steelhead run size estimates[3] are unsubstantiated by quantitative data. Establishment of achievable management and recovery objectives is hampered by the lack of reliable historic and current population data.

The historic run size estimate in the Southern California Steelhead Recovery Plan[4], which is cited by the CalTrout petition, comes from "The Updated Status of Federally listed ESUs of West Coast Salmon and Steelhead" (Good et al. 2005) and includes steelhead estimates for each

---

[1] CalTrout Petition. See pg. 13, paragraph 1.

[2] United operates the Freeman Diversion to conserve, maintain, and put to beneficial use the waters of the Santa Clara River watershed, with one of the primary goals being to combat seawater intrusion in the Oxnard Plain. United has diverted water from the Santa Clara River at the Freeman Diversion to provide for surface water deliveries and groundwater recharge in accordance with water right license 10173 and permit 18908. CDFW protested the original application to the water rights permit in 1980, citing a remnant steelhead resource in the river. Through much coordination and consultation between United, CDFW, the State Water Resources Control Board (SWRCB), and the Department of Water Resources (DWR), a steelhead study was completed in the river in the early 1980s, which resulted in the installation of a Denil fish ladder and implementation of bypass flows for fish passage at the request of and based on specifications provided by CDFW. SWRCB issued water right permit 18908 to United in 1987 and subsequently amended it in 1992. The permit incorporated CDFW's recommended fish ladder and bypass flow provisions, which were notably protested by DWR due to the importance of combating the severe seawater intrusion experienced in the Oxnard Plain. Nevertheless, United accepted the fish passage provisions and began implementation when the Freeman Diversion became operational in 1991. Over the years, United has modified bypass flows several times for the benefit of steelhead, each time decreasing diversion yield compared to its water rights license and permit. As a result, the seawater intrusion conditions have been magnified by the ongoing drought conditions and limited diversion yield.

of the major watersheds. Within the Ventura River watershed, the estimate traces back to a 1946 CDFW letter commenting on the future Matilija Dam.[5] Within the Santa Clara River watershed, the 1980 estimate by Moore[6] of the average population traces back to the same 1946 CDFW letter from which Moore extrapolated an estimate in the Santa Clara River by comparing the potential habitat of the two watersheds. This fact is echoed in CDFW's 1996 Steelhead Restoration and Management Plan for California[7] and again by NMFS (2005)[8], which also includes a review of the historical run sizes in the major southern California watersheds. Moore's knowledge of the Santa Clara Watershed comes from the late 1970s and early 1980s, one of the wettest periods on record, causing an overestimation of river miles of suitable steelhead habitat. In the same 1980 report, Moore notes that projecting the average run size can be misleading, particularly in systems subject to extreme flow fluctuations from year-to-year.

In a review of the history of steelhead in the Santa Ynez River, Alagona et al. (2012)[9] acknowledges the natural variation in steelhead run sizes, particularly in the southern California ecosystems, noting that "[a]ll of these perturbations and processes affect steelhead populations, which may have varied by two orders of magnitude annually owing to natural changes alone." The original source of the Santa Ynez River estimate came from a report generated by Shapovalov[10], a CDFW employee, which relied upon the opinion of another CDFW employee (Carl Tegen) who was working as a trapper in the Santa Ynez River watershed. Tegen compared the number of steelhead in the Santa Ynez River to counts in the Eel River and deduced that the Santa Ynez steelhead run during the year in question (1944) was "at least as large" as the Eel River. While it is apparent that there were many adult steelhead in the Santa Ynez in 1944, it would be inaccurate to assume that his estimate was a running average of a natural run of steelhead for the same reason that Moore notes in his 1980 report regarding year-to-year fluctuations in flows within these river systems.

CDFW acknowledges this subjectivity in quoting the U.S. Fish and Wildlife Service (USFWS) in the Fish Species of Special Concern in California.[11] CDFW notes that the estimates of historical run sizes "are highly subjective and probably correct only within an order of magnitude". In Good et al. (2005), NMFS concurs with the earlier CDFW statement and goes a

step further to adjust down the historical run size estimate for the Santa Ynez based on a logical inference regarding Tegen's experience in the Santa Ynez and Eel Rivers. Good et al. (2005) summarizes their review of historical run sizes by stating that "the estimates of historical run sizes for the Southern California steelhead ESU are based on very sparse data and long chains of assumptions that are plausible but have not been adequately tested." Therefore, to properly evaluate southern California steelhead, CDFW must first develop an accurate estimate of adult run size necessary to establish the status of the species and appropriate recovery goals in southern California watersheds.

Furthermore, another concern is that the estimates were based on an artificially stocked population supported during the extensive steelhead planting program implemented by CDFW beginning in the 1890s and continuing up to the 1930s (Bowers 2008). In the 1910s, southern California rivers, including the Santa Clara and Ventura, along with their tributaries, were receiving up to 3 million trout from northern hatcheries per year. The fish planted were predominantly steelhead and a mix of resident with the anadromous form. This topic is discussed further below.

The focus on human induced population decline in steelhead[12] in southern California ignores the influence of artificial steelhead planting by CDFW.

In southern California, the rise and fall of the steelhead population directly correlates with CDFW's planting of northern steelhead in southern California waters. Prior to the planting from northern hatcheries, records of steelhead in the southern California rivers are minimal. For example, records from the missionary period never mention trout or steelhead, which contrasts with the rivers further north, and scarce records from the pre-colonial period. As noted in the review of steelhead in the Santa Ynez River by Alagona et al. (2012)[13], "we found relatively few explicit records of Chumash exploitation of riverine fish, such as steelhead in the Santa Ynez River, from Spanish, Mexican, and early American explorers and settlers," indicating that steelhead were possibly not as prevalent and abundant as previously asserted. Alagona et al. (2012) continues: "At present, the only archaeological evidence for steelhead presence comes from several theses and a museum contribution describing excavations of sites in former inland Chumash villages with associated information on the identity of fish elements… [s]teelhead remains were found at three of four excavated sites… 6 salmonid bone elements found at Xonxon'ata [located on Zaca Creek 6 miles above its confluence with the Santa Ynez River] constituted only 0.2% of the identifiable fish bones recovered at this site, with the rest assignable to marine species, and these bones appeared to come from immature steelhead or rainbow trout." Alagona et al. (2012) acknowledges that more research is necessary to draw conclusions

[12] CalTrout Petition. See pg. 3, paragraph 3

[13] Alagona P.S., Cooper S.D., Capelli M., Stoecker M., Beedle P. H. A History of Steelhead and Rainbow Trout (*Oncorhynchus mykiss*) in the Santa Ynez River Watershed, Santa Barbara County, California

regarding the presence of salmonid bones at the Santa Ynez River archaeological sites; however, the findings provide an indication of limited steelhead presence during the pre-colonial period.

As noted above, large numbers of trout from northern hatcheries were planted in southern California rivers in the 1890s up to the 1930s. The planted fish were predominantly steelhead and a mix of resident with the anadromous form. The history of the steelhead fisheries during this time is well documented.[14,15] By the early 1930s, there was a trend towards planting larger "catchable-sized" trout. In the late 1930s, the focus of the hatcheries had changed to producing and planting "catchables" that were mostly from a resident form of *O. mykiss.*[16] The decline in steelhead in southern California rivers coincided with the change in hatchery practices.

The population decline following the cessation of planting from northern hatcheries is evident in correspondence generated by CDFW officials and numerous newspaper articles at the time (McEachron 2007 and Bowers 2008). Alagona et al. (2012) also cited Spanne (1975), which "noted that runs of anadromous fish in the Santa Ynez River occurred right up to the construction of Bradbury Dam, but that they were much more predictable and frequent in the late nineteenth and early twentieth centuries based on the memories of elderly residents." The late nineteenth and early twentieth century time period is coincident with the steelhead planting program that was underway in southern California at that time. By 1951, the mention of a steelhead fishery in the newspapers had almost ceased to exist. During that year (1951), CDFW biologist Willis Evans stated: "The fisheries value of these drainages lies primarily in the existence of a resident population of rainbow trout in the head waters areas. Their range throughout most of the subject drainages is curtailed by the lack of sustained year long stream flows. High summer water temperatures above the tolerance of trout also prevent trout development in otherwise suitable streams such as lower Piru Creek."[17] "These drainages" referred to the Ventura and Santa Clara River watersheds. The following year (1952), the Santa Paula Chronicle reported that "Steelhead fishing season ended this year without a single catch being made." In 1954, a few steelhead were reported in the Ventura River but no catches were reported. Notably, these statements from CDFW were made prior to any major dams being constructed in the Santa Clara River watershed. Santa Felicia Dam, constructed on Piru Creek in 1955, was the first such dam. More

recent records of steelhead in the Santa Clara River, primarily made by fisherman, CDFW, and by United were reported and are also well-documented.[18,19,20]

The CalTrout petition refers to steelhead monitoring at the Freeman Diversion fish ladder, stating that it, in part, "supports the finding that little to no change has been observed in total abundance or spatial structure of Southern steelhead since the initial federal listing." United does not refute this statement. However, it should be noted that it is consistent with previous CDFW surveys in the Santa Clara River watershed, which found low numbers of steelhead going back to the 1950s. Later, CDFW conducted a two year study in coordination with United in 1982-1983 and 1983-1984.[21] It resulted in the trapping and identification of a total of 3 steelhead over the two-year study period. As noted above, monitoring at the Freeman Diversion fish ladder has identified low numbers of adult steelhead, typically 0 to 2 individuals per year, since beginning operation in 1991 up to 2021. Combined with earlier observations, monitoring at the Freeman Diversion indicates that the total abundance of steelhead has remained relatively stable since well before the federal listing.

Further research into the relationship between resident and anadromous life-histories must be included in the analysis[22] of the status of steelhead, species stability, and recovery.

When considering the petition and potential future listing, the contribution of resident rainbow trout must be considered. A document prepared by NOAA-NMFS Southwest Fisheries Science Center supports this approach by stating: "Steelhead and rainbow trout belong to the same species (*O. mykiss*), and steelhead are the ocean-migratory ("anadromous") form and rainbow trout are the freshwater-resident form. There is a growing body of literature showing that steelhead and rainbow trout share freshwater habitat, mate with one another, and their offspring can either undergo physiological changes necessary to migrate to the ocean as a steelhead or undergo freshwater maturation as a rainbow trout."[23] As evidenced by this interplay, the ecology of the species clearly requires close examination by CDFW.

The CalTrout petition states that "[f]ish that express the resident freshwater life-history strategy play a central role to the continued existence of southern steelhead." United agrees with the CalTrout petition regarding this interplay of the freshwater resident and anadromous *O. mykiss* life-histories. NMFS recognizes the importance of the life history plasticity between the resident and the anadromous form of *O. mykiss*. In the recovery plan process, NMFS stated: "It is difficult to envision a successful recovery effort without a better

[23] Ohms H.A. and Boughton D.A. 2019. Carmel River Steelhead Fishery Report - 2019.

understanding of the functional relationship between resident and anadromous fish." They go on to explain that "this continuum has a significant implication for viability criteria."[24] The most recent NMFS 5-year review of the species referred to resident *O. mykiss*, their importance to the viability of anadromous steelhead populations, and how viability criteria in the Recovery Plan should be updated to account for the contribution of resident fish, a topic that is discussed in more detail below. Recently, several authors that have worked extensively with the southern California steelhead population published a study[25] that makes a key point: "Resident *O. mykiss* in upper watershed areas outside the designated critical habitat are not protected by either state or federal endangered species acts, despite their documented link in maintaining maximum numbers of [s]teelhead (NMFS 2012)." Dagit et al. (2020) also states that the Southern California Steelhead Recovery Plan (NMFS 2012) and Boughton et al. (2007) proclaim that an important consideration to prevent extinction is "protecting existing populations and all life history expressions."

The current recovery population viability goal of 4,150 spawners per year on average for southern California steelhead comes from Lindley's (2003) "random walk with drift" model using field data from the Central Valley (Boughton et al. 2007; Williams et al. 2016). However, the "random walk" model considers only 100 percent anadromous spawners (thereby disregarding the significant contribution of resident *O. mykiss*). This approach effectively means that in terms of achieving recovery goals, resident trout would not contribute to the anadromous form even though NMFS recognized that the Santa Clara River has maintained a population of smolts emigrating to the ocean while upstream migrant runs were too small to be self-sustaining. The limited consideration of purely anadromous fish for the recovery goal is biologically inappropriate for this species, and contrary to the wide recognition that resident *O. mykiss* play a key role in conservation of native coastal *O. mykiss*, including the steelhead life history strategy – particularly in arid southern California where intermittent flow regimes and prolonged droughts are common (Dagit et al. 2020). The viability studies recognized that the "interchange between resident and anadromous fish groups would almost certainly lower the extinction risk of both groups."[26] They go on to state that during their performance-based criteria analysis the interchange between the resident and anadromous form could have large consequences when determining extinction. Specifically, "we suspect that extinction risk of steelhead fraction is likely to be highly sensitive to the details of this interchange."

In the most recent 5-year review of the species, NMFS states that "the criteria that mean annual spawner abundance 1) be greater than 4,150, and 2) be composed of 100% anadromous individuals, were recommended as a risk-averse approach. It was expected that

[26] Boughton. 2007. See pg. 8, paragraph 2.

further scientific work would either support these criteria or allow one or both to be relaxed" depending on the scientific research to fill key knowledge gaps including "uncertainty about the magnitude of normal fluctuations in adult abundance, and… uncertainty about the underlying biological mechanisms for expression of life-history diversity, especially factors triggering anadromous versus resident life-histories within populations."[27] Thus, there is clear acknowledgment that additional research is needed to gain a more complete understanding of steelhead ecology and, among other things, refine the viability goal under the federal ESA. These findings and research questions would also need to be closely considered by CDFW in the evaluation of the petition.

Dagit et al. (2020) also notes that, "[a]s reported by Williams et al. (2016) and confirmed by our observations, at no point since [southern California] steelhead were listed as endangered in 1997 was the preliminary provisional viable population goal of 4,150 annual anadromous spawners observed in any individual watershed, nor through the DPS as a whole."

Finally, Dagit et al. (2020) states that "[b]uilding quantitative models that consider both anadromous and resident fish in the production of smolts, in addition to watershed-specific carrying capacities would be a valuable effort towards refining population goals." United strongly agrees, and points to the last southern California steelhead 5-year review that also stated: "Overall, these results show that resident and anadromous forms are tightly integrated at the population level, suggesting a revision of the viability criterion for 100 [percent] anadromous fraction" (NMFS 2016). Moyle (2017) acknowledges that the life-history trait of "partial anadromy is an active area of research to gain insight into underlying environmental and genetic influences. This multigenic trait has important implications for endangered steelhead recovery and fisheries management strategies."

The CalTrout petition states that "[t]he resident component of the ESU covers a large number of native rainbow trout that are geographically dispersed, but are genetically demonstrable remnant populations of Southern steelhead;" however, the information presented above demonstrates that the interplay between the anadromous and resident life-histories is an open and ongoing area of research with direct implications on the status of the species. A review of the best available scientific information results in numerous findings and conclusions regarding the need for additional research on this topic. Researchers and regulatory agencies acknowledge that further study is necessary to ascertain key data required to make informed management decisions. Therefore, United urges CDFW to evaluate the entire breeding population, including resident fish as well as south-central coast steelhead (discussed below) in their review of the CalTrout petition. Should southern California steelhead become a candidate species, CDFW must again evaluate the entire breeding population in the status review to achieve a more realistic recovery goal that is true

[27] NMFS. 2016. 5-Year Review: Summary and Evaluation of Southern California Coast Steelhead Distinct Population Segment. National Marine Fisheries Service. West Coast Region. California Coastal Office. Long Beach, California. See pg. 20, paragraph 2.

to the biology and genetic structure of the native *O. mykiss* population in southern California. In considering the appropriate population, CDFW can employ a more holistic approach to protecting native *O. mykiss* in southern California, and permit applicants and restoration biologists will be afforded more viable options for project proposals that will lead to meaningful improvements for this population.

The fraction of anadromy must be considered at the sub-watershed level due to highly variable environmental conditions.

Tributaries within the Santa Clara watershed support a healthy population of *O. mykiss*. Stoecker and Kelley (2005) summarized various surveys conducted by CDFW and academic institutions documenting observations of over 100 *O. mykiss* per 100 feet of stream length. Moore, as referenced in Stoecker and Kelley (2005), did an extensive survey of both Santa Paula Creek and Sespe Creek, and their tributaries, reporting "abundant" trout in most of the tributaries. Some of his observations included 15 *O. mykiss* per 100 feet in Lion Creek and 70 *O. mykiss* per 100 ft in Howard Creek. A survey by CDFW, also referenced in Stoecker and Kelley (2005), found *O. mykiss* to be abundant in various tributaries to Sespe Creek in 1994 to 1995. As an example, they observed over 100 *O. mykiss* per 100 feet in Howard Creek. While no estimates were made to calculate the total abundance of *O. mykiss* observed in the Santa Clara River watershed, it would be safe to assume that during these surveys the totals were substantial given that, for example, on Sespe Creek about 47 miles of spawning and rearing habitat *O. mykiss* were reported by CDFW[28]. During this same period, various studies documented the anadromous migration within the watershed. A two-year study conducted by CDFW in 1982-1984 found no smolts migrating out of the Sespe despite trapping, electroshocking, and netting downstream of the Sespe tributary throughout the primary smolt migration period[29]. In the early 1990s, smolts were trapped and counted at the Freeman Diversion. In 1994, for example, United operated a downstream migration trap from February 21 through May 25 and a total of 83 smolts were collected at the trap during this period.[30] It is worth noting that smolts collected at the facility ranged from 0 to approximately 800 during the operation of the downstream migrant trap.

With survey and monitoring results documenting an abundant resident population but relatively few smolts produced from these watersheds, there is a strong indication that *O. mykiss* in the Santa Clara River have a natural low fraction of anadromy. A naturally low fraction of anadromy is expected where the cost to migrate to and from the ocean is high (i.e., low success rate) compared to staying within the watershed as residents. This observed low fraction of anadromy may be explained by the dynamics of many of the rivers in southern California.

As an example, the Santa Clara River is a large watershed (1,625 square miles) dominated by a sandy braided channel in the mainstem. During high flows, suspended sediment levels in the

[28] CDFW. 1996. See pg. 205, paragraph 5
[29] Puckett L.K. and Villa N.A. 1985.
[30] Entrix. 1994. Results of Fish Passage Monitoring at the Vern Freeman Diversion Facility, Santa Clara River, 1994. See pg. 3-10, Table 3-4

Santa Clara River are elevated to a point that is expected to preclude upstream migration opportunity[31]. A key section of the river for emigration to the ocean is well documented by observations dating back to the 1700s to go dry, thus precluding passage. During large portions of the year, portions of the river mainstem remain dry due to percolation to the underlying groundwater basins as surface water is quickly lost in the broad alluvial floodplain.[32]

Kendall et al. (2015) reviewed various studies documenting the factors that may influence the fraction of anadromy. One study found that "migration cost did influence life histories in one model which indicated that emigration survival was one of the critical factors shaping the expression of anadromy."[33] Residency was predicted to increase as emigration survival decreased. Kendall found other studies that concluded that perhaps the southern portions of the species range may be skewed towards residency with the higher cost of anadromy due to seasonally dry stream reaches and lagoon sandbar formations limiting migration opportunities.

Using over 20 years of data collected at the Freeman Diversion from the downstream migrant trap, Booth (2020) concluded that smolt migration timing was correlated with the day length and was less dependent on flow magnitude. Booth found that 95% of all smolts arrived between mid-March and late May with the majority arriving at the collection system in mid-April to mid-May. Most importantly, Booth concluded that "downstream migration in the Santa Clara River often may occur too late in the season to be synchronized with likely opportunities for downstream migration to the estuary and ocean."[34] Upon reviewing the historic hydrology for the system, Booth found that it is a relatively common occurrence for smolts in the Santa Clara River to be unable to successfully migrate to the ocean even with natural hydrology conditions. In summary, *O. mykiss* in the Santa Clara River watershed produce a very small fraction of anadromy, which is expected due to high cost for anadromy and the lack of opportunities for successful emigration and upstream migration. It is likely that the historic planting of steelhead, discussed in more detail above, temporarily modified the fraction of anadromy, thereby increasing the anadromous run size in the system for a short period. Prior surveys have revealed that the resident form of *O. mykiss* are well established within the watershed and are likely to continue to produce the anadromous form. This relationship needs to be studied before a CESA listing determination can be made. As NMFS has stated, the viability of the species would be expected to rise when considering the resident contribution.

Genetics on the population structure. The CalTrout petition discusses nuclear DNA with respect to geography, but fails to consider genetic evidence establishing that there is no differentiation between the southern California and the south-central coast populations of steelhead.

The best available scientific information does not support southern California steelhead being distinct from south-central coast steelhead. In 2008, scientists at National Oceanic and Atmospheric Administration (NOAA) Southwest Fisheries Science Center concluded that "[n]o genetic basis was found for the division of populations [from southern California] into two distinct biological groups, contrary to current classification under the US and California Endangered Species Acts."[35] The Clemento et al. (2008) study analyzed nuclear DNA, representing the best available scientific information and a far superior approach to identifying genetic structure in coastal *O. mykiss* populations compared to the prior studies cited in the original listing that used allozymes (proteins), maternally inherited mitochondrial DNA (Busby et al. 1996), and karyotyping (chromosome sampling). Thus, the more recent – and more reliable – studies from 2008 demonstrate that the two populations should be reclassified as one based on the most updated and most rigorous genetic data.

Other comments on the CalTrout petition:

- The CalTrout petition fails to acknowledge that the language of CESA covers the listing of a "species or subspecies" and not a distinct population segment (DPS).
- While arguing for the listing of the anadromous life-history form, CalTrout recommends not listing the resident life-history form above total barriers even though both forms are genetically identical and comprise a single species, *O. mykiss*. The CalTrout petition stops short of identifying the anadromous life-history form as a species or subspecies, likely owing to the fact that the anadromous and resident life-history forms comprise one species. In the status review of the northern California summer steelhead, CDFW indicated that this ecotype should not be listed under CESA, a recommendation based at least partially on the genetics of the species,[36] which indicated closer relation between localities as opposed to run-timing, and failed to meet the definition of a subspecies, as the petition requested. The same finding should apply to the genetics of anadromous and resident *O. mykiss*.
- The CalTrout petition recommends that catch-and-release fishing with barbless lures only be permitted in waters demonstrated to have steelhead lineage.[37] Catch-and-release

---

[35] Clemento A.J, Anderson E.C., Boughton D., Garza J.C. 2008. Population genetic structure and ancestry of *Oncorhynchus mykiss* populations above and below dams in south-central California. See pg. 1321, paragraph 1.

[36] CDFW. 2021. California Endangered Species Act Status Review for Northern California Summer Steelhead (*Oncorhynchus mykiss).* See pg. 149, paragraph 4.

[37] CalTrout Petition. See pg. 17, paragraph 1.

fishing results in a percentage of mortality, so the recommendation runs contrary to the arguments presented in the CalTrout petition.

- The CalTrout petition states that the listing of steelhead under CESA is needed to augment the protections provided by the federal ESA listing[38] but the effective protections for the species would not change significantly. Currently, while NMFS administers protections for steelhead under the federal ESA and CDFW administers protections for steelhead under the Fish and Game Code (F&G Code), "take" is already prohibited under the federal ESA without an incidental take permit and is also effectively prohibited by CDFW's interpretation and application of F&G Code.
- It is important that CDFW use the best available scientific information when describing the species' basic life history. The CalTrout petition states that "the timing of out-migration is influenced by a variety of environmental cues including streamflow, temperature, and breaching of the sand berm at the river's mouth."[39] It is important to add that recent new evidence points to day length (also known as photoperiod) as being a major driver of juvenile outmigration timing[40] and potentially as important, if not more so, than the environmental cues listed by CalTrout's petition.
- The CalTrout petition notes that "[e]xcessive sedimentation and turbidity are critical water quality components in all habitat types and impacts how southern California steelhead utilize each habitat type."[41] United agrees, and would note that as part of the Freeman Diversion MSHCP currently in development, United has completed an analysis of the effects of suspended sediment concentrations and turbidity on the behavior of steelhead. United encourages CDFW to evaluate the effects of sedimentation and turbidity as part of their analysis.
- The CalTrout petition notes that "7 inches is considered the minimal water depth needed for successful migration" for adult steelhead.[42] United agrees that the minimum water depth necessary for adult migration in southern California rivers is something other than the 0.7 feet (8.4 inches) referenced in the CDFW critical riffle analysis standard operating procedure,[43] which was developed based on an analysis completed for the SWRCB Policy for Maintaining Instream Flows in Northern Coastal California Streams.[44] United encourages CDFW to evaluate region specific data on fish size and river flows in their analysis to determine more appropriate flow depth criteria.

The lack of reliable historic and current population data, compounded by artificial planting, and the lack of proper research into resident and anadromous life histories, fraction of anadromy, and genetic differentiation compels further study of southern California steelhead prior to making a CESA listing decision based on CalTrout's petition. The evaluation must consider all available sources of information to reach the best available scientific information threshold, including the information provided herein, and the attached reference documents, as a starting point for this species.

Respectfully,

Anthony Emmert
Assistant General Manager

Re: CDFW evaluation report on California Trout petition to list Southern California steelhead as endangered pursuant to the California Endangered Species Act (CESA)

Dear California Fish and Game Commission:

In June 2021, California Trout submitted a petition to the California Fish and Game Commission (Commission) to list Southern California steelhead (Oncorhynchus mykis) as endangered pursuant to the California Endangered Species Act (CESA), Fish and Game Code section 2050 et seq. Thereafter, the Commission referred the petition to the California Department of Fish and Wildlife (CDFW) pursuant to Fish and Game Code section 2073 for preparation of an evaluation report on the petition. Pursuant to Fish and Game Code section 2073.4, on August 17, the United Water Conservation District (United) submitted a 13-page written comment letter and supporting evidence to aid CDFW in its review. United's letter provided additional information and supporting evidence directly relevant to CDFW's mandated evaluation, which included corrections of a number of factual and scientific inaccuracies in the petition. We have enclosed a copy of United's letter and supporting evidence. On November 30, CDFW released its written evaluation report to the public.

We have since reviewed the evaluation report and discovered that it contains no discussion of the substance of United's August 17 letter, or, for that matter, a discussion of the substance of any of the other timely submitted comment letters. CDFW, however, is mandated by Fish and Game Code section 2073.5 and Section 670.1 of Title 14 of the California Code of Regulations to consider all relevant information it receives on the petition and to evaluate the petition in light of that information. The obvious purpose of the mandate is to ensure that the Commission receives an objective evaluation report rather than an advocacy piece favoring the petitioner.

Of specific concern in CDFW's evaluation is its clarification of CalTrout's inclusion of both resident and anadromous DPS in their listing petition. As we stated in our previous comments letter: "When considering the petition and potential future listing, the contribution of resident rainbow trout must be considered. A document prepared by NOAA-NMFS Southwest Fisheries Science Center supports this approach by stating: "Steelhead and rainbow trout belong to the same species (0. *mykiss),* and steelhead are the ocean-migratory ("anadromous") form and rainbow trout are the freshwater-resident form . There is a growing body of literature showing that steelhead and rainbow trout share freshwater habitat, mate with one another, and their offspring can either undergo physiological changes necessary to migrate to the ocean as a steelhead or undergo freshwater maturation as a rainbow trout."[1]

1. Ohms H.A. and Boughton D.A. 2019. Carmel River Steel head Fishery Report - 2019

For this reason, it is critical that the Commission consider the whole O.mykiss population when contemplating the validity of the petition to list. This is just one of the numerous comments cited in United's original comment letter of August 17, 2021.

In light of CDFW's failure to include in its evaluation report any discussion of the relevant public comments it received concerning the petition, United respectfully requests that the Commission remand the evaluation report back to CDFW with the direction that it prepare a revised evaluation report that actually evaluates the scientific information discussed and cited in the petition in relation to the public comments CDFW has received.

Respectfully,

Mauricio E. Guardado, Jr., general manager

California Fish and Game Commission
PO Box 944209
Sacramento, CA 94244-2090

Subject: California Fish and Game Commission proceedings on California Trout's petition to list southern California steelhead as endangered under the California Endangered Species Act (CESA), and California Department of Fish and Game's evaluation of the petition

Dear California Fish and Game Commission:

Before the California Fish and Game Commission (Commission) reaches its decision regarding whether listing of southern California steelhead under the California Endangered Species Act (CESA) may be warranted, it is necessary for the Commission to consider fatal errors in the California Department of Fish and Wildlife's (CDFW) evaluation of California Trout's (CalTrout) petition. Specifically, despite CalTrout's failure to adequately define southern California steelhead, or sufficiently address resident steelhead, CDFW allowed CalTrout to significantly alter its petition with a dramatically expanded definition of southern California steelhead. CDFW also assumes that CalTrout's assertions without specific support are true. This falls woefully short of the Commission and CDFW's statutory and regulatory requirements, thus compelling the Commission to reject CalTrout's petition.

California Fish and Game Code (FGC) section 2072.3 provides: "To be accepted, a petition shall, at a minimum, include sufficient information that a petitioned action may be warranted." FGC section 2073.5(a) requires CDFW to "evaluate the petition on its face and in relation to other relevant information the department possesses or receives," and California Code of Regulations (CCR), Title 14, section 670.1(b) requires the Commission to return incomplete petitions to the petitioner. However, rather than return CalTrout's deficient petition, CDFW states:

> to the extent the Petitioner makes assertions without citing specific support, the Department assumes these statements to be true for purposes of the Petition Evaluation. If the Commission accepts the Petition for further consideration, the Department will need to verify these statements during the status review period. Petition Evaluation Section III, p. 9.

Also, despite identifying another deficiency in CalTrout's petition, CDFW requested CalTrout's intended definition of southern California steelhead. In response, CalTrout broadly defined southern California steelhead as follows:

> All *Oncorhynchus mykiss,* including anadromous and resident life histories, below manmade and natural complete barriers to anadromy from the Santa Maria River, San Luis Obispo County (inclusive) to the U.S.-Mexico Border with the understanding that anadromous (adult southern steelhead) arise from anadromous and resident naturally spawning adults.

The inclusion of resident *Oncorhynchus mykiss* (*O. mykiss*), or rainbow trout, below barriers along with anadromous steelhead as part of the listing unit is a significant deviation from the original petition. This clarification also exposes a shortcoming of the petition, specifically, that it does not address resident *O. mykiss* sufficiently, but rather relies on information relevant to anadromous steelhead. As a result, CalTrout's petition and CDFW's evaluation of it are both fundamentally insufficient to substantiate a listing based on CalTrout's definition of southern California steelhead. Notably, FGC section 2074.2(e)(1) and CCR section 670.1(e)(1) provide that "a petition will be rejected by the commission if it fails to include sufficient scientific information" under the statutorily required categories in FGC section 2072.3.

Consideration and evaluation of all readily available information regarding the combined population dynamics and demographics for both resident and anadromous *O. mykiss* is essential to inform the Commission before making a determination on this matter. In fact, readily available data and literature provides evidence that resident *O. mykiss* are significantly more abundant than anadromous *O. mykiss*, have more viable populations than anadromous steelhead in the region (and statewide), and contribute substantially to the persistence of the overall species. Given the larger populations of the resident life history, an evaluation of the combined life histories is more likely to result in a determination that listing is <u>not</u> warranted. Therefore, we strongly urge the Commission to reject the petition pursuant to FGC section 2074.2(e)(1) and CCR section 670.1(e)(1).

General Comments:

United Water Conservation District (United) provided comments on the petition to CDFW on August 17, 2021. In addition to corrections of factual and scientific inaccuracies in the petition, as well as additional references for consideration by CDFW, the comments provided relevant information pertaining to several required components of the petition (see FGC section 2072.3): the population trend, range, abundance, factors affecting the ability to survive and reproduce, the degree and immediacy of threat, impact of existing management, and suggestions for future management.

As indicated in United's December 2, 2021 letter, CDFW's evaluation of the petition did not contain a substantive discussion of United's August 17, 2021 comments. CDFW set a low bar for the petition, disregarding information that is either already available to reviewers or made available through the public review process. This is inconsistent with FGC section 2072.3, FGC section 2073.5 and CCR section 670.1(d).

To determine whether there is sufficient scientific information that a petitioned action may be warranted, the Commission must know whether the information cited in favor of listing is factually true and scientifically accurate and supported, rather than CDFW simply "assuming" that some unsupported statements made by a petitioner about the species are true, even though those statements could, upon further investigation, turn out to be without basis. Knowing the information in the evaluation that is reliable, and that which is not reliable, is critical to the Commission's determination.

Comments on Components of the Evaluation

Population trend

The population trend section of the petition discusses only the anadromous form of *O. mykiss* – not the resident form. And in its evaluation of the petition, CDFW also discusses only the anadromous form of *O. mykiss* when describing the population trend in the region, including providing numbers of returning adults and observed declines in population compared to historic population estimates. CDFW added one reference regarding residents (see the CDFW and Santa Monica Mountains Resource Conservation District (SMMRCD) reference); however, this does not provide any information regarding the population (current or historic), population trend, or a discussion of the status of resident *O. mykiss* in the Santa Monica Mountains specifically or in the overall southern California region. Thus, this component of the petition and CDFW's evaluation is incomplete.

United has compiled readily available survey data and reports from several watersheds within the region; however, it is expected that other data (published or unpublished) is available to CDFW as part of the Heritage and Wild Trout Program and/or the Coastal Salmonid Monitoring Program, which are both led by CDFW.

Regarding the SMMRCD data referenced by CDFW, Moyle et al. (2017)[1] provides a discussion of a portion of the data, indicating a high level of variability in *O. mykiss* numbers from year-to-year. For example, following an observed die-off in Malibu Creek in 2006, the results of subsequent surveys resulted in the observation of five adult steelhead in 2007 and 2,200 *O. mykiss* young of the year (YOY) in 2008. During surveys completed in 2005, 2008, 2011, 2014, and 2015, YOY observations varied from 11 to 590 individuals – the latter surveys completed during the 2012-2016 extreme drought.

Other surveys include those within the Santa Clara River watershed and the CDFW Heritage and Wild Trout Program 2008 report[2] on the Agua Blanca Creek and Fish Creek (tributaries to Piru Creek) yielded estimates of 1,316 and 3,113 *O. mykiss* per mile, with the report noting that "[b]oth Fish and Agua Blanca Creeks contain relatively high densities of coastal rainbow trout, especially given the habitat limitations that salmonids face in this mountainous desert region." Surveys reported in Stoecker and Kelley (2005)[3] within the Sespe Creek drainage found a total of 2,954 *O. mykiss* largely from streambank observations and some snorkel surveys of deeper pools and, of the Santa Clara River sub-watersheds surveyed, the Sespe Creek drainage was found to have the highest relative abundance of *O. mykiss*. It is important to note that the Piru Creek surveys were

conducted in tributaries above Lake Piru, a manmade barrier to upstream migration, and the Sespe Creek surveys were conducted in areas above and below natural barriers to upstream migration.

In a study conducted for CDFW in the Ventura River watershed, Allen (2015)[4] reported on extensive *O. mykiss* surveys between 2006 and 2012. In that report, Allen reported that in the lower segment of the river, *O. mykiss* abundance is highly variable with a near zero abundance of fry and juvenile *O. mykiss* observed in 2006 and 2007 but increasing to a maximum of 3,739 juvenile and 2,348 fry *O. mykiss* in 2008 and 2012, respectively. Of the total in the lower river, the vast majority were observed in the study reach near the confluence with San Antonio Creek, known as historically important for *O. mykiss*. In the middle segment of the Ventura River, above the fish ladder on the Robles Diversion, Allen (2015) reported maximum abundance of fry in 2012 totaling 6,637 individuals and maximum abundance of juveniles in 2008 totaling 3,555 individuals. Abundance estimates were higher still in the upper segment, above Matilija Dam, even though total stream length was less than the combined reaches below Matilija Dam (Allen 2015). Overall, *O. mykiss* are generally most abundant in headwater spawning and rearing tributaries across the region and elsewhere.

The results presented above represent only a few examples of the data and findings of relatively recent *O. mykiss* surveys in the region and Attachment A provides a summary of additional *O. mykiss* survey data and reports compiled by United. These references show that there is a resilient and, in favorable years, robust population of resident *O. mykiss* both below and above natural and manmade barriers; however, conclusions regarding population trends and stability are qualitative in nature. For example, Moyle et al. (2017) states that "[o]nly the [resident] coastal rainbow trout (*Oncorhynchus mykiss*) is considered secure in its status" and that "the boundary between [anadromous] steelhead and resident coastal rainbow trout is fuzzy because it is not biologically based, but a distinction of convenience for management." Resident *O. mykiss* are defined by Moyle et al. (2017) as those populations above barriers, though there are populations of residents that are connected to populations below barriers.

When considering whether the listing may be warranted, the Commission should not solely rely upon information contained in the petition and evaluation that is limited to the anadromous life history of *O. mykiss*. The combined population of anadromous and resident *O. mykiss* must be considered to adequately evaluate the petition, which CDFW neglected to incorporate into the evaluation.

Range

As noted in the CDFW evaluation of the petition, Clemento et al. (2008)[5] found that there is no genetic basis for the division of populations (from southern California) into two distinct biological groups (the south-central California coast steelhead and southern California steelhead), contrary to the current classification under the federal Endangered Species Act (ESA). The federal ESA allows for the designation of Distinct Population Segments (DPS) based on metrics other than

[4] Allen M.A. 2015. Steelhead Population and Habitat Assessment in the Ventura River/ Matilija Creek Basin 2006-2012 Final Report. March 31.

[5] Clemento A.J, Anderson E.C., Boughton D., Garza J.C. 2008. Population genetic structure and ancestry of *Oncorhynchus mykiss* populations above and below dams in south-central California.

genetics; however, CESA allows for the listing of a "species or subspecies" and does not include the same DPS policy. It is unclear what basis CDFW or the Commission could use to justify that the petitioned action may be warranted given the lack of a genetic distinction between the federally designated southern California steelhead DPS and the south-central California coast steelhead DPS, as well as the lack of a genetic distinction of the species *O. mykiss* from across the state.

Distribution

Early in the evaluation (see Executive Summary, pg. 1), CDFW notes that the petition defines southern California steelhead as "all *O. mykiss*, including resident and anadromous life histories, below manmade and natural complete barriers…(hereinafter, all references to 'Southern steelhead' are to this definition of Southern California steelhead)." The CDFW evaluation neglects to clearly and consistently present information describing anadromous versus resident *O. mykiss*, as appropriate.

The CDFW evaluation refers to a statement in the petition that the southern California steelhead DPS has been extirpated from approximately 60% of its historical range; however, CDFW does not acknowledge that this is a reference to the NMFS Recovery Plan for southern California steelhead (NMFS 2012)[6] and refers to the anadromous life history. The Southern Steelhead Resources Evaluation (Becker et al. 2010)[7] provides a detailed account of the habitat for *O. mykiss* throughout the region, including both qualitative and quantitative accounts of *O. mykiss* presence in numerous river mainstems and tributaries. This reference, along with the information presented in Attachment A, shows that resident *O. mykiss* are distributed across many of the watersheds in the region.

CDFW neglected to evaluate the available information to determine the accurate distribution of *O. mykiss* within the region. Without reasonable consideration of this readily available information, the evaluation of the petition is incomplete and insufficient to inform the Commission regarding whether the proposed listing is warranted.

Abundance

The petition and CDFW's evaluation both focus on the anadromous life history. As discussed in more detail in the "Population trend" section above and summarized in Attachment A, resident *O. mykiss* are abundant across many of the watersheds in the region and this information, as well as any additional survey data, were not considered by CDFW in their evaluation.

Regarding residents, the CDFW evaluation includes the statement that "the Petition also notes that shrinking populations of freshwater resident *O. mykiss* are vulnerable to loss of genetic diversity and fitness." A reader could interpret this statement to mean that resident populations are in fact shrinking, which may not be CDFW's intent. The petition language reads that "[e]xcessive loss of local freshwater resident populations can lead to lower genetic variability and fitness," which followed a discussion of risks to resident populations from wildfires, drought, climate change, and anthropogenic factors. To clarify, United's understanding is that the petition is referring to

[6] NMFS. 2012. Southern California Steelhead Recovery Plan.

[7] Becker G.S., Smetak K.M., Asbury D.A. Southern Steelhead Resources Evaluation. Identifying Promising Locations for Steelhead Restoration in Watershed South of the Golden Gate. Cartography by D.A. Asbury. Center for Ecosystem Management and Restoration. Oakland, CA.

potential risks and does not state that resident *O. mykiss* populations are shrinking. United requests that CDFW clarify the statement in the evaluation.

Degree and immediacy of threat

Again, the petition and CDFW's evaluation, including their respective references, focus only on the anadromous life history form of *O. mykiss* and do not take resident *O. mykiss* into consideration. Overall, a discussion of resident *O. mykiss* is lacking and, therefore, this component of the CDFW evaluation is incomplete.

The importance of the resident *O. mykiss* life history contribution to the establishment and persistence of the anadromous life history is best stated by Moyle et al. (2017):

> in southern California many, if not most, returning 'steelhead' likely originate as migratory smolts produced from resident headwater trout populations many of which persist *above* man-made and natural barriers to anadromy. The polygenic nature of the anadromy indicates that the trait can persist for a long time in a large resident population. This has been demonstrated in an Argentina river flowing to the Atlantic, where steelhead have developed from resident fish, apparently of California origin, with resident and migratory fish forming one interbreeding population (Pascual et al. 2001) (emphasis from citation).

Elsewhere, Moyle et al. (2017) states:

> If resident rainbow trout populations are considered part of the southern steelhead complex, then the extinction threat of the overall population is somewhat less. Reconnecting the anadromous and resident forms of the native *O. mykiss* populations, however, is essential for maintaining both the anadromous and resident trout populations in the future.

In some watersheds, the connection of resident and anadromous *O. mykiss* remains intact, and in others, there is active progress toward projects that will reestablish this connection. This is essential for consideration by the Commission given that resident *O. mykiss* are secure in their status and contribute to the anadromous life history.

As discussed in more detail in the "Population trend" section above, a resilient population of resident *O. mykiss* persist in many watersheds both above and below barriers and these systems are capable of supporting robust populations that provide a substantial, yet under-evaluated contribution to the species in the region. Many efforts to improve existing fish passage facilities as well as efforts to reconnect isolated populations are currently underway within the existing regulatory framework that would aid in meeting recovery goals under the NMFS recovery plan (NMFS 2012).

Conclusion

The petition and CDFW's evaluation of the petition provide incomplete and insufficient information to inform the Commission's decision regarding whether the proposed listing may be warranted. As CDFW identified, the petitioner did not clearly articulate the intended definition of southern California steelhead. Once clarified, the arguments provided by the petitioner were insufficient to support a finding that the requested listing is warranted. In addition, the near complete reliance on the information presented in the petition (without supporting evidence) results in an evaluation report that lacks key considerations, primarily associated with the resident *O. mykiss* life history. Furthermore, CDFW did not follow statutory requirements in conducting its evaluation of the petition. CDFW did not consider readily available data and scientific literature, much of which was collected under oversight of the agency itself, in evaluating the petition, nor did they consider and address the relevant information provided by stakeholders through the public review and comment period.

The Commission's determination has serious consequences. If the species becomes a candidate species, it will be protected by CESA's take prohibition. As a result of the take prohibition, water supply and wastewater treatment agencies may become subject to civil and criminal liability for incidental, unintended take of the species that may occur in connection with their public health and safety activities. When the regulatory consequence of implementing public health and safety activities may be that an agency becomes liable for criminal and civil penalties, it is incumbent on the Commission to assure that high quality information, and not mere conjecture, supports the determination that the species should be a candidate species.

Overall, CDFW used a deeply flawed approach in preparing the evaluation, and one that is inconsistent with its statutory and regulatory requirements. A determination by the Commission that the listing may be warranted based on the information contained in the petition and CDFW's evaluation would not be legally defensible. Therefore, based on the foregoing, we respectfully request that the Commission reject the petition.

Sincerely,

Mauricio E. Guardado, Jr.
General Manager

Subject: United Water Conservation District Comments and Summary of Key Information Regarding the California Department of Fish and Wildlife 12-Month Status Review of Southern California Steelhead (*Oncorhynchus mykiss*)

Dear Fisheries Branch Staff:

United Water Conservation District (United) submits the following comments and attached information for consideration by the California Department of Fish and Wildlife (CDFW) in conducting the 12-month status review associated with the petition to list southern California steelhead (*Oncorhynchus mykiss*) (steelhead; *O. mykiss*) as endangered under the California Endangered Species Act (CESA). On June 14, 2021, California Trout (CalTrout) submitted a petition to the California Fish and Game Commission (Commission) to list southern California steelhead as an endangered species under CESA. On April 21, 2022, the Commission accepted the petition for consideration. On May 13, 2022, the Commission provided public notice that southern California steelhead is now a candidate species under CESA. Pursuant to Fish and Game Code (FGC) § 2074.6, CDFW is in the process of completing a status review of southern California steelhead and has invited the public to submit comments on the petitioned action, including ecology, genetics, life history, distribution, abundance, habitat, the degree and immediacy of threats to its reproduction or survival, and the adequacy of existing management or recommendations for management of southern California steelhead. In its status review, CDFW is required to evaluate the breadth of available scientific literature and develop a summary of the status of southern California steelhead. The petitioned listing unit, as defined in the CDFW evaluation report and contained in the status review:

> All *Oncorhynchus mykiss,* including anadromous and resident life histories, below manmade and natural complete barriers to anadromy from the Santa Maria River, San Luis Obispo County (inclusive) to the U.S.-Mexico Border with the understanding that anadromous (adult southern steelhead) arise from anadromous and resident naturally spawning adults.

This comment provides a summary of key information contributing to the best available science relevant to the status of resident and anadromous *O. mykiss* and is intended to inform CDFW's status review. Reference documents cited in this comment are available for download via OneDrive: CESA Status Review Comment References. United requests these documents be included in CDFW's administrative file for its review of listing status.

Relationship Between Resident and Anadromous *O. mykiss*

The petition submitted by CalTrout did not address resident *O. mykiss* sufficiently. Rather the petition relied on information relevant to the anadromous form, specifically in presenting population numbers. This resulted in the characterization of only a portion of the total species population; however, in the status review, consideration and evaluation of *all* readily available information regarding the combined population dynamics and demographics for both resident and anadromous *O. myki*ss is essential. Assessment of both resident and anadromous life-history forms will provide a complete account of the prevalence of *O. mykiss* as well as the contributions and interplay across the life-history forms, which is necessary to determine, based on the best available science, the status of the species.

In the status review of southern California steelhead, as well as in the ultimate listing decision, the status and contribution of resident *O. mykiss* must be considered. A document prepared by the National Oceanic and Atmospheric Administration-National Marine Fisheries Service (NOAA-NMFS) Southwest Fisheries Science Center supports this approach by stating: "Steelhead and rainbow trout belong to the same species (*O. mykiss*), and steelhead are the ocean-migratory ("anadromous") form and rainbow trout are the freshwater-resident form. There is a growing body of literature showing that steelhead and rainbow trout share freshwater habitat, mate with one another, and their offspring can either undergo physiological changes necessary to migrate to the ocean as a steelhead or undergo freshwater maturation as a rainbow trout."[1] As evidenced by this interplay, the status of the species clearly requires close examination of the relationship between resident and anadromous *O. mykiss* in the assessment of their status as well as the viability of the life-history forms.

The CalTrout petition states that "[f]ish that express the resident freshwater life-history strategy play a central role to the continued existence of southern steelhead." United agrees with this statement regarding the interplay of the freshwater resident and anadromous *O. mykiss* life-histories. This submittal offers supporting evidence related to the status of resident *O. mykiss* in the **Population Trend** and **Viability Criteria** sections below, evidence which was absent from the CalTrout petition. Readily available data and literature supports the position that resident *O. mykiss* are significantly more abundant than anadromous *O. mykiss*, have more viable populations than anadromous steelhead in the region (and statewide), and contribute substantially to the persistence and viability of the overall species.

Population Trend

Information presented in the CalTrout petition regarding the population trend of southern California steelhead discussed only the anadromous form of *O. mykiss* – not the resident form – including numbers of returning anadromous adults and declines in numbers compared to historic population estimates (note that historic population estimates are addressed in the **Distribution and Abundance** section below). In the petition evaluation report, CDFW noted that information on population abundance and trends of resident *O. mykiss* is limited. United disagrees, as information that contributes to the best available science is readily available and would allow for reasonable inference regarding the status of residents as it relates to the proposed listing.

In this submittal, we present a compilation of readily available survey data and reports from several watersheds within our region for CDFW's consideration; however, it is expected that other data (published or unpublished) relevant to the status review is available to CDFW as part of the Heritage and Wild Trout Program and/or the Coastal Salmonid Monitoring Program, which are both led by CDFW.

[1] Ohms H.A. and Boughton D.A. 2019. Carmel River Steelhead Fishery Report - 2019.

Regarding the Resource Conservation District of the Santa Monica Mountain (RCDSMM) data referenced by CDFW in the petition evaluation report, Moyle et al. (2017)[2] provides a discussion of a portion of the data, indicating a high level of variability in *O. mykiss* numbers from year-to-year. For example, following low numbers observed in Malibu Creek in 2006, the results of subsequent surveys observed five adult steelhead in 2007 and 2,200 *O. mykiss* young of the year (YOY) in 2008. During surveys completed in 2005, 2008, 2011, 2014, and 2015, YOY observations varied from 11 to 590 individuals – with the latter surveys completed during extreme drought conditions experienced between 2012-2016.

Other surveys include those within the Santa Clara River watershed with the CDFW[3] Heritage and Wild Trout Program 2008 report[4] yielding estimates from Agua Blanca Creek and Fish Creek (tributaries to Piru Creek) of 1,316 and 3,113 *O. mykiss* per mile. The report noted that "[b]oth Fish and Agua Blanca Creeks contain relatively high densities of coastal rainbow trout, especially given the habitat limitations that salmonids face in this mountainous desert region." Surveys reported in Stoecker and Kelley (2005)[5] within the Sespe Creek drainage found a total of 2,954 *O. mykiss* largely from streambank observations and some snorkel surveys of deeper pools and, of the Santa Clara River sub-watersheds surveyed, the Sespe Creek drainage was found to have the highest relative abundance of *O. mykiss*. It is important to note that the Piru Creek surveys were conducted in tributaries above Lake Piru, a manmade barrier to upstream migration, and the Sespe Creek surveys were conducted in areas both above and below natural barriers to upstream migration.

In a study conducted for CDFW in the Ventura River watershed, Allen (2015)[6] reported on extensive *O. mykiss* surveys between 2006 and 2012. In that report, Allen reported that in the lower segment of the river, *O. mykiss* abundance is highly variable, with a near zero abundance of fry and juvenile *O. mykiss* observed in 2006 and 2007 but a document maximum of 3,739 juvenile and 2,348 fry *O. mykiss* in 2008 and 2012, respectively. Of the total in the lower river, the vast majority were observed in the study reach near the confluence with San Antonio Creek, known as historically important habitat for *O. mykiss*. In the middle segment of the Ventura River, above the fish ladder on the Robles Diversion, Allen (2015) reported maximum abundance of fry totaling 6,637 individuals in 2012 with a maximum abundance of juveniles totaling 3,555 individuals in 2008. Abundance estimates were higher still in the upper segment, above Matilija Dam, even though total stream length was less than the combined reaches below Matilija Dam (Allen 2015). Overall, *O. mykiss* are documented to be most abundant in headwater spawning and rearing tributaries across the region and elsewhere.

The information presented above represents only a handful of examples of the data and findings from relatively recent *O. mykiss* surveys in the region. Attachment A provides a summary of additional *O. mykiss* survey data and reports compiled by United for use by CDFW in the status review. These references show that there is a resilient and, in favorable years, robust population of resident *O. mykiss* both below

and above natural and manmade barriers; however, conclusions regarding population trends and stability are qualitative in nature. For example, Moyle et al. (2017) states that "[o]nly the [resident] coastal rainbow trout (*Oncorhynchus mykiss*) is considered secure in its status" and that "the boundary between [anadromous] steelhead and resident coastal rainbow trout is fuzzy because it is not biologically based, but a distinction of convenience for management." Resident *O. mykiss* are defined by Moyle et al. (2017) as those populations above barriers; however, populations of residents that are connected to populations below barriers, thus contributing downstream migrants (smolts) to the proposed listing unit, must be factored into the overall population viability. Specific examples of tributaries in the Santa Clara River watershed with a downstream migrant connection above barriers to upstream migration include Sespe Creek and Santa Paula Creek. NMFS recognizes this significant dynamic noting in their 5-year review that persistent returns of anadromous adults "could be maintained either by natural dispersal from some source population located elsewhere and/or from the consistent production of smolts by the local population of freshwater non-anadromous *O. mykiss*, including *O. mykiss* populations currently residing upstream of introduced, long-standing barriers to upstream migration."[7]

The status review should also consider the potential for shifts in the proportion of anadromous and resident *O. mykiss*. Kendall et al. (2017) observed declines in Pacific northwest anadromous steelhead and posited that "declining survival to and from the ocean and in the ocean can lead to an increase in the proportion of resident individuals in *O. mykiss* populations (Kendall et al. 2015). Thus, steelhead population abundance declines may not represent a trend towards the population's extirpation but may instead suggest a change in the dominant life history strategy. Under these conditions it will be important for the resident component to remain viable and capable of producing anadromous offspring."[8]

The Southern Steelhead Resources Evaluation (Becker et al. 2010) includes qualitative and quantitative accounts of *O. mykiss* presence in numerous river mainstems and tributaries including southern California streams located south of the Santa Maria River. And, as noted above, Attachment A provides a summary of *O. mykiss* survey data and reports compiled by United for CDFW's consideration to ensure that its evaluation is based on the best available science.

Viability Criteria

NMFS has documented a recognition of the importance of the life history plasticity between the resident and the anadromous forms of *O. mykiss*. In the Recovery Plan process, NMFS stated: "It is difficult to envision a successful recovery effort without a better understanding of the functional relationship between resident and anadromous fish." They go on to explain that "this continuum has a significant implication for viability criteria."[9] The most recent NMFS 5-year review of the species refers to resident *O. mykiss*, their importance to the viability of anadromous steelhead populations, and how viability criteria in the Recovery Plan should be updated to account for the contribution of resident fish, a key element of the listing evaluation. Recently, several authors that have worked extensively on the southern California steelhead population issue published a study[10] that makes an important point: "Resident *O. mykiss* in upper

watershed areas outside the designated critical habitat are not protected by either state or federal endangered species acts, despite their documented link in maintaining maximum numbers of [s]teelhead (NMFS 2012)." Dagit et al. (2020) also note that the Southern California Steelhead Recovery Plan (NMFS 2012) and Boughton et al. (2007) proclaim that an important consideration to prevent extinction is "protecting existing populations and all life history expressions."

The current NMFS recovery population viability goal of 4,150 spawners per year on average for southern California steelhead comes from Lindley's (2003) "random walk with drift" model using field data from the Central Valley (Boughton et al. 2007; Williams et al. 2016). However, the "random walk" model considers only 100 percent anadromous spawners (thereby disregarding the significant contribution of resident *O. mykiss*). This flawed model forecasts that in terms of achieving recovery goals, resident *O. mykiss* would not contribute to the anadromous form even though NMFS recognizes that the Santa Clara River has maintained a population of smolts emigrating to the ocean while upstream migrant runs were too small to be self-sustaining. The construct of purely anadromous *O. mykiss* for the recovery goal is biologically inappropriate for this species, and contrary to the common recognition among experts that resident *O. mykiss* play a key role in conservation of native coastal *O. mykiss*, including the steelhead life history strategy – particularly in arid southern California where intermittent flow regimes and prolonged droughts are common (Dagit et al. 2020). The viability studies recognized that the "interchange between resident and anadromous fish groups would almost certainly lower the extinction risk of both groups."[11] The authors state that during their performance-based criteria analysis the interchange between the resident and anadromous form could have large consequences when determining extinction. Specifically, "we suspect that extinction risk of steelhead fraction is likely to be highly sensitive to the details of this interchange." Moyle et al. (2017) provides a more definitive conclusion stating, "[i]f resident rainbow trout populations are considered part of the southern steelhead complex, then the extinction threat of the overall population is somewhat less." Moyle et al. (2017) notes that reconnecting resident and anadromous *O. mykiss* is necessary to maintain the overall population in the future. In some watersheds, the connection of resident and anadromous *O. mykiss* remains intact, and in others, there is active progress toward projects that will reestablish this connection and aid in meeting recovery goals under the NMFS Recovery Plan (NMFS 2012). It is essential that CDFW considers the contribution of resident *O. mykiss* in the viability of the overall population given that residents are secure in their status and contribute to the anadromous life history (Moyle et al. 2017).

Dagit et al. (2020) also notes that, "[a]s reported by Williams et al. (2016) and confirmed by our observations, at no point since [southern California] steelhead were listed as endangered in 1997 was the preliminary provisional viable population goal of 4,150 annual anadromous spawners observed in any individual watershed, nor through the [Distinct Population Segment] DPS as a whole." A cursory comparison between the number of anadromous returns within the Santa Clara River watershed prior to and following the 1997 listing results in largely consistent numbers of individuals[12,13]. Indeed, in their 5-year review, NMFS states that the available data "indicate small (<10 fish) but surprisingly persistent annual runs of anadromous *O. mykiss*" within those watersheds currently being monitored (NMFS 2016). These are important observations which indicate that the anadromous *O. mykiss* population has remained stable in the region, supported by a resilient population of resident *O. mykiss* that persist in many watersheds both above and below barriers. These systems are capable of supporting robust populations that provide a substantial, yet under-evaluated contribution to the species in the region.

Finally, Dagit et al. (2020) states that "[b]uilding quantitative models that consider both anadromous and resident fish in the production of smolts, in addition to watershed-specific carrying capacities would be a valuable effort towards refining population goals." United strongly agrees, and points to the last southern California steelhead 5-year review that also stated: "Overall, these results show that resident and anadromous forms are tightly integrated at the population level, suggesting a revision of the viability criterion for 100 [percent] anadromous fraction" (NMFS 2016). Moyle (2017) acknowledges that the life-history trait of "partial anadromy is an active area of research to gain insight into underlying environmental and genetic influences. This multigenic trait has important implications for endangered steelhead recovery and fisheries management strategies." The best available science indicates that the entire breeding population, including resident *O. mykiss* as well as south-central California coast steelhead DPS (discussed in the **Genetics** section below) be evaluated in the status review. This is also necessary to ascertain a recovery goal that is representative of the biology and genetic structure of the native *O. mykiss* population in southern California.

Ecology, Life History, and Habitat

Anadromous *O. mykiss*, resident O. *mykiss*, and lagoon-anadromous *O. mykiss* may interbreed, and the offspring can result in any life history group (Kendall et al. 2015). As stated before, life history trajectories affect the survivorship of an individual, and there are tradeoffs with various life history strategies. For example, an individual exhibiting the anadromous life history strategy in southern California may result in faster growth, a larger individual, and higher fecundity than a resident *O. mykiss* due to the time it spent in the marine environment. However, a steelhead may not have an opportunity to migrate upstream within southern California due to drought conditions, whereas the resident *O. mykiss* may have better accessibility to spawning areas within the natal watershed.

The CalTrout petition states that "the timing of out-migration is influenced by a variety of environmental cues including streamflow, temperature, and breaching of the sand berm at the river's mouth."[14] It is important to add that recent new evidence points to day length (also known as photoperiod) as being a major driver of juvenile outmigration timing. Using over 20 years of data collected at the Freeman Diversion from the downstream migrant trap, Booth (2020) concluded that smolt migration timing was correlated with the day length and was less dependent on flow magnitude. Booth (2020) found that 95% of all smolts arrived between mid-March and late May with the majority arriving at the collection system in mid-April to mid-May. Most importantly, Booth (2020) concluded that "downstream migration in the Santa Clara River often may occur too late in the season to be synchronized with likely opportunities for downstream migration to the estuary and ocean."[15] Upon reviewing the historic hydrology for the system, Booth (2020) found that it is a relatively common occurrence for smolts in the Santa Clara River to be unable to successfully migrate to the ocean even with natural hydrology conditions.

O. mykiss in the Santa Clara River watershed produce a very small fraction of anadromy, likely related to the high cost for anadromy and the lack of opportunities for successful emigration and upstream migration. Kendall et al. (2015) reviewed various studies documenting the factors that may influence the fraction of anadromy. One study found that "migration cost did influence life histories in one model which indicated

[14] CalTrout Petition. See pg. 9, paragraph 1.

[15] Booth M. 2020. Patterns and Potential Drivers of Steelhead Smolt Migration in Southern California. North American Journal of Fisheries Management, Volume 40, Issue 4: pp 1032-1050. See pg. 24, paragraph 2.

that emigration survival was one of the critical factors shaping the expression of anadromy."[16] Residency was predicted to increase as emigration survival decreased. Kendall et al. (2015) found other studies that indicated the southern portions of the species range may be skewed towards residency with the higher cost of anadromy due to seasonally dry stream reaches and lagoon sandbar formations limiting migration opportunities. For example, the Santa Clara River is a large watershed (1,625 square miles) dominated by a sandy, braided channel in the mainstem. During high flows, suspended sediment levels in the Santa Clara River are elevated to a point that is believed to preclude upstream migration opportunities.[17] A key section of the river for emigration to the ocean is well documented to go dry based on observations dating back to the 1700s, thus precluding passage. During large portions of the year, several reaches of the river mainstem remain dry due to percolation to the underlying groundwater basins as surface water is quickly lost in the broad alluvial floodplain.[18] It is likely that the historic planting of steelhead, discussed in more detail in the **Distribution and Abundance** section below, temporarily modified the fraction of anadromy, thereby increasing the anadromous run size in the system for some period of time. Historic planting is also a cause of genetic mixing among steelhead within the state, a topic discussed in more detail in the **Genetics** section below. As detailed in the **Population Trend** section above, prior surveys have documented that the resident form of *O. mykiss* are well established within the watershed and will continue to produce the anadromous form.

Genetics

In 2008, scientists at the National Oceanic and Atmospheric Administration (NOAA) Southwest Fisheries Science Center concluded that "[n]o genetic basis was found for the division of populations [from southern California] into two distinct biological groups, contrary to current classification under the US and California Endangered Species Acts."[19] A study by Clemento et al. (2009) analyzed nuclear DNA, representing the best available scientific information and a far superior approach to identifying genetic structure in coastal *O. mykiss* populations compared to the prior studies cited in the original listing that used allozymes (proteins), maternally inherited mitochondrial DNA (Busby et al. 1996),[20] and karyotyping (chromosome sampling). Thus, Clemento et al. (2009) demonstrates that the two population segments should be reclassified as one based on the most updated and most rigorous genetic data. In the status review of the Northern California (NC) summer steelhead, CDFW (2021) indicated that the NC summer steelhead should not be listed under CESA, a recommendation based at least partially on the genetics of the species,[21] which indicated closer relation between localities as opposed to run-timing. In the case of NC summer steelhead, CDFW found that the petitioned listing unit failed to meet the definition of a subspecies, as required under CESA.

Shifts from the historic composition of *O. mykiss* is another consideration in terms of genetic variation, or lack of variation, across geographies. Pearse et al. (2011) compared *O. mykiss* from historic populations (1897 and 1909 samples obtained from the Smithsonian) with contemporary *O. mykiss* populations to analyze genetic differences across distance. Historic samples showed that genetic differentiation increased based on distance between watersheds. However, contemporary samples led to findings of significant changes from the historic samples but little to no genetic differences as distances between watersheds increased. Pearse et al. states, "[h]ere we show that these steelhead populations had a historically strong correlation between genetic and geographic distance that has been virtually erased in modern populations, suggesting that current relationships among modern steelhead populations are no longer reflective of natural migratory pathways. This demonstrates the critical role of migration in maintaining population relationships of threatened species and highlights the importance of natural history museums in providing historical baseline information." These results add to the findings of Clemento et al. (2009) and indicate that the *O. mykiss* populations across DPSs, in this case the south-central California coast steelhead DPS and southern California steelhead DPS, are not genetically distinct. One reason posed by Pearse et al. is the historic planting of steelhead by CDFW across various watersheds within the state, which is discussed in more detail in the **Distribution and Abundance** section below.

Another consideration is introgression of hatchery stock with native populations. Abadía-Cardoso et al. (2016) conducted a genetic analysis of *O. mykiss* to evaluate the origins and ancestry of the populations from 10 watersheds spanning the southern California steelhead range. The study found that "In the northern part of this region, nearly all populations appeared to be primarily descendants of native coastal steelhead. However, in the southern, more urbanized part of this region, the majority of the sampled populations were derived primarily from hatchery trout, indicating either complete replacement of native fish or a strong signal of introgression overlaying native ancestry." Notably, the study examined the genetics of several contemporary hatchery *O. mykiss* strains obtained from the Fillmore Hatchery, American River Hatchery, and Hot Creek Hatchery to determine introgression of native *O. mykiss* with hatchery *O. mykiss*. As shown in the results of Pearse et al. (2011), historic mixing of populations has an effect on the contemporary genetic variation, which would be a factor in the comparison of contemporary native and hatchery *O. mykiss* populations. While their study does not address the relationship of historic versus contemporary populations, Abadía-Cardoso et al. (2016) does present management elements for *O. mykiss* related to introgressed populations stating,"[n]evertheless, these genetically introgressed populations represent potentially critical genetic resources for the continued persistence of viable networks of *O. mykiss* populations, given the limited native ancestry uncovered in this region and the importance of genetic variation in adaptation."

The **Relationship Between Resident and Anadromous *O. mykiss*** section above addresses the interrelatedness between the various life-histories, which is further supported by genetic information. In a genetic analysis of *O. mykiss* in Hood River, Christie et al. (2011) concluded that "closer to 40% of all steelhead genes come from wild trout each generation." These findings provide a quantified link between the different life-histories as well as a basis for population viability that account for the entire population when concluding that their results "suggest that wild resident fish contribute substantially to endangered steelhead 'populations' and highlight the need for conservation and management efforts to fully account for interconnected *Oncorhynchus mykiss* life histories." The information regarding *O. mykiss* genetics summarized in this submittal provides further support for the assessment of the entire resident and anadromous *O. mykiss* population, including those within the range of the indistinguishable south-central California coast steelhead DPS, when evaluating the status of the species.

Distribution and Abundance

The historic run size estimate in the NMFS Recovery Plan,[22] comes from "The Updated Status of Federally listed [Evolutionarily Significant Units] ESUs of West Coast Salmon and Steelhead" (Good et al. 2005) and includes steelhead estimates for each of the major watersheds. Within the Ventura River watershed, the estimate traces back to a 1946 CDFW letter commenting on the future Matilija Dam, the basis of which included personal observations and interviews with locals, also noting that a stocking program averaging 70,000 to 100,000 hatchery plantings each year had been ongoing for "the past years".[23] Within the Santa Clara River watershed, the 1980 estimate by Moore (1980)[24] of the average population traces back to the same 1946 CDFW letter from which Moore extrapolated an estimate in the Santa Clara River by comparing the potential habitat of the two watersheds. This fact is echoed in CDFW's 1996 Steelhead Restoration and Management Plan for California[25] and again by NMFS in Good et al. (2005),[26] which also includes a review of the historical run sizes in the major southern California watersheds. Moore's knowledge of the Santa Clara Watershed comes from the late 1970s and early 1980s, one of the wettest periods on record – which resulted in wetted reaches that would be dry in average or dry periods – resulting in an overestimation of river miles of suitable steelhead habitat. In the same 1980 report, Moore notes that projecting the average run size can be misleading, particularly in systems subject to extreme flow fluctuations from year-to-year.

In a review of the history of steelhead in the Santa Ynez River, Alagona et al. (2012)[27] acknowledges the natural variation in steelhead run sizes, particularly in the southern California ecosystems, noting that "[a]ll of these perturbations and processes affect steelhead populations, which may have varied by two orders of magnitude annually owing to natural changes alone." The original source of the Santa Ynez River estimate came from a report generated by Shapovalov,[28] a CDFW employee, and relied upon the opinion of another CDFW employee (Carl Tegen) who was working as a trapper in the Santa Ynez River watershed. Tegen compared the number of steelhead in the Santa Ynez River to counts in the Eel River and deduced that the Santa Ynez steelhead run during the year in question (1944) was "at least as large" as the Eel River. While it is apparent that there were many adult steelhead in the Santa Ynez in 1944, a time period following several years of above average rainfall[29], it would be highly inaccurate to assume that his estimate was a running average of a natural run of steelhead for the same reason that Moore notes in his 1980 report regarding year-to-year fluctuations in flows within these river systems.

CDFW acknowledges this subjectivity in quoting the U.S. Fish and Wildlife Service (USFWS) in the Fish Species of Special Concern in California.[30] CDFW notes that the estimates of historical run sizes "are highly subjective and probably correct only within an order of magnitude." In Good et al. (2005), NMFS concurs with the earlier CDFW statement and goes a step further to adjust down the historical run size estimate for the Santa Ynez River based on a logical inference regarding Tegen's experience in the Santa Ynez and Eel Rivers. Good et al. (2005) summarizes their review of historical run sizes by stating that "the estimates of historical run sizes for the Southern California steelhead ESU are based on very sparse data and long chains of assumptions that are plausible but have not been adequately tested."

Beginning in the 1890s, CDFW implemented an extensive steelhead planting program that continued until the 1930s (Bowers 2008). In the 1910s, southern California rivers (including the Santa Clara and Ventura) along with their tributaries, received up to 3 million trout per year from northern hatcheries. Planted fish were predominantly a mix of resident and anadromous *O. mykiss*. In southern California, the rise and fall of the anadromous *O. mykiss* population directly correlates with CDFW's planting of northern California steelhead in southern California waters. Prior to the planting from northern hatcheries, records of steelhead in the southern California rivers are minimal. For example, records from the missionary period never mention trout or steelhead, which contrasts with the rivers further north. As noted in the review of steelhead in the Santa Ynez River by Alagona et al. (2012), "we found relatively few explicit records of Chumash exploitation of riverine fish, such as steelhead in the Santa Ynez River, from Spanish, Mexican, and early American explorers and settlers," indicating that steelhead were possibly not as prevalent and abundant as previously asserted. Alagona et al. (2012) continues: "At present, the only archaeological evidence for steelhead presence comes from several theses and a museum contribution describing excavations of sites in former inland Chumash villages with associated information on the identity of fish elements… [s]teelhead remains were found at three of four excavated sites… 6 salmonid bone elements found at Xonxon'ata [located on Zaca Creek 6 miles above its confluence with the Santa Ynez River] constituted only 0.2% of the identifiable fish bones recovered at this site, with the rest assignable to marine species, and these bones appeared to come from immature steelhead or rainbow trout." Alagona et al. (2012) acknowledges that more research is necessary to draw conclusions regarding the presence of salmonid bones at the Santa Ynez River archaeological sites; however, the findings provide an indication of limited steelhead presence during the pre-colonial period.

As noted above, large numbers of trout from northern hatcheries were planted in southern California rivers in the 1890s through the 1930s. The history of the steelhead fisheries during this time is well documented.[31,32] By the early 1930s, there was a trend towards planting larger "catchable-sized" trout. In the late 1930s, the focus of the hatcheries had changed to producing and planting "catchables" that were mostly from a resident form of *O. mykiss.*[33] The decline in the anadromous form of *O. mykiss* in southern California rivers coincided with the change in hatchery rearing and planting practices. The population decline following the cessation of planting from northern hatcheries is evident in correspondence generated by CDFW officials and numerous newspaper articles at the time (McEachron 2007, Bowers 2008). Alagona et al. (2012) also cited Spanne (1975), which "noted that runs of anadromous fish in the Santa Ynez River occurred right up to the construction of Bradbury Dam, but that they were much more

[30] CDFW. 1995. Fish Species of Special Concern in California. See pg. 81, paragraph 4.
[31] McEachron M. 2007. A Review of Historical Information Regarding Steelhead Trout in the Piru Creek Watershed, Ventura County, California.
[32] Bowers K. 2008. History of Steelhead and Rainbow Trout in Ventura County: Newsprint Accounts from 1870 to 1955. Vol I.
[33] CDFW. 1970. Fish Bulletin 150 A History of California Fish Hatcheries. See pgs. 50-52.

predictable and frequent in the late nineteenth and early twentieth centuries based on the memories of elderly residents.” The late nineteenth and early twentieth century time period is coincident with the steelhead planting program that was underway in southern California at that time. By 1951, mention of a steelhead fishery in the newspapers had almost ceased to exist. During that same year, CDFW biologist Willis Evans stated: “The fisheries value of these drainages lies primarily in the existence of a resident population of rainbow trout in the head waters areas. Their range throughout most of the subject drainages is curtailed by the lack of sustained year long stream flows. High summer water temperatures above the tolerance of trout also prevent trout development in otherwise suitable streams such as lower Piru Creek.”[34] “These drainages” referred to the Ventura and Santa Clara River watersheds. The following year (1952), the Santa Paula Chronicle reported that “[s]teelhead fishing season ended this year without a single catch being made.” In 1954, observations of a few steelhead were reported in the Ventura River, but no catches were reported. Notably, these statements from CDFW were made prior to any major dams being constructed in the Santa Clara River watershed. Santa Felicia Dam, constructed on Piru Creek in 1955, was the first such dam. Contemporary records of steelhead in the Santa Clara River, primarily made by fisherman, CDFW, and United are also well-documented.[35,36,37]

In 1979, Moore, as referenced in Stoecker and Kelley (2005), performed extensive surveys in both Santa Paula Creek and Sespe Creek. Moore reported “abundant” trout in most of the tributaries, including 15 *O. mykiss* per 100 feet in Lion Creek and 70 *O. mykiss* per 100 feet in Howard Creek. CDFW conducted a two-year study in coordination with United in 1982-1983 and 1983-1984 (Puckett and Villa 1985). It resulted in the trapping and identification of a total of three adult steelhead over the two-year study period. In Sespe Creek, the CDFW study found no smolts despite trapping, electroshocking, and netting downstream of the Sespe tributary during the primary smolt migration period. As noted above, monitoring at the Freeman Diversion fish ladder has identified low numbers of adult steelhead, typically between 0-2 individuals per year, since beginning operation in 1991 through 2022[38]. Consistent with earlier observations, ongoing monitoring at the Freeman Diversion indicates that the total abundance of steelhead has remained relatively stable since well before the federal listing.

In the early 1990s, smolts were trapped and counted at the Freeman Diversion. In 1994, for example, United operated a downstream migration trap from February 21 through May 25 and a total of 83 smolts were collected at the trap during this period.[39] It is worth noting that smolts collected at the facility ranged from 0 to approximately 800 during the operation of the downstream migrant trap; however, the use of the trap was discontinued in 2015 at the direction of NMFS, and a trap efficiency study was not conducted so an estimation of total smolt production based on the proportion of smolts trapped is unknown.

The **Population Trend** section above provides additional information compiled by United regarding the distribution and abundance of *O. mykiss* in the region. The information and summaries provided in this letter contributes to the best available science on the subject; however, as indicated above, additional information available to CDFW and/ or contributed by other stakeholders is anticipated to further inform the status review.

Degree and Immediacy of Threat

As noted by Moyle et al. (2017), resident *O. mykiss* are generally considered to be secure in their status. There are many factors contributing to the status of anadromous *O. mykiss* (NMFS 2016) and the interplay between the resident and anadromous life-histories is key in developing a better understanding of the persistence of southern California steelhead. Numerous studies have pointed to the importance of accurately defining this relationship and information provided in the **Population Trend, Viability Criteria**, and **Genetics** sections above contributes to the best available science on the subject. As stated by Moyle et al. (2017), "[i]f resident rainbow trout populations are considered part of the southern steelhead complex, then the extinction threat of the overall population is somewhat less. Reconnecting the anadromous and resident forms of the native *O. mykiss* populations, however, is essential for maintaining both the anadromous and resident trout populations in the future." Resident and anadromous *O. mykiss* occupy the same watersheds in the region and known contributions of residents to the anadromous life history (and vice versa) indicate that the overall species will persist and improve given the restoration efforts currently underway.

A resilient population of resident *O. mykiss* persists in many watersheds both above and below barriers, and these systems are capable of supporting robust populations that provide a substantial and well documented contribution to the overall species[40]. A recent study of a different steelhead population (California Central Valley Steelhead DPS) concluded that the monitoring of all life-histories, including resident and anadromous, is necessary for comprehensive status assessments as well as for the quantification of watershed capacity to support and improve conditions for the overall species[41]. Given the known interrelatedness of the life-history strategies of *O. mykiss*, these findings can readily be applied to southern California steelhead as part of the status review.

Adequacy of Existing Management or Recommendations for Management of the Species

Existing protections for southern California steelhead, typically applied to both resident and anadromous life-history forms, are primarily afforded by the federal Endangered Species Act (ESA). Southern California steelhead were listed as endangered under the federal ESA in 1997 and as such, "take" and modification of critical habitat is prohibited absent consultation with NMFS and execution of a Biological Opinion/ Incidental Take Statement under Section 7 of the ESA, or a Habitat Conservation Plan/ Incidental Take Permit under Section 10 of the ESA. Other existing regulatory mechanisms that provide a level of protection to southern California steelhead include the National Environmental Policy Act (NEPA), Clean Water Act (CWA), Federal Power Act (FPA), California Environmental Quality Act (CEQA), California Fish and Game Code (FGC) (including §1600, 5901, 5937, etc.) California Water Code, Porter-Cologne Act, Forest Practice Act, federal Wild and Scenic Rivers Act, and California Wild and Scenic Rivers Act.

Under the federal ESA, "take" is defined as "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct" (16 U.S.C., §1532). Under CESA, "take" is defined as "hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill" (Fish & G. Code, §86). Notably, the federal ESA includes a broader "take" definition (i.e., including "harass" and "harm")

---

[40] Kendall N.W., McMillan J.R., Sloat M.R., Buerhens T.W., Quinn T.P., Pess G.R., Kuzischin K.V., McClure M.M., Zabel R.W. 2015. Anadromy and residency in steelhead and rainbow trout (*Oncorhynchus mykiss*): a review of the processes and patterns

[41] Eschenroeder J., Peterson M., Hellmair M., Pilger T.J., Demko D., Fuller A. 2022. Counting the Parts to Understand the Whole: Rethinking Monitoring of Steelhead in California's Central Valley.

as well as "take" prohibitions for habitat for the listed species. CESA does not include a comparable habitat take prohibition; however, CDFW applies the Lake or Streambed Alteration Agreement (LSAA) (FGC §1600-1607) process to effectively protect habitat of listed and non-listed species under the jurisdiction of the state.

A listing under CESA would not effectively increase the protections afforded to southern California steelhead. While NMFS administers protections for southern California steelhead under the federal ESA and CDFW administers protections for steelhead under the FGC, "take" is already prohibited under the federal ESA without an incidental take permit and is also effectively prohibited by CDFW's interpretation and application of FGC. Under the federal ESA, impacts to steelhead must be avoided, minimized, and mitigated to fully offset, or offset to the maximum extent practicable, the impacts of the taking. Under CESA, the impacts of the taking must be avoided, minimized, and "fully mitigated", which is typically interpreted by CDFW to require compensatory mitigation beyond what is required under the federal ESA. This represents a possible additional protection afforded by a listing under CESA; however, specifics regarding how this provision of CESA would translate to additional benefits to southern California steelhead are not supported by the best available science.

United appreciates the opportunity to provide comments and information to inform CDFW's status review of southern California steelhead. Along with contributing to the best available science, the information summarized herein demonstrates the need for close examination of all relevant scientific information of the proposed listing unit, which includes both the resident and anadromous life-history forms of *O. mykiss*. Given this, the status review is an opportunity to evaluate all factors related to the status of the overall species, leading to biologically sound and appropriate conclusions. United implores CDFW to continue outreach and engagement with interested stakeholders, as well as the scientific community, during the status review process to ensure that a comprehensive assessment that reflects the complexity of the species is completed.

Respectfully,

Anthony Emmert
Assistant General Manager

RANCHO MISSION VIEJO

Via Email: fgc@fgc.ca.gov
April 3, 2024

The Honorable Samantha Murray
President
California Fish and Game Commission
P.O. Box 944209
Sacramento, CA 94244-2090

Reference: Agenda Item 22: Southern California Steelhead (*Oncorhynchus mykiss*) CESA Petition

Subject: Rancho Mission Viejo – Additional Comments

Dear President Murray:

Rancho Mission Viejo (RMV) writes in regard to the petition currently pending before the California Fish and Game Commission (Commission) to list Southern California Steelhead (*Oncorhynchus mykiss*) ("Steelhead Petition") as an Endangered Species under the California Endangered Species Act (CESA, Fish and Game Code § 2050 et seq.).

RMV lands are located in Southern Orange County and are owned and managed by the O'Neill family. Since 1882, the O'Neill family has been a responsible steward of these lands ("the Ranch"). We have and continue to actively manage the Ranch to protect the resources on it. We intend to continue this tradition of stewardship into the future through implementation of the Southern Subregion Habitat Conservation Plan (SSHCP), approved by U.S. Fish and Wildlife Service on January 10, 2007.

RMV is the principal permittee under the SSHCP. In summary, the SSHCP Conservation Strategy provides a comprehensive, habitat-based approach to the protection of SSHCP Covered Species and their habitats by focusing on the lands and aquatic resource areas essential for the long-term conservation of these species and by providing for appropriate management for those lands. The SSHCP Habitat Reserve ultimately will conserve approximately 32,818 acres in southern Orange County, comprised of historical RMV lands and three County of Orange wilderness parks.

RMV previously provided comments on the Steelhead Petition (RMV, August 9, 2022 and September 17, 2021) in which we summarized our actions to protect and manage San Juan Creek within RMV lands through implementation of the SSHCP. In our prior correspondence we noted our plans to remove a large Arizona style crossing of San Juan Creek identified as fish passage barrier in the Southern California Steelhead Recovery Plan and build a bridge downstream of the crossing location. Removal of this barrier (Action #SJT-SCS-3.2) is ranked as 1A in the Southern California Steelhead Recovery Plan. We wish to inform the Commission that RMV has built the bridge (Gibby Bridge) and removed the Arizona style crossing. We are in the process of restoring all areas impacted by either the bridge construction or removal of the crossing. Exhibits 1 and 2 show before and after photos.

As we previously indicated, by protecting potential suitable habitat and implementing management measures thereon, consistent with the SSHCP, RMV has provided suitable habitat conditions for Southern steelhead should it colonize San Juan and/or Arroyo Trabuco creeks upstream of I-5 in the future Thus, if the Southern steelhead is listed under CESA, RMV requests that the SSHCP be recognized as contributing to the protection and management of the Santa Catalina Gulf Coast population such that "Covered Activities" under the SSHCP (including specified development and infrastructure projects) would not be considered "take" pursuant to California Fish and Game Code Section 86 and would not require a Section 2081(b) Incidental Take Permit.

RMV appreciates the opportunity to provide these comments. Should you have any questions regarding our comments, please feel free to contact me at (949) 240-3363 Ext. 297 or via email at lcoleyeisenberg@ranchomv.com.

Sincerely,

Laura Coley Eisenberg
Senior Vice President, Regulatory Compliance & Open Space Management

RE: California Trout, Inc.'s Petition to list Southern California Steelhead (*Oncorhynchus mykiss*) as Endangered Office - Administrative Law's Notice ID #Z2021-0702-02 and Z2022-0426-01

President Murray and Commissioners,

We express our full support for designating the Southern California steelhead as endangered under California's Endangered Species Act. Southern steelhead are on the brink of extinction. You must act now, without delay, to prevent the total and irreversible loss of this species.

Recent research tells us that Southern steelhead populations are in danger of extinction within the next 25 to 50 years if current trends persist. Since their listing as endangered under the federal Endangered Species Act in 1997, Southern steelhead numbers have continued to decline to dangerously low levels. This is the result of continued urbanization, agriculture, and water development. These activities have compromised and drastically reduced their essential required habitat. The legacy of degradation will only be exacerbated by climate crisis projections of intensified floods, droughts, and extreme heat.

The rivers and streams in Southern California once saw Southern steelhead adults return in the tens of thousands. In the past 25 years, only 177 adult Southern steelhead were documented in their native range. Allowing this species to disappear is not acceptable. CalTrout's petition, reaffirmed in State Courts as containing sufficient information to warrant a decision, and California Department of Fish and Wildlife's (CDFW) peer-reviewed species status report present you with the best available science and a clear mandate to make the decision to fully list this species immediately.

These fish play a key role in our ecosystems on which we all depend. They are a crucial part of the integrity of watersheds in which they swim. Their continued survival and recovery will reflect the resilience of our communities in the face of growing climate crisis challenges. We can look to them for clues on how California must work to address bigger problems in our Southern California rivers, streams, watersheds, and coastlines. These aquatic ecosystems, extending from summits to the seabed, provide countless environmental, social, and economic benefits for the entire state. We believe that we prosper, now and in the future, when Southern steelhead are thriving in our rivers.

For all these reasons, we, without reservation, support listing Southern steelhead as endangered in all waters within historic range below natural or man-made barriers.

RE: California Trout, Inc.'s Petition to list Southern California Steelhead (Oncorhynchus mykiss) as Endangered Office - Administrative Law's Notice ID #Z2021-0702-02 and Z2022-0426-01

President Murray and Commissioners:

As a concerned California resident, I write to you today to express my full support for designating the Southern California steelhead as endangered under California's Endangered Species Act.

Southern steelhead are an iconic native species, but without further protections we risk losing them forever. That's not a California I want to live in. Do you? You must act immediately to put in place all precautions to prevent this species from total loss.

Recent research tells us that Southern steelhead populations are in danger of extinction within the next 25 to 50 years if current trends persist. Since their listing as an endangered species in 1997 under the federal Endangered Species Act, Southern steelhead numbers have continued to decline to precariously low levels. In the past 25 years, only 177 adult Southern steelhead were documented in their native range! Allowing this species to disappear is not acceptable, and more protections are essential.

These fish play a key role in our ecosystems, and they can give us crucial information about the greater health of the watersheds they swim in (and that our communities rely upon). We can look to them for clues on how California must work to address bigger problems in our southern rivers and streams, watersheds that provide countless societal and economic benefits for the entire state. I believe that we prosper when rivers and waterways in key locations are thriving, and in many of these places there is work to be done.

These fish may also play a role in providing resiliency for ecosystems further north along the coast. Southern steelhead are uniquely adapted to Southern California's warmer Mediterranean climate. As climate change continues to increase water temperatures and alter flow regimes along the entire West Coast, Southern steelhead could be critical to the long- term resiliency of their northern relatives.

For all these reasons, I wholeheartedly support California Trout's recommendation that Southern California steelhead be listed as endangered in all waterways within historic range below natural or man-made barriers. CalTrout chose this delineation thoughtfully, so that fishing and continued management for rainbow trout, the freshwater form of this amazing species, would still be possible above these barriers.

It's not too late to save the Southern California steelhead species from blinking out – but if you don't act urgently, we may very well miss our chance. Please make protection of these amazing and important fish a conservation priority by listing them as endangered under the state's Endangered Species Act.

Sincerely,

A Concerned Californians and Individuals All Over

California Fish and Game Commissioners. I fully support the listing of Southern Steelhead as endangered under the CA ESA. This segment of the West Coast steelhead species faces many ongoing threats to its existence from past dams and diversions of its spawning and rearing streams, development of its watersheds, and past and future impacts from climate change.

The listing will heighten the public's awareness of its endangered status, help focus efforts to conserve, restore and manage its critical habitat (streams and their watersheds), and meet California's commitment to provide effective conservation of its natural resources heritage.

298. **Corey Butler** (*ZIP code: 93041)*
I've been a resident of both Northern and Southern California. I've experienced the high-sierras and the costal ranges, and I know, clean clear waters and healthy streams are California's life source. The Salmon and Steelhead run along our entire coastline is vitally important. It provides nutrients and life to predators and streams that many anglers will never see or touch. This is not about sport fishing. This is about trying to retrieve a natural equilibrium in our California ecosystems and making sure our future generations are better off than we are. Protect the runs!

304. **Ellen James** (*ZIP code: 93001)*
As a resident of Ventura who lives a mile from the Ventura River, I know how vitally important it is to protect salmonid habitat: we have regular homeless encampments in the river bottom just upstream from the mouth of the Ventura River (similar situation as the Santa Clara River estuary a few miles south). These estuaries are home to a lot of wildlife, but still get fouled up by human use and no one seems to mention that estuarine habitats for critically endangered species are supposed to be protected by law!

Please Protect the California Southern Steelhead

596. **Emily Morrison** (*ZIP code: 93117)*

597. **Erik Owens** (*ZIP code: 95926)*
I saw one in Big Chico creek along Bidwell Ave

598. **Ethan Newby** (*ZIP code: 94960-2734)*

599. **Edward Patten** (*ZIP code: 92082)*

600. **Enoch Hale** (*ZIP code: 95525)*
Please commit to saving this species and biodiversity.

601. **Ethan Zubak** (*ZIP code: 92881)*

602. **Edgar Pierluissi** (*ZIP code: 94134)*

603. **Eric Pirone** (*ZIP code: 94901)*
This is mandatory. We have one chance to stop this decline. Thanks!

604. **Ron Melin** (*ZIP code: 95570)*
They've been in coastal so. Cal. forever and have survived in an environment
that have been extremely altered by humans to the point they're on the brink. We can't wait any longer to save these amazing fish.

605. **Erynn Rebol** (*ZIP code: 95403)*

606. **Eric Arentsen** (*ZIP code: 90266)*
I fully support listing Southern California steelhead as endangered under California's Endangered Species Act

607. **Eric Abramson** (*ZIP code: 92104)*
The Southern California Steelhead should absolutely be protected under California's Endangered Species Act.

This species is remarkably important to Californians and ecosystem health. Allowing them to go extinct when we completely have the ability to save them is, quite simply, morally wrong.

Protecting them would ensure an important cultural species is around for my kids' generation and beyond. It would also have the add on effect of protecting human communities since classifying them as endangered would promote actions such as removing obsolete dams, securing instream flow, and restoring watersheds; all actions that protect communities from catastrophic flooding and local ecosystem collapse.

Again, it's completely in your power to stop a species from irreversibly going extinct, and I implore you to use that power in the morally and ethically correct way. Thank you

608. **Erik Nelson** (*ZIP code: 92630)*

I taught at a school a short walk from San Juan creek. I have seen smolts in the estuary at Doheny and in Trabuco creek near Holy Jim. We can do this. Nature will reclaim the watersheds if we just pave the way. That dam on Malibu creek needs to go among other things

609. **Erin Viera** (*ZIP code: 91505)*

610. **Erin Telford** (*ZIP code: 90290)*

611. **Ernesto Anguiano** (*ZIP code: 95062)*

612. **elise roberts** (*ZIP code: 93117)*

613. **Evan Sedlock** (*ZIP code: 94903)*

614. **Ronald Escue** (*ZIP code: 91011)*
Save our steelhead before it's too late

615. **Ed Sozinho** (*ZIP code: 98177)*

616. **Elizabeth Taylor** (*ZIP code: 92672)*

617. **Ethan Nelson** (*ZIP code: 91730)*

California steelhead and salmon need our help. Please help protect the watershed sand their environment.

968. **John Jarve** (*ZIP code: 94027)*
Please protect and improve our waterways! Thank you!

969. **John Kim** (*ZIP code: 91381)*
Thank you for all you do!!!!

970. **John Baxter** (*ZIP code: 85396)*

971. **john moniz** (*ZIP code: 95220)*

972. **John Charbonneau** (*ZIP code: 91977)*

973. John Collins (*ZIP code: 92131)*
Save our steelhead!

974. John Finney (*ZIP code: 92630)*

975. John Frankot (*ZIP code: 60618)*

976. john dorwin (*ZIP code: 93427)*
Bureau of Reclamation, County of Santa Barbara , and Cachuma Operating and Maintenance Board have been evading environmental review of the Cachuma Project for years. They have done nothing to restore the Santa Ynez River Fishery and wasted hundreds of thousands of dollars of taxpayer money in the process. State enforcement outside the Cachuma Project is long overdue to protect the remaining Southern Steelhead Trout below the Bradbury Dam in the River and the critical habitat which can still be preserved.

977. John Mykkanen (*ZIP code: 92706)*
We need steelhead!!!

978. John Stanley (*ZIP code: 95688)*

979. John Pelley (*ZIP code: 93908)*

1218. Louis Ternullo (*ZIP code: 93105)*
Southern steelhead are the seminal fish all steelhead originate from. Climate change could wipe out many populations in other areas. Having Southern steelhead in decent numbers could provide strong fish to rebuild stocks effected by these changes. Please give them a chance to return to their native waters where they used to number in the thousands before the interference of humans.

1219. Luis Chaves (*ZIP code: 90503)*

1220. Luis Rincon (*ZIP code: 90031)*

1221. Luke Paterson (*ZIP code: 93110)*
I am an advocate for all wildlife who uses art to try to support organizations. Despite my 13 years of life I have only

seen a steelhead once. I am down to help save them.

1222. Luke Daynard (*ZIP code: 95519)*

1223. LARRY LUNDBERG (*ZIP code: 95112)*
Once gone, they can never be brought back. Please protect them!

we need to do what it takes to protect these iconic native fish

1511. Peter Steinhart (*ZIP code: 94301)*

1512. Peter Xander (*ZIP code: 92391-0502)*
In 1984, I was a staff member working on permits in Malibu, and the Tapia Water Treatment Plant came in for a permit to quadruple the size of their treatment capacity from 2 million gallons per day to 8 mgd. I conditioned the permit to require tertiary treatment of the effluent and to discharge all of the water into Malibu Creek, in order to protect the southern steelhead spawning and smolt rearing habitat in Malibu Lagoon and the lower part of Malibu Creek>

Even with Rindge Dam blockig th vast majority =of spawning habitat in Malibu and Cold Creeks, my brother caught and released over 3 dozen smolts EACH the year before, in February, 1983, during a break in that El Nino winter. We used 2# test line, ultralight gear, and 1/32 oz lures with barbless hooks to release all fish we caught. All were smolts, fresh in from the sea, with sea lice still attached to the anal fins -- what Rogue River steelheaders call "half-pounders. My brother hooked and later lost a 6 to 18 lb steelhead that was spawned out and resting, or else it would have towed him out to the Channel Islands.

It is shocking that 40 years after I took that action on the permit that kept the southern steelhead population ALIVE during droughts in the late1980s and early 1990s droughts, in which all streams dried up but for Malibu Creek, that the 75+number of fish my brother caught and released that day represents about the total size of the population of southern steelhead in much of its remaining habitat.

IMMEDIATE protections are needed. The Rindge Dam MUST be removed, the natural sand transport system restored, and the full watershed be available for upstream spawning and rearing habitat. That was my dream and fervent wish in 1984; it saddens and ticks me off that 40 years later, not enough has happened to restore Malibu Creek and other passage-blocking manmade obstructions nd save the species.

Saving the southern steelhead population, with their unique adaptations to the harsh conditions now found in an urbanized, global warming, screwed-up planet, MUST be saved. That very genetic diversity has kept scattered populations of ALL steelhead -- within a few years of reproduction, those survivors can pass on their genes and adaptations to a changing world and altered environment. But they PERSIST, barely, and we MUST protect them for future generations.

I want to show my young grandsons what it was like to catch and released unharmed steelhead that their PAPA had tried to save 4 decades ago. That was one of my very proudest achievements, but a spine injury eight years later ended my career as a resource planner, biologist, and inter- governmental agency negotiator whose Mitigation and Monitoring Program policy I wrote in 1988 to increase the amount of restored riparian habitat on a 4:1 basis and a 5-year monitoring program to ENSURE the viability of restored hanitat is STILL used by the State of California for all projects requiring the preparation of a Environmental Impact Report. The U.S. Fish and Wildlife Service and EPA used those same policies for projects all across the nation, until the SCTUS struck those down on a now disgustingly familiar 6-3 right-wing antigovernment Supreme Court vote that removed virtually ALL protected wetlands through the US, setting the stage for a level of environmental destruction not seen since the Industrial Revolution.

YOU can show the nation how resource management and endangered species protection can and MUST be done. Human are that rare species that does all it can to kill itself off, only instead of lemmings diving into the sea to drown, we're killing the entire damn planet. WE have to stand up for what's right. Please give the southern steelhead the protection it needs under California laws and regulations. Show the nation how to cope with changes wrought by urbanization, pollution, habitat loss, and pure reckless stupidity and show people even a critical "canary in the coal mine" species like the southern steelhead CAN be protected before their extirpation.

The choice is easy: Do the right thing, or kill off another valuable species through man's greed and stupidity. I'd like to think that we here i California are some of the remaining true keepers of the faith: We try to do the right thing, even when the situation is critical. THIS is one of those moments in history when you can DO the right thing.

1513. Peter Xander (*ZIP code: 92391)*
Cont….. When on the staff of the CA Coastal Commission's office in Long Beach, I conditioned a permit for the expansion of the Tapia Sewage Treatment Plant. Its wastewater came from out of the Malibu Creek watershed but discharged into upper Malibu Creek. They expanded from 2 mgd to 8, and I required upgrading to tertiary treatment and to discharge all treated effluent into Malibu Creek. This action made Malibu Creek a perennial stream. When droughts i the late 1980s and early 1990s dried up all other streams from Pt Conception to below the Mexican border, Malibu Creek was THE habitat of last resort for the southern steelhead. The NMFS action to declare populations of steelhead threatened or endangered credited that single permit action for keeping the southern steelhead from extinction.

You have the power to increase the protections for this critically endangered population. Please declare them endangered within the meaning of state law and protect this important population. Steelhead and salmon species and populations all have adaptations specific to their home habitats, and the massive introduction of hatchery-created monoculture "factory" rainbow trout has been one of the greatest threats to species and subspecies of trout and salmon species. Yet this endangered species still clings to life in heavily populated southern California and the devastating alteration to native habitats.

It is YOUR charge, your responsibility, to protect this endangered population of steelhead. Please DO so.

1519. Milton Reynolds (*ZIP code: 94577)*
Times is wasting, but there are actions we can take to protect this cornerstone species. An important first step in the process of saving these amazing fish is getting them listed as endangered. With this protection, we can begin the process of habitat restoration that will allow these fish an opportunity to rebound. Nature work when we allow it to do so. Please support the listing of the Southern California Steelhead so that future generations can witness this amazing fish and that we can do our part to repair some of the harms we have visited upon this species and its native environment.

To the above rationale I would add concerns about the likely impacts of climate change and associated wildfire threats to the distinctive watersheds/catchments that have kept southern steelhead hanging on in the context of expanding human land uses. I could not agree more that the genetic heritage of southern steelhead is doubtless critical to sustaining the species as a whole through anticipated environmental changes as our climate gets crazier.

Ms. Samantha Murray, President & Members
California Fish and Game Commission
P.O. Box 944209
Sacramento, CA 94244

Subject: Comments on the California Department of Fish and Wildlife Status Report submitted for consideration by the Fish and Game Commission regarding the California Endangered Species Act Status Review of Southern California Steelhead

Dear President Murray and Members:

The Santa Clarita Valley Water Agency (SCV Water) is a California Special District providing water supply services to 278,000 people living in the Santa Clarita Valley in northern Los Angeles County. SCV Water, created in 2018 by Senate Bill 634, strives to create a "one watershed" approach and regional perspective on watershed-wide issues. This letter provides comments on the "California Endangered Species Act Status Review for Southern California Steelhead (*Oncorhynchus mykiss*)" (Status Report) prepared and submitted by the California Department of Fish and Wildlife in January 2024 for consideration by the California Fish and Game Commission. We understand that the Status Report has been prepared in anticipation of the Commission's evaluation whether listing of the Southern California Steelhead (*Oncorhynchus mykiss*) is warranted under the California Endangered Species Act (CESA).

In reviewing the Status Report, SCV Water has identified what appears to be an error in Figure 7 (see copy of Figure 7 below, highlighting the area of our concern). The figure shows in blue lines the "current" and "suspected current" distribution of Steelhead extending within the mainstem of the Santa Clara River eastward of the Piru Dry Gap into the upper basin and south fork tributaries of the Santa Clara River within Los Angeles County. A fundamental concern with Figure 7 is that the Status Report does not disclose any references, justification, underlying occurrence or observation data, or basis for the various occurrence determinations depicted in the figure's stream bodies. SCV Water has seen no evidence either within the Status Report or within any other literature that would support the distribution expressed in this figure either for existing populations or historic populations. We have reviewed the text of the Status Report and we have done a deep review of the references identified in the Status Report and other available information and have found no confirmed indication of the presence of Steelhead ever occurring east of Piru Dry Gap. The attached whitepaper prepared by ESA summarizes the investigation of supporting documentation.

Due to the lack of substantiated evidence of steelhead occupation in the upper watershed, we can only surmise that this determination was made based on the absence of man-made passage impediments in the mainstem. However, lack of barriers is not a determination of presence. Further, this same logic is not applied consistently in Figure 7 (or other distribution figures in the Status Report) where numerous other streams have no passage barriers yet are shown only as historically occupied.

We request that the error in Figure 7 (shown in the attached figure) be corrected to indicate no designation for the mainstem or tributaries of the Santa Clara River eastward of the Piru Dry Gap (approximately the Ventura/Los Angeles County line). If CDFW does not concur that Figure 7 is inaccurate, we request an explanation of the following questions prior to proceeding further with the CESA process.

1) We request that data be provided substantiating the “current” and “suspected current” presence of Steelhead anywhere east of the Ventura County line.
2) We request definitions of “current”, “suspected current”, “historical”, and “suspected historical” used in the Status Report.
3) We request a description of the methodology used by CDFW to assign geographies for these distribution categories in the Upper Santa Clara River watershed.
4) We request a meeting with CDFW to discuss the data substantiating the assignment of distribution categories in the Upper Santa Clara River.

Thank you for your consideration of our comments, and we look forward to receiving responses prior to any action being taken by the Commission.

Sincerely,

Stephen L. Cole
Assistant General Manager
Santa Clarita Valley Water Agency

memorandum

date	April 2, 2024
to	Santa Clarita Valley Water Agency
cc	
from	Joel Mulder
subject	Review of Current and Historical Oncorhychus mykiss Occurrences in the Upper Santa Clara River Watershed (Los Angeles County)

Purpose

ESA has prepared this technical memorandum (memo) for Santa Clarita Valley Water Agency to review and document available information on the current and historical distribution of *Oncorhynchus mykiss (O. mykiss)*, including both the anadromous (southern California steelhead, referred to as steelhead herein) and resident (rainbow trout) life history forms of the species, in the upper Santa Clara River watershed within Los Angeles County (i.e., the watershed upstream of the Piru Dry Gap[1]). Information from a variety of sources is summarized in this memo, including biogeographic datasets, state and federal documents, peer-reviewed publications, historical source compilations, non-governmental organization information, and survey data.

Biogeographic Datasets

A query of California Department of Fish and Wildlife (CDFW) California Natural Diversity Database data (both processed and unprocessed data) found no documented occurrence of steelhead in the Santa Clara River watershed upstream of the Piru Creek confluence.

The CDFW Biogeographic Information and Observation System online mapping tool (BIOS) layers for steelhead range and distribution offer conflicting mapping of southern Steelhead distribution, as described below.

Winter Steelhead Range (ds699).

This dataset, developed by CDFW, contains all CalWater 2.2.1 Planning Watersheds where CDFW has documented winter run steelhead to be present (representing planning watersheds intersecting the known distribution, which is based on where the species has been observed and reported) during or after 1990. This

[1] Beginning about 3.5 river miles downstream of the Los Angeles - Ventura County line, the Santa Clara River surface flow is infiltrated into the underlying eastern Piru groundwater basin. Surface flow reappears approximately 6 miles downstream, past the confluence of Piru Creek. The river is dry through this reach most of the year, with water present only when rainfall events create sufficient stormwater runoff into the river (GSI 2008, LARWQCB 2007). This dry ephemeral reach of the river is informally known as the “Piru dry gap” in the Santa Clara River.

dataset does not show winter steelhead range as occurring in the Santa Clara River watershed upstream of the Piru Creek confluence.

Winter Steelhead Distribution (ds340)

This dataset, developed by CDFW, depicts observation-based stream-level geographic distribution of anadromous winter-run steelhead in California. It was developed for the express purpose of assisting with steelhead recovery planning efforts. The distributions reported in this dataset were derived from a subset of the data contained in the Aquatic Species Observation Database (ASOD), a Microsoft Access multi-species observation data capture application. Data source contributors, as well as CDFW fisheries biologists, have been provided the opportunity to review and suggest edits or additions during a recent review. Data contributors were notified and invited to review and comment on the handling of the information that they provided. The distribution was then posted to an intranet mapping application, and CDFW biologists were provided an opportunity to review and comment on the dataset. During this review, biologists were also encouraged to add new observation data. The dataset does not show steelhead distribution as occurring in the Santa Clara River watershed upstream of the Piru Creek confluence.

Southern California Steelhead Range (ds1290)

This dataset, developed by the University of California at Davis (U.C. Davis), shows a species extant range layer for steelhead by HUC12 watersheds based on datasets and interpreted by PISCES, which is software and data describing the best-known ranges for California's 133 native fish and numerous non-native fish. PISCES “models” presence, with corresponding probabilities if appropriate, based on expert opinion and observation data. PISCES biogeographic modeling outcomes reflect environmental and anthropogenic variables that “predict” where a given species may occur (Santos et al. 2014). The metadata for the layer describes the references for the datasets interpreted by PISCES as Moyle, Quinines and Bell (expert opinion) and NMFS Southern California Steelhead ESU Current Stream Habitat Distribution Table.pdf. It is not clear what the source is for the NMFS current stream habitat distribution table.

There are two primary layers in the PISCES model for steelhead. One is HUC12 watersheds with observations of *O. mykiss*. No HUC12 watersheds upstream of the Piru Creek confluence are shown as having positive observations. The other layer is a “historical expert” layer, which depicts HUC12 watersheds where steelhead occurred historically based on expert opinion. This layer shows steelhead occurring in the HUC12 watersheds containing the mainstem from Piru Creek upstream to about Soledad Canyon, and Castaic Creek, based on expert opinion but not on observational data.

Coastal Steelhead Trout Watersheds (ds962)

This dataset, developed by CDFW, provides a minimal set of watershed fields used to identify coastal steelhead management units. This data set is an extract of the California Watershed (CalWater) dataset. It has been generalized to hydrologic sub-areas for those watersheds that are considered part of the coastal steelhead range. However, the source data for the inclusion of hydrologic units in the “coastal steelhead trout range” is not cited or referenced in the dataset metadata. The dataset depicts hydrologic units in the upper Santa Clara River basin (upstream of the Piru Creek confluence) as coastal steelhead watersheds.

Federal and State Documents

Federal Endangered Species Act designated critical habitat for southern California steelhead in the Santa Clara River watershed extends from the Pacific Ocean, upstream the main Santa Clara River to the confluence with Piru Creek; critical habitat in the Santa Clara River does not extend beyond the confluence with Piru Creek (70 FR 52487).

In the NMFS population characterization for steelhead recovery planning, the discussion of the Santa Clara River states “The available evidence suggests that steelhead have been limited to the western part of the Santa Clara basin (Kelley 2004)” (Boughton et al. 2006). The document uses Boughton and Goslin’s (2006) over-summering habitat model (described below) as the basis for its findings.

Boughton and Goslin (2006) developed a model of potential steelhead over-summering habitat using the method of environmental envelopes. Under the envelope method, predicted habitat is the set of stream segments falling within the same range of conditions that encapsulate the known occurrences of the species. In the discussion of results from the Los Angeles Basin, the authors note “The model predicted a distinct patch of potential habitat in the far eastern end of the Santa Clara basin (upper right quadrant, east of Newhall). This did not conform to expectations. Reports from the area suggested that steelhead were confined to the western end of the Santa Clara system. Visits to the eastern area between Newhall and Palmdale indicated that this area is drier than implied by the model, due to a rain-shadow effect from the San Gabriel Mountains (C. Swift, personal communication, Entrix). It probably did not contain potential habitat in reality”. In their discussion of the model’s environmental envelope outputs, the authors note that the Southern California Coast ESU[2] may have more false positives (warm areas with no potential for thermal refugia), but that these false positives may occur at a finer resolution than addressed by the model. In other words, the model may indicate suitable habitat in some areas of Southern California where in reality temperatures and lack of thermal refugia preclude steelhead occurrence.

In NMFS’ 2023 5-Year Review for the species, there is no mention of areas of the Santa Clara River watershed upstream of the Piru Creek confluence (NMFS 2023). In the Southern California Steelhead Recovery Plan (NMFS 2012) discussion of current watershed conditions the only mention of the Santa Clara River watershed upstream of the Piru Creek confluence is that “Fish passage is further impacted by the operation of Castaic Dam on Castaic Creek”. Table 2-1 of the Recovery Plan lists the Santa Clara River watershed as historically occupied by steelhead, citing Becker et al. 2009, Boughton et al. 2005, and Titus et al. 2010 (NMFS 2012). A discussion of those sources is provided below, with a focus on historical occurrences in the upper watershed.

Boughton et al. (2005) assessed the current occurrence of anadromous *O. mykiss* in each coastal basin of southern California in which it occurred historically. While the current and historical occurrences in the Santa Clara River are not described specifically in the memorandum, Figure 4 shows the historic distribution of spawning and rearing basins for steelhead in southern California. The figure shows the Santa Clara River basin up to approximately the Ventura-Los Angeles County line as historically occupied. The figure notes that shading of entire basins implies only that steelhead occurred somewhere, not necessarily everywhere, in a basin. The source

---

[2] Listed steelhead are now referred to as a ‘‘distinct population segment’’ (DPS), which is not recognized in the scientific literature. In 1991, NMFS issued a policy for delineating Pacific salmon DPS (56 FR 58612; November 20, 1991). Under this policy a group of Pacific salmon populations is considered an ‘‘evolutionarily significant unit’’ (ESU) if it is substantially reproductively isolated from other conspecific populations, and it represents an important component in the evolutionary legacy of the biological species. Further, an ESU is considered to be a DPS (and thus a ‘‘species’’) under the ESA.

for the historical occurrence data for the figure is noted as Titus et al. 2003, Stoecker et al. 2002, and a third source which was omitted from the figure description (text is cut off). Further discussion of Titus et al. is provided below. Stoecker et al. (2002) is a report on steelhead assessment and recovery opportunities in southern Santa Barbara County as is not relevant to the Santa Clara River.

The Titus et al. 2003 in preparation document cited in Boughton et al. 2005 and Titus et al. 2010 in preparation document cited in the species recovery plan (NMFS 2012) is cited as several sources under different publication years as the document has been in draft form with various updates for some time. As of April 2, 2024, the manuscript is still a draft[3]. The report provides stream-specific information on steelhead in central and southern California gathered from three main sources: (1) A literature search of pertinent journal articles, CDFW (known as California Department of Fish and Game until 2013) administrative reports and fish bulletins, and other resource agency, university, and consultant publications; (2) Resource agency files, especially CDFW stream survey files; (3) Interviews conducted with professional biologists, academicians, and representatives of sportfishing organizations and other special interest groups for information from personal files, and anecdotes based on personal observations. The report's description of the Santa Clara River Headwater Tributaries in Los Angeles County states no historical evidence of steelhead runs. San Francisquito Canyon and Soledad Canyon are noted as two streams for which there are CDFW records for rainbow trout presence and/or stocking dating back to circa 1930.

Non-Governmental Organization Resources

Becker et al. (2009) summarizes historical accounts of *O. mykiss* in streams south of San Francisco Bay based on thousands of documents in public and private collections, and interviews with biologists. Only three areas in the upper Santa Clara River watershed are described in the report as having fish observations. It is important to note that these observations are for fish in general, and not specifically steelhead.

Elizabeth Lake Canyon, tributary to Castaic Creek - Field notes from US Forest Service staff from 1947 indicate that "some fish" were caught in Elizabeth Lake Canyon Creek in the previous season (CDFG 1952). The author noted that the creek was unlikely to support fish life throughout the year, presumably due to low flow.

Fish Canyon, tributary to Castaic Creek - A 1956 CDFW stream inventory for Fish Canyon Creek states, "…some native fish reported in upper reaches" (CDFG 1956b). It adds, "This is definitely a marginal water…"

Bouquet Canyon - According to CDFW records, rainbow trout fry from the Shasta hatchery were planted in Bouquet Canyon Creek in 1943 (CDFG 1943). A 1947 stream survey indicates that *O. mykiss* including a "few fingerlings" were observed in the creek but notes, "Fishing maintained only be frequent plantings" (CDFG 1947b).

In a previous document, Becker et al. (2008) appears to acknowledge the unreliable nature of these observations in Figures 24 and 25 of the report, describing the historic and current, respectively, status of *O. mykiss* in coastal streams of southern Ventura County. In the figures, Castaic Creek and its tributaries, as well as San Francisquito and Bouquet Canyon creeks, are shown as "unknown or insufficient data". Paradoxically, the mainstem Santa Clara River upstream of the Piru Creek confluence is shown as "definite run or population" despite no

---

[3] Available at: https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=10194

documentation in the report of any observations currently or historically in that section of river. CalTrout, an organization focused on healthy waters and resilient wild fish, provides on The Southern Steelhead page of their website[4] as well as their publication "SOS II: Fish in Hot Water: Status, threats and solutions for California salmon, steelhead, and trout" a map of current and historical steelhead range. The source of the map is noted as PISCES (2017). See the discussion above under Biogeographic Datasets - Southern California Steelhead Range (ds1290) for PISCES.

The conservation group Trout Unlimited's website[5] provides maps of the historical and current status of *O. mykiss* in coastal streams of southern Ventura County, California. Both maps show the mainstem of the upper Santa Clara River from the Piru Creek confluence up to about the N3 Angeles Forest Highway as historically and currently having a "definite run or population". However, the cited source for these maps is Becker et al. 2009, described above, which does not appear to substantiate the steelhead historical and current distribution depicted on these figures.

Other Sources

Stoecker and Kelley (2005) analyzed the habitat conditions, population status and barriers to migration for steelhead in the lower Santa Clara River watershed from the Piru Creek tributary downstream, including significant drainages. There is no mention of steelhead resources upstream of the Piru Creek confluence.

Bowers (2008) compiled historical steelhead accounts in Ventura County, primarily from newspaper accounts, personal fishing logs, books, pamphlets, and Ventura County Board of Supervisors' Minutes. Because the report looked at Ventura County, little mention is made of the upper Santa Clara River watershed in Los Angeles County except two articles from the Santa Paula Chronicle. The first, in 1925, noted five thousand "trout" were planted in Bouquet Canyon. The second, in 1943, described Bouquet Canyon as being "in good shape with plenty of good-sized fish left over from last year's plant", presumably referring to planted *O. mykiss.*

Bell (1978) described the fishes of the Santa Clara River and made collections at 46 stations from the river mouth upstream as far as water existed. In the upper watershed, this included San Francisquito Creek, Castaic Creek, Arrastre Canyon, and the mainstem river. No *O. mykiss* were encountered. Bell cites Hubbs (1946) as reporting large and consistent runs of *Salmo gairdneri* (the former scientific name for *O. mykiss*) in the Santa Clara River. However, Bell notes that at the time of his survey, *Salmo* were abundant in Sespe Creek, but Piru Creek and the Santa Clara mainstem were much less suitable habitat, and trout were restricted to a few deep holes in Piru Creek and as escapees to the mainstem from Fillmore fish hatchery. No mention is made of trout in the upper watershed.

Numerous fish sampling events have been conducted in the upper Santa Clara River, particularly the mainstem, in more recent years. Table 1 below presents a list of the sources examined. No *O. mykiss* were encountered in any of the surveys.

Discussion

In review of the available information, no verifiable or concrete observations of native *O. mykiss* in the upper Santa Clara River watershed have been described or recorded historically or currently. Observations that potentially could have been native *O. mykiss* are described in Becker et al. 2009. However, observations of “some fish" or "some native fish" in Elizabeth Canyon and Fish Canyon do not specifically mention *O. mykiss.* The references could be to other native fish in the upper watershed such as threespine stickleback (*Gasterosteus williamsoni*) which were formerly more common in the upper headwater tributaries (Bell 1978). Titus et al. (*In preparation*) also notes San Francisquito Canyon and Soledad Canyon as two streams for which there are CDFW records for rainbow trout presence and/or stocking dating back to circa 1930.

These observations may all well have been planted trout. As described in Titus et al. (*In preparation*) above and in newspaper accounts (Bowers 2008), extensive stocking was occurring in the upper watershed as early as 1925, and it would have been impossible to distinguish native resident trout or steelhead from stocked trout.

Given these unreliable historic accounts and lack of any other verifiable observations, it is of concern that Becker et al. 2008 and Titus et al. (*In preparation*) appear to be the basis for some historic and current distribution maps for southern California steelhead in the upper Santa Clara River (e.g., Boughton et al. 2005, Trout Unlimited), particularly since Becker et al. 2008 itself shows occurrence maps in upper watershed tributaries where there are questionable fish observations as "unknown or insufficient data". It is also not apparent why the upper watershed is considered to have been historically occupied by experts for the U.C. Davis PISCES model, and historically and currently occupied in Figures 24 and 25 of in Becker et al. 2008 despite the absence of observations. Perhaps the underlying assumption is that because the lower Santa Clara River had a well-documented and robust steelhead run (Hubbs 1946, Stoecker and Kelley 2005, Bowers 2008), fish would have inevitably made their way all the way up the river to the upper basin headwaters. However, an examination of habitat conditions in this area suggests that the habitat in the upper basin may have precluded or greatly limited steelhead migration in most years, and that even in particularly wet years when migration was possible, available upstream spawning and over-summering habitat was and is extremely limited or of poor quality.

The Santa Clara River is a perennial stream from Interstate 5 downstream to just west of the Los Angeles - Ventura County line. Beginning about 3.5 river miles downstream of the county line the entire surface flow is infiltrated into the underlying eastern Piru groundwater basin. Surface flow reappears approximately 6 miles downstream, past the confluence of Piru Creek. The river is dry through this reach most of the year, with water present only when rainfall events create sufficient stormwater runoff into the river (GSI 2008, LARWQCB 2007). This dry ephemeral reach of the river is informally known as the "Piru dry gap" in the Santa Clara River. Flood flows in the Upper Santa Clara River increase, peak, and subside rapidly in response to high-intensity rainfall. The "flashy" hydrograph produced by these conditions shows a rapid increase in discharge over a short time period with a quickly developed peak discharge compared to normal baseflow (Kennedy/Jenks 2014). Thus, migration opportunities through the dry gap for upstream migrating steelhead adults and downstream migrating smolts would have historically been limited to typically brief high flow events. The same is true under current conditions, though flows through the dry gap may be artificially altered in duration due to releases from or withholding in upstream reservoirs (e.g., Castaic Lake).

Habitat conditions in the upper watershed tributaries are described in historic accounts as generally poor for *O. mykiss*. For example, field notes from US Forest Service staff from Elizabeth Lake Canyon Creek in 1952 note that the creek was unlikely to support fish throughout the year "presumably due to low flow", and in 1956 regarding Fish Canyon "This is definitely a marginal water…", and in Bouquet Canyon Creek, 1943, "Fishing maintained only by frequent plantings" (Becker et al. 2009). Boughton and Goslin (2006) acknowledge that the watershed between Newhall and Palmdale is subject to a rain-shadow effect from the San Gabriel Mountains and "probably did not contain potential habitat in reality". No current information or surveys reviewed suggest that suitable habitat for *O. mykiss* is extant in the upper basin tributaries. Becker et al. (2010) analyzed information on rearing habitat to identify regionally significant watersheds, which are those offering the greatest potential for producing steelhead smolts, including over-summering opportunities and conditions favoring high growth rates. Within these watersheds the report identifies "essential" streams or reaches that offer the best habitat resources. Within the upper Santa Clara River watershed, portions of the mainstem and several tributaries are identified as “essential” stream, but no waterbodies in the upper watershed are identified as “available” or “suitable” *O. mykiss* habitat (see Figure 14 in the report).

In conclusion, there is no record of current *O. mykiss* occupation in the upper Santa Clara River watershed (east of the Piru Creek confluence) on which to support any determination of species “presence”. Despite extensive fish sampling in the area over the last few decades, no *O. mykiss* have been encountered. Habitat conditions currently do not suggest suitable habitat is present for this species in the area.

There are no verifiable or concrete historical observations of native *O. mykiss* in the upper Santa Clara River watershed, and historical descriptions of habitat conditions do not suggest suitable, perennial habitat was present for *O. mykiss* in the area.

Subject: ACWA Comment Letter - Southern California Steelhead Petition

Dear California Fish and Game Commission,

The Association of California Water Agencies (ACWA) appreciates the opportunity to provide written comments for consideration on the petition to list southern California steelhead (*Oncorhynchus mykiss*) as endangered. For your reference, you can access Cramer Fish Sciences' (Cramer) cohort-based life cycle simulation model (model) that is discussed in our comment letter here. Our comment letter includes two appendices: (1) a technical memorandum developed by Four Peaks Environmental Science & Data Solutions (Four Peaks) that evaluates Cramer's model and California Department of Fish and Wildlife's status review and (2) a technical memorandum developed by Cramer that discusses their model.

ACWA kindly requests that our comment letter, Cramer's model and technical memorandum, and Four Peaks' technical memorandum be shared with President Samantha Murray, Vice President Erika Zavaleta, and Commissioners Darius Anderson, Jacque Hostler-Carmesin, and Eric Sklar.

Please do not hesitate to contact me if you have any questions regarding our comments.

Thank you,

Stephen Pang
State Relations Advocate
Association of California Water Agencies

The Honorable Samantha Murray
President
California Fish and Game Commission
P.O. Box 944209
Sacramento, CA 94244-2090

RE: California Department of Fish and Wildlife Southern California Steelhead (*Oncorhynchus mykiss*) Status Review Submission to Commission

Dear President Murray,

The Association of California Water Agencies (ACWA) appreciates the opportunity to provide public comments to the California Fish and Game Commission (Commission) related to the status review of southern California steelhead (*Oncorhynchus mykiss)* (Status Review) submitted by the California Department of Fish and Wildlife (Department)—pursuant to Fish and Game Code § 2074.6. ACWA represents more than 460 public water agencies that collectively deliver approximately 90 percent of the water in California for domestic, agricultural, and industrial uses. ACWA and its members are invested in healthy watersheds and habitats that support robust populations of native fish and wildlife. However, ACWA has significant concerns regarding both the scientific basis for a listing determination and the potential impacts on public water agencies' ability to reliably provide water if southern California steelhead are listed as endangered pursuant to the California Endangered Species Act (CESA). Section 3, below, elaborates on these concerns.

1. Background

On June 14, 2021, California Trout (CalTrout) submitted a petition to the Commission to list southern California steelhead as an endangered species under CESA. On June 23, 2021, the Commission referred the petition to the Department for evaluation. On October 29, 2021, the Department submitted their evaluation report of the petition to the Commission. On April 21, 2022, the Commission accepted the petition for consideration. On May 13, 2022, the Commission provided public notice that southern California steelhead are a candidate species under CESA. On July 15, 2022, the Department noticed that it had initiated a 12-month Status Review of southern California steelhead and invited the public to submit comments, including data and other scientific information related to the species. In its Status Review, the Department was required to evaluate the breadth of available scientific literature and develop a summary of the status of southern California steelhead. The Department was also required to seek independent peer review of its Status Review. On October 12, 2022, the Commission granted a six-month extension to the Department for their Status Review. On January 18, 2024, the Department submitted its Status Review to the Commission.

ACWA and its member agencies have been actively engaged throughout this process, submitting multiple comment letters to both the Commission and Department in response to the CalTrout petition, evaluation report of the petition, and Status Review for southern California steelhead.

2. Standard for Determination

The standard for listing is whether the species' "continued existence is in serious danger or is threatened by any one or any combination of the following factors: (1) Present or threatened modification or destruction of its habitat; (2) Overexploitation; (3) Predation; (4) Competition; (5) Disease; or (6) Other natural occurrences or human-related activities"—pursuant to 14 CCR 670.1(i)(1)(A). The Department's Status Review must be "based on the best scientific information available" and the Commission's decision whether to list must be "based solely upon the best available scientific information" pursuant to Fish and Game Code § 2074.6 and Fish and Game Code § 2070, respectively.

3. ACWA Comments

ACWA appreciates the mission of the Commission, which is to ensure that California will have abundant, healthy, and diverse fish and wildlife that thrive within dynamic ecosystems. Public water agencies are intimately involved in the management of watersheds and wildlife habitats and ACWA member agencies have become increasingly involved in the proactive resolution of fishery and other aquatic species resource management issues. ACWA has the following significant concerns regarding the petition to list southern California steelhead pursuant to CESA.

a. <u>The Department's Status Review Does Not Incorporate the Best Available Science</u>

While the Status Review assesses the status and trends of southern California steelhead rainbow trout[1] (Southern SH/RT), the Department evaluates sympatric populations of anadromous and resident *O. mykiss* separately. Because of this

[1] In the Status Review, the Department defines southern California steelhead as "all *O. mykiss* below manmade and natural complete barriers to anadromy, including anadromous and resident life histories". To accurately capture this life history variability, the Department uses "southern California steelhead rainbow trout" to describe the proposed CESA listing unit.

separate treatment, the reproductive contributions of sympatric resident spawners to the production of smolts and anadromous *O. mykiss* are not accounted for in measures of population status or the evaluation of long-term viability of southern California steelhead. In addition, the Department does not consider the potential contributions from above-barrier populations of resident *O. mykiss* to Southern SH/RT populations, resulting from the downstream migration of juvenile rainbow trout over barriers. While above-barrier *O. mykiss* are not included in the petition, a subset of that population may increase the effective population size or rescue below-barrier populations from extirpation, therefore improving the viability and persistence of Southern SH/RT.

This interchange between resident and anadromous fish populations, and the associated "rescue effect", reduces the extinction risk of both groups and allows for recolonization should low steelhead abundance occur.[2] In their Viability Assessment for Pacific Salmon and Steelhead Listed Under the Endangered Species Act: Southwest, the National Marine Fisheries Service (NMFS) recognizes that "freshwater-resident (non-anadromous) forms of *O. mykiss* co-occur and appear to interbreed with the anadromous form in many populations" and concludes that "resident (nonanadromus) [sic] *O. mykiss* warrant consideration in managing for the anadromous life history."[3] Similarly, in October 2023, Judge James Chalfant expressed concerns during *United Water Conservation District v. California Fish and Game Commission*, acknowledging that "it may be true that an evaluation of rainbow trout [abundance and] its ability to produce [smolts] is required before [southern California steelhead] can be the subject of stage 2 protection as an endangered species."[4]

The Population Trends and Abundance analysis in Chapter 4 of the Status Review also presents several flaws. First, it utilizes problematic trap data which (1) only account for individuals that are migrating or biologically motivated to move within the watershed (e.g., due to resource availability), (2) are limited to periods when flows allow for the installation and operation of traps—that is, high flow conditions may preclude trap operation <u>when migration is most likely to occur</u>, and (3) are not representative of the trapped portion of *O. mykiss* without a trap efficiency study. Trap efficiency studies are required to develop accurate population estimates from numbers of trapped fish. Unfortunately, the Status Review does not disclose or describe whether trap efficiency studies are available in connection with the different datasets.

Second, while the Status Review acknowledges additional data sources (e.g., snorkel surveys, video-based and surveillance system fish counts), which in some watersheds

---

[2] Boughton, D.A., et al. 2007. Viability criteria for steelhead of the South-Central and Southern California coast. NOAA Technical Memorandum NOAA-TM-NMFS-SWFSC-407.
[3] NMFS. 2023. Viability assessment for Pacific salmon and steelhead listed under the Endangered Species Act: Southwest. U.S. Department of Commerce, NOAA Technical Memorandum NMFS-SWFSC-686. Page 155.
[4] Case No. 22STCP02661. Page 9.

may more accurately characterize the overall *O. mykiss* population, they appear not to have been incorporated into the Population Trends and Abundance analysis consistently.

In addition to statistically inappropriate treatment of the trap data, many of the data presented in the Status Review were not analyzed appropriately. In Section 4.1, the evaluation erroneously compared trap data directly with snorkel survey/bankside observation data (instead of evaluating the different types of survey data separately), evaluated total fish counts per year (instead of fish counts per number of days of trap operation or per distances visually surveyed), and included zero values in some years when monitoring did not occur (instead of consistently excluding all years when monitoring did not occur). Furthermore, in Section 4.3's trend analysis, annual fish count data from the Santa Ynez, Ventura, and Santa Clara Rivers were inappropriately evaluated across the c. 1994 to c. 2021 timeseries without considering methodological changes that occurred within those years—which the Department noted in Appendix C of the Status Review.[5]

Finally, the Department's focus on a 5-year timeframe (i.e., 2013 to 2018) when discussing productivity in the Population Trends and Abundance analysis in Section 4.5 is non-representative and skews their conclusions. This timeframe coincides with the most recent extreme drought period and conditions associated with the loss of suitable spawning and rearing habitat, insufficient instream flows required for migration, diminished water quality, reductions in available food supply, and increases in direct mortality. While most populations do not have enough data available following the drought to determine if rebounding has occurred, the Department does note potential post-drought rebounding in the only population (i.e., Santa Ynez River) with a dataset through 2021. In NMFS' Southern California Steelhead Recovery Plan, Dr. David A. Boughton explains that "steelhead recovery as a form of human stewardship has to be judged over a broader timeline, with multi-year setbacks in population size considered to be a normal and expected event, and progress judged at the scale of multiple decades and even multiple human generations."[6]

b. <u>Consider Information and Data That Use the Best Available Science to Assess the Viability of the Distinct Population Segment (DPS) in the Context of Threats to the DPS</u>

Consistent with the Department's July 15, 2022, solicitation, various water agencies have shared information for the Department's Status Review. The information

[5] Cramer, S.P. and Caldwell, L. 2020. Bias and consequences in attempts to estimate historic salmon abundance. *Canadian Journal of Fisheries and Aquatic Sciences*, 77(1):132-145.
[6] National Marine Fisheries Service. 2012. Southern California Steelhead Recovery Plan. Southwest Region, Protected Resources Division, Long Beach, California. Page 5-1.

submitted contributes to the best available science and highlights the basis for ACWA's concerns with the potential listing of Southern SH/RT.

A new cohort-based life cycle simulation model (model), developed by Cramer Fish Sciences in collaboration with ACWA member agencies, includes the diverse and interrelated life history variants of *O. mykiss*. The model incorporates anadromous, below-barrier resident, and above-barrier resident sub-populations to evaluate population dynamics and assess extinction risk when resident *O. mykiss* are available to contribute to anadromous populations. When appropriately structured and parameterized, the model is a tool for evaluating these contributions and determining whether sympatric resident populations support long-term viability of southern California steelhead populations. The model demonstrates that the contribution of anadromous and resident (below- and above-barrier) life history variants and their connectivity can affect a population's trajectory, and that omitting them may not fully capture the DPS's long-term resiliency. Cramer Fish Sciences, ACWA, and collaborating member agencies met with the Department on December 12, 2023, to discuss and review the model, prior to the Department's submittal of the Status Review to the Commission.

Cramer Fish Sciences' model reflects existing literature indicating freshwater populations of both below- and above-barrier resident *O. Mykiss* improve the viability of the anadromous life history and contribute to the long-term persistence of the overall *O. Mykiss* population across the range of life histories it exhibits. Although anadromous spawners alone could support the DPS, the model predicted that southern California steelhead are always at or close to collapse without reproductive contributions from below- and above-barrier resident spawners under all conditions but the highest ocean survival scenarios. Depending on contributions to anadromous spawning populations in wet years, the resident life histories provide additional population stability and reduced extinction risk that should be accounted for when making regulatory determinations and setting recovery targets.

The model is supported by the extensive research conducted by ACWA member agencies, survey data, and the available scientific literature and fills a key data gap highlighted by water agencies in past comments and information submittals to the Commission and the Department throughout the petition process. The model is formulated using sound logic and consistent with prevailing practices, with its structure and default parameterization informed by the empirical data that align with the current scientific understanding. Therefore, the model—when combined with other data, analyses, and tools—constitutes the best available scientific information. As a consequence, the Department is obliged to utilize the model and model results to inform its Status Review, and the Commission is obliged to consider the model and model results to inform its ultimate listing decision.

c. <u>Consider Ongoing Restoration and Recovery Activities That Contribute to Conservation and Reduce Threats to the Species</u>

The Department, California Department of Transportation, California State Parks, U.S. Forest Service, County of Ventura, City of San Buenaventura, City of Santa Barbara, City of Carpinteria, City of Malibu, Cachuma Operation and Maintenance Board, Casitas Municipal Water District, United Water Conservation District, Santa Monica Mountains Resource Conservation District, South Coast Habitat Restoration, CalTrout, and many other organizations are currently engaged in significant ongoing restoration and recovery work throughout the DPS. Numerous small- and large-scale recovery actions have already been implemented by the agencies listed above while other actions are in the advanced planning phases. These actions include, but are not limited to:

- Robles Fish Passage Facility modifications on the Ventura River
- Matilija Dam Ecosystem Restoration Project on Matilija Creek
- Foster Park Fish Passage Improvement Projects on the Ventura River
- San Antonio Creek fish passage barrier removal
- Freeman Diversion Habitat Conservation Plan and fish passage improvements on the Santa Clara River
- VenturaWaterPure Program for Santa Clara River Estuary habitat improvements
- Rindge Dam decommissioning on Malibu Creek
- Hilton Creek fish passage barrier removal
- Quiota Creek fish passage barrier removals
- Salsipuedes Creek and El Jaro Creek Fish passage barrier structures
- Gaviota Creek fish passage barrier removal
- Tajiguas Creek fish passage barrier removals
- Arryo Burro fish passage barrier removal and Mesa creek restoration project
- Mission Creek fish passage barrier removals
- Carpinteria Creek fish passage barrier removals
- Maria Ignacio Creek fish passage barrier removal
- Arroyo Hondo Creek Fish Passage Project
- Solstice Creek Fish Passage Restoration
- Malibu Creek fish passage barrier removal project and Malibu Lagoon restoration project
- San Juan Creek dams and fish passage barrier removals
- Trabuco Creek Fish Passage Project

These current and anticipated restoration and recovery actions are consistent with NMFS' Southern California Steelhead Recovery Plan and are anticipated to result in a measurable increase in *O. mykiss* abundance within the southern California DPS over a reasonable timeframe.[7] Large-scale recovery actions are underway or have already occurred in the neighboring south-central steelhead DPS (e.g., San Clemente Dam decommissioning, Los Padres dam fish passage design, Arroyo Grande Creek and watershed improvement projects) that may also aid in the recovery of the southern California steelhead DPS.

Some of these restoration and recovery actions have taken, and will continue to take, years to permit and implement. Some of these completed projects may take years to realize population recovery due to the natural stochasticity of populations and the complex chain of effects between the action and the population-level response. Consequently, prematurely dismissing the efficacy of restoration efforts resulting from the federal listing and NMFS' Southern California Steelhead Recovery Plan is unwarranted. Evaluating the success of this work will likely require a decades-long perspective because of the time required for planning and executing recovery projects, as well as realizing their benefits for the species. In addition, external factors such as precipitation patterns, ocean conditions, and stochastic events may cause annual fluctuations in *O. mykiss* abundance, even if the population experiences a positive growth rate over longer timescales. It is a disconcerting reality that a state listing of the population is likely to increase the time and cost incurred to implement restoration and recovery actions to benefit the population.

d. Consider That a State Listing Would Not Trigger Additional California Environmental Quality Act (CEQA) Evaluations or Afford Additional Protection Beyond that Provided by the Federal Endangered Species Act (FESA)

FESA already prohibits steelhead "take" by law, and the federal definition is wider ranging than the "take" definition under the Fish and Game Code (§ 86), and includes "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect or attempt to engage in any such conduct," 16 U.S.C. 1532(19), and "harm" is further defined as "an act which actually kills or injures wildlife. Such an act may include significant habitat modification or degradation where it actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering," 50 C.F.R. 17.3.

Effects to all special-status species and designated critical habitat are evaluated under CEQA. The Status Review, in Section 7.1.1, fails to explain that CEQA is already triggered if a project would affect southern California steelhead because the species is federally listed. In Section 11, the Status Review erroneously claims that: "Additional protection of Southern SH/RT following listing would also occur during required state and local agency environmental review under CEQA. CEQA requires affected public agencies to analyze and disclose project-related environmental effects, including

[7] National Marine Fisheries Service. 2012. Southern California Steelhead Recovery Plan. Southwest Region, Protected Resources Division, Long Beach, California.

potentially significant impacts on endangered, threatened, and rare special status species. Under CEQA's "substantive mandate," state and local agencies in California must avoid or substantially lessen significant environmental effects to the extent feasible. With that mandate, and the Department's regulatory jurisdiction generally, the Department expects related CEQA review will likely result in increased information regarding the status of Southern SH/RT in California as a result of pre-project biological surveys."[8] Because the species is already listed under FESA and it is presumed that "all juvenile *O. mykiss* in streams where listed steelhead occur are listed juvenile steelhead", there would be no additional CEQA reviews or collection of biological information on the species' status due to listing southern California steelhead under CESA.[9]

The Department is typically already included in interagency coordination and project evaluations through the Lake and Streambed Alteration Program, Fish and Game Code § 1600. Section 7(a)(2) of FESA, 16 U.S.C. 1536(a)(2), requires federal agencies to ensure actions are not likely to jeopardize the continued existence of a species or adversely modify its designated critical habitat. The Status Review claims that application of this section of FESA is limited in scope because it applies only to federal actions and areas under federal ownership; however, most or all projects physically affecting streams that support *O. Mykiss* require permitting and approval by the U.S. Army Corp of Engineers, which would trigger Section 7(a)(2). In addition, the take prohibition under FESA applies irrespective of whether there is a federal nexus.

Under FESA, for incidental take to be authorized, impacts to endangered species must be minimized and jeopardy of the species and/or adverse modification of critical habitat must be avoided. The only additional protection afforded by listing the species under CESA would be that impacts and take must be minimized or "fully mitigated"; however, this standard is tempered by the CESA requirement that the mitigation must be "roughly proportional" to the impact of the take, Fish and Game Code § 2081(b)(2). In sum, there is no evidence that CESA would provide additional protections for *O. mykiss* above and beyond that provided by FESA.

e. <u>Minimize Impacts on Water Management and Programs That Benefit Southern California Steelhead</u>

Designation of southern California steelhead as an endangered species could have significant impacts on water management operations in the region that are critical to public health and safety. Long-term water resilience and the successful

---

[8] California Department of Fish and Wildlife. 2024. Report to the California Fish and Game Commission. California Endangered Species Act Status Review for Southern California Steelhead (*Oncorhynchus mykiss*). Sacramento, California. Page 142.

[9] National Oceanic and Atmospheric Administration. Endangered and Threatened Species: Final Listing Determinations for 10 Distinct Population Segments of West Coast Steelhead, 71 Fed. Reg. Jan. 5, 2006. Page 841.

implementation of CESA requires that regulatory agencies collaborate with interested parties to develop an approach that accounts for the various and unique needs of the region and balances water supply reliability and ecosystem enhancement.

Steelhead listings under FESA, which already provides protection to the species as a matter of federal law, have resulted in substantial curtailments of water diversions and extractions in southern California coastal streams. A CESA listing could result in infeasible avoidance and minimization measures for water management and water facility operation activities occurring in streams populated or potentially suitable for future population by *O. mykiss*. In addition, instream flow mandates have the potential to diminish local water supplies at the same time the State is requiring local water agencies to reduce reliance on water supplies that flow through the Sacramento-San Joaquin Delta or are derived from the Colorado River. Regionally, this reduction in available water supply would have significant impacts including, but not limited to, increased overdraft of groundwater basins; reductions in water for municipal, agricultural, and industrial users; water quality degradation detrimental to human health (e.g., increased nitrate concentrations); reductions in agricultural production; job losses; and financial stress to disadvantaged communities and their water systems. More broadly, reductions in available water supply from local sources would place added stress on the State Water Project and other regional and state-level water infrastructure. A CESA listing would have significant impacts to water management, water agencies, and water users throughout the region.

These regulatory effects would impact ongoing or planned projects intended to protect and contribute to recovery of the DPS—such as fish passage projects, habitat restoration projects, and multi-benefit water supply projects designed to meet the state's resiliency and sustainability goals. If the Commission decides to designate *O. mykiss* as an endangered species, water agencies will be subject to additional permitting that could delay projects, increase costs, and generate redundancies given that the species is already listed under federal law and given other federal, state, and local environmental protections. The Department is already a partner in federal consultation and recovery efforts and has developed site-specific protection measures through individual permits and agreements in collaboration with NMFS. In addition, a CESA listing could have unanticipated detrimental effects on southern California steelhead if water agencies are reluctant to implement watershed projects with the potential to benefit anadromous *O. mykiss* because of the possibility of incidental take. For example, the planned removal of the Matilija Dam in Ventura County has been delayed, in part, because of concerns over inadvertent take caused by the mass release of sediment into the Ventura River system as a result of the project.

Moreover, in order to allow the Department and other resource agencies to focus their efforts on the recovery of southern California steelhead, and to allow ACWA member agencies to commit resources to meaningful watershed projects that contribute to the recovery of the DPS, it would be prudent for the Commission to exclude from the proposed listing coastal watersheds where the Department had previously identified concrete-lined flood control channels that present hydraulic (i.e., velocity) barriers to steelhead passage. These structures can extend many miles inland from the river mouth and have been recognized throughout California as barriers to successful upstream migration.

Public water agencies in the impacted central and southern coastal watersheds are working diligently to effectively manage limited water supplies and continue efforts to conserve the species, and they are doing so per the existing federal listing of *O. mykiss*. ACWA member agencies should be allowed to continue their work without an additional layer of regulations and prohibitions in watersheds that are not anticipated to ever provide passage for southern California steelhead. Great care should be taken during the listing process to ensure that existing watershed projects, that will ultimately benefit anadromous *O. mykiss* and other riparian species, are not frustrated by a CESA listing—which is indicated herein does not appear to be supported by the best available science. Managing drought emergencies and long-term climate change impacts requires close collaboration between local and state agencies to continue to provide safe, affordable, and reliable water to southern Californians, and the listing in its current form has the potential to frustrate required coordination.

Conclusion

ACWA appreciates the responsibility currently before the Commission in evaluating the petition and Status Review. There are many factors that will determine the current status of southern California steelhead and a thorough review and analysis of the best available science is needed. ACWA's members along California's South Coast are closely following this effort as the Commission's ultimate decision could have significant impacts on water management operations throughout the region and hinder their ability to provide water supplies to their diverse customers in one of the most densely populated parts of the country.

ACWA appreciates the opportunity to comment and the collaboration of Department and Commission staff. If you have any questions regarding these comments, please contact me at StephenP@acwa.com or (916) 669-2369.

TECHNICAL MEMORANDUM

04/03/2024

TO: Stephen Pang, Association of California Water Agencies
FROM: Lucius Caldwell, Elizabeth Ng, and Grant Woodard, Four Peaks Environmental Science & Data Solutions
SUBJECT: Review of Cramer Fish Sciences Southern California Steelhead Life Cycle Model

Executive Summary

The distinct population segment of Southern California steelhead (*Oncorhynchus mykiss*) below impassible migration barriers is currently listed as Endangered under the federal Endangered Species Act (ESA). This federal ESA-listed population, which is managed by the National Marine Fisheries Service (NMFS), includes only anadromous *O. mykiss* and does not protect freshwater resident life histories. However, the interdependencies of sympatric resident and anadromous life histories was acknowledged by NMFS in their 2006 listing determination, and in 1997 NMFS had defined Southern California steelhead to include resident fish.

In 2021, California Trout petitioned the California Fish and Game Commission to list Southern California steelhead (including all *O. mykiss* below impassible barriers to migration) as an endangered species under the California Endangered Species Act. In an evaluation of this petition published in 2021, the California Department of Fish and Wildlife (CDFW) determined listing may be warranted. This prompted a full evaluation of the status of Southern California steelhead populations by CDFW in a January 2024 report.

The Association of California Water Agencies contracted with Four Peaks Environmental Science & Data Solutions (Four Peaks) to provide a critical review and evaluation of the 2024 CDFW Southern California Steelhead Status Report delivered to the California Fish and Game Commission (CDFW Report), as well as a Southern California steelhead life cycle model developed by Cramer Fish Services (CFS LCM). The CFS LCM was designed to address deficiencies in the current population viability assessments by CDFW and NFMS that only include anadromous spawners. The CFS LCM aims to estimate anadromous and freshwater resident Southern California *O. mykiss* dynamics more accurately by including the effects of both resident and anadromous life histories on anadromous population dynamics.

The CDFW Report provides a relatively comprehensive review of the current status of Southern California steelhead but has some key flaws. First, the underlying data used for some of the analyses in the CDFW Report are limited in terms of their duration, spatial extent, and completeness. These data gaps limit the quality of inferences that can be drawn from the resulting analyses. This issue of limited data availability is heightened by the omission of some key sources of available data. Additionally, some of the data presented in the report are not analyzed correctly. Specifically, some count data—which are indices of population abundance and not abundance estimates themselves—are presented as abundance data, resulting in an inaccurate estimate of abundance. Finally, the CDFW Report analyzes the freshwater resident and anadromous life histories separately, despite their documented interbreeding and ability to give rise to one another, raising questions about the validity of their population viability assessment.

The initial draft of the CFS LCM provides a mechanism for assessing population dynamics when including the interrelated life histories of anadromous and freshwater resident *O. mykiss* populations both above and below barriers to migration. The structure of this model is logical, and the initial default parameterization is defensible and based on empirical data. However, it does have limitations that need to be addressed before it can be used to rigorously evaluate Southern California steelhead population dynamics. Notably, key life stage transition rates such as smolt rates and ocean survival are not parameterizable for individual life histories (anadromous versus resident). This does not allow for these rates to vary, as would be expected due to underlying genetic differences between the two life histories. Additionally, the fecundity parameter is not age-specific, even though fecundity tends to be highly correlated with fish size.

To evaluate the influence of certain key parameters, a sensitivity analysis of the CFS LCM was conducted by Four Peaks. The purpose of this effort was to determine the effects on population dynamics that may propagate through the model from inaccuracies around starting values for population size, fecundity rates, smolt rates, and ocean survival rates. Results from this effort indicated that population dynamics were relatively robust to the starting population size; however, fecundity, smolt rate, and ocean survival rates substantially influenced population dynamics, with higher values of the parameters increasing the long-term viability of the anadromous population. In general, anadromous spawners contributed more to the long-term viability of the anadromous population than resident spawners, though the extent was influenced by environmental conditions.

1 Introduction

1.1 Context

The Association of California Water Agencies has contracted with Four Peaks Environmental Science & Data Solutions (Four Peaks) to provide a critical review of documents related to a petition from California Trout (CalTrout) to list Southern California steelhead (*Oncorhynchus mykiss*) as an endangered species under the California Endangered Species Act (CESA) (CalTrout 2021). The petition notably includes freshwater resident *O. mykiss* (rainbow trout) below impassable barriers. In November 2021, the California Department of Fish and Wildlife (CDFW) published their evaluation of the petition to list Southern California steelhead/rainbow trout[1] (Southern SH/RT), which concluded that, "the petition action may be warranted," (CDFW 2021). In May 2022, the California Fish and Game Commission (Commission) published a Notification of Findings indicating they accepted the petition for consideration (CFGC 2022), prompting CDFW to compile a Southern SH/RT status review to determine if the petition action is warranted.

In October 2023, United Water Conservation District (UCWD) challenged the Commission's decision in court (UCWD v. California Fish and Game 2023). During this hearing, Hon. James C. Chalfant, Judge, stated that an evaluation of freshwater resident rainbow trout abundance and the ability of these

[1] To disambiguate the intended treatment of resident fish within the population proposed for listing under the CESA, CDFW refers to the population as Southern California steelhead rainbow trout.

freshwater resident fish to produce smolts (anadromous individuals) would be required to support a decision to protect Southern SH/RT as an endangered species. Chalfant also raised questions about the rate of smolting among freshwater resident rainbow trout and about precise estimates of rainbow trout population[2] abundance that would be needed before listing. These questions about abundance of freshwater resident fish, ability of freshwater resident fish to smolt, and the rate at which freshwater resident fish smolt are pertinent to the ongoing deliberations regarding Southern SH/RT listing.

In January 2024, CDFW published their status review, in which they stated, "The Department recommends that the Commission find the petitioned action to list Southern SH/RT as an endangered species to be warranted," (CDFW 2024). This memorandum provides a review and evaluation of CDFW's Southern California steelhead status review report (2024) and a review of a technical memorandum prepared by Cramer Fish Science describing a life cycle model (CFS LCM) developed to evaluate Southern California steelhead population viability (CFS 2024).[3] The following specific objectives were defined to support this goal:

1. Summarize the key regulatory issues related to CESA-listing of Southern California steelhead
2. Review and critique the CDFW status report
3. Review, summarize, and critique the CFS technical memorandum

The remainder of this technical memorandum presents the following components:

- A summary of the current regulatory status of Southern California steelhead (Section 1.2)
- A summary of the petition to list (Section 1.3)
- Four Peaks' review and evaluation of the CDFW Report (Section 2)
- Four Peaks' review and evaluation of the CFS technical memorandum (Section 3), which includes an Executive Summary of this technical memorandum suitable for dissemination as a standalone document to brief interested parties in advance of future discussions (Section 3.1)
- Results from Four Peaks' sensitivity analysis of the CFS LCM to evaluate the relative influence of model parameter assumptions on model predicted population dynamics for Southern California steelhead (Section 4)

1.2 Current Regulatory Status of Southern California Steelhead

The Southern California steelhead evolutionarily significant unit (ESU) was initially listed as endangered under the federal Endangered Species Act (ESA) in 1997 (NMFS 1997). At that time, the National Marine Fisheries Service (NMFS) listed only the anadromous form of *O. mykiss* within the stated range of Southern California steelhead (NMFS 1997, pg. 43938). In 2002, the southern range limit of Southern California steelhead was extended under the ESA listing (NMFS 2002). The initial 1997 decision by NMFS to list only anadromous *O. mykiss* has been followed in each subsequent listing: in 2006, the ESA listing

[2] Note that the term "population" is used throughout this document to refer to groups of individuals that, in some cases, exist at different hierarchical levels. For example, there is the worldwide population of steelhead, the Southern California steelhead population, populations of Southern California steelhead that exist within each basin, and populations of anadromous and resident fish within those populations of Southern California steelhead within each basin. To maintain readability and avoid introducing excessive terminology, no effort has been made throughout this document to disambiguate these groups except for cases in which a subpopulation is referred to in direct reference to its parent population.
[3] "Viability" in this context implies less than 5% extinction risk over the next 100 years (see NMFS 2023b, pg. 16).

was further modified to relist the Southern California steelhead ESU as a distinct population segment (DPS), further distinguishing between the anadromous and resident forms of *O. mykiss* (NMFS 2006). In the 2006 listing, NMFS reiterated, "Within these geographic boundaries, we further conclude that the anadromous life form is markedly separate from the resident life form… We therefore are delineating… steelhead-only DPSs," (NMFS 2006, pg. 848). In summarizing their status assessment leading to this 2006 listing, NMFS stated, "the BRT [*an expert panel of scientists from several Federal agencies including NMFS, FWS, and the U.S. Geological Survey*] concluded that the contribution of the resident life-history form to the viability of an *O. mykiss* ESU in-total is unknown and may not substantially reduce extinction risks to an ESU in-total," (NMFS 2006, pg. 851). The current understanding, summarized in NMFS's most recent Status Review, is that individuals of the resident life history do contribute to anadromous populations, although the degree to which this affects population dynamics remains unquantified (NMFS 2023a).

1.3 California Trout Petition to List Southern California Steelhead

On June 7, 2021, CalTrout submitted a Petition to the Commission to list Southern California steelhead, including both anadromous and freshwater resident life histories of *O. mykiss*, as endangered under CESA (CalTrout 2021). In their petition, CalTrout states their position as follows,

> *"CalTrout supports following the federal ESA listing coverage for below barrier steelhead, while keeping the above-barrier resident rainbow trout outside the ESA listing coverage."*

However, the CalTrout Petition deviates from the ESA listing by including freshwater resident fish below barriers within the listed steelhead distinct population segment (DPS).

On June 23, 2021, the petition to list Southern California steelhead under CESA was referred to CDFW for an evaluation of the scientific information presented therein and a recommendation whether to list, which was published in November 2021 (CDFW 2021). In their evaluation, CDFW (2021) notes that CalTrout (2021) defined Southern California steelhead as, "all *O. mykiss*, including anadromous and freshwater resident life histories, below manmade and natural complete barriers to anadromy" (CDFW 2021).

CDFW highlighted the fact that this proposed state designation differs from the ESA listing of a DPS of steelhead with the same geographic range that includes, "only naturally spawned anadromous *O. mykiss*," (CDFW 2021), referring to NMFS's 2006 listing of Southern California steelhead cited above. This deviation in the treatment of freshwater resident fish under the proposed state designation and existing federal designation raised uncertainty regarding the intent of the initial CalTrout Petition, which was resolved in a series of unpublished emails between CDFW and CalTrout in October 2021 confirming,

> *"CalTrout defines Southern California steelhead as all Oncorhynchus mykiss, including anadromous and resident life histories, below manmade and natural complete barriers to anadromy… with the understanding that anadromous (adult southern steelhead) arise from anadromous and resident naturally spawning adults," (as quoted in CDFW 2021).*

At the heart of this confusion between CalTrout—the listing organization—and CDFW—the regulatory agency tasked with providing the best scientific information to inform CESA listing by the Commission—is the issue of appropriate treatment of freshwater resident *O. mykiss* in an evaluation of sympatric (occupying the same geographic areas) anadromous *O. mykiss*. That keystone issue led to the development of the CFS LCM reviewed here, to address NMFS's and CDFW's lack of inclusion of the effects of freshwater life histories on anadromous Southern California steelhead population dynamics.

2 Review of California Department of Fish and Wildlife Status Report

2.1 Summary

2.1.1 Purpose and Context

CDFW's Status Review (CDFW 2024) evaluates whether there is sufficient scientific information to indicate that the continued existence of Southern SH/RT, throughout all or a significant portion of its range, is endangered or threatened. Although the federal ESA listing for the Southern California steelhead DPS includes only the anadromous life-history component, CDFW recommends the Commission list Southern SH/RT, which includes freshwater resident fish below barriers, under CESA. CDFW asserts legal authority to interpret what constitutes a species, justifying their departure from the federal listing.

2.1.2 Life History Considerations

Southern SH/RT enacts both freshwater and ocean migratory (anadromous) life history forms. The enacted life history depends on genetic factors, as well as environmental conditions such as freshwater rearing habitat availability, hydrologic conditions, and ocean access. CDFW provides evidence that the preservation of existing life history diversity within Southern SH/RT is important to foster long-term population stability, as this diversity provides a measure of redundancy that distributes risk, buffering populations from local extirpation or population-level extinction (collapse). They summarize their position regarding the importance of this life history diversity as follows:

> *"Ideally, all three Southern SH/RT life-history types (i.e., fluvial-anadromous, freshwater-resident, lagoon-anadromous) would be expressed within a single population, or the population would harbor the underlying genetic variation to express those life-history types when environmental conditions allow,"*
> *(CDFW 2024, pg. 80).*

CDFW states that, "it is unclear that the resident component can reliably produce anadromous fish after prolonged periods of unfavorable conditions in the long term."[4] A recent viability assessment includes the statements of NMFS's understanding regarding the contributions of resident *O. mykiss* to steelhead populations:

- "We recognize that there may be situations where reproductive contributions from non-anadromous *O. mykiss* may mitigate short-term extinction risk for some steelhead DPSs," (NMFS 2023b, pg. 5).
- "Freshwater-resident (non-anadromous) forms of O*. mykiss* co-occur and appear to interbreed with the anadromous form in many populations, and new research has improved our understanding of the genetic architecture of the populations exhibiting both nonanadromous and anadromous forms (Pearse et al. 2014, Pearse et al. 2019). Thus, while not formally considered part of the DPS, resident

[4] In support of this statement, CDFW cites "Boughton et al. 2022a," which is listed in their references as Boughton 2022. The Boughton or Boughton et al. 2022 document listed in the references of CDFW 2024 could not be located. It appears the correct citation for this statement is NMFS (2023): "Viability Assessment for Pacific Salmon and Steelhead Listed Under the Endangered Species Act: Southwest."

(nonanadromous) *O. mykiss* warrant consideration in managing for the anadromous life history" (NMFS 2023b, pg. 155).
- "To meet criteria for life-history expression, viable populations would need to consistently exhibit both the resident and anadromous life history, as well as a third life history of anadromous fish that rear in estuaries for a significant time prior to smolting," (NMFS 2023b, pg. 176).

2.1.3 Life Histories Included in the Proposed Listing and Associated Assessments

CDFW states that,

> *"Non-anadromous resident O. mykiss… reside in many of these same streams and interbreed with anadromous adults, contributing to the overall abundance and resilience of the populations. Southern SH/RT as defined in the Petition include both anadromous (ocean-going) and resident (stream-dwelling) forms of O. mykiss below complete barriers to anadromy in these streams," (CDFW 2024, pg. 139).*

In fact, this proposition to include freshwater resident fish harkens back to NMFS's initial position of including this life history within the listed DPS,[5] which was retracted only after considering the substantial comments advocating against this approach, including comments from the U.S. Fish and Wildlife Service (FWS).[6] Although the freshwater resident form is not considered in NMFS's ESA listing, NMFS did include co-occurring freshwater resident *O. mykiss* in population assessments, where data were available. An expert panel of scientists from several federal agencies initially concluded the contribution of the freshwater resident life-history form to the viability of an *O. mykiss* ESU in-total is unknown and may not substantially reduce extinction risks to an ESU in-total (NMFS 2006). However, more recent science indicates that these resident life histories are likely to provide some mitigation to anadromous population viability, but the extent remains unquantified (NMFS 2023a).

2.1.4 Population Status and Trends

CDFW states that populations of freshwater resident and anadromous *O. mykiss* have both experienced drastic reductions in their abundances and ranges since the early 20th century, with declines in anadromous returns estimated to be over 90%. They further assert that available data indicate that populations of both the anadromous and nonmigratory life histories have remained critically low in the 21st century and have not recovered since listing under the ESA.

2.1.5 Departmental Position on Listing

Given the continued low abundances of freshwater resident and steelhead *O. mykiss* populations, CDFW believes consideration for CESA listing is justified. CDFW identifies multiple primary actions for protecting and restoring Southern SH/RT populations.

---

[5] "While conclusive evidence does not yet exist regarding the relationship of resident and anadromous *O. mykiss*, NMFS believes available evidence suggests that resident rainbow trout should be included in listed steelhead ESUs in certain cases," (NMFS 1997, pg. 43941).

[6] "However, the FWS, which has ESA authority for resident fish, maintains that behavioral forms can be regarded as separate DPSs… and that absent evidence suggesting resident rainbow trout need ESA protection, the FWS concludes that only the anadromous forms of each ESU should be listed under the ESA," (*ibid*).

2.2 Critical Evaluation of California Department of Fish and Wildlife Findings

The CDFW report provides an assessment of the status and trends of Southern California SH/RT, as well as the probable reasons for their decline and current obstacles to recovery. However, this assessment is based on limited data that may be incomplete and appear to have been inappropriately analyzed in certain cases. Moreover, while CDFW acknowledges interbreeding between sympatric populations of anadromous adult steelhead and freshwater resident rainbow trout, the populations are evaluated separately, with no accounting for the contributions of freshwater resident fish to steelhead population viability.

2.2.1 Data That Were Omitted from Analysis

Although a complete review of available data was beyond the scope of this evaluation, information provided by UCWD indicates that CDFW (2024) may have omitted important *O. mykiss* monitoring data from their assessment. For example, camera data from a diversion on the Santa Clara (Booth 2016) are mentioned by CDFW (2024) in Section 7.5.2 of their report (Other Monitoring Programs), but apparently not included in their analysis of steelhead population status and trends. Additional sources of data are mentioned in Section 7.5.2 of CDFW's report that appear not to have been incorporated into their status and trends analyses include snorkel surveys of fish abundance in the Santa Ynez River and video-based fish counts in the Ventura River.

2.2.2 Data That Were Inappropriately Analyzed

To paraphrase John G. Sheperd, Emeritus Professor at University of Southampton and former principal scientific adviser to the UK government on marine fisheries management, counting fish is like counting trees, except that you cannot see them and they keep moving around.[7] Observed counts of a sample of animals or plants do not provide accurate estimates of population abundance unless they are statistically analyzed to account for the methods under which these data were collected (Cormack 1964; Jolly 1965; Seber and Le Cren 1967). Such treatment is needed to expand count data into an accurate estimate of population size. Abundance estimations derived from appropriate statistical treatment are less affected by the inevitable undercounting and double counting that occurs when counting individuals. Without this treatment, count data are observations that, at best, provide an index of total population abundance, but do not provide a robust estimate or quantify uncertain around that estimate.

However, count data from fish passage monitoring on the Santa Clara River (Booth 2016) are presented in CDFW's report as an estimate of *O. mykiss* abundance in the Santa Clara system. These observations of juvenile and adult *O. mykiss* presented in the Booth (2016) report have not been statistically analyzed to derive a robust estimate of overall population size (e.g., see Carlson et al. 1998; Macdonald and Smith 1980). Such analyses are required to account for trap efficiency, periods when gear was not operational, and differences in the overall level of effort associated with gear deployment.

After reviewing Section 4.2 (Sources of Information) in CDFW's report, it is not clear if any trap data or other fish enumeration data were treated statistically to develop the estimates of population size used in their Abundance and Trends Section (4.4).

[7] The original quote is, "Managing fisheries is hard: it's like managing a forest, in which the trees are invisible and keep moving around," – John G Sheperd. Source: https://jgshepherd.com/thoughts/.

2.2.3 No Acknowledgment of Interbreeding

Within the CDFW (2024) report, abundance and trend data are presented separately for anadromous adults and "other" *O mykiss* (i.e., freshwater resident forms). Because of this separate treatment, the reproductive contributions of sympatric freshwater adult spawners to the production of smolts and future adult steelhead are not accounted for in measures of population status or the evaluation of long-term viability of Southern California steelhead.

Similarly, CDFW does not consider the potential contributions from above barrier populations of rainbow trout to the number of smolts resulting from downstream migration over barriers that can occur in some systems:

> *"The Department also considers Southern SH/RT to be markedly separate from above-barrier populations of O. mykiss in watersheds that are within the geographic scope of the proposed listing unit, because these above-barrier populations do not contribute substantially to the below-barrier populations of Southern SH/RT," (CDFW 2024, pg. 37).*

A more specific definition of what CDFW considers to be an "impassable" barrier would enable a more thorough evaluation of CDFW's approach. Depending on the level of contribution from above barrier populations to smolt production and anadromous adult spawners via downstream migration, these above barrier populations might also merit inclusion and protection under the CESA if they are measurably contributing to the anadromous populations.

3 Cramer Fish Sciences Life Cycle Model Technical Memorandum Review

3.1 Executive Summary

Cramer Fish Sciences (CFS) developed a technical memorandum in which they present a mathematical model (CFS LCM) for evaluating Southern California steelhead viability (CFS 2024). The CFS LCM was developed to address the California Department of Fish and Wildlife's lack of inclusion of the effects of freshwater resident life histories on anadromous Southern California steelhead population dynamics in their assessment of overall Southern California steelhead population viability, by accounting for freshwater resident contributions to the anadromous population. The model was constructed to accommodate variable environmental conditions and population demographics, enabling the exploratory evaluation of alternative scenarios.

3.1.1 Background

Within the petition to list under the California Endangered Species Act, Southern California steelhead is defined to include, "all *O. mykiss* below manmade and natural complete barriers to anadromy, including anadromous and resident life histories," from five biogeographical population groups.

The National Marine Fisheries Service (NMFS) has established a recovery goal for Southern California steelhead based on the number of adult anadromous spawners. NMFS acknowledges that freshwater resident trout and anadromous steelhead interbreed, but NMFS has not accounted for contributions to anadromous spawners from offspring of freshwater resident parents in the development of their recovery goal. Accounting for these contributions may change conclusions about population viability, as viability is assessed in relation to a recovery goal stated in terms of anadromous spawners.

To evaluate this possibility, CFS developed the CFS LCM, which is a "cohort-based life cycle simulation model" that includes both freshwater resident and anadromous life histories. The purpose of the CFS LCM is to simulate population dynamics (changes in abundance over time) and thereby evaluate extinction risk when freshwater life histories are available to contribute to anadromous populations.

3.1.2 Model Approach and Overview

The CFS LCM includes freshwater resident and anadromous populations and evaluates the effects of reproductive contributions from freshwater residents on the overall population viability of Southern California steelhead. The model has been initially parameterized using data compiled from a literature review and from a similar model developed by CFS for the Central California Coast steelhead DPS (the "Suisun Creek LCM").

The structure of the CFS LCM draws from the following simulation models developed for salmonids:

- NOAA's Habitat Restoration Planning (HARP) model (Jorgensen et al. 2021)
- The Shiraz model, developed collaboratively by researchers from NOAA, the University of Washington, Snohomish County Public Utility District, and the Tulalip Tribe (Scheuerell et al. 2006)
- CFS's Nooksack and Suisun Creek models

The CFS LCM simulates population dynamics over a modifiable time period (default of 125 years) for ten subpopulations of Southern California steelhead. The dynamics of all ten subpopulations are then aggregated to estimate overall Southern California steelhead DPS population dynamics.

The CFS LCM includes the following three life histories for each modeled subpopulation of Southern California steelhead:

1. Below-barrier anadromous populations
2. Below-barrier freshwater resident populations[8]
3. Above-barrier (perched) freshwater resident populations

The number of adults within each life history group are modeled separately, but the number of juveniles is modeled collectively for life history groups that are connected, with connection being based on environmental conditions. Offspring both from anadromous adults and from below-barrier freshwater resident adults always contribute to a collective pool of juveniles that either "smolt" in preparation for an anadromous life cycle or develop into freshwater resident adults (rainbow trout). Depending on the annual hydrologic regime (wet, average, or dry), offspring from perched freshwater resident adults may also contribute to this collective pool of juveniles that can smolt. Annual environmental conditions also affect juvenile survival and the proportion of below barrier juveniles that smolt. The CFS LCM follows cohorts of each life history group as they develop through distinct life stages (e.g., eggs, fry, smolts). The model accounts for survival associated with the transitions between these life stages and among the three modeled life history groups (Table 1). The default model settings for these transition rates are informed by empirical data that align with the current scientific understanding, but they can be adjusted individually by the user, for example, to simulate environmental scenarios.

Table 1. List of life stages and transitions included in the Cramer Fish Sciences life cycle model for Southern California steelhead

Life Stage or Transition Process	Description and Notes
Returns to Spawners	Determines the number of spawners for each life history group
Spawners to Eggs	Determines the number of eggs produced by adult females of each group
Egg to Fry	Determines the number of early-stage juvenile fish (fry)
Fry Rearing and Colonization (Survival)	An estimate of fry survival to the point of their initial winter
Winter Rearing Capacity and Survival	A density-dependent function for imposing fry mortality during winter
Summer Rearing Capacity and Survival	A density-dependent function for imposing parr mortality during summer
Smolt Rate	Rate that freshwater fish convert to anadromous life strategies.
Lagoon Rearing	Rate at which lagoon rearing occurs for smolts; alternative to estuary/ocean rearing
Estuary Survival	Rate at which anadromous smolts survive during estuary phase; default conditions for anadromous smolt rearing
Ocean Survival	Rate at which anadromous smolts survive during ocean phase; default conditions for anadromous smolt rearing
Maturation	Rate at which fish mature to spawners
Iteroparity	Rate at which spawners return and spawn again next year

[8] CFS refers to this population as "Resident."

3.1.3 Impact of Environmental Conditions on Model Rates

The model includes three types of annual hydrological conditions: wet, regular[9], and dry. The reference condition is regular water availability, which is based on an average of historical records of the last 40 years of streamflow data.

During regular years, anadromous connection is maintained so that smolts can emigrate and anadromous adults can return to spawn. Perched populations do not contribute to below-barrier freshwater resident populations, and thus cannot contribute to anadromous populations through smolts.

During dry years, several adjustments are made to the regular year baseline. Perched and below-barrier freshwater resident populations experience reduced carrying capacity, smolt rate is reduced, and stray rate is increased. Perched populations do not contribute to below barrier freshwater populations.

During wet years, several adjustments are made to the regular year baseline. In wet years during which the perched freshwater resident population exceeds its carrying capacity, perched freshwater resident fish contribute to downstream (below-barrier) freshwater resident populations. These below-barrier freshwater residents can then contribute to the anadromous population by smolting.

The model also allows parameterization of a reduction event, which simulates a catastrophic die-off. This can be used to model a decrease in the number of spawners that can be applied for a set number of years to simulate drastic negative environmental impacts to the populations.

3.1.4 Four Peaks' Assessment of the Value of the Cramer Fish Sciences Life Cycle Model

When appropriately structured and parameterized, the CFS LCM will provide a tool for evaluating contributions from freshwater resident fish to the anadromous adult population. The model provides a logical mechanism for evaluating whether sympatric freshwater rainbow trout populations can support long-term viability of steelhead populations.

3.2 Critical Evaluation

3.2.1 Model Summary

The CFS LCM simulates transition rates among a set of model states to represent the transitions among various life stages of a developing fish (Table 2). The model simulates how eggs and parr mature and smolt to capture the interplay between anadromous and resident populations. Adults from the below-barrier freshwater resident group (referred to by CFS simply as the "Resident" group in the model framework and associated Shiny application) can contribute to anadromous adult returns, because all below barrier juveniles are "available" for smolting. Adults from the perched freshwater resident fish (referred to by CFS simply as the "Perched" group in the model framework and associated Shiny application) can contribute to below-barrier freshwater resident populations in wet years when the perched population density exceeds carrying capacity. The simulation-based framework allows users to account for uncertainty by entering different values for certain parameters (e.g., sequence of wet and dry years, survival rates).

[9] CFS alternatively refers to average, medium, and normal environmental conditions. For the purposes of this evaluation, these three terms are assumed to refer to the same "Regular Years" condition described in CFS's technical memorandum.

Table 2. Description of life stages and transitions included in the CFS LCM for Southern California steelhead

Life Stage or Transition Process	Description and Notes
Returns to Spawners	• Determines the number of spawners for each life history group • Estimated as the total number of spawners within each group, multiplied by pre-spawn mortality and harvest rates for that group • Parameterizable for each of the three life histories
Spawners to Eggs	• Determines the number of eggs produced by adult females of each group • Estimated as 50% of the total number of spawners (assuming half are female) times the fecundity value (the average number of eggs produced per female), which is parameterizable for each of the three life histories
Egg to Fry	• Determines the number of early-stage juvenile fish (fry) • Estimated by multiplying the number of eggs times the egg to fry survival parameter • Egg to fry survival is parameterizable for both above- and below-barrier freshwater populations
Fry Rearing and Colonization (Survival)	• An estimate of fry survival to the point of their initial winter • Estimated by multiplying the number of fry times the fry survival rate parameter • Separate estimates for perched and below barrier resident populations • Reduced in dry years
Winter Rearing Capacity and Survival	• A density-dependent function for imposing mortality during winter • This is parameterizable for each of the two freshwater life histories. • Uses a Beverton-Holt function (density dependent asymptotic function) so that incremental increases in rearing capacity/survival approach 0 as fry density increases • The Beverton-Holt function is dependent on habitat capacity and productivity, which differ among watersheds • This function assumes capacities by age account for effects of other age classes
Summer Rearing Capacity and Survival	• A density-dependent function for imposing mortality during summer • Otherwise, as above for Winter Rearing Capacity and Survival
Smolt Rate	• Rate that freshwater fish convert to anadromous life strategies • Each freshwater juvenile age class has an associated smolt rate that determines the proportion of that age class that will migrate to the ocean • Age and watershed dependent, only juveniles up to age 4 have the capacity to smolt, individuals older than this enact a fully freshwater life history
Lagoon Rearing	• Rate at which lagoon rearing occurs for smolts • Accounts for a strategy of anadromous smolts that provides greater survival for individuals rearing in lagoons compared to estuary and nearshore rearing • Density dependent function calculating amount of smolts that can rear in the lagoon, with the others being relegated to the estuary
Estuary Survival	• Default conditions for anadromous smolt rearing • Age specific survival rate times the number of estuary rearing smolts
Ocean Survival	• Default conditions for anadromous smolt rearing • Age-specific survival rate times the number of estuary rearing smolts
Maturation	• Rate at which fish mature to spawners • Separate rates for each life history group and age • Estimates of spawners within each life history group determined by multiplying age specific maturation rates times the number of fish in each age class for each life history and watershed • Also, anadromous spawners may stray to neighboring watersheds and contribute to the number of spawners via a straying rate
Iteroparity	• Rate at which spawners return and spawn again next year • Determines the number of adults that will repeat-spawn • Number of repeat spawners is calculated by multiplying number of spawners times the proportion of fish that respawn (iteroparity rate) and their probability of surviving spawning (respawn survival rate) • Assumes fish cannot change life histories once it is determined • Separate value for each life history

CFS has developed a reasonable and logically sound foundation for a cohort-based LCM to assess the role of environmental conditions and freshwater resident trout contributions on anadromous steelhead population dynamics. The CFS LCM was developed to address CDFW's lack of inclusion of the effects of freshwater life histories on anadromous Southern California steelhead population dynamics. If freshwater resident contributions to anadromous returns change population dynamics enough to affect viability, population recovery targets may benefit from a reevaluation. The modular nature of the cohort-based model provides a high degree of flexibility. Individual parameters can be used for different life stages, life histories, age classes, watersheds, and sub-watersheds. This means the CFS LCM can be used to evaluate knowledge gaps, test the effects of environmental and demographic conditions, and be updated as more information becomes available.

The CFS LCM is designed to evaluate relative differences in population outcomes as a consequence of changes to environmental or life history parameters relative to some baseline, providing guidance for future management and research actions. It is not designed to forecast accurate population abundances or develop recovery targets. However, it can be used to evaluate the assumptions used to determine recovery targets. While the basic model structure is adequate for examining Southern California steelhead population dynamics, key additions to the model structure are needed for the model to adequately address the questions posed by Association of California Water Agencies regarding current population abundance and the rate at which freshwater resident fish contribute to the anadromous population.

3.2.2 Strengths

- The CFS LCM is built on a flexible framework that incorporates relevant, recent, empirical data and information about Southern California steelhead.
- The CFS LCM includes components for resident and perched life history types, whose impacts were not included previously in CDFW's and NMFS's minimum viable population size assessments.
- The interactive GUI facilitates exploratory analyses and simple simulations.
- The model provides a framework for evaluating complex population dynamics that emerge from the interaction of freshwater resident, anadromous, and perched populations. The model incorporates effects of environmental variability, for example by modifying the contribution of perched fish and fry survival under different hydrologic conditions (i.e., "wet year" versus "dry year").
- Perched *O. mykiss* may contribute to below barrier populations and provide a buffering effect. Including a model structure with this phenomenon allows users to parameterize the magnitude of this effect based on professional opinion or emerging empirical data.
- Systematic simulations (e.g., sensitivity analyses) can be used to explore the ramifications of variance in these biological factors (see Section 4 for results from a set of these simulations).
- Other environmental factors that vary across years (e.g., ocean survival) are included in the model, but cannot be parameterized dynamically, to allow for differences among years.
- Systematic simulations can be used to explore the ramifications of variance in these environmental factors (see Section 4 for results from a set of these simulations).

3.2.3 Limitations

3.2.3.1 Summary of Limitations

While the current iteration of the CFS LCM uses sound logic and science, it does have several key flaws and limitations. One potentially important limitation of the model is that two key transition rates—the smolting rate and the ocean survival rate—are not life history specific. Offspring from anadromous parents and those from below-barrier freshwater resident parents are grouped together and share one set of transition rates between successive juvenile life stages (i.e., egg, fry, parr, smolt). While the framework accounts for contributions from freshwater resident adults to the number of returning anadromous adults, it does not support individually setting model parameters for these groups separately. This omission limits the range of simulations that can be analyzed and has implications for the accuracy of model output. Also, the fecundity rate for anadromous adults does not vary with age, to reflect the fact that older fish are larger and produce more eggs.

These flaws and other minor additional limitations are discussed in the following sections. These flaws and limitations should be addressed before the model is used in scientifically rigorous assessments of Southern California steelhead population dynamics and viability. However, upon incorporation of the revisions suggested below, the model would likely be an appropriate model of potential Southern California steelhead population dynamics.

3.2.3.2 Key Transition Rates Are Shared Between Life History Groups

The smolt rate is not individually parameterizable for offspring of each life history group. Smolt rate determines the relative occurrence of anadromy within the population being modeled, and thus the number of anadromous adult returns in the model's next step. In some ways, grouping all below-barrier juveniles is a strength of the model, as it considers all these fish to be freshwater residents, until they smolt. This approach enables a comprehensive Southern SH/RT viability assessment based on abundance of all juveniles, regardless of parentage. However, this identical treatment of all juveniles does not accurately reflect current scientific understanding.

Substantial evidence indicates that there are important genetic differences between populations of anadromous, below-barrier freshwater resident, and perched freshwater resident *O. mykiss*. A review of this evidence is presented in CDFW's recent Southern California steelhead Status Review (CDFW 2024). Key for this critical evaluation of the CFS LCM, the relative contributions to returning anadromous spawners differ among the different life histories, with anadromous spawners producing the highest proportion of future anadromous spawners (Abadía-Cardoso et al. 2019; Fraik et al. 2021). Thus, one set of smolt rates for all life histories is not appropriate in modeling the effects of these different life histories on anadromous steelhead abundance. The structure of the CFS LCM does not capture any reproductive isolation or reflect the genetic underpinnings of smoltification that may lead to different smolt rates between offspring of freshwater resident rainbow trout parents and those of steelhead parents.

The model also lacks the ability to set different rates of ocean survival for offspring of freshwater resident parents and those of anadromous parents. The size at which fish within a population smolt (size threshold) differs among life history groups, reflecting a heritable genetic component to smoltification (Phillis et al. 2016). Different size thresholds for smolting may translate into differences in size at ocean entry among smolts that originate from parents with different life histories. Size at ocean entry has been shown to be affect marine growth rate—and, importantly, ocean survival—of smolts (Weitkamp 2015). Different ocean survival rates can contribute to differences in smolt-to-adult return ratios between life history groups, which would affect their respective ability to meaningfully contribute to returning adult steelhead abundance.

While this structure does not represent a "fatal flaw" in the CFS LCM, the model could be improved by including age-specific smolt rates for each life history, with a default parameterization that established offspring of anadromous fish having higher smolt rates than offspring of non-anadromous fish.

3.2.3.3 Fecundity of Anadromous Adults Does Not Vary Among Ages

The fecundity parameter within the model appears to be an average value (numbers of eggs) per female. All salmonids exhibit "size dependent fecundity," meaning larger females produce more eggs (Fleming 1998), and *O. mykiss* are no exception (Jenkins et al. 2018; Schill et al. 2010). *O. mykiss* spawn at different ages and are capable of repeat-spawning over a range of ages, a process called kelting among steelhead that do so. Salmonids also exhibit "indeterminate growth," meaning they continue to grow throughout their lifespan, and older fish are larger than younger fish (Mommsen 2001). Taken together this means that older *O. mykiss* are larger and produce more eggs than younger *O. mykiss*.

The range of size variation across age classes, and therefore fecundity, may not be very large in spawning female freshwater resident *O. mykiss* (Schill et al. 2010). However, the range in size at spawning for anadromous steelhead can be very large, leading to dramatic differences in fecundity (Jenkins et al. 2018). For example, adult steelhead kelts continue to grow after their first spawning, which has been shown to lead to an approximately 10% increase in fecundity between subsequent spawning events (Seamons and Quinn 2010). The CFS LCM could be improved by including an age-dependent fecundity parameter for all life history groups, especially the anadromous life history.

3.2.3.4 Additional Considerations

In addition to the model limitations described in Sections 3.2.3.2 and 3.2.3.3, the CFS technical memorandum could be improved by addressing the following concerns. These are less critical but addressing them would enable a more thorough evaluation of the mechanics of the model.

First, mathematical equations are not included in the memorandum or on the Shiny application. Equations should be included in all modeling efforts to enable evaluation of model assumptions. Similarly, the baseline parameterization of density dependent relationships is unclear. In several places (e.g., spawner to egg, winter rearing, summer rearing), baseline transition rates are unclear.

The choice of functional relationships and rationale for selection are not explained. Decisions regarding the type of functional relationships may be appropriate, but these are difficult to evaluate without an explanation of the rationale. Density dependent relationships can have strong effects on simulation trajectories. It is unclear why the "hockey stick" function is used to calculate egg production from spawners, but the Beverton-Holt function is used to calculate other metrics of density dependence such as winter rearing capacity and summer rearing capacity, and the lack of consistency was not explained.

Parameterization of Beverton-Holt and other density-dependent functions is not documented or described in the technical memorandum. These parameters of the density dependent relationships should be modifiable within the CFS LCM to best suit the system and population, as the level of density dependence could have a strong impact on simulation results. Additionally, the fry rearing calculations do not appear to incorporate any density dependent dynamics. This is odd, because fry should also be subjected to similar density dependent phenomena as the other juvenile rearing populations. Further, while the lagoon rearing dynamics mention they are subject to density dependence, the memorandum does not indicate what mathematical function is being used (i.e., Beverton-Holt, hockey stick, or something else).

CFS's intention to publish the model in peer-reviewed scientific literature would provide an opportunity to subject the details of the model's structure, parameterization, and justification to a high level of scientific rigor. These details could also be included in an appendix to the Shiny application, but must be available somewhere, whether in peer-reviewed literature or the Shiny application for reference and evaluation.

3.3 Conclusions from Review of Life Cycle Model

Depending on contributions to anadromous spawning populations by below barrier freshwater resident populations and above barrier freshwater resident populations in wet years, the freshwater life histories may provide additional population stability and reduced extinction risk that should be accounted for when setting recovery targets. When appropriately structured and parameterized by addressing the aforementioned limitations, the CFS LCM will provide a tool for evaluating these contributions and determining whether sympatric freshwater rainbow trout populations support long-term viability of steelhead populations.

4 Cramer Fish Sciences Life Cycle Model Sensitivity Analysis for Southern California Steelhead

4.1 Sensitivity Analysis Introduction

Sensitivity analysis is a technique used to evaluate the performance of complex models and to understand the relative effect that individual model inputs or assumptions (parameters) exert on determining model outputs (predictions). In sensitivity analysis, critical parameters are identified and then varied systematically. The robustness of model predictions is evaluated by observing the change in model output that results from adjusting each parameter. Insights can be gleaned about the relative importance of each parameter by evaluating the range and distribution of outcomes.

In this way, the model's overall "sensitivity" to the value of individual parameters (sometimes referred to as parameterization, or parameter settings) can be evaluated, to identify the parameters that have the greatest effects on model results. The model is understood to be "sensitive" to the values of those parameters, which are thus considered important in determining the accuracy of model predictions. Those important parameters to which the model is highly sensitive then become a research priority to improve the accuracy of model predictions. This is particularly important for model parameters with high uncertainty. Highly uncertain parameters that strongly influence model results provide important caveats for model interpretation, and these should be prioritized when developing future research.

Four Peaks conducted a sensitivity analysis to test the influence of both basic model assumptions (robustness to starting population size) and uncertainty in important life history parameters including smolt rate, fecundity, and ocean survival. The following sections present a summary approach for the analyses, the results from these simulations, and finally a discussion of the implications of the findings. Of note, as it constitutes a point of departure from language used in the preceding sections, CFS's terminology regarding life history groups has been retained. Thus, in the subsections that follow, "Resident" refers specifically to the below-barrier freshwater resident group, while "Perched" refers to the above-barrier freshwater resident group.

4.1.1 General Approach

To evaluate the CFS LCM's sensitivity to individual parameters, a series of scenarios were constructed by systematically varying individual parameters while holding others constant. The parameters that were varied included initial abundance, fecundity, smolt rate, and ocean survival rate. This approach enabled an assessment of the differences in population trajectories under different values of that specific parameter.

Because the CFS LCM depends on the sequence of annual environmental conditions (wet, dry, or normal), Four Peaks ran all simulation scenarios under the following four different sets of environmental conditions:

1. All dry years
2. All normal years
3. Normal and dry (repeating sequence of normal, dry, dry, dry, normal)
4. Normal, wet, and dry (repeating sequence of normal, wet, dry, dry, normal)

These environmental conditions were chosen to represent potential proportions of wet, dry, and average moisture years. Table 3 presents a summary of the default conditions used for the eight model scenarios (varying initial abundance, varying fecundity, varying smolt rate, varying ocean survival).

Table 3. Default parameter values used in the eight model scenarios

Scenario	Life History	Initial Abundance (Number of Spawners)	Fecundity (Number of Eggs)	Smolt Rate	Ocean Survival
Default	Perched, resident, and anadromous	1,000 for all life histories	2,000 for anadromous populations 1,000 for freshwater populations	0.15, 0.5, 0.25, and 0.25 for ages 0 through 3 respectively	0.6, 0.36, 0.3, 0.3, 0.3, and 0.4 for ages 1 through 7 respectively
Vary starting abundance	All life histories simultaneously	0,500, 1000, 1500, 2000 for all life histories	Default Parameter Setting	Default Parameter Setting	Default Parameter Setting
Vary fecundity	All life histories simultaneously	Default Parameter Setting	0, 500, 1,000, 1,500, 2,000 for freshwater life histories 0, 1,000, 2,000, 3,000, 4,000 for anadromous life history	Default Parameter Setting	Default Parameter Setting
Vary fecundity	Resident/perched spawners only	1,000 for freshwater life histories, 0 for the anadromous life history	0, 500, 1,000, 1,500, 2,000 for freshwater life histories 0 for the anadromous life history	Default Parameter Setting	Default Parameter Setting
Vary fecundity	Anadromous spawners only	1,000 for anadromous life histories, 0 for the freshwater life history	0, 1,000, 2,000, 3,000, 4,000 for the anadromous life history 0 for freshwater life histories	Default Parameter Setting	Default Parameter Setting
Vary smolt rate	Resident/perched spawners only	1,000 for freshwater life histories, 0 for anadromous life history	1,000 for freshwater life histories 0 for anadromous life history	Defaults times factors of between 0 and 2	Default Parameter Setting
Vary smolt rate	Anadromous spawners only	1,000 for anadromous life history, 0 for freshwater life history	1,000 for anadromous life history 0 for freshwater life histories	Defaults times factors of between 0 and 2	Default Parameter Setting
Vary ocean survival	Resident/perched spawners only	1,000 for freshwater life histories, 0 for the anadromous life history	1,000 for the freshwater life histories 0 for the anadromous life history	Default Parameter Setting	Defaults times factors of between 0 and 2
Vary ocean survival	Anadromous spawners only	1,000 for anadromous life histories, 0 for the freshwater life history	2,000 for the anadromous life history 1,000 for the freshwater life histories	Default Parameter Setting	Defaults times factors of between 0 and 2

4.1.2 Vary Initial Abundance Simulations

A basic assumption of the CFS LCM is that the model's final population abundance estimates (and thus, the overall assessment of population viability) are robust to small differences in starting abundance. This assumption has implications regarding the importance of accurate estimates of current population size. To evaluate this assumption, Four Peaks ran scenarios that varied initial population abundances from the default of 1,000 spawners for each life history type by a factor from 0 to 2, in increments of 0.5 (e.g., [0, 1,000, 2,000, 3,000, 4,000] for anadromous spawners and [0, 500, 1,000, 1,500, 2,000] for freshwater spawners). The population trajectories for the 150-year time series were then averaged across all watersheds. Varying the initial population sizes was not expected to substantially affect model results because of the relative predictive nature of the model.

4.1.3 Vary Fecundity Simulations

Typically, age and life stage-structured models are sensitive to fecundity and other state transition rates. These parameters may also have the highest uncertainty. Simulations were constructed to evaluate variance in the fecundity parameter. Four Peaks ran scenarios that used the default initial population sizes for all life history groups, and varied fecundity estimates from the default of 1,000 eggs per spawner for resident fish and 2,000 eggs per spawner for anadromous fish, by a factor from 0 to 2, in increments of 0.5. The population trajectories for the 150-year time series were then averaged across all watersheds. Varying fecundity was expected to affect model results because fecundity has a direct impact on the number of progeny produced by spawners in each generation, which can affect the minimum number of spawners required to prevent population collapse (minimum viable population), a common recovery target that has been applied to Southern California steelhead.

4.1.4 Anadromous Contribution Simulations (Vary Smolt Rate and Vary Ocean Survival)

One of the major questions regarding the anadromous steelhead recovery target—quantified as the minimum viable population—is the degree to which resident and perched freshwater populations contribute to the anadromous spawning population. As discussed in Section 3.2.3.1, anadromous spawners have a higher probability than resident spawners of producing future returning anadromous adults. Two potential mechanisms of action for this have been identified: 1) a difference in smolt rates between the two life histories, or 2) a difference in ocean survival between the two life histories. Differences in smolting and other behavioral and physiological aspects of an anadromous life history are determined in part by genetics (Pearse et al. 2014). Survival after smolting is greater among larger sized smolts (Tatara et al. 2017), and anadromous parents generally give rise to larger offspring (Kendall et al. 2015). As currently formulated, the CFS LCM does not allow life history specific smolt rates (to specify a higher probability of smolting for offspring of anadromous parents) or ocean survival rates (to specify a higher probability of surviving in the ocean for offspring of anadromous parents).

To evaluate freshwater parent contributions to the anadromous population within the current structure of the CFS LCM, Four Peaks ran a scenario that set the anadromous starting population size and fecundity to 0, while maintaining the resident and perched starting population sizes and fecundities at the defaults (1,000 for both parameters). In this scenario, anadromous fish must arise from offspring of freshwater parents, so this tests the ability of the combined resident population to wholly support an anadromous population without any reproductive contributions from those anadromous adults.

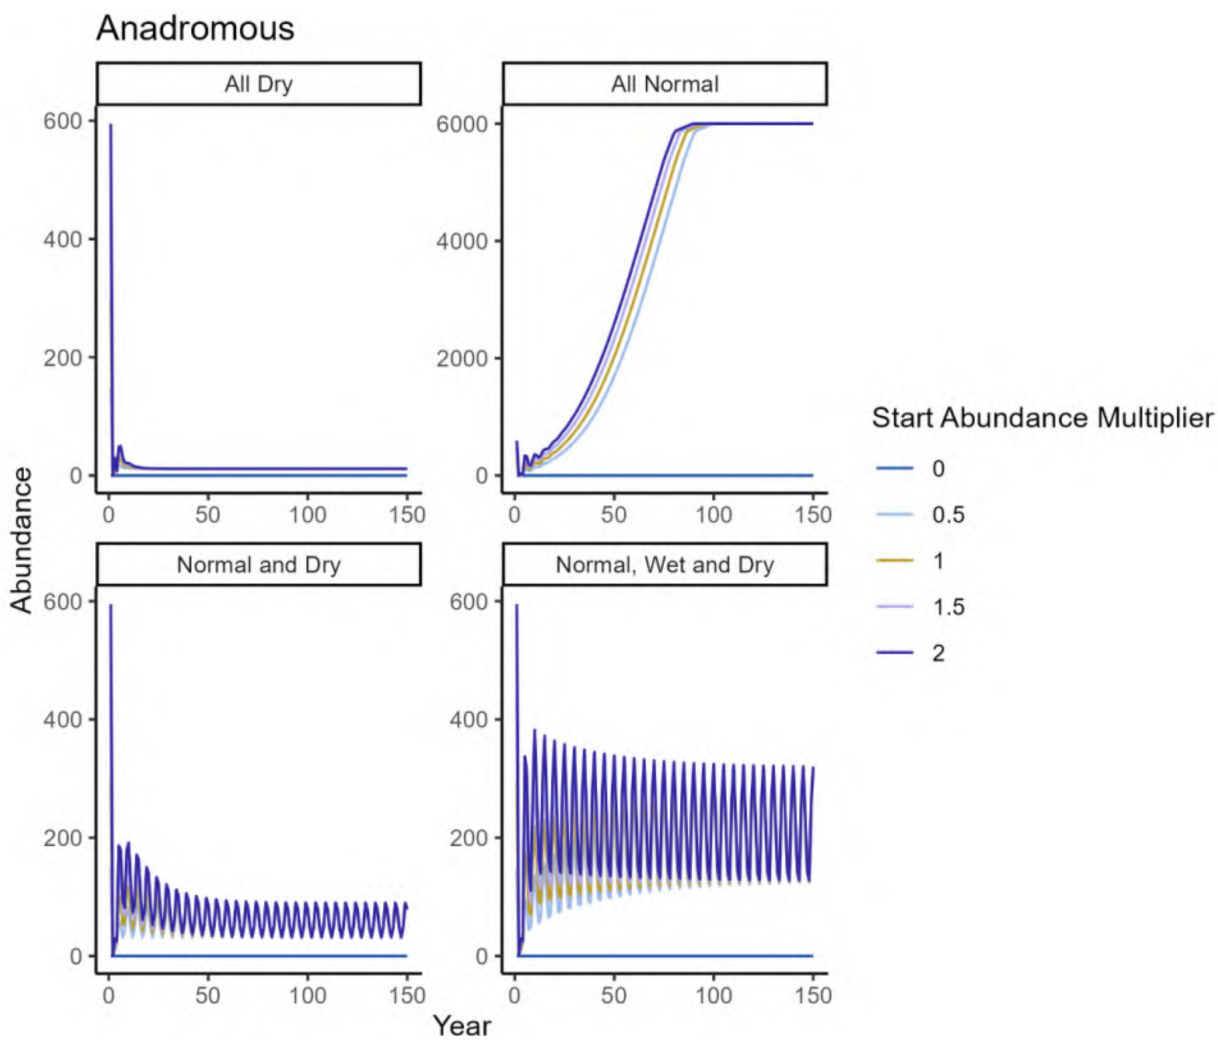
The converse of this scenario was also run, setting freshwater fecundities and starting populations at 0, the anadromous population fecundity at the default 2,000, and anadromous population size at the default 1,000. This scenario tests the ability of the anadromous population to support itself without any reproductive contributions from the resident adults.

Two sets of these scenarios were run: one that varied the smolt rate and one that varied ocean survival. These two parameter sets were varied from the default by factors between 0 and 2 with a step size of 0.5. Default smolt rates were 0.15, 0.5, 0.25, and 0.25 for ages 0 through 3, respectively. Default ocean survival rates from one age class to the next (starting at age 1 and ending at age 7) were 0.6, 0.36, 0.3, 0.3, 0.3, and 0.4, respectively. This allowed an assessment of the consequences of overestimation or underestimation of the unknown true parameter value.

4.2 Sensitivity Analysis Results

4.2.1 Vary Starting Abundance Simulations

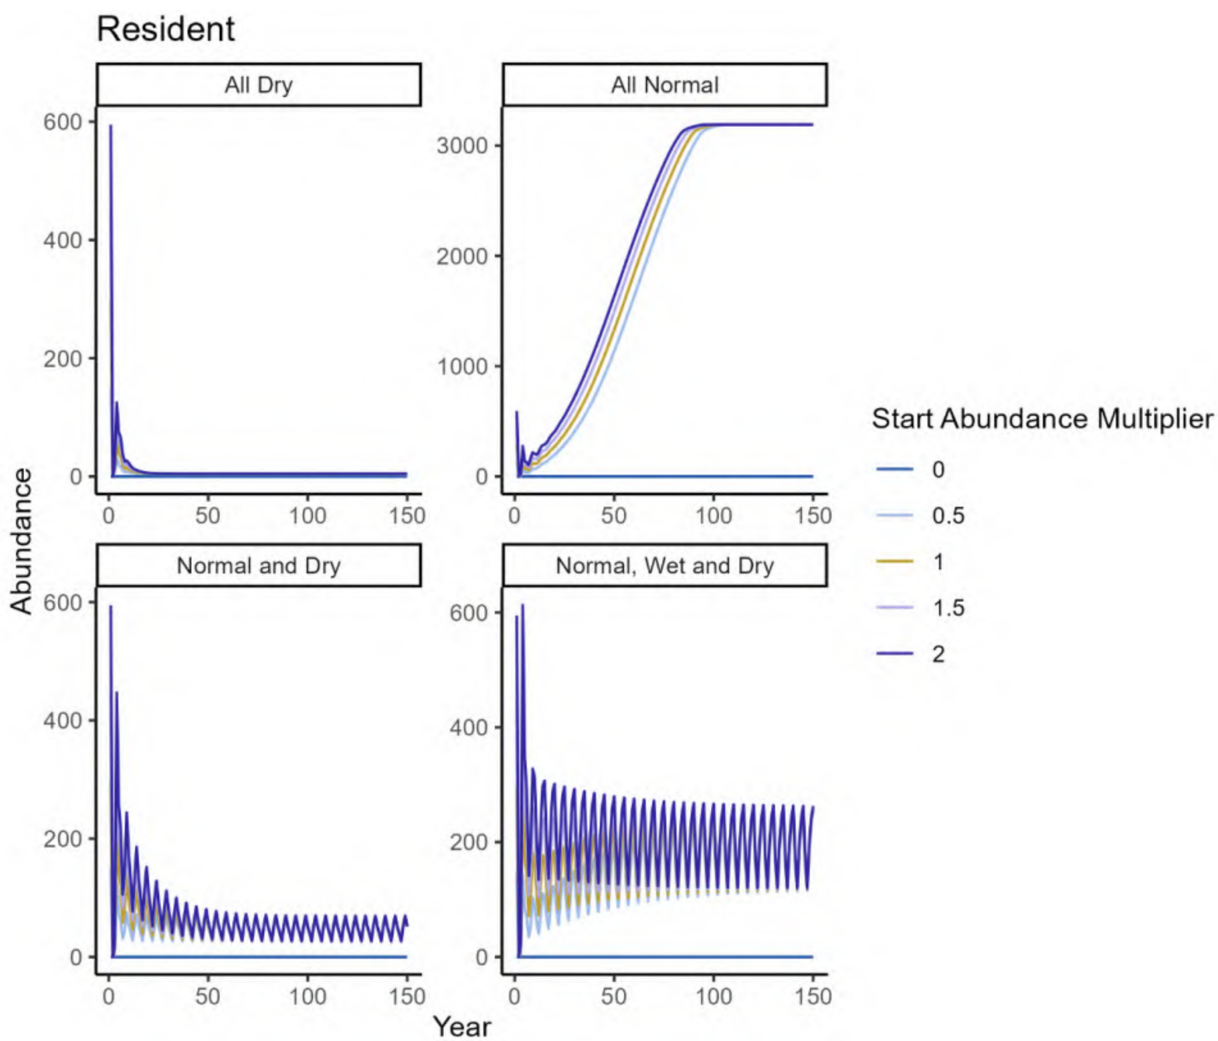
As expected, model results (i.e., ending abundance estimates and overall conclusions about population viability) were robust to starting population abundances (Figure 1 through Figure 3). Abundances towards the ends of the time series were similar among different starting abundances, provided the starting abundances were not extremely small. Only when wet years were included did the starting abundance make a noticeable but small difference in the average ending population abundances. Under scenarios with wet years and higher starting abundance, ending populations sizes were also slightly larger.



Notes:

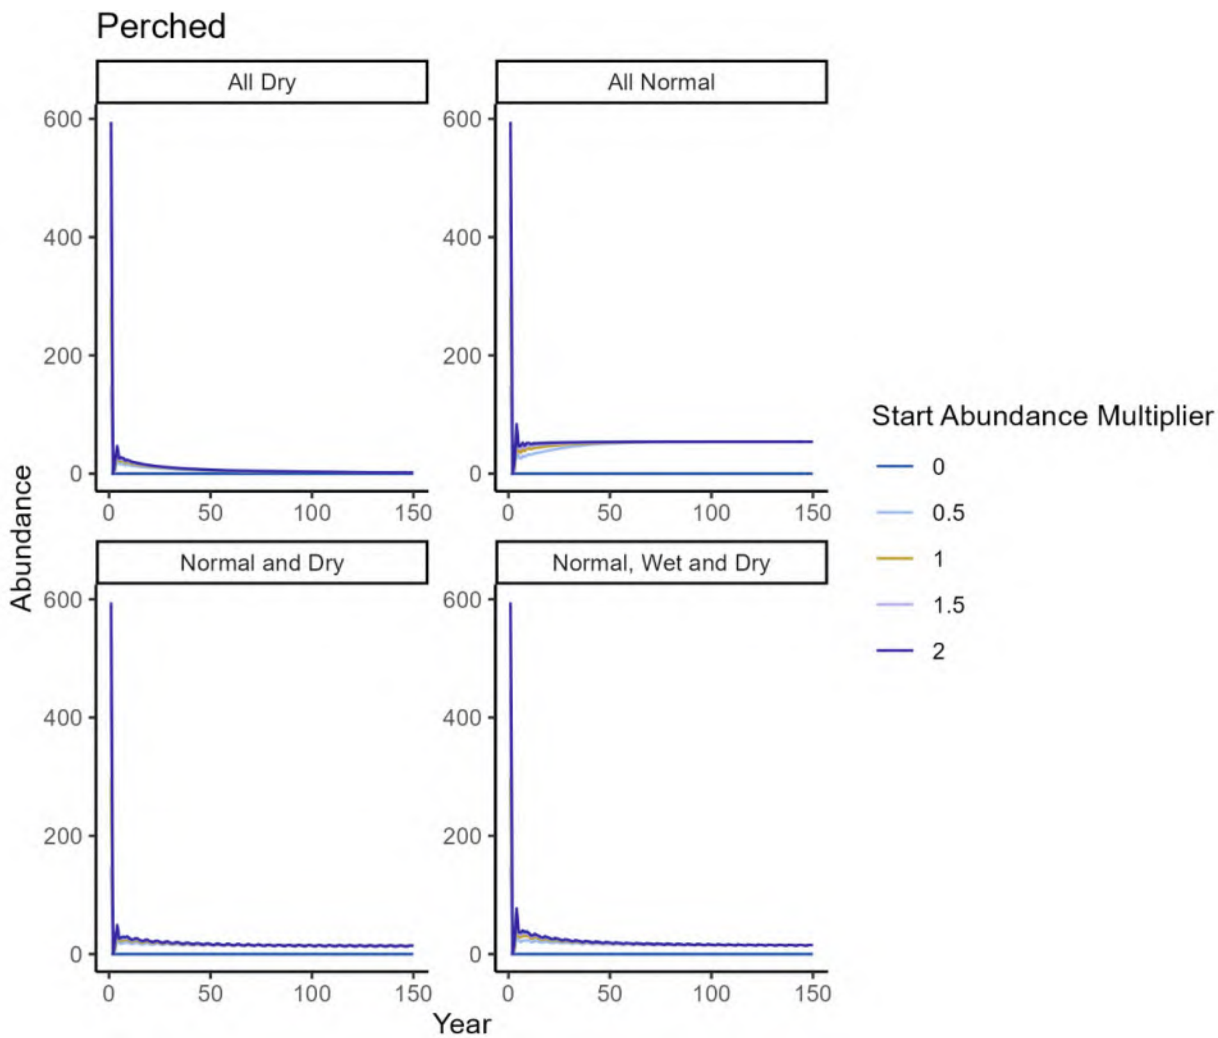
- Multiplier 0: Anadromous Start Abundance = 0, Resident and Perched Start Abundance = 0
- Multiplier 0.5: Anadromous Start Abundance = 500, Resident and Perched Start Abundance = 500
- Multiplier 1: Anadromous Start Abundance = 1000, Resident and Perched Start Abundance = 1000
- Multiplier 1.5: Anadromous Start Abundance = 1500, Resident and Perched Start Abundance = 1500
- Multiplier 2: Anadromous Start Abundance = 2000, Resident and Perched Start Abundance = 2000

Figure 1. Vary starting abundances, all life histories simulation: anadromous population trajectory using default fecundities of 1,000 eggs for resident and perched life histories and 2,000 eggs for anadromous life histories



Notes: See Figure 1 notes for multiplier ranges.

Figure 2. Vary starting abundances, all life histories simulation: resident population trajectory using default fecundities of 1,000 eggs for resident and perched life histories and 2,000 eggs for anadromous life histories



Notes: See Figure 1 notes for multiplier ranges.

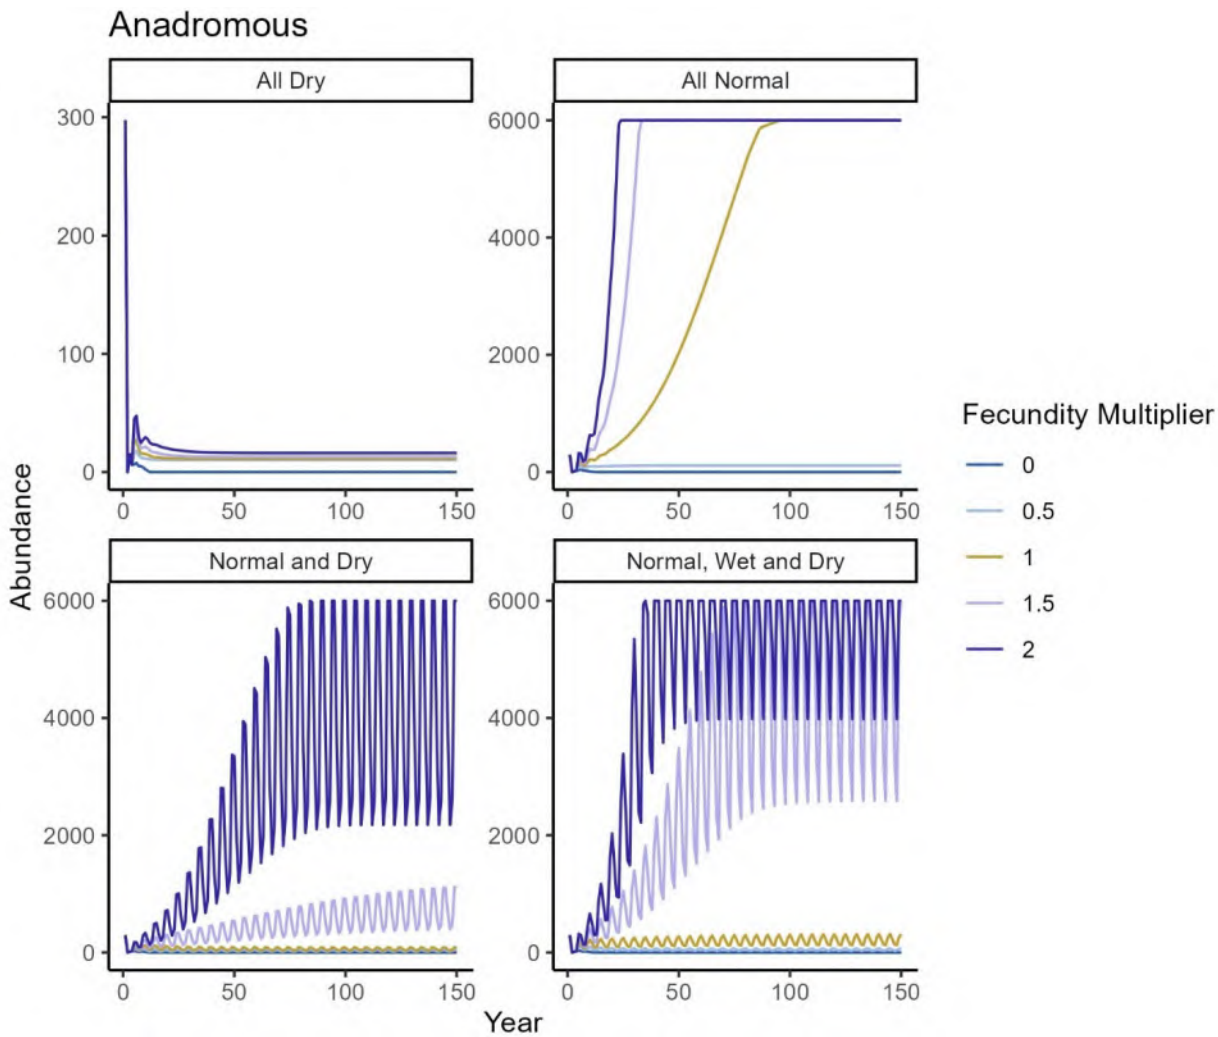
Figure 3. Vary starting abundances, all life histories simulation: perched population trajectory using default fecundities of 1,000 eggs for resident and perched life histories and 2,000 eggs for anadromous life histories

4.2.2 Vary Fecundity Simulations

4.2.2.1 Varying Fecundity for All Life History Groups

4.2.2.1.1 Effect on Anadromous Abundance

The effect of varying fecundity on model predicted ending abundance of anadromous adults depended on the environmental conditions of that model run (Figure 4). Under all dry conditions (top left panel in Figure 4), over- or under-estimation of the fecundity parameters for all three life histories had a relatively small impact on the model predicted average anadromous population abundance, because the model predicted average abundance is small regardless of fecundity. Under normal conditions (top right panel in Figure 4), overestimating the fecundity parameters increases the rate of population increase but has no impact on model predicted ending abundance, because abundance is limited by the carrying capacity parameter. However, underestimating anadromous fecundity resulted in sharp reductions in model predicted ending abundance. Under normal and dry conditions (bottom left panel in Figure 4), if the default fecundity parameter estimate is an overestimate for each of the life history groups, it will have little impact because the model predicted ending abundances are already so low. However, if the current fecundity parameter estimate is below the true value, the model substantially underestimates the population abundance. Under normal, wet, and dry conditions (bottom right panel in Figure 4), if the current fecundity value is overestimated it will have little impact (populations are already very small), but if it is underestimated, the model may severely underpredict anadromous population abundances.



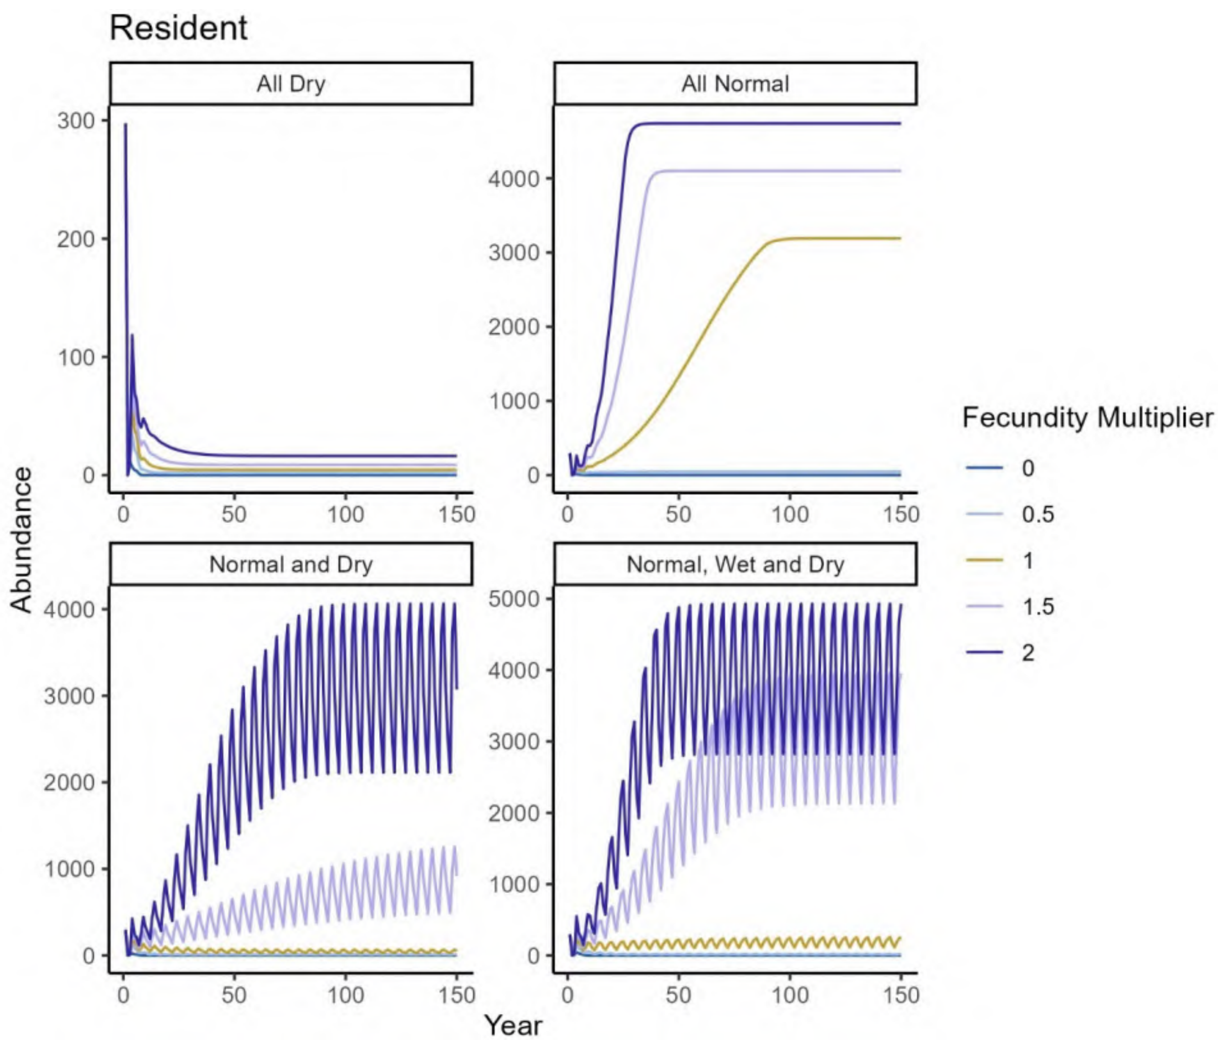
Notes: Starting population abundances were 1,000 for all life histories.

- Multiplier 0: Anadromous Fecundity = 0, Resident and Perched Fecundity = 0
- Multiplier 0.5: Anadromous Fecundity = 1000, Resident and Perched Fecundity = 500
- Multiplier 1: Anadromous Fecundity = 2000, Resident and Perched Fecundity = 1000
- Multiplier 1.5: Anadromous Fecundity = 3000, Resident and Perched Fecundity = 1500
- Multiplier 2: Anadromous Fecundity = 4000, Resident and Perched Fecundity = 2000

Figure 4. Vary Fecundity, all life histories simulation: anadromous population trajectory (averaged across watersheds) when varying fecundity for each life history group relative to the default of 2,000 for the anadromous population and 1,000 for the freshwater populations

4.2.2.1.2 Effect on Resident Abundance

The effect of varying fecundity on model predicted ending abundance of resident adults also depended on the environmental conditions of that model run (Figure 5). Under all dry conditions (top left panel in Figure 5), bias in the estimate of population fecundity would minimally impact model predicted ending freshwater population abundance. Under these conditions, extremely low population abundance reduces the potential variation in population abundance overall, and all scenarios result in near population collapse.



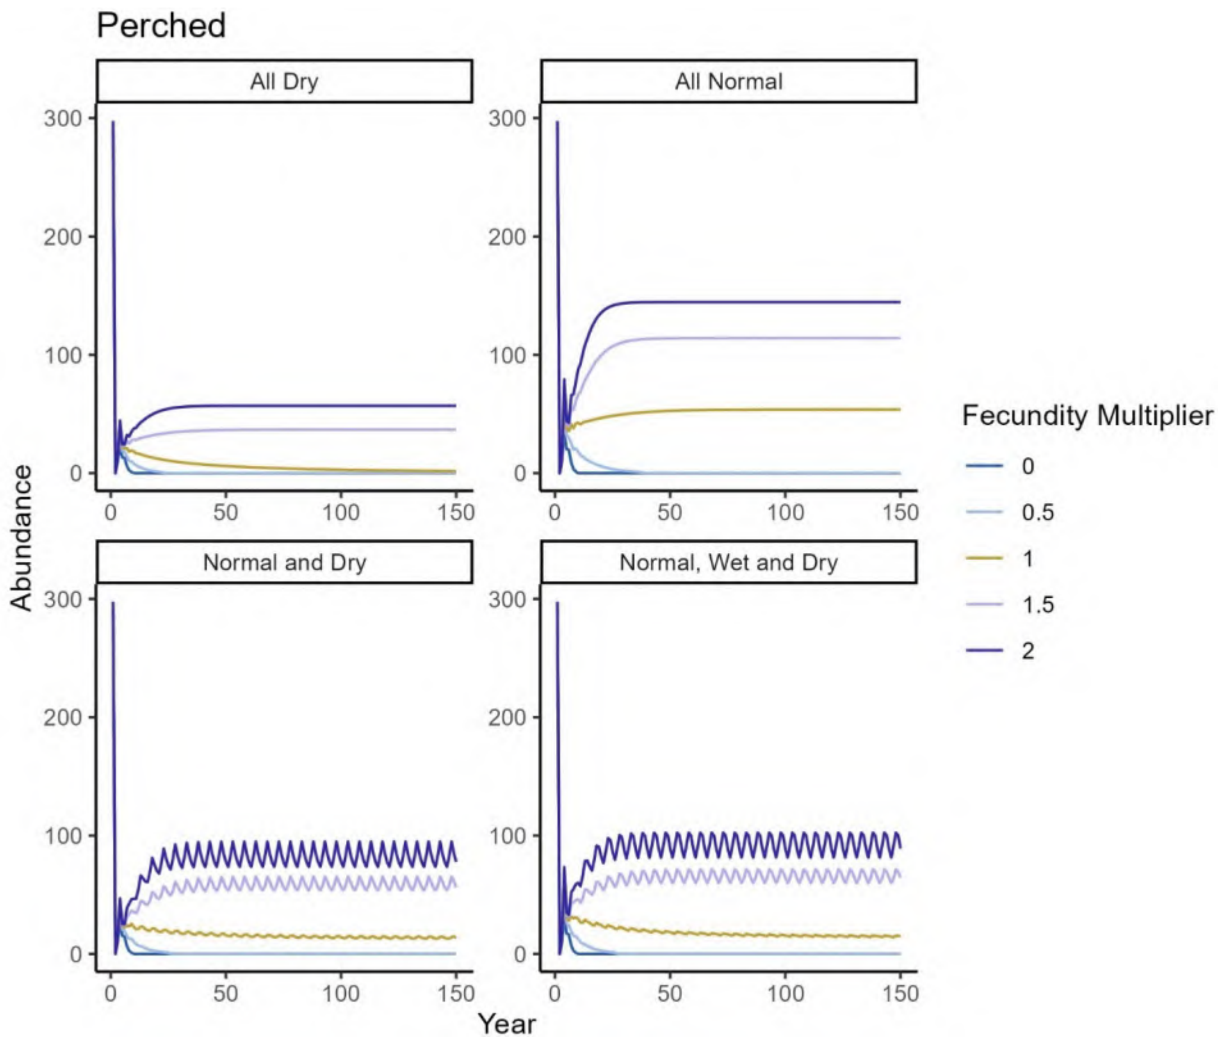
Notes: Starting population abundances were 1,000 for all life histories. See Figure 4 notes for multiplier ranges.

Figure 5. Vary fecundity, all life histories simulations: resident population trajectory (averaged across watersheds) when varying fecundity relative to the default of 1,000 for freshwater life histories and 2,000 for anadromous life histories

Under all normal conditions (top right panel in Figure 5), if current fecundity parameters are overestimated, the model would severely overestimate the model predicted ending population abundance. If the model's default fecundity is an underestimate, the model would only moderately underestimate the model predicted ending population abundance. Under normal and dry conditions (bottom left panel in Figure 5) or normal, wet, and dry conditions (bottom right panel in Figure 5), if the current fecundity value is an overestimate it would have little impact, but if the current fecundity estimate is an underestimate the model could be drastically underestimating the model predicted ending abundance of the freshwater below barrier populations.

4.2.2.1.3 Effect on Perched Abundance

The effect of varying fecundity on model predicted ending abundance of perched adults was similar regardless of the environmental conditions of that model run (Figure 6). Generally, if the current perched fecundity is an underestimate, the impacts are more substantial on the average model predicted ending perched population abundance than if it is an overestimate. If the default perched population fecundity is overestimated, these populations are already relatively low, so the difference is small. If it is an underestimate, the model will underestimate the perched population size potentially substantially (though at a declining rate as the degree of underestimation increases).

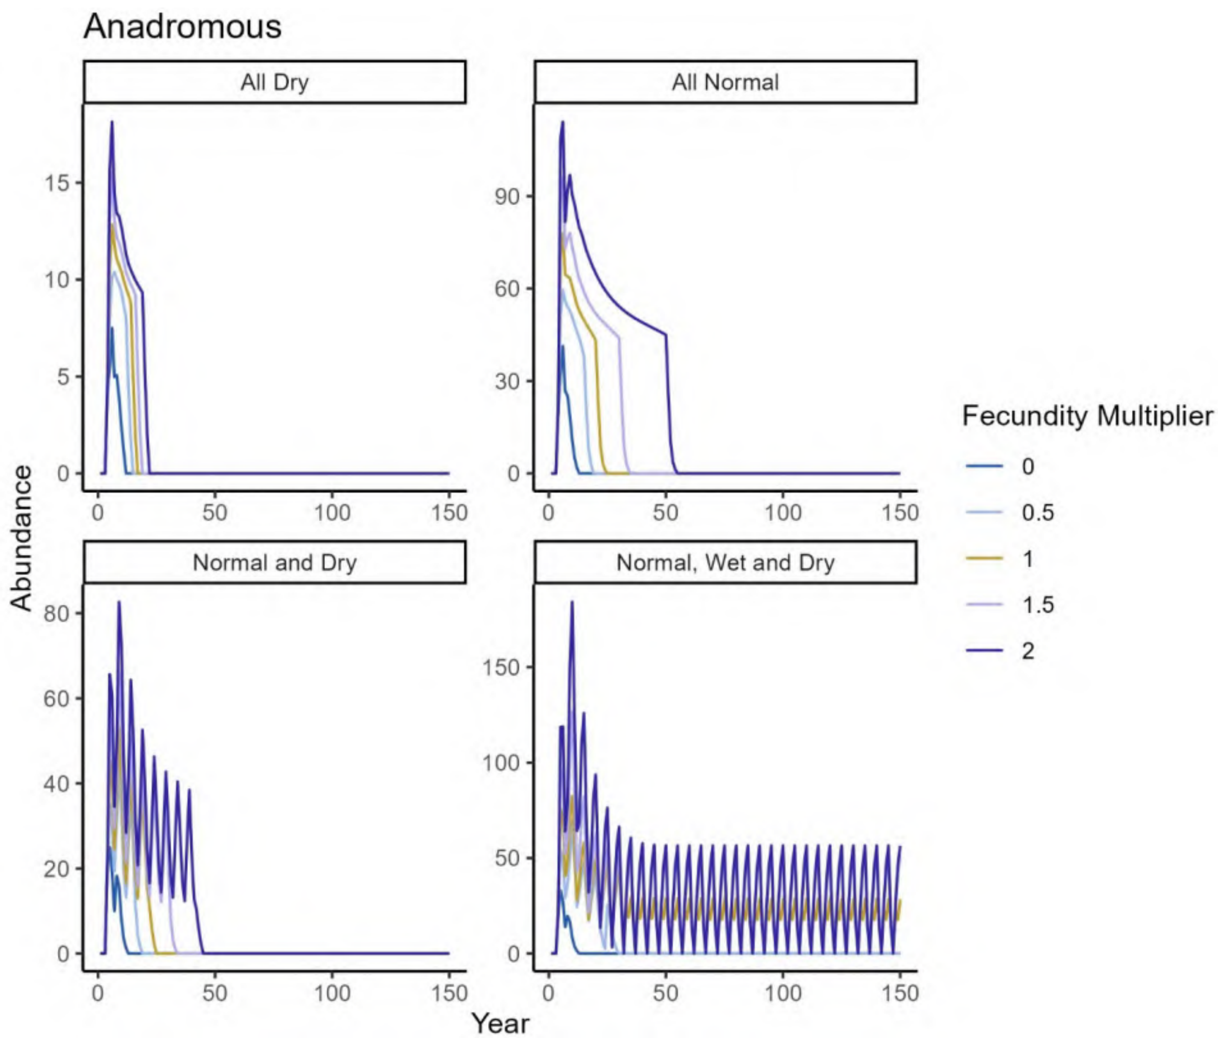


Note: Starting population abundances were 1,000 for all life histories. See Figure 4 notes for multiplier ranges.

Figure 6. Vary fecundity, all life histories simulations: perched population trajectories (averaged across watersheds) when varying fecundity relative to the default of 1,000 eggs for freshwater life histories and 2,000 eggs for anadromous life histories

4.2.2.2 Varying Fecundity for Resident and Perched Life History Groups Only

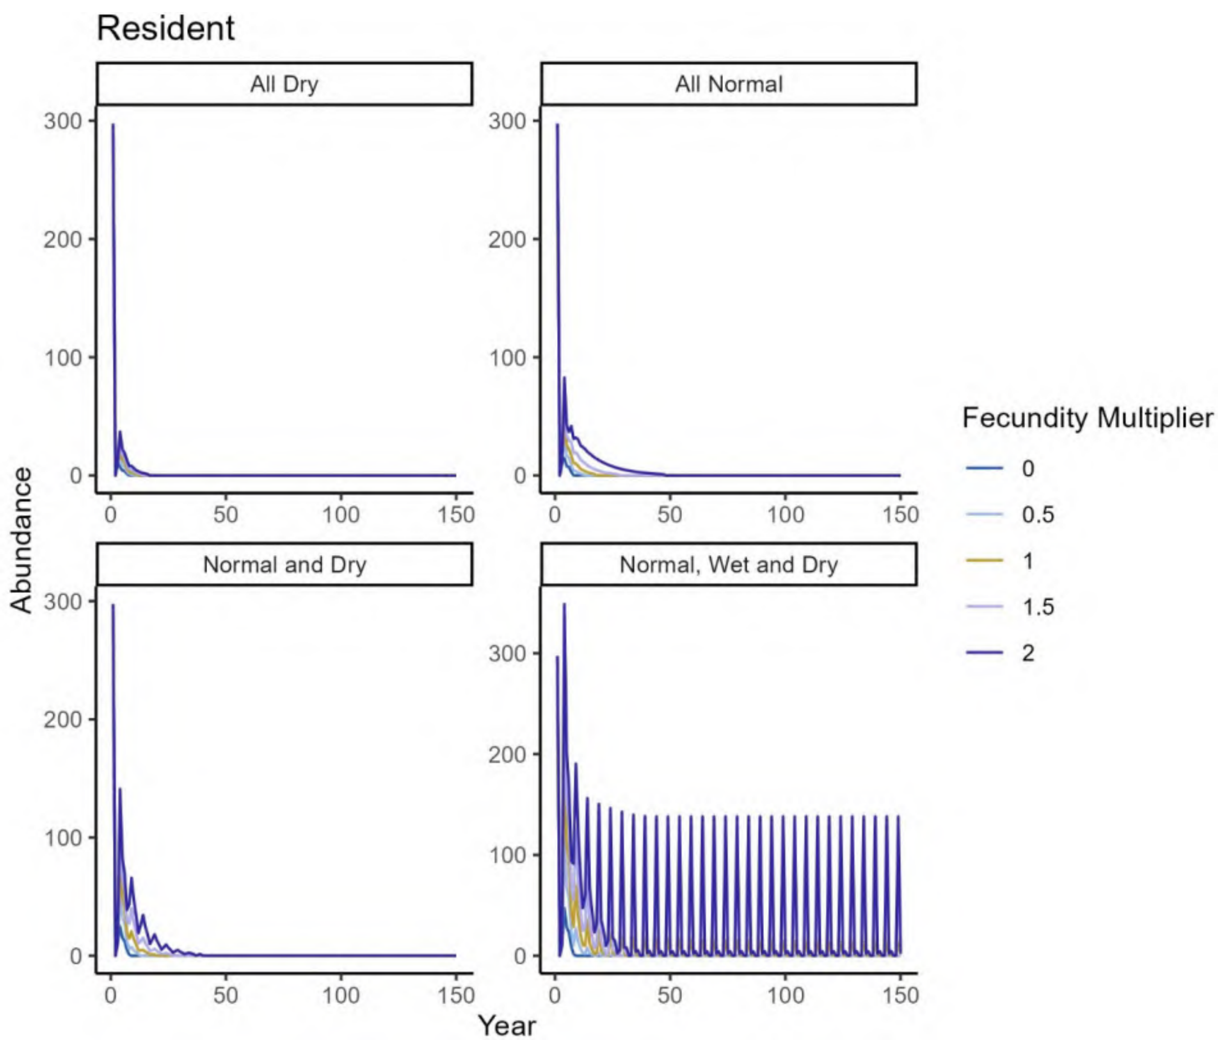
When anadromous adults are prevented from reproducing (i.e., fecundity is set to zero), under all dry, all normal, and normal and dry conditions, the anadromous population collapses (Figure 7). The freshwater populations are only capable of supporting the anadromous population when wet years are included, highlighting the importance of contributions from the perched population to downstream migrants in wet years (lower right panel in Figure 7). Even under these conditions, the model predicted average abundance is low at the end of the time series for the anadromous population.



Notes: See Figure 4 notes for multiplier ranges.

Figure 7. Vary fecundity, resident and perched spawners only simulation: anadromous population trajectory (averaged across watersheds) when omitting anadromous fecundity contributions and varying perched and below barrier freshwater fecundity relative to the default of 1,000 for all populations

As the anadromous population declines, so too does the below barrier freshwater population (Figure 8), which eventually collapses unless wet years that allow support from the perched population are included (bottom right panel in Figure 8). This is an indicator that the below barrier freshwater and anadromous populations appear to be supporting each other. A collapse in one facilitates a collapse in the other under climatic conditions that do not include wet years. Thus, only under the most optimistic conditions can freshwater populations maintain steelhead populations by themselves.



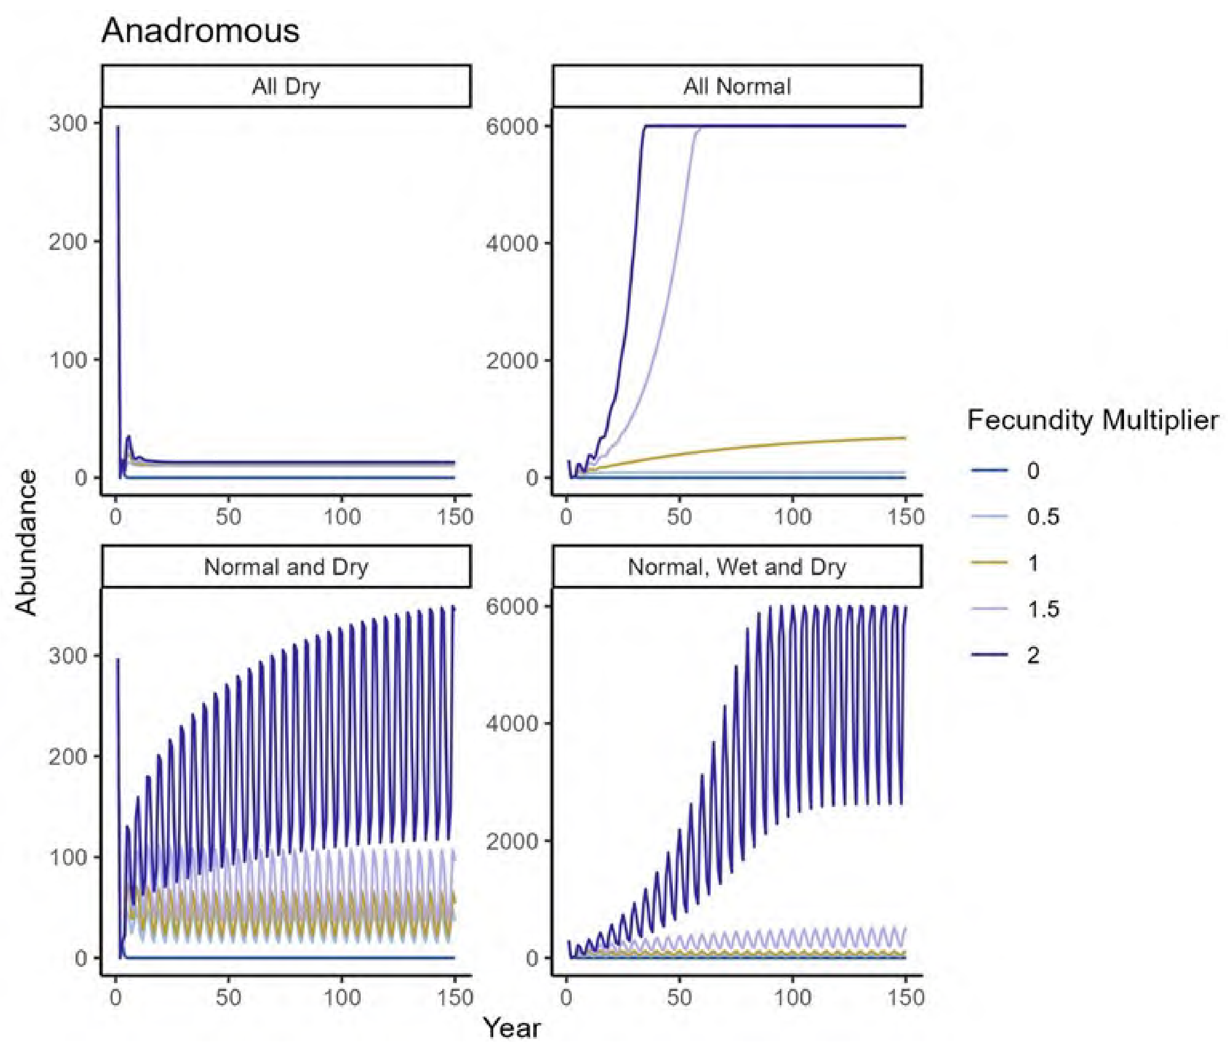
Notes:

- Multiplier 0: Anadromous Fecundity = 0, Resident and Perched Fecundity = 0
- Multiplier 0.5: Anadromous Fecundity = 0, Resident and Perched Fecundity = 500
- Multiplier 1: Anadromous Fecundity = 0, Resident and Perched Fecundity = 1000
- Multiplier 1.5: Anadromous Fecundity = 0, Resident and Perched Fecundity = 1500
- Multiplier 2: Anadromous Fecundity = 0, Resident and Perched Fecundity = 2000

Figure 8. Vary fecundity, resident and perched spawners only simulation: below barrier freshwater population trajectory (averaged across watersheds) when omitting anadromous fecundity contributions and varying perched and below barrier freshwater fecundity relative to the default of 1,000 for all populations

Varying Fecundity for Anadromous Life History Groups Only

Anadromous populations are capable of preventing their population's collapse without reproductive contributions from freshwater populations in all but the most adverse all dry scenario, but maintaining a robust population size required fecundity to be higher than the default model setting (Figure 9).



Notes:

- Multiplier 0: Anadromous Fecundity = 0, Resident and Perched Fecundity = 0
- Multiplier 0.5: Anadromous Fecundity = 1000, Resident and Perched Fecundity = 0
- Multiplier 1: Anadromous Fecundity = 2000, Resident and Perched Fecundity = 0
- Multiplier 1.5: Anadromous Fecundity = 3000, Resident and Perched Fecundity = 0
- Multiplier 2: Anadromous Fecundity = 4000, Resident and Perched Fecundity = 0

Figure 9. Vary fecundity, anadromous spawners only simulation: anadromous population trajectory (averaged across watersheds) when omitting resident and perched spawner fecundity contributions and varying anadromous fecundity relative to the default of 2,000 for all populations

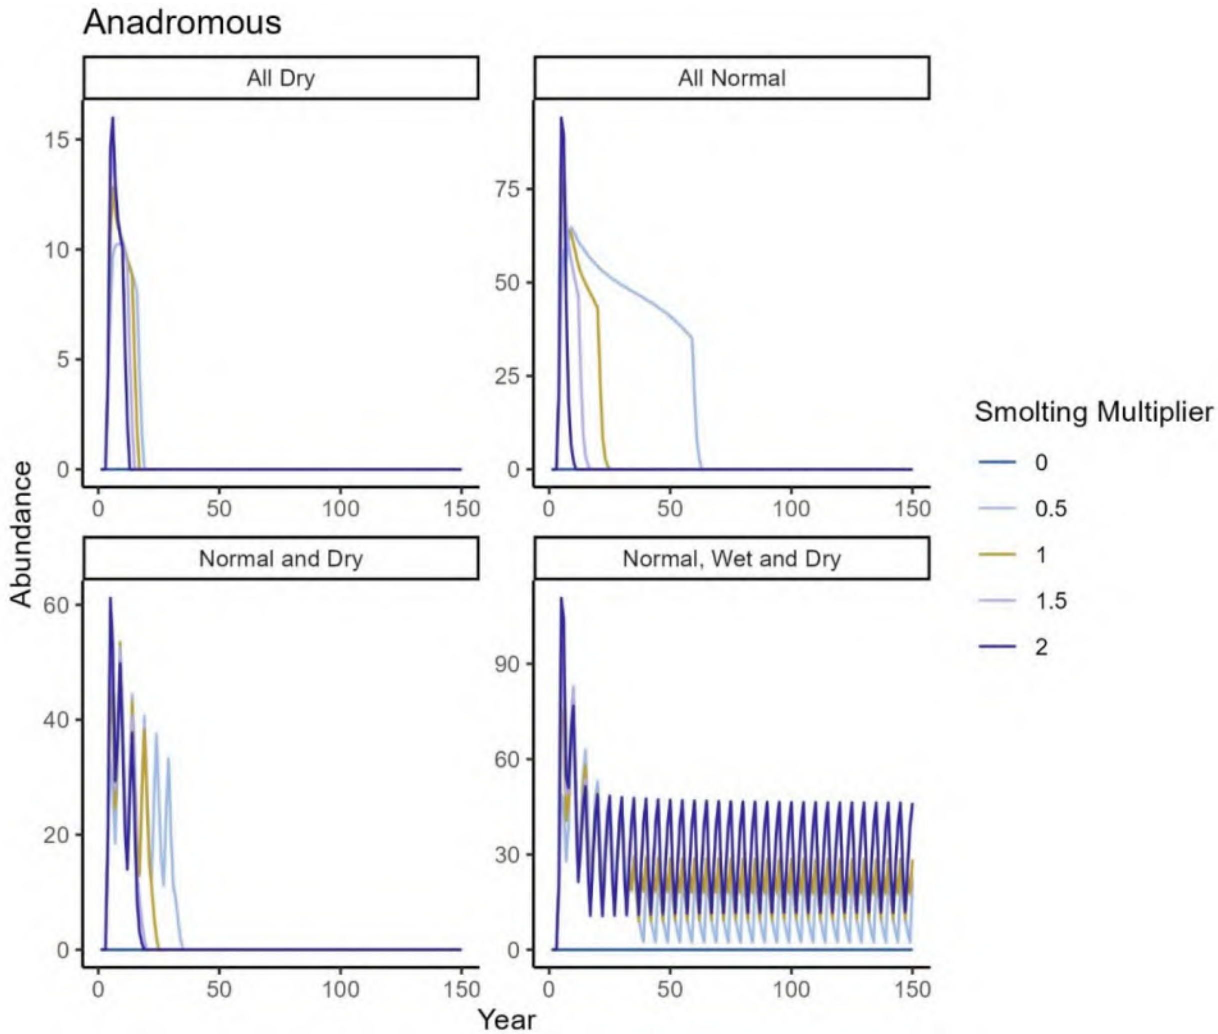
4.2.3 Anadromous Contribution Simulations (Vary Smolt Rate and Vary Ocean Survival)

4.2.3.1 Vary Smolt Rate

4.2.3.1.1 Resident and Perched Life History Groups Only

When anadromous fish starting population abundance and fecundity are set to 0, meaning all juvenile fish are offspring of resident adults, varying the smolt rate did not prevent the anadromous population from collapsing under all environmental conditions except the normal, wet, and dry conditions scenario

(Figure 10). Under these conditions, varying the smolt rate leads to a proportional difference in the model predicted ending abundance of anadromous adults. Regardless, even under these improbable future environmental conditions, the average anadromous population abundance is extremely low.



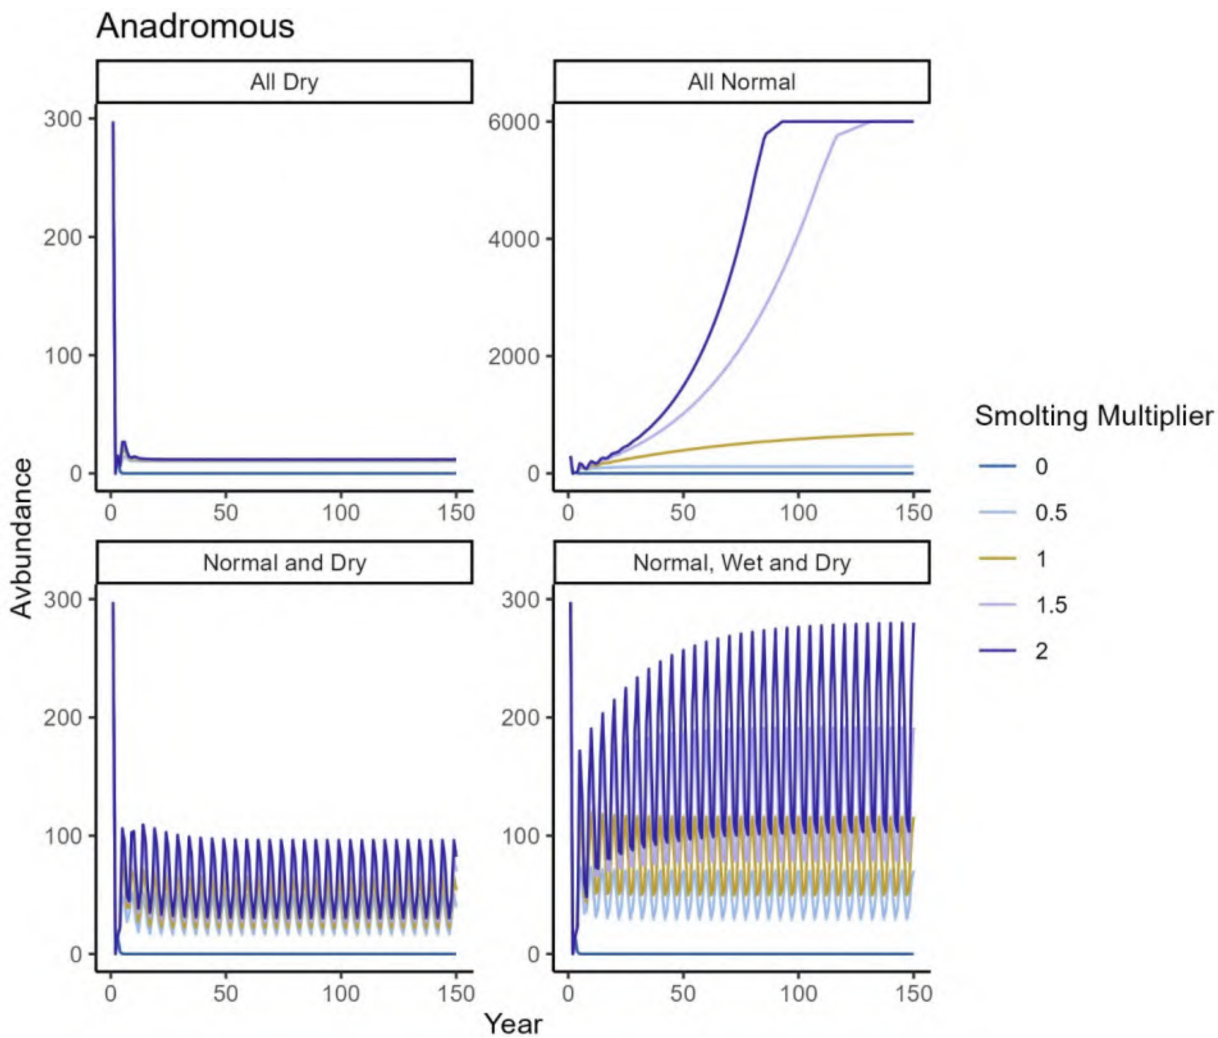
Notes:

- Multiplier 0: Smolt Rates (Ages 0 through 3) = 0
- Multiplier 0.5: Smolt Rates (Ages 0 through 3) = 0.075, 0.250, 0.125, and 0.125
- Multiplier 1: Smolt Rates (Ages 0 through 3) = 0.15, 0.5, 0.25, and 0.25
- Multiplier 1.5: Smolt Rates (Ages 0 through 3) = 0.225, 0.750, 0.375, and 0.375
- Multiplier 2: Smolt Rates (Ages 0 through 3) = 0.3, 1.0, 0.5, and 0.5

Figure 10. Vary smolt rates, resident and perched spawners only simulation: anadromous population trajectory (averaged across watersheds) when omitting anadromous fecundity contributions and varying smolt rates relative to the defaults of 0.15, 0.5, 0.25, and 0.25 for ages 0 through 3

4.2.3.1.2 Anadromous Spawners Only

Conversely, the anadromous population can maintain itself and avoid collapse without reproductive contributions from freshwater spawners in most environmental conditions, depending on the rate of smolting (Figure 11). Based on current default smolting estimates, the anadromous population is able to maintain itself in all tested environmental sequences except the all dry sequence (top left panel in Figure 11). If smolt rates are higher than the default estimate, they are able to maintain a small population even in all dry years. Under other environmental conditions, the model predicted ending abundance varies with smolt rate. This effect is greatest under all normal year conditions (top right panel in Figure 11) and least under normal and dry year conditions (bottom left panel in Figure 11).



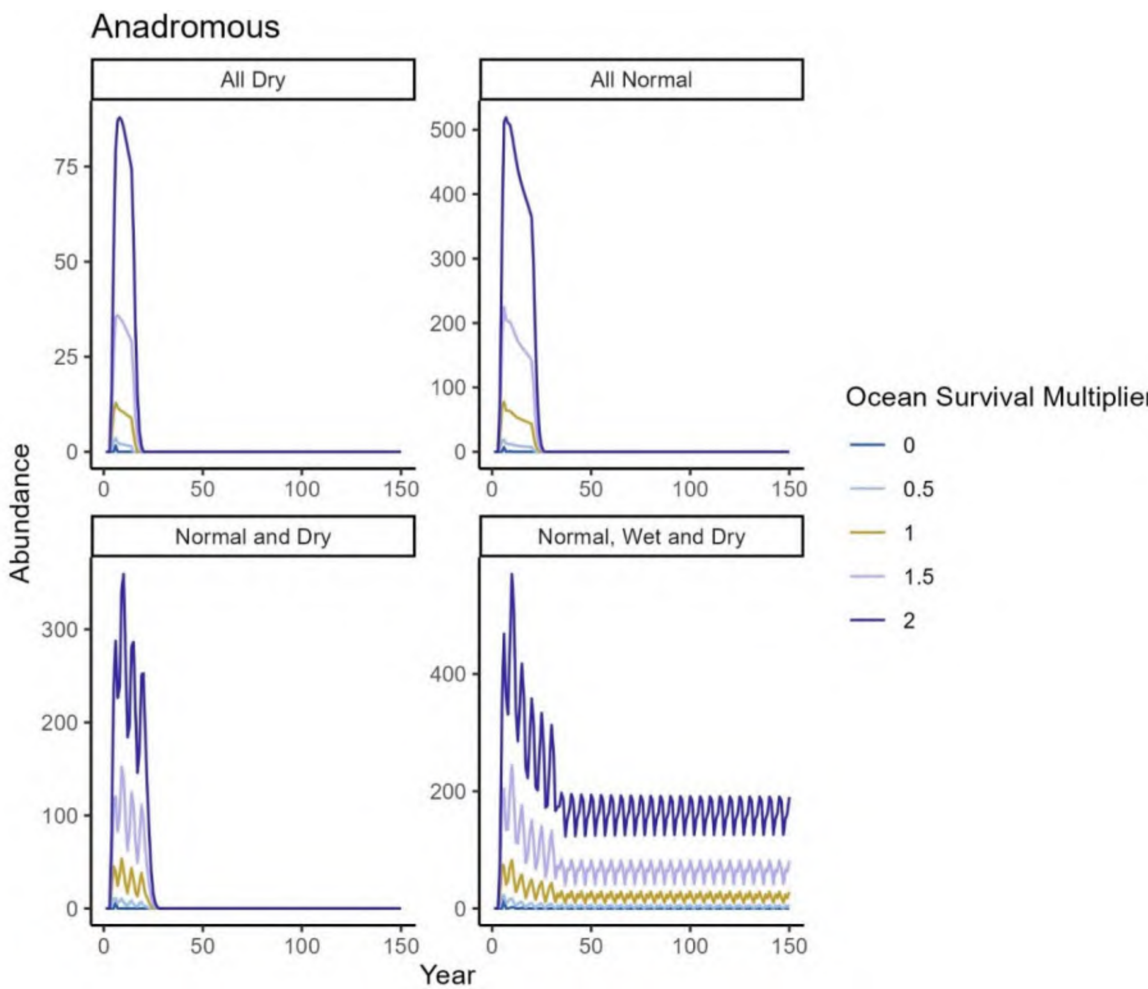
Notes: See Figure 10 notes for multiplier ranges.

Figure 11. Vary smolt rates, anadromous spawners only simulation: anadromous population trajectory (averaged across watersheds) when omitting freshwater fecundity contributions and varying smolt rates relative to the defaults of 0.15, 0.5, 0.25, and 0.25 for ages 0 through 3

4.2.3.2 Vary Ocean Survival

4.2.3.2.1 Resident and Perched Life History Groups Only

When excluding anadromous reproductive contributions, and only freshwater perched and below barrier fish are allowed to contribute to the population, varying ocean survival had a substantial impact on model predicted ending anadromous abundance in years and under conditions when the population did not collapse (Figure 12). However, the anadromous population collapsed within the first 25 years (essentially, during model burn-in) under all tested environmental conditions except under the normal, wet, and dry sequence (lower right panel in Figure 12). Under this scenario, if the current ocean survival estimate is an overestimate, the impact on model predicted average anadromous abundance is minimal because the population is already so low. However, if the current ocean survival parameter estimate is an underestimate, it would severely underestimate the true anadromous population abundance. This scenario of 1 in every 5 years being wetter than average is improbable when most climate change projections predict the drier environmental condition to become more common. Given that the resident and perched populations could not support an anadromous population under the less favorable drier scenarios (and even under all normal years), it is unlikely the resident and perched populations alone will be able to contribute meaningfully to anadromous spawner populations in the future.



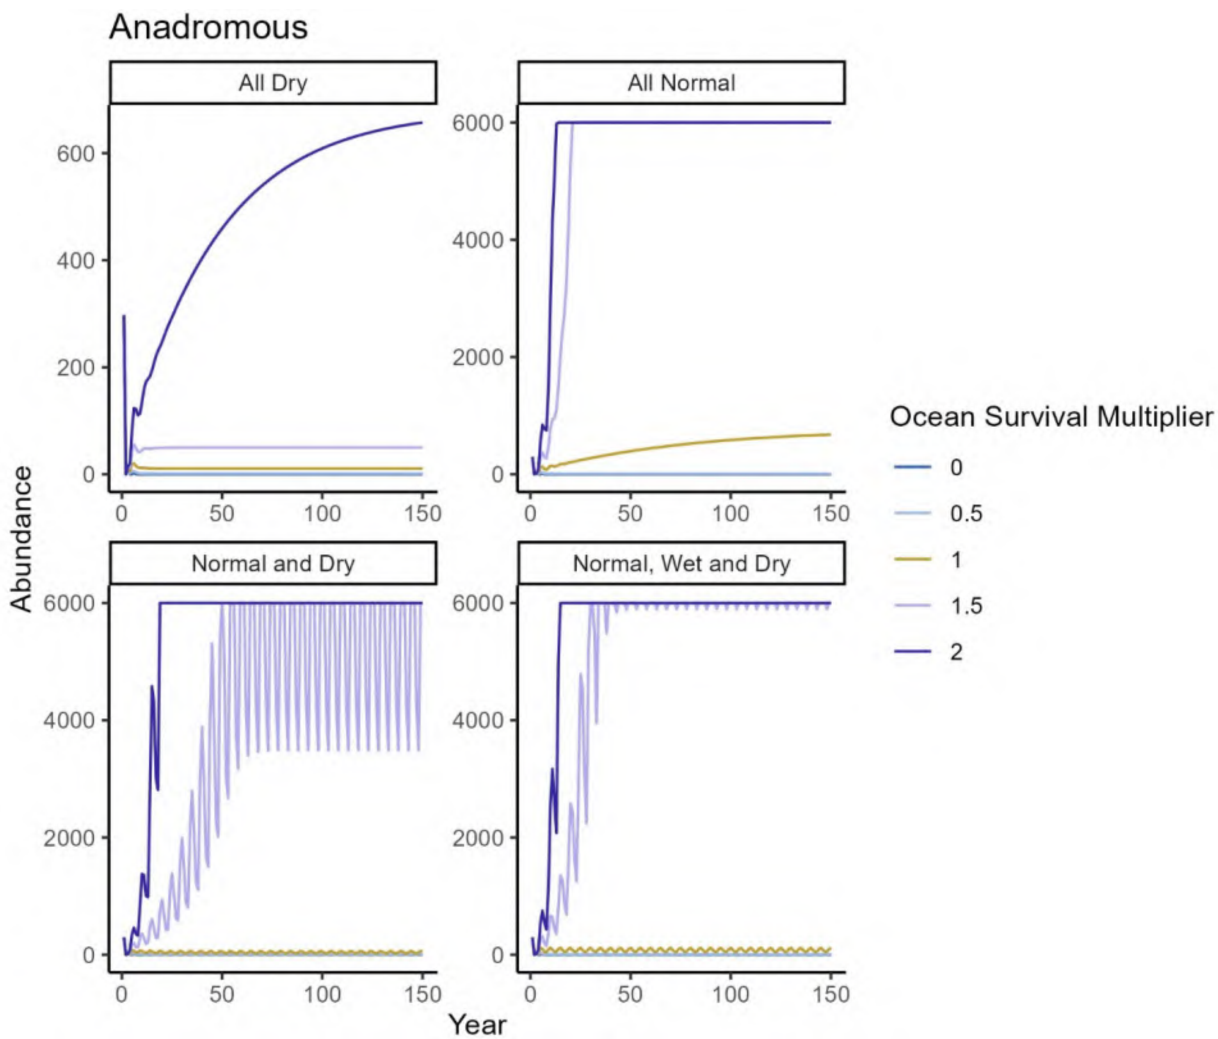
Notes:

- Multiplier 0: Smolt Rates (Ages 1 through 7) = 0
- Multiplier 0.5: Smolt Rates (Ages 1 through 7) = 0.30 0.18 0.15 0.15 0.15, and 0.20
- Multiplier 1: Smolt Rates (Ages 1 through 7) = 0.6, 0.36, 0.3, 0.3, 0.3, and 0.4
- Multiplier 1.5: Smolt Rates (Ages 1 through 7) = 0.90 0.54 0.45 0.45 0.45, and 0.60
- Multiplier 2: Smolt Rates (Ages 1 through 7) = 1.20 0.72 0.60 0.60 0.60, and 0.80

Figure 12. Vary ocean survival, resident and perched spawners only simulation: anadromous population trajectory (averaged across watersheds) when omitting anadromous fecundity contributions and varying ocean survival relative to the age specific defaults 0.6, 0.36, 0.3, 0.3, 0.3, and 0.4 for ages 1 through 7

4.2.3.2.2 Anadromous Spawners Only

Once again, the anadromous population can maintain itself without perched and resident reproductive contributions under all four tested environmental sequences depending on the ocean survival rate (Figure 13). However, under all environmental conditions, when ocean survival is at or below current default estimates, the population is frequently at or close to collapse without reproductive contributions from resident and perched spawners. Only if ocean survival rates are higher than the current default estimate, would anadromous populations alone be capable of supporting themselves without perched and resident reproductive contributions.



Notes: See Figure 12 notes for multiplier ranges.

Figure 13. Vary ocean survival, anadromous spawners only simulation: anadromous population trajectory (averaged across watersheds) when omitting resident and perched fecundity contributions and varying ocean survival relative to the age specific defaults 0.6, 0.36, 0.3, 0.3, 0.3, and 0.4 for ages 1 through 7

4.3 Conclusions from Model Sensitivity Analysis

- Importance of Starting Abundances
  - The CFS LCM is robust to starting abundances, provided they are not extremely small (less than 50% of default starting abundance estimates).
  - Populations fared better with more normal or wet years compared to more dry years.
- Importance of Fecundity
  - Model results are sensitive to fecundity estimates, particularly if fecundity is truly higher than the current default estimate.
  - If only resident and perched populations contribute to reproduction—even if the fecundity for these freshwater life history groups was set to be double the default model value—the anadromous population is predicted to collapse or to oscillate near collapse, and the freshwater life history groups also decline, due to less support from the alternate life history groups.
  - Only if anadromous fecundity was 50-100% greater than the default model estimate could anadromous spawning support a robust anadromous population without reproductive support from resident and perched spawners.
  - Model simulations lend support for the conclusion that maintaining robust populations of both anadromous steelhead and freshwater populations of both resident and perched fish will be important to maintaining viability of the anadromous life history.
  - Fecundity is an influential model parameter that is sensitive to parameterization
  - Four Peaks recommends that future model iterations prioritize accurate estimation of fecundity, particularly for anadromous spawners, to minimize uncertainty around this parameter; this may include age-specific fecundity rates that account for different numbers of year spent maturing in the ocean and kelting.
- Importance of Smolt Rates
  - If relying solely on resident contributions, the anadromous population persisted only in the presence of wet years with moderate to high smolt rates; even under these conditions, ending anadromous population abundances were still low.
  - However, under most environmental conditions, the anadromous population could sustain itself without reproductive support from resident and perched spawners, provided smolt rate is moderate to high.
  - Smolt rates were less influential than ocean survival rates on model predicted ending abundance.
- Importance of Ocean Survival
  - Resident and perched spawners alone (i.e., assuming no anadromous spawners) could support an anadromous population only under the improbable future scenario of high ocean survival and an environmental regime that included 1 of every 5 years being wetter than average.
  - Similarly, although anadromous spawners alone could support an anadromous population, under all conditions but the highest ocean survival scenarios, the model predicted ending anadromous population abundances were low if resident and perched spawners did not contribute to reproduction.

- Thus, high ocean survival could contribute to population viability regardless of the mixture of adult spawner life histories, but maintaining spawner populations of all life histories will provide the best chance of maintaining a robust population of the anadromous life history over the long term.
- Ocean survival was an influential parameter that is sensitive to parameterization.
- Four Peaks recommends that future research prioritize accurate estimation of age specific ocean survival to minimize uncertainty around this parameter, despite its difficulty.

Cramer Fish Sciences’ Technical Memorandum

Southern California Steelhead Lifecycle Model

Draft technical memo on the lifecycle model developed by Cramer Fish Sciences for Association of California Water Agencies

Background

California Trout petitioned the California Fish and Game Commission (Commission) to list Southern California steelhead (*Oncorhynchus mykiss*; SCS) as endangered under the California Endangered Species Act (CESA). The petitioner defined SCS as all *O. mykiss*, including anadromous and resident life histories, below artificial and natural complete barriers to anadromy from the Santa Maria River, San Luis Obispo County (inclusive) to the United States-Mexico Border. The petition states that remaining SCS populations are in danger of extinction within the next 25-50 years. It also states that based on available abundance estimates, presence/absence data, and various threats within SCS range, populations appear extremely depressed or extirpated, and remaining populations are likely in immediate danger of extirpation. Therefore, the petitioner requested the Commission list SCS as endangered under the CESA. The Commission found that the petition contains sufficient scientific information to indicate action may be warranted.

The current National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service (NMFS) recovery population viability goal for SCS is 4,150 spawners per year on average, based on a "random walk with drift" model (Lindley 2003) and parameterized using Central Valley field data (Boughton et al. 2007; Williams et al. 2016).The NMFS report acknowledges interchange between the anadromous and resident populations, but does not include these effects in their viability goal. Viability studies recognize that genetic exchange between resident and anadromous groups would lower extinction risks of both groups and interchange between resident and anadromous forms could have consequences when determining extinction risk. In fact, the recovery plan for SCS (NMFS 2012) specifically states that recovery of the distinct population segment (DPS) will require "…protection, restoration, and maintenance of habitats of sufficient quantity, quality, and natural complexity throughout the SCS Recovery Planning Area so that the full range of all life history forms of *O. mykiss* (e.g., switching between resident and anadromous forms, timing and frequency of anadromous runs, and dispersal rates between watersheds) are able to successfully use a wide variety of habitats in order to overcome the natural challenges of a highly variable physical and biological environment."
Therefore, it is important to assess if SCS extinction risk is sensitive to the details of the exchange between resident and anadromous life histories.

Model Purpose

The purpose of this work was to develop an adaptive lifecycle model that incorporates the proposed SCS listing population goals and allows for assessment of listing proposal improvements to better protect and manage SCS into the future. We developed and enhanced this model to simulate various recovery goals, strategies, and what-if scenarios that also allow managers to manipulate specific portfolio parameters to understand how changes to key vital rates might influence population trajectories, under explicit model assumptions. Specifically, this model can be employed to understand how strengthening or weakening portfolios, including residency in the proposed goals, or inclusion of above barrier populations, influences the implied probability of future SCS extinction risk.

A goal of the Southern California steelhead life-cycle model (SCS LCM) is to better understand the influence of source-sink dynamics between resident and anadromous *O. mykiss* on population viability (i.e., the 100-year extinction risk) for Southern California DPS populations, as well as the potential for long-term Southern California DPS persistence as a whole. The model is meant to simulate various strategies including ratios of anadromy and residency, and various migration strategies that support each *O. mykiss* life stage along entire watershed corridors accessible to anadromous fish (including assumption of fish passage at artificial barriers). This exercise facilitates identification of key strategy alternative(s), and combinations thereof, and how they might best be implemented to support viable SCS population goals over various time periods (e.g., 20, 50, 100 years). To support this endeavor, this model was developed to simulate population trajectories under various SCS life history strategies (e.g., anadromy, residency, potamodromy, etc.), including management of a healthy SCS population into the future. This undertaking follows a general process for determining what combination of resident and anadromous strategies may support viable SCS population goals.

This lifecycle modeling effort incorporates well accepted modeling components to test key hypotheses and assumptions related to the proposed listing unit for SCS. It includes components of the Lindley (2003) and other models, such as the NOAA Habitat Assessment and Restoration Planning model (Jorgensen et al. 2021) or the Shiraz model (Scheuerell et al. 2006) which both rely on a multistage Beverton-Holt function to model production across the entire salmonid life cycle under a unified conceptual framework. In addition, the model is fully transparent, and is linked to well accepted functional relationships from population dynamics theory with the best available data to drive model outcomes. The model is also adaptable, so that as new data are available or outcomes from future hypotheses tests are received, they can be incorporated into the model. To facilitate collaborative stakeholder engagement in exploring model scenarios, we developed a user-friendly dashboard (or graphical user interface). By linking a state-of-the-science modeling framework with a user-friendly front-end, this effort provides a fully transparent, accessible modeling tool for assessing the conservation status of SCS and offers sound scientific guidance to discuss strategies and scenarios for future SCS population viability. This graphical user interface (GUI) provides a transparent tool with the ability to easily adjust parameters relevant to conservation.

Model Development Methods

Task 1: Gather and review background information

The goal of Task 1 was to gather and review background information relevant to the construction of a life cycle model (LCM) for Southern California steelhead (SCS). A literature search (e.g., Google Scholar, Web of Science) was used to identify, screen, and compile relevant biological information to inform and parameterize the life cycle model with empirical data where available. The following keywords were used to conduct the initial literature search:

> Steelhead **OR** *Oncorhynchus mykiss* **OR** *O. mykiss* **OR** Rainbow trout
> **AND** California **OR** Southern California **OR** Santa Maria **OR** Santa Ynez **OR** Santa Clara **OR** San Gabriel **OR** Santa Ana **OR** San Luis Rey **OR** San Diego **OR** Piru Creek **OR** Sisquoc River **OR** Cuyama River **OR** Ventura River **OR** San Mateo Creek **OR** Los Angeles River
>
> **AND** Egg **OR** egg-to-fry **OR** larval **OR** emergent fry **OR** fry **OR** parr **OR** smolt **OR** adult **OR** spawning **OR** spawner **OR** half-pounder **OR** resident **OR** resident life history **OR** life history
>

Objective 1.1 Quantify minimum viable steelhead population

Source-sink dynamics is an established ecological theory which describes how dispersal between habitats of variable quality and connectivity can explain patterns in population viability and persistence (i.e., long-term viability) over large spatial or temporal scales (Pulliam 1988; Dias 1996). In source-sink theory, population viability can be maintained via the exchange of organisms between geographically separate meta-populations in a network of “source” populations (exhibiting positive population growth rates), and “sink” populations (exhibiting negative population growth rates). Habitat fragmentation, in part due to installation of dams and diversions, has blocked upstream migration in much of Southern California and has geographically divided *O. mykiss* spawning populations by life-history types (Boughton et al. 2015; Fejtek 2017; Abadía-Cardosa et al. 2016). Non-anadromous *O. mykiss* frequently co-occur with anadromous *O. mykiss* within the same watersheds in Southern California and can co-occur within the same below-barrier stream reaches, but are often geographically separated where fish passage barriers block migration, thus forming potential source (above barrier) and sink (below barrier) populations. Genetic analyses of microsatellite data have concluded that geographically separated *O. mykiss* populations within the same watersheds (above and below barriers) are closer relatives than populations between watersheds (Clemento et al. 2009; Leitwein et al. 2017). Closer genetic distance and potential for population spillover implies that resident populations above barriers could mediate population viability and long-term persistence.

A viable individual population is defined in the 2012 Southern California Steelhead Recovery Plan (hereafter; the SCS Recovery Plan) as having less than a 5% risk of extinction due to threats from demographic, environmental, and genetic variation over the next 100 years (NMFS 2012). Similarly, a viable distinct population segment (DPS) is defined by a sufficient number of **spatially dispersed**, yet **genetically connected** populations to maintain long-term (1000+ years) persistence and evolutionary potential (McElhany et al. 2000; NMFS 2012). A "random-walk-with-drift" model was used in the SCS Recovery Plan to determine population-level biological recovery criteria based on a minimum viable population (MVP) size of individual populations for SCS steelhead, as well as DPS-level recovery criteria based on viable individual minimum populations within each Biogeographic Population Group, and other considerations (Lindley 2003; Boughton et al. 2007; NMFS 2012). This approach recommended an MVP of 4,150 annual anadromous spawners, on average, for an individual population. However, the approach assumed no empirical data were available for specific local populations, thus it is highly generalized and may not be well suited for every watershed (Boughton et al. 2007). A NMFS (2016) report also proposes using a 20-year window to evaluate the population, as opposed to simple annual check (Figure 1). Further, due to a lack of data on life history polymorphism and inability to estimate the magnitude of a "rescue effect" between resident and anadromous populations, the prescriptive criteria assumed that such a rescue effect is negligible; a 100 percent anadromous fraction was required of the mean annual run size criterion, and resident spawner life history variants (i.e., Rainbow Trout) were not considered in the MVP size criteria developed by NMFS (Boughton et al. 2007).

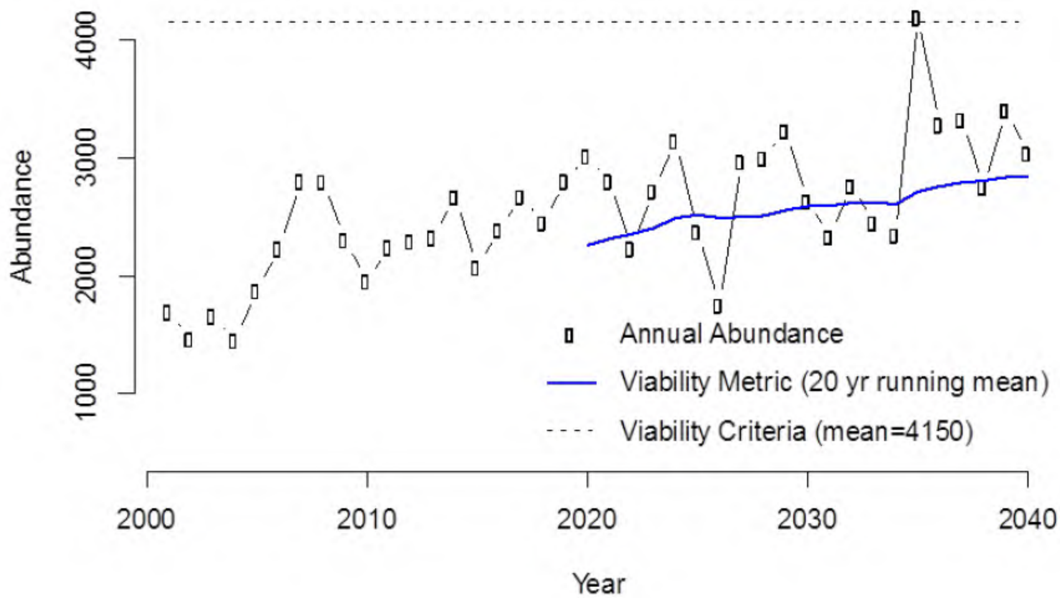

Figure 1. Concept of viability metric and a viability criterion applied to a hypothetical population. Figure 2 in NMFS 2016.

Objective 1.2 Identify population goals and dispersal amongst key watersheds

There is limited data to speak to potential and historical population demographics of steelhead in each watershed and basin. The literature has provided wide variations in estimated contributions to the population between basins. For example, Titus et al. (2002) estimated historical capacity of 20,000 for the Santa Ynez, but only 4,000 for the Ventura. Henke (1994) proposed between 7,000—9,000 for the Santa Clara, while Clanton and Jarvis (1946) only estimated 2,000—2,500 for the Matilija. Similarly, we have observed that smolt rates differ between basins, which again emphasizes the need to model the resident life history simultaneously to the anadromous population (Sogard et al. 2012). Although the SCS population is currently thought to be under capacity, these estimates help us determine the potential watershed population goals, the allocations that could contribute to the spawners needed for a MVP, if 4,150 anadromous spawners are appropriate and how resident spawners should be accounted for (e.g., less than a 100 percent anadromous fraction recovery criterion).

Objective 1.3 Southern California steelhead life history

Cramer Fish Sciences previously compiled data on 92 steelhead population parameters across 10 categories from 23 unique sources for the Suisun Creek LCM (Central California Coast DPS). Where data and parameter estimates from the Southern California DPS were not available, we used the information compiled for the Suisun Creek LCM to help inform parameterization. The following information on life histories, periodicity, and other demographic parameters from the literature review were completed as part of this project.

Migration and Spawning

Migration and spawn timing data from the Mokelumne River (California Central Valley DPS) shows entry into freshwater beginning in October and extending through April the following year, and spawning ranging from December to April (Figure 2) (East Bay Municipal Utility District, unpublished data).

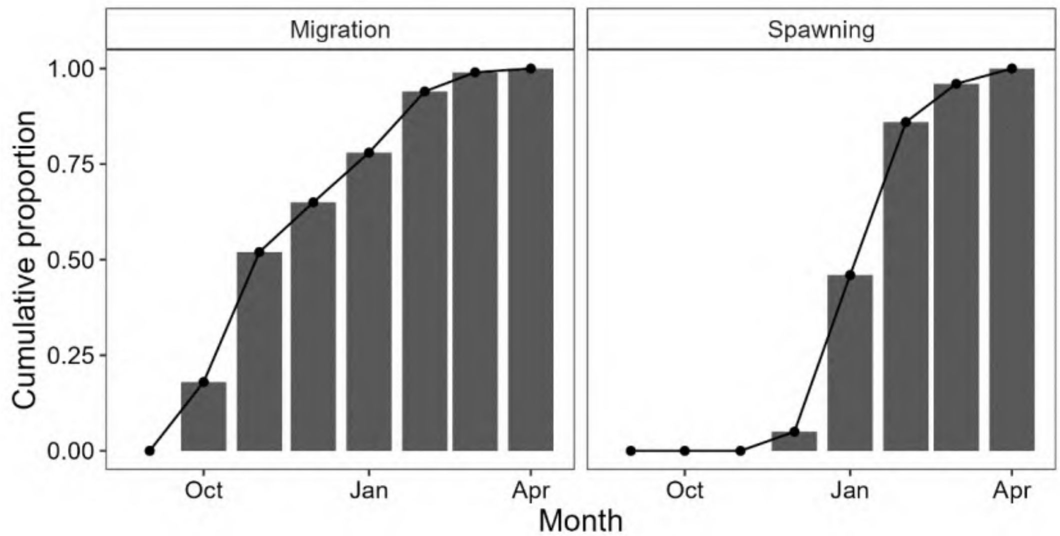

Figure 2. Cumulative proportion curves for migrating and spawning steelhead adults from the Mokelumne River (East Bay Municipal Utility District, unpublished data).

We assumed a 1:1 spawner sex ratio (Shapovalov and Taft 1954). Egg deposition assumes an average of 1,000 eggs per female, an optimistic estimate determined through a power-law relationship with fork length (Figure 3) (Shapovalov and Taft 1954).

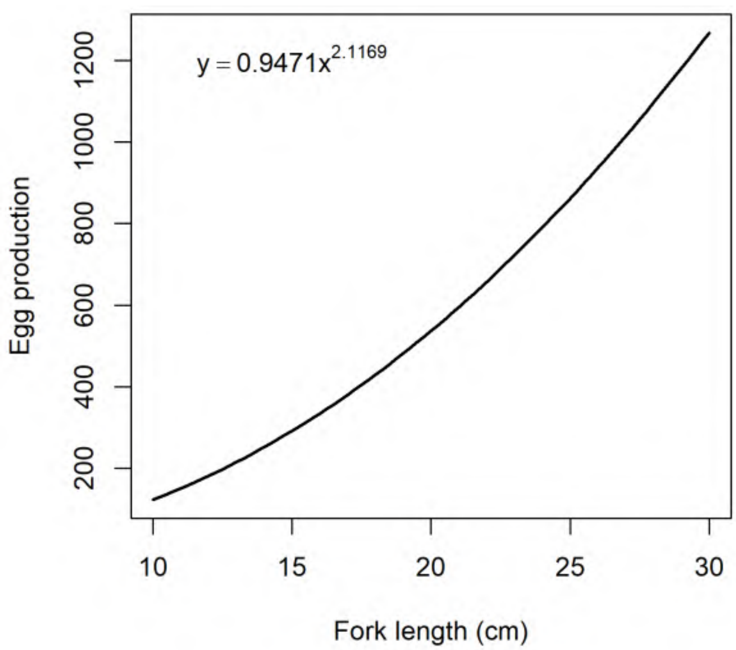

Figure 3. Relationship between female fork length and egg production from Scott Creek, CA (Shapovalov and Taft 1954).

The model assumes 1 redd per female spawner at an average size of 1.78 m^2 (SE = 0.14) (Gallagher and Gallagher 2005). Total spawning capacity is calculated within the model using a spawning habitat ratio requirement of 4:1 (Burner 1951); however, this calculation will assume uniform distribution of suitable spawning habitat within streams. We applied a hockey-stick function to limit spawners to spawning capacity and omit superposition or competition for spawning habitat.

Straying

According to Thorpe (1994), salmonids are famous for their homing precision and straying is usually regarded as a failure of individuals to achieve the population norm. However, without straying there would be no salmonid populations throughout much of their present range, as much of that area has been colonized by modern salmonids over the past 8000–15000 years (Thorpe 1994). Straying not only occurs in episodic pulses but also at relatively low and steady levels. Straying is important because it enables salmonids to colonize new areas over a relatively short time frame (Hendry et al. 2004; Quinn 2005), and is the behavior that has allowed salmonid populations over the course of thousands of years to colonize their existing habitats (Quinn 1984; Hendry et al., 2004), including establishing themselves within decades of glacial retreat (Milner and Bailey 1989; Milner and York 2001). Homing and straying are typically viewed as population-scale phenomena. According to Sandercock (1991), a return to the parental spawning ground provides a mechanism for enhancing survival by the repeat usage of good sites. Straying can also be a survival mechanism in that it may protect against the loss of an entire stock due to some environmental catastrophe in the home stream (Lieder 1989). It is clear that straying buffers against spatial and temporal variation in habitat quality and allows colonization of new habitats (Milner and Bailey 1989; Burger et al. 1997; Quinn et al. 2001; Stephenson 2006). Adults generally return to their natal streams to spawn, and stray rates are low in steelhead compared to other *Oncorhynchus* spp. (Westley et al. 2013). Straying rate estimates range from 1.2% to 11% in the Columbia River Basin and along the Oregon Coast (Keefer et al. 2005; Westley et al. 2013). The majority of straying occurs in non-natal tributaries within natal watersheds, however long-distance straying events (100 – 650km) can occur (Schroeder et al. 2001; Donohoe et al. 2021). Annual straying rates for the model were set to 5% (2.5% in either direction along the coast) with options to select values between 0% and 10%. For more detailed straying information, see the Natal Straying section withing Task 3.

Incubation

An estimated 97.5% of deposited eggs are successfully fertilized (Briggs 1953; Shapovalov and Taft 1954). Egg-to-fry survival estimates have ranged from 30% to 90% under controlled laboratory conditions (Shapovalov 1937; Shapovalov and Taft 1954) and 15% to 100% for steelhead in an in-river study of Central Valley steelhead (Merz et al. 2004); however, *in situ* estimates have been observed as low as 12% (Bley and Moring 1988). By default, egg-to-fry survival was set to 65%, based on populations in Humboldt County, CA (Briggs 1953), with options to reduce the survival to as low as 15% or as high as 90%.

Juvenile Rearing, Growth, and Outmigration

Juvenile steelhead typically rear in freshwater for 1 to 3 years after emergence (Shapovalov and Taft 1954). Estimated spring (February – April) growth for age-0 steelhead in Topanga Creek, CA is at least 24 mm and annually 61mm average (0.17 mm/day; Bell et al. 2011). These results are similar to estimates from the California Central Coast (Scott and Soquel creeks; Sogard et al. 2012) and but less than observed in the California Central Valley (Mokelumne and American rivers) (Sogard et al. 2012; Merz et al. 2016). Inhospitable conditions (e.g., low flows, high temperatures) in southern California can force early outmigration or encourage greater dependence on coastal lagoons or nearshore rearing (Moyle et al. 2008). Higher productivity in lagoons often leads to more rapid growth and increased survival (Smith 1990; Bond 2006; Hayes et al. 2008, 2011). A tagging study and analysis of scale morphology of returning adult steelhead in Scott Creek, CA showed that between 87% and 95.5% returning adults had reared in the lagoon, despite comprising less than half of the initial downstream outmigrants (Bond et al. 2008). For watersheds that form seasonal freshwater lagoons, an estimated 20% of fish are trapped when lagoons form and experience higher growth for an additional ~6 months, or until sandbars erode reconnecting the stream to the ocean (Smith 1990; Bond 2006; Hayes et al. 2008, 2011). Higher growth rates confer a survival advantage onto lagoon-reared fish by increasing their size at ocean entry (Bond 2006). Specific daily growth rates (% change in FL/day) for steelhead in Scott Creek, CA was 0.36 (SD = 0.20) in the lagoon compared to 0.06 (SD = 0.09) in riverine only individuals (Figure 4).

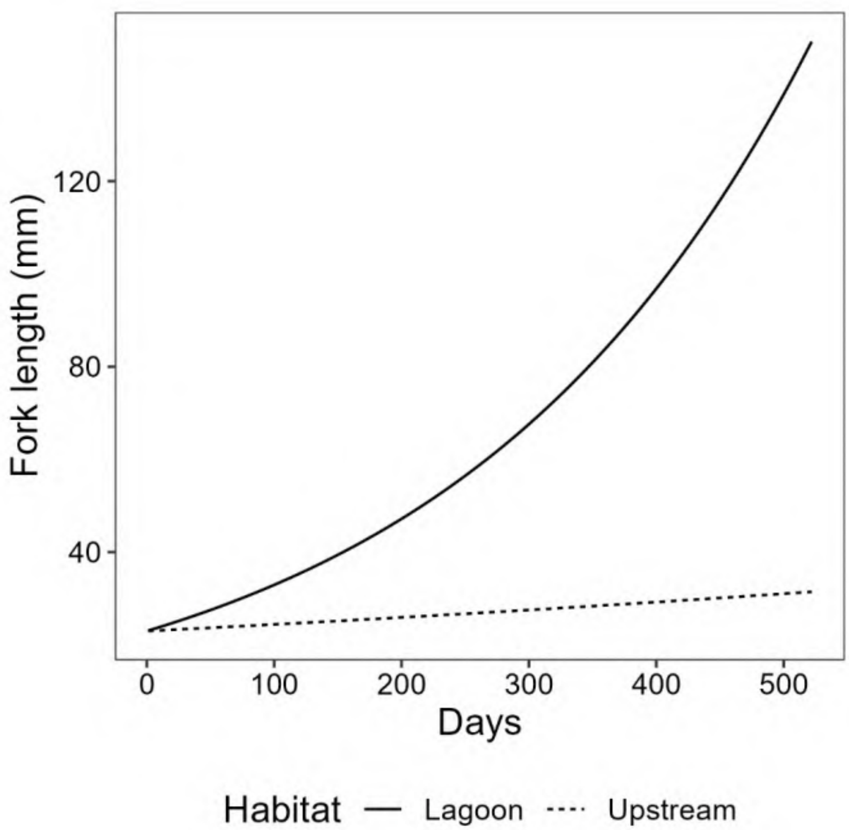

Figure 4. Simulated growth curves for juvenile steelhead rearing in lagoon and upstream habitats in Scott Creek, CA based on specific daily growth rates (Lagoon = 0.36 %FL/day, Upstream = 0.06%FL/day) presented in Bond (2006).

Data from an Above-Barrier Perched Resident population (see model framework for description) in middle Piru Creek also suggests populations dominated by younger age classes, with more than 90% of observations consisting of year-0 and year-1 juveniles and virtually no observations of age-5 or older individuals (Figure 5).

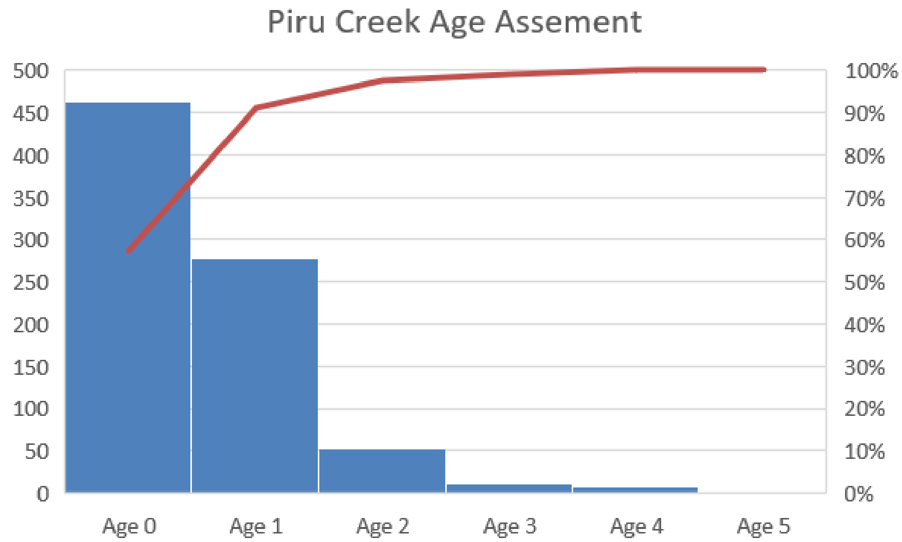

Figure 5. Age distribution of sampled fish at Piru Creek. United unpublished data from pre-implementation study.

Task 2: Identify and review available relevant models

Cramer Fish Sciences reviewed existing salmonid life cycle modeling frameworks to prepare for the development of the SCS Life Cycle Model. The purpose of reviewing existing modeling frameworks was to ensure the SCS LCM would be on par with the current existing life cycle modeling methods for Pacific salmonids. We drew heavily on examples from the Pacific Northwestern United States, where Chinook and steelhead life cycle models feature prominently in state and federal population management programs. The following sections summarize each of the different life cycle models we considered during development of the SCS Life Cycle Model.

Objective 2.1: Summarize/Evaluate general strengths and weaknesses

We identified four models previously built to evaluate salmonid population responses to management actions. Except for the Suisun Creek LCM, the models we reviewed were built specifically for Pacific Northwest rivers. Nonetheless, these LCMs provide a good general framework considering salmonid life cycle modeling.

Random Walk with Drift Model (Lindley, 2003)

The “random walk with drift” model (hereafter: the “Lindley model”), based on Lindley (2003) and parameterized with Central Valley field data for the 2007 and 2016 NMFS population viability criteria analyses (Boughton et al. 2007; Williams et al. 2016), is essentially a state-space model based on a simple exponential growth function (Equation 1).

Equation 1

$$N_t = N_{t-1}e^{r+\epsilon_t}$$

Where the number of individuals at time (N_t) is a function of the number of individuals in the previous time step (N_{t-1}) and the mean population growth rate (r). Random deviates (ϵ_t) in the mean population growth rate are added in each time step to create the "random walk" effect in population growth trajectories to represent process variance. The model can be modified (see Boughton et al. 2007) to simulate density-dependent growth.

State-space models are powerful modeling frameworks in ecology which link one or more mechanistic models (the process model) to an observation model (Patterson et al. 2008). The process model is usually some deterministic process which predicts the future state of some variable based on its current state. The predictions from the process model are then weighted by the likelihood of some observed data. Because the observation model essentially estimates the probability of observing some state, conditional on the 'true' state determined by the process model, state-space models offer a powerful way to handle uncertainty. Additionally, the process model can be parameterized with environmental data, providing an avenue for encoding realistic biological relationships into the model.

The Lindley model is broadly applicable; however, there are several drawbacks to the model and to the state-space modeling approach that should be considered. First, its process model (Equation 1) is fairly simple and assumes that population growth is not sensitive to age or stage-structure (Lindley 2003). Furthermore, the Lindley model does not consider alternative life history strategies (e.g., resident Rainbow Trout) or environmental influences. The Lindley model is capable of being expanded to include additional states and covariates; however, such an endeavor would require an advanced modeling approach and may include nested models. The parameters in state-space models (and in nested models generally) can be difficult to estimate, requiring maximum likelihood estimation (MLE) or a Bayesian Markov Chain Monte Carlo (MCMC) sampler (Patterson et al. 2008). Building the SCS LCM as a state-space model would provide a powerful tool for interrogating SCS population dynamics while explicitly incorporating uncertainty into the model; however, the current template (Lindley model) needs to be modified considerably to be able to incorporate all the desired life history stages, stage-transition processes, and environmental covariates. Thus, the model is liable to increase in complexity quickly and require advanced parameter estimation techniques (e.g., Kalman filtering, Bayesian MCMC).

Shiraz Model

The Shiraz model is based on a Beverton-Holt mortality function which adjusts life stage survival depending on life-stage specific relationships with environmental parameters. Movement between life stages can either follow an ideal free distribution to maximize fitness in the population, based on relative survival rates in different habitats, or occur in fixed fractions of the population. The Shiraz model also simulates hatchery operations and harvest policy and provides estimates of four important population criteria: abundance, productivity, spatial structure, and life-history diversity. Furthermore, it provides a general modeling framework upon which many subsequent life cycle models have been at least partially based, including the NOAA HARP model and the CFS Nooksack LCM. The Shiraz model has several limitations, some of which have been addressed in subsequent modeling efforts, including a limited ability to model restoration actions, inability to predict increases in habitat quality as a consequence of increased habitat quantity, and reliance on fixed values for several model parameters. The Shiraz model therefore provides a foundation for model conceptualization, particularly in ensuring that the SCS LCM will be capable of properly assessing steelhead population viability.

NOAA Habitat Restoration Planning Model

The NOAA Habitat Restoration Planning (HARP) model is a multistage population dynamics model developed for Chinook, Coho, and steelhead in Pacific Northwest rivers that includes spatial, habitat, and life history components (Jorgensen et al. 2021). The NOAA HARP model receives spatial data as input, which are processed into habitat data layers to inform salmonid life-stage capacity and productivity relationships. Capacity is defined as the number of individuals a given habitat can support while productivity refers to population growth parameters such as fecundity and survival. Life-stage specific capacities and productivities depend on the habitat conditions present within the study system and may take on either fixed values or adjust dynamically according to either statistical or theoretical relationships to habitat-related variables (e.g., temperature, flow, fine sediments). The ensemble of data and functional relationships are then used to simulate cohort-based population growth on an annual time-step.

The model tracks annual cohorts as they move through individual subbasins and transition through various life-stages. The freshwater component of the model included nine life-stages: upstream migration, spawning, egg incubation, and age-0+ through age-2+ summer and winter rearing (Figure 6). Alternative pathways for smoltification occur within the model at age-1, age-2, or age-3 at which point smolts are subject to a delta-bay survival multiplier. Delta-bay survival is difficult to estimate *in situ*. Therefore, delta-bay productivity was back-calculated from smolt-to-adult return (SAR) rates reported in the literature by dividing the SAR by the age-weighted average ocean survival estimate.

Iteroparity in steelhead is handled in the NOAA HARP model by determining the cumulative respawn rate, determined by the product of the kelt rate, the ocean reconditioning rate, and the return rate.

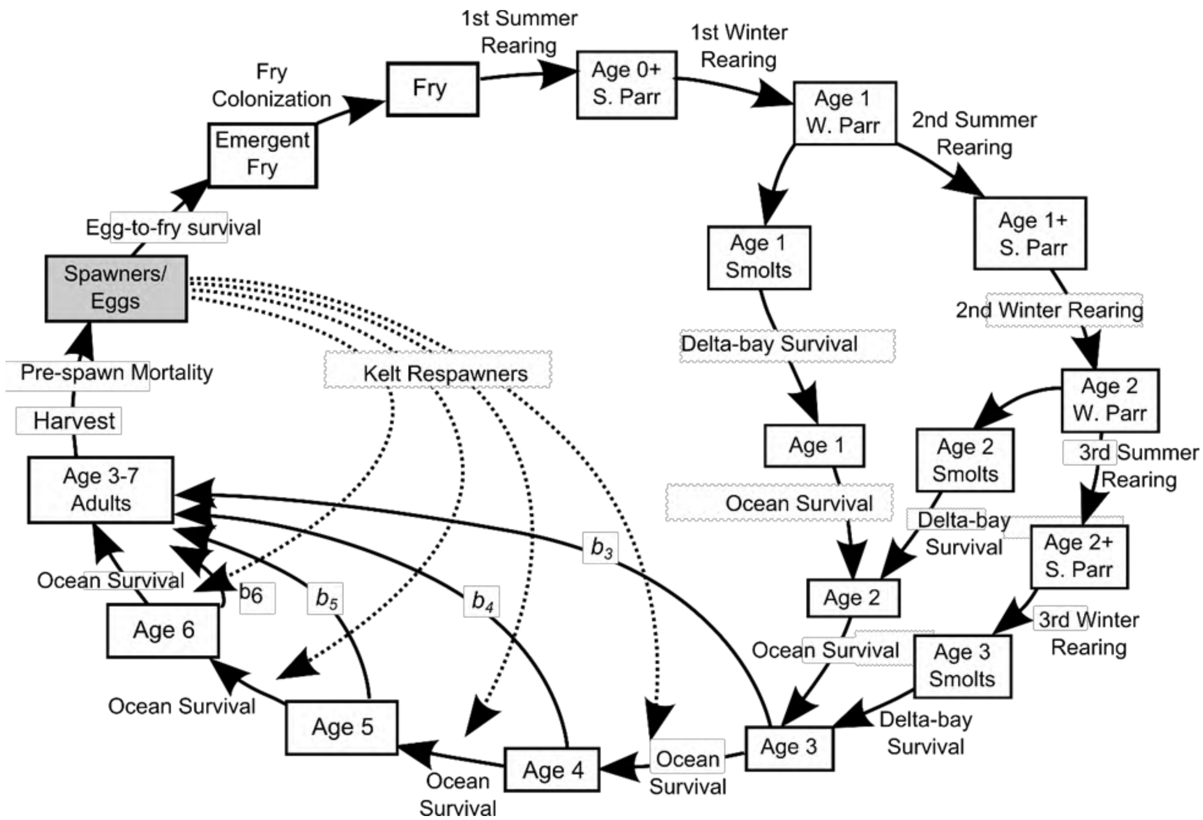

Figure 6. Steelhead life-cycle diagram developed for the Chehalis River basin (Jorgensen et al. 2021).

The NOAA HARP Model does not include a resident life history component and the capacities and productivities are tuned to reflect Pacific Northwest stream conditions. Nonetheless, it is one of the most comprehensive and transparent steelhead life cycle models and offers a solid frame upon which to base the SCS LCM.

CFS Nooksack Life Cycle Model

The CFS Nooksack LCM is largely based on the NOAA HARP model but includes several unique features. First, it utilizes a weighted connectivity matrix to account for spatial variation among populations and life stages, which allows for variable outmigration speeds in juveniles. Second, the CFS Nooksack LCM incorporates a highly detailed spatial layer of its watershed delineated at the reach scale for freshwater, estuary, and nearshore habitats. The CFS Nooksack LCM differs from the NOAA HARP model in the level of spatially explicit habitat detail built into the model, which allows for precise evaluation of life-stage specific population dynamics in response to habitat management scenarios and allows for complex population behaviors like straying. It is worth noting that this functionality was added to address specific issues observed within the Nooksack system that had previously been identified by regional experts and those familiar with the system.

CFS Suisun Creek Life Cycle Model

The CFS Suisun Creek Life Cycle Model is a cohort-based Steelhead LCM parameterized for a central California watershed. The focus was to determine the minimum spawning and rearing habitat requirements needed to support a viable steelhead population in using a life cycle model approach. The model was parameterized with data from nearby central California watersheds whenever possible, and helped to highlight data gaps that would limit / improve the modeling effort over time. The LCM was automated as both a workbook model in MS Excel, as well as an R Shiny application to facilitate use, and help highlight model behaviors (E.g., loss of a population cohort). The model is simplified, and lacks spatial components for spawning, incubation etc. and relies on coarse assumptions, omitting flow, season, and habitat quality. That being said, the components are well described and identify areas of potential enhancement. This model serves as a good example of a focused LCM used to explore specific questions about known (potential) limiting factors, like available habitat, and provides many data sources that will be relevant for this work.

Objective 2.2: Pull together useful pieces into the best model framework

Models are most useful when they are developed to address specific questions (Rose et al. 2011). It follows that the technical details of modeling (e.g., scale and complexity) must be informed by the question(s) being asked. To that end, the SCS LCM is being developed to shed light on two key questions; the first question is asked at a population scale, the second at the watershed or subbasin scale:

1. How much does freshwater residency (e.g., Rainbow Trout) contribute to the overall population dynamics of SCS?
2. How does connectivity and/or drought affect population dynamics?

Here, it is important to distinguish between **prediction** and **forecast** modeling and between **relative** and **absolute** results (see Rose et al. 2011 for detailed discussion). **Prediction** models are used to determine some expectation under a specific set of conditions, which can be modified and compared across alternative scenarios. The results of such models are typically interpreted **relative** to a null model or some baseline modeling results. By contrast, **forecast** models are used to obtain the “best guess” results, and may be extrapolated beyond the range of observed data in an anticipatory manner. Such results can be considered **absolute** because they are supposed to represent an actual expected value. Because the two key questions posed are primarily concerned with understanding the relative contributions of freshwater residency and connectivity/drought to SCS population dynamics and not with estimating actual population abundances, prediction modeling is the most appropriate path forward.

We recommended that the SCS LCM be developed at the finest level of detail necessary to fully address the questions posed, but we caution against excessive complexity where it is unwarranted. The Lindley modeling framework is somewhat general, aimed at setting minimum viable population targets for the entire region, is not age- or stage-specific, and does not explicitly model life cycle processes. Furthermore, the Lindley model is more well suited for forecasting population abundances than it is for addressing the influence of life history and environmental factors on population dynamics. By contrast, the conceptual foundation established by the Shiraz model and adopted by the NOAA HARP and CFS Nooksack LCMs (from here forward, we refer to this suite of models as the “cohort-based life cycle simulation models") provides a flexible modeling approach well suited for addressing the key questions posed. The cohort-based simulation LCM approach merely requires a set of well defined, connected functional relationships and some initial conditions. Model results can be generated under alternative scenarios, potentially representing competing hypotheses, and compared relative to one another. An additional advantage of cohort-based simulation LCMs is that that they require less empirical data to produce useful results. Data-poor watersheds may produce imprecise or biased results; however, if the model and all its components are properly specified, its results can nonetheless provide valuable insights into the question being asked when interpreted properly (i.e., relative to a baseline). The Suisun Creek LCM serves as a good example of the application of a cohort-based simulation LCM.

We recommended adopting a modeling approach similar to that used in the Shiraz, NOAA HARP model, and CFS Nooksack LCM, all of which provide an appropriate scaffolding upon which to build the SCS LCM. The modular nature of cohort-based simulation LCMs means that model components can be easily tuned to specific study systems by incorporating data and parameter estimates from regional monitoring and/or studies. Further, the cohort-based simulation LCM framework allows for flexibility in spatial scale, which will enable us to build the model at the appropriate level of detail required to address the key questions without introducing unnecessary complexity. For example, the CFS Nooksack LCM incorporates a very fine level of habitat detail (reach-scale) beyond what is necessary given the purpose of this modeling study; however, the backbone of the model, and others like it, are its functional relationships representing the various life history stages and transitions which typically do not have any influence on scale. Because each process in a cohort-based simulation LCM runs in isolation, functional relationships can be easily added or removed representing productivity and survival at specific life histories and stages, and data can be leveraged from disparate sources to parameterize those relationships. Furthermore, existing code from the CFS Nooksack LCM, while currently built for Pacific Northwest Chinook, can be easily adapted, modified, and expanded in order to satisfy the goals and objectives of this study.

Task 3. Quantitative Life Cycle Model

Model Framework:

The goal of the Southern California steelhead life-cycle model (SCS LCM) is to understand the influence of source-sink dynamics between resident and anadromous *O. mykiss* on population viability (i.e., the 100-year extinction risk) for Southern California DPS populations, as well as the potential for long-term Southern California DPS persistence as a whole. The SCS LCM links individual life-cycle sub-models parameterized for three distinct life-history variants (Figure 7), The Anadromous population (A), Below-Barrier Freshwater Resident (R), and Above-Barrier Perched Resident (P) *O. mykiss* to a state-space model simulating exchange between populations and life-history variants (see definitions below). Exchange is dependent on habitat connectivity determined by instream flow and fish passage barrier ratings. The potential for spillover between populations within and between watersheds, and between life-history variants, is an important life-cycle dynamic not reflected in current SCS MVP size estimates for individual watersheds (i.e., 4,150 anadromous spawners per year on average; NMFS 2012). Our model improves upon previous efforts to quantify the SCS MVP by considering the contributions of alternative life-history variants to the anadromous spawner population. By including a watershed scale spatial framework, MVP estimates can be obtained for individual watersheds to demonstrate their potential contributions to the population as a whole.

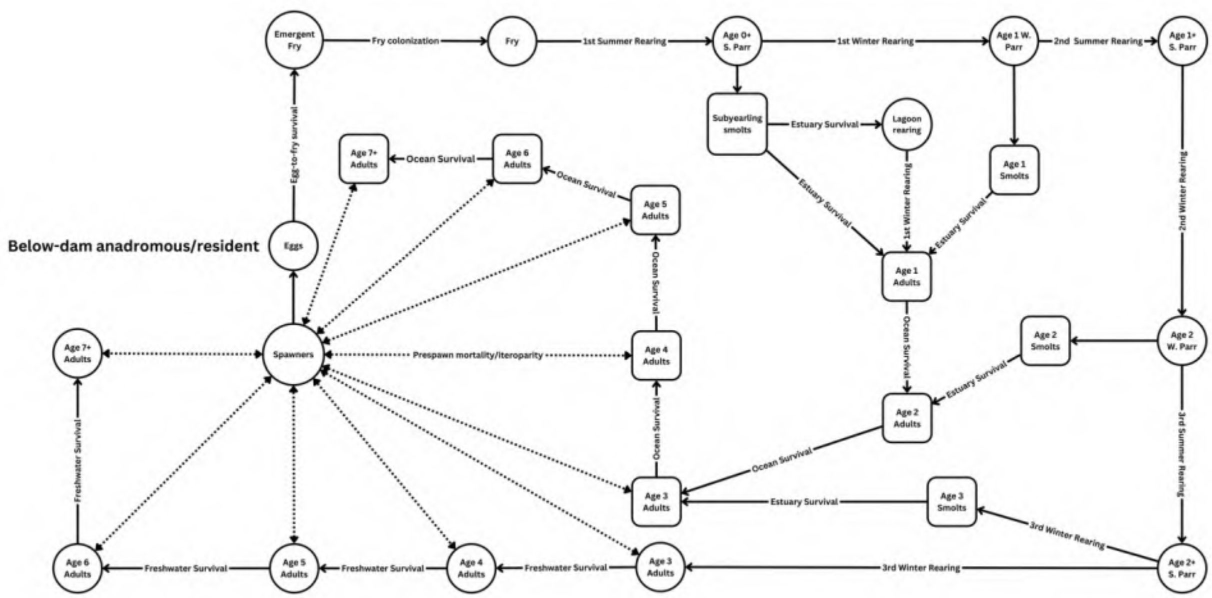

Figure 7. Conceptual life cycle diagram for Southern California steelhead which includes both freshwater (circles) and anadromous (squares) life stages.

Modeled Life Histories

As previously mentioned, this model considers three distinct life history variants that interact with each other to create the overall dynamics observed for the SCS population:

Anadromous (A) – Often referred to as the steelhead life history, these fish leave their natal basins and head out to the estuary and marine environment, where they rear for <1 to several years, before returning to spawn. They are affected by estuary and nearshore conditions, as well as the overall ocean conditions, and can exhibit straying behavior (see "Natal Straying" below).

Freshwater Resident (R) – The freshwater life history is often referred to as "Rainbow Trout" and represent fish that fully rear in freshwater. The Freshwater Resident population serves as the source of the Anadromous population, as all juveniles are considered freshwater residents until they smolt and head to the ocean.

Perched Freshwater Resident (P) – The perched freshwater life history represents freshwater residents that have no consistent connection to ocean, and therefore, cannot exhibit anadromous life histories outside of specific conditions (see Wet and Dry year effects below). Although this population does not directly affect the anadromous population, it can increase the freshwater resident population via spillover (R) which, in turn, effects the anadromous population (A).

By modeling all three life history variants simultaneously we are able to demonstrate complex population dynamics like reseeding and recolonization of extirpated habitats. When combined, we can demonstrate how *O. mykiss* adaptations, through life history variation, can extend the fitness and longevity of the overall population.

Modeled Basins

The SCS LCM considers multiple Basins within the DPS listing of SCS. The model is structured around the following river basins: Santa Maria River (Cuyama River and Sisquoc River as separate sub-basins), Santa Ynez River, Ventura River, Santa Clara River (with Piru Creek as a separate sub-basin), Los Angeles River, San Gabriel River, Santa Ana River, San Mateo Creek, San Luis Rey River, and San Diego River (Figure 8). Although each of the basins contribute to the population, the specific habitat and capacities vary widely, and necessitate separate parametrizations.

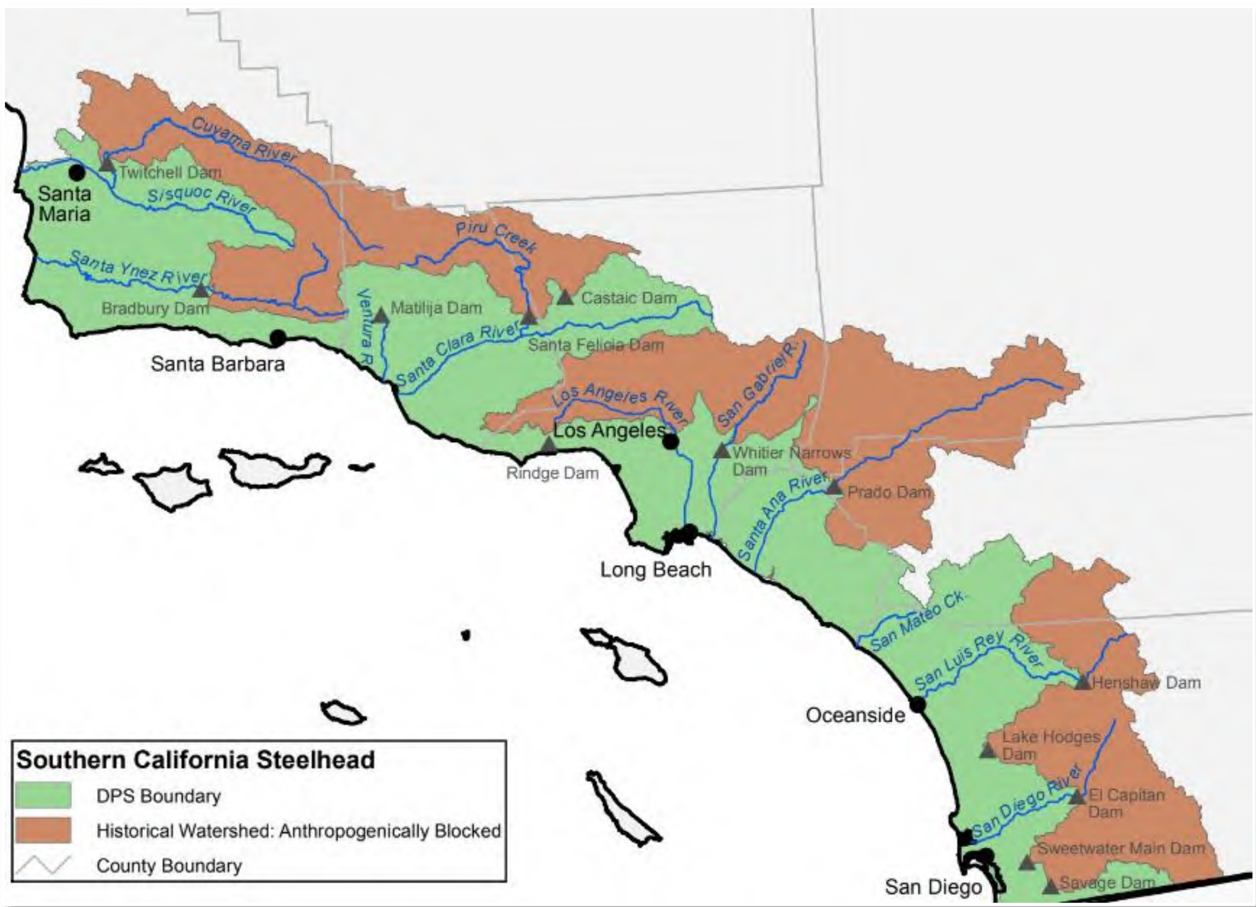

Figure 8. Basins modeled, and approximate extent of historical habitat. From NMFS 2016.

Natal Straying

Straying is typically defined as adult migration to—and attempted reproduction at—non-natal sites (Quinn 1993). Natal straying refers to the phenomenon where spawners do not return to their natal basin, but instead return to a nearby watershed to spawn. This process is responsible for recolonizing areas with previously extirpated populations and has been widely documented amongst many species as an adaptation to density dependence or overall lack of quality habitat. For the SCS we model straying using a transition matrix that determines how much of a population might stray each year, and where they stray to. The transition matrix is an *n x n* matrix that represents all *n* watersheds. Each row represents a watershed, and values indicate what other watersheds (columns) receive straying. The diagonal of this matrix represents the amount of spawners that successfully return to their natal basin. Given limited data to parameterize the matrix, we have assumed small amounts of straying occur up and down the coast to adjacent watersheds, and that this rate may adjust based on available habitat (see dry year effects below).

Wet and Dry year effects

The model assumes three broad categories representing the overall hydrological conditions across the year: Wet, Regular, and Dry. These categories were determined by looking at historical records and binning model components and data into equal quantiles. Although this is aggregated and simplified classification, it allows us to incorporate and explore how wet and dry years can affect the population overall.

Regular Years- The model's default state assumes regular conditions. These conditions allow for anadromous connection and rely on the full reach capacities to drive density dependence. Perched populations have no emigration below blockages and remain "perched".

Wet Years- In wet years, we assume there is the opportunity for spill-over and downstream connection to anadromy for perched populations. In these years, we model volitional movement downstream of blockages by allocating the overage from the density dependent survival downstream into the resident population. This increase in resident population then also contributes to an increase in the anadromous population via the resident population smolt rate.

Dry years- In dry years, several adjustments are made. First, there is reduction in capacity for Freshwater and Perched populations representing both disconnection from habitat, as well as reduction of available habitat. Second, there are reduced smolting rates from resident populations to model the effect of disconnection to anadromous waters that can occur. Overall, these processes combine to have an overall negative effect on all three populations (perched, resident, and anadromous). Finally, following the assumptions of Quinn (1984) related to less stable streams in that we model an increase in straying rates in dry years to represent the potential disconnection from natal streams.

LCM Stages:

The state-space model moves fish through life stages (Figure 7) and records and reports metrics on an annual time step. Following is a brief description of how each transition occurs, and what values control it in the model.

(A) Returns to Spawners: Represents moving back to the natal spawning range and preparing to spawn. Reductions from both pre-spawn mortality, and harvest rate. Both factors are separated by LHP as well as region.

(B) Spawner to Eggs: Shifts successful return into spawners. Calculated using the Female ratio (fixed), as well as a hockey stick function for spawning capacity (separate for each LHP and region). Successful spawners are then converted to eggs via the fecundity parameter. Note, that successful spawners are not all removed from their population, see “Iteroparity” below.

(C) Egg to Fry: Egg survival and successful hatching into fry. Controlled by the ‘Egg to Fry’ parameter. Separate for freshwater and perched populations.

(D) Fry Rearing and Colonization: Fry survival to initial winter rearing. Controlled by the ‘Fry Survival’ parameter that represents the proportion of fry that survive. Separate for Resident and Perched populations. Reduced value in dry years.

(E) Winter Rearing: Density dependent reduction using Beverton-Holt based on capacity and productivity. Separate for Resident and Perched populations. Capacity and productivities by watershed and age. We assumed that the capacities by age account for effects of other age classes (NOAA HARP Model).

(F) Summer Rearing: Density dependent reduction using Beverton-Holt based on capacity and productivity. Separate for Resident and Perched populations. Capacity and productivities by watershed and age.

(G) Smolting: Rate that freshwater fish convert to Anadromous life strategies. Determined by smolt rates. Rates vary by age and potential to adjust for each watershed. Reduced values in dry years to represent disconnection to the anadromous floor. Only applied up to age 4.

(H) Lagoon Rearing: Specific adaptation strategy observed for anadromous population. Provides greater survival compared to estuary and nearshore rearing. Limited by lagoon capacity. Relies on density dependent curve to allocate population to lagoon (preferred), with overage rearing in estuary. Reduced lagoon capacities in dry years. We assume similar dynamics are at play for perched populations where reservoirs are present (Leidy 2004).

(I) Estuary Survival: Default conditions for anadromous rearing when lagoon area is unavailable/ occupied. Fixed rate that depends on age.

(J) Ocean Survival: Represents annual survival in the ocean using a fixed proportion. Separate values by age.

(K) Maturation: Rate that fish mature to spawners. Determined by maturation rates with separate rates for each LHP and age (fixed proportion).

(L) Adult Freshwater Annual Survival: Represents annual survival of freshwater adults. fixed rate. Separate value for resident and perched populations

(M) Iteroparity: Ability for spawners to return and spawn again next year. Controlled by iteroparity rate and respawn survival factor. Separate values for Resident and Perched populations. Assumes that a spawner's LHP is fixed and does not change on repeat spawning.

Initial conditions

The model requires initial conditions to seed the various populations. Long term dynamics are controlled by functional relationships and capacities, and are somewhat robust to initial conditions, however, the ramp up time to stable conditions will depend on the initial seeding and should not be overlooked. Given the potential for a 7-year anadromous return, we would not expect to hit stable dynamics in less than 10 years for most initial values. For this reason, the default model length is set to 125 years to account for the model's "warm up" time.

Demonstrated Population Dynamics – Useful tool without exact empirical data

As mentioned in the modeling section, one benefit of prediction models is the ability to compare a baseline scenario to alternate parameterizations to explore how changes in values (or assumptions) affect overall outcomes. Evaluating population dynamics often poses a challenge when empirical data is scarce or limited. In the case of the SCS population, the lack of empirical data has necessitated the use of a simplified model. However, despite these data limitations, we can still gain valuable insights by exploring how population dynamics are affected by individual modeling components and their values.

To that end, we have developed a model baseline scenario that serves as a fundamental starting point for our analysis. This model baseline parameterization not only helps us navigate the complexities of the SCS population dynamics but also serves as a crucial tool for demonstrating key phenomena in a controlled environment. While the model baseline scenario is an abstraction, it allows us to dissect and understand the impact of various factors, such as reproductive rates, mortality, and environmental variables, on population growth and sustainability.

These concepts, while derived from a simplified model, are robust and reveal core features of the model, and SCS adaptations. By focusing on these fundamental principles, we can uncover insights that may guide future data collection efforts or help refine more complex models as data becomes available. Thus, the use of the simplified model not only provides a pragmatic solution to data limitations but also offers a valuable framework for examining critical population dynamics and their sensitivity to different parameters and assumptions.

Impacts of Wet and Dry years

The model baseline assumes an 'regular' water year and has multiple parameters and capacities that are directly tied to 'dry' years to represent deleterious effects on the population. Similarly, 'wet' years offer opportunities for the perched population to 'spill' into connected freshwater habitat. The model's default behavior assumes a sequence of water years that match historic trends, but the model also allows users to generate alternate randomized sequences to explore the impact of longer or shorter sequences of wet and dry years.

To emphasize these effects, consider the following parametrization. By setting the model to only include 'Dry' years, the perched population cannot contribute to the Resident population (and therefore the Anadromous population), and we can generate a downward trend for population, reaching an asymptote of the Perched population total (Figure 9).

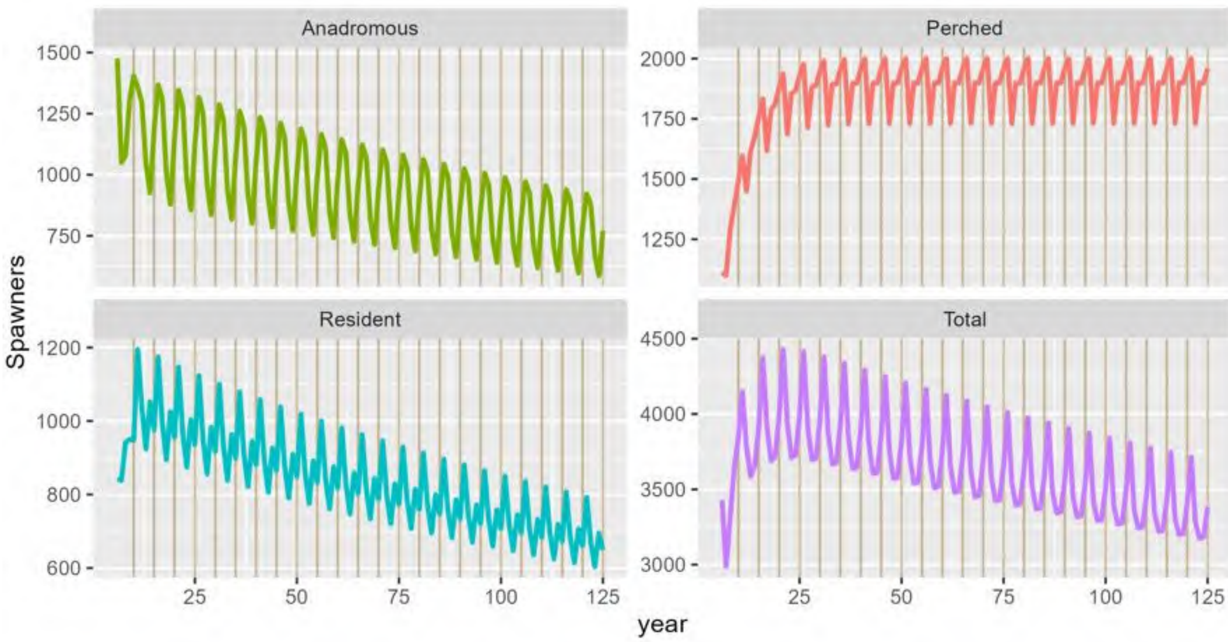

Figure 9. Example of Dry year effects. Plots of Spawners over time for the life history variants modeled in the SCS LCM, along with an aggregated total. Vertical brown lines represent 'dry' years in the run.

Introducing 'wet' years allows the perched population to contribute to the Resident population and can help offset the impacts of the 'dry' years in the run, eventually achieving values approaching MVP (Figure 10).

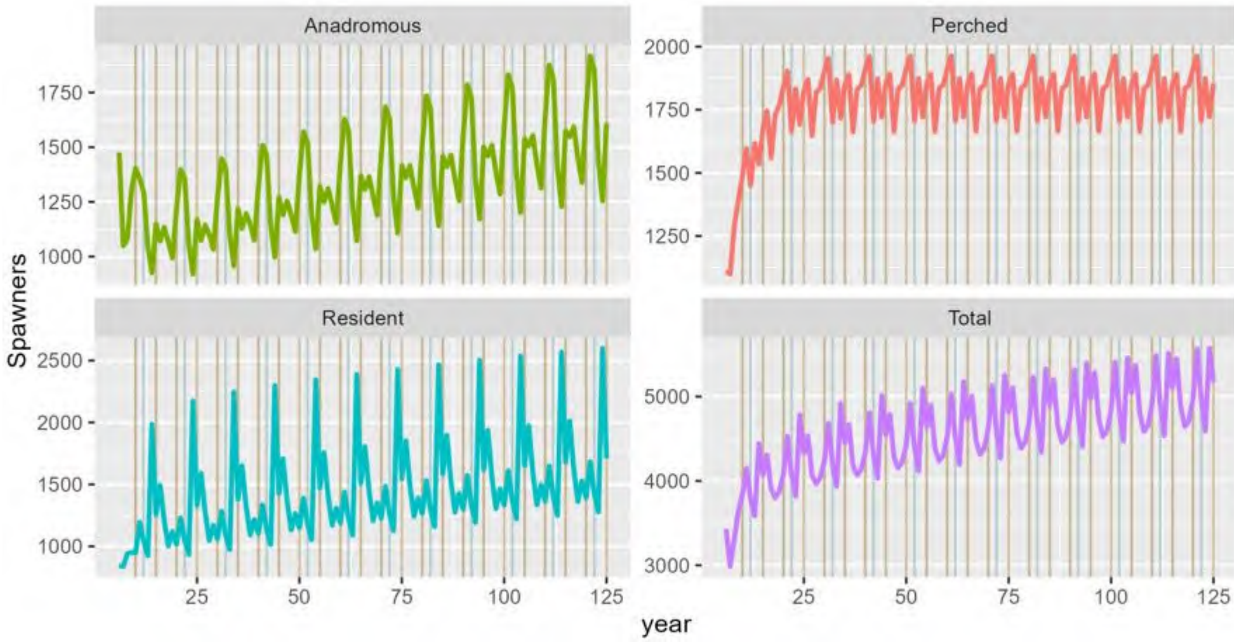

Figure 10. Example of Wet and Dry year effects. Plots of Spawners over time for the life history variants modeled in the SCS LCM, along with an aggregated total. Vertical brown lines represent 'dry' years in the run while blue lines indicate 'wet' years.

Reseeding Populations

Interchange between the resident and anadromous population allows for reseeding an extirpated anadromous population through smolting. Similarly, anadromous adults in the ocean may be able to reseed the freshwater resident population given their lagged return. Finally, the Perched population can reseed the resident population in wet years via ephemeral connections and spillover.

To highlight these dynamics, consider the following parametrization that extirpates the Resident and Anadromous populations after a series of 'dry' years, only to reseed the population from the perched population in a subsequent 'wet' year (Figure 11).

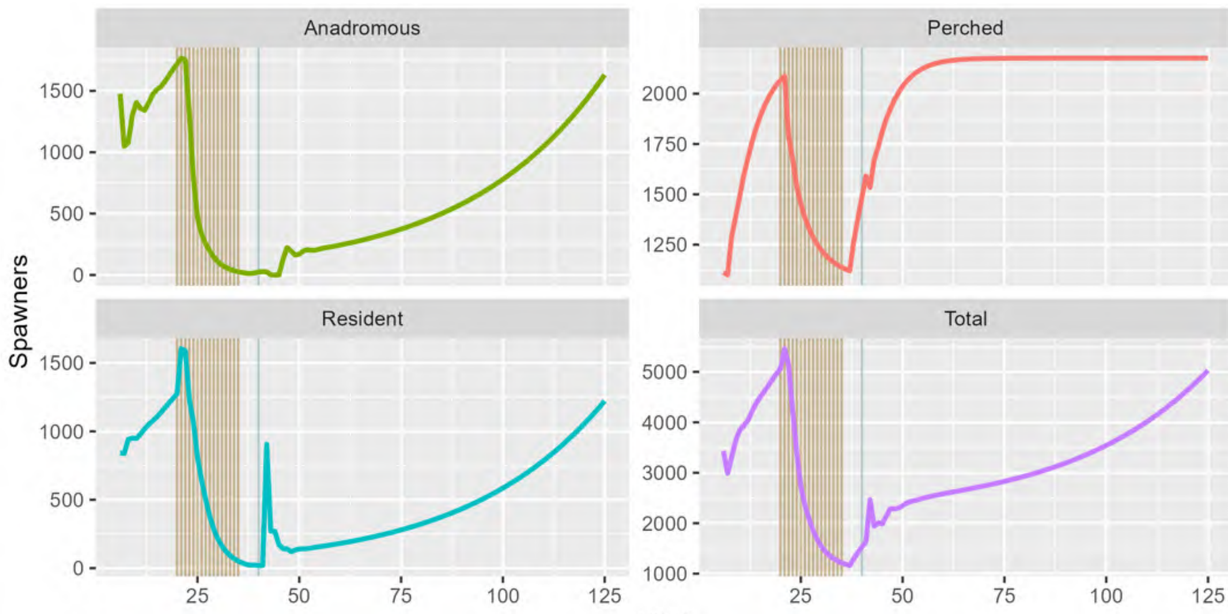

Figure 11. Example reseeding extirpated populations using interchange with a perched population. Plots of Spawners over time for the life history variants modeled in the SCS LCM, along with an aggregated total. Vertical brown lines represent 'dry' years in the run while vertical blue lines represent 'wet' years.

By including both 'wet' and 'dry' years, as well as the potential for interchange between populations, we can begin to produce complex population dynamics (Figure 12).

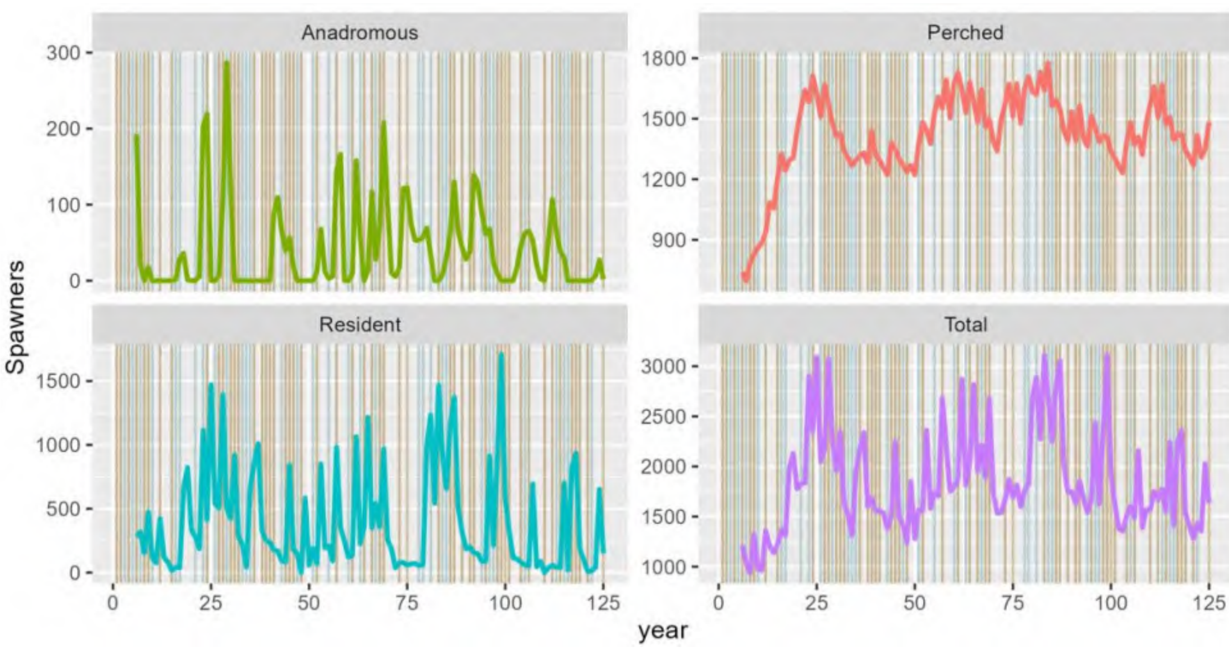

Figure 12. Example of complex populations dynamics by simulating a random sequence of water type years from an empirical distribution. Plots of Spawners over time for the life history variants modeled in the SCS LCM, along with an aggregated total. Vertical brown lines represent 'dry' years in the run while vertical blue lines indicate 'wet' years. Note the anadromous population being reseeded multiple times across the 125-year model run.

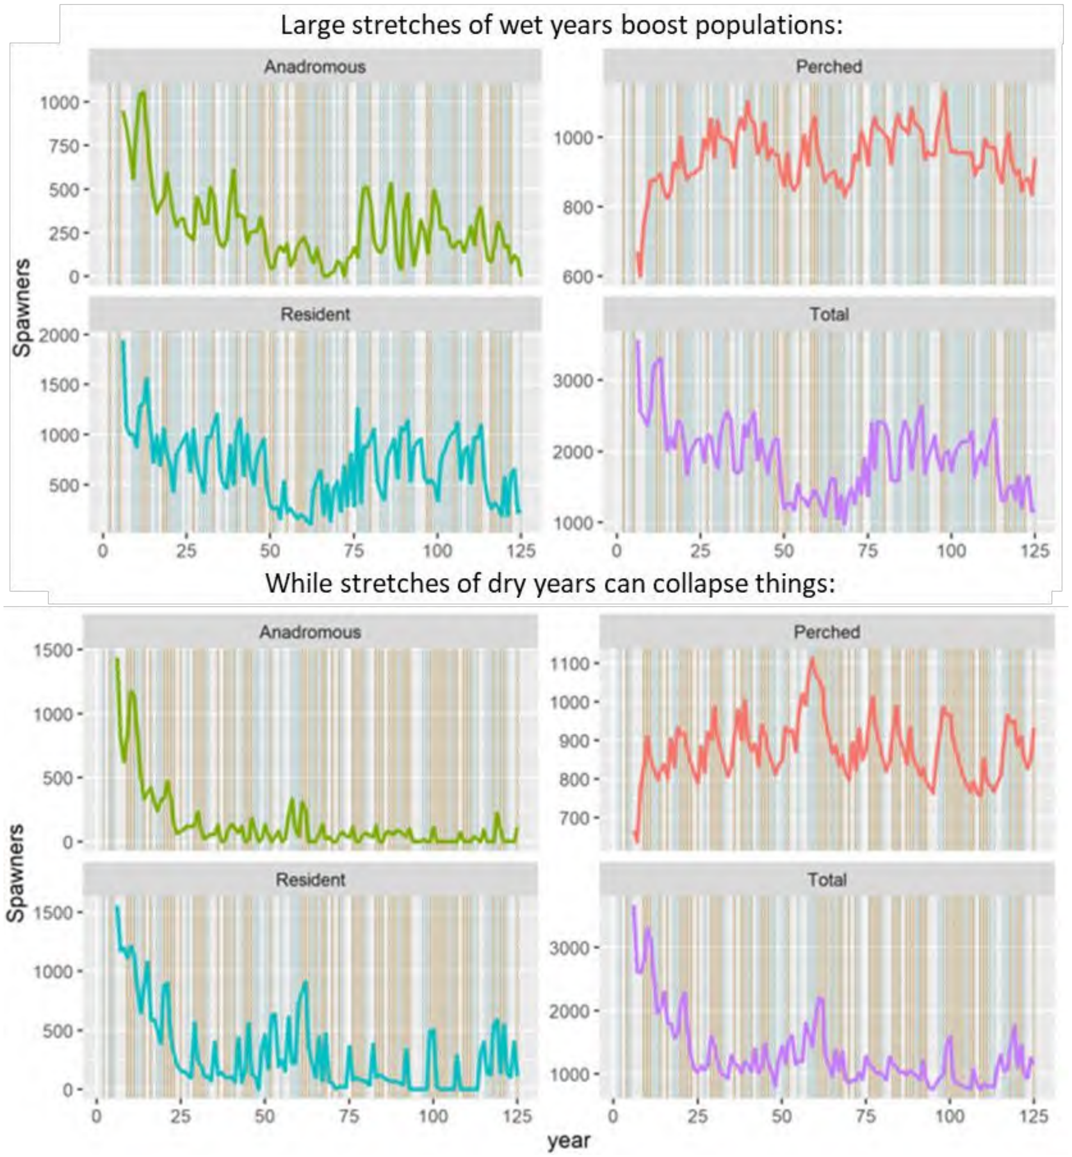

Figure 13. Further examples of complex dynamics demonstrating effects of wet and dry effects. Plots are the same as in Figure 12, but with larger stretches of Wet and dry years highlighting the importance of these environmental factors.

Recolonizing Extirpated Habitats

Beyond local interchange between Resident, Anadromous, and Perched populations, natal straying from the anadromous population can recolonize extirpated habitats. To demonstrate this, we created a diagnostic scenario that forces extirpation in a basin for a set of continuous years to highlight how recolonization can manifest (Figure 14). In the following example, Santa Clara River is recolonized from Natal Straying from nearby systems (Figure 14). Note that the model does not allow the upstream exchange of the Resident population to the Perched population (only the converse), and so the Perched population remains extirpated here:

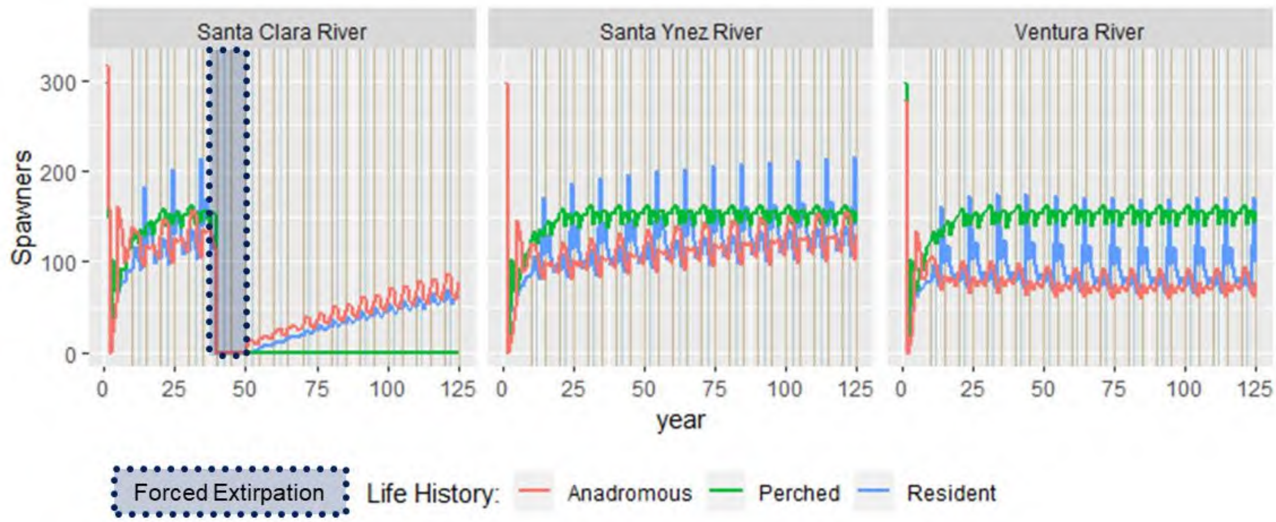

Figure 14. Example of recolonization of extirpated habitat by long-distance natal straying from alternate basins. Plots are of Spawners by year with three basins shown separately, with each Life History Variant distinguished by color. The shaded box represents a forced extirpation lasting 10 years. Vertical brown lines represent 'dry' years in the model while vertical blue lines represent 'wet' years. Note that the water year types match those presented in Figure 10.

Baseline scenario and default Parametrization:

For the model baseline scenario, we set the Anadromous return spawner total to just over the MVP needed to ensure genetic viability (~833 [2500 over 3 years for low extinction risk], Spence et al 2008), while aiming for a total population (including Freshwater and Perched populations) to exceed 4000 fish to achieve an MVP that is more robust to catastrophes and environmental stochasticity (Reed et al 2003 suggests ~5800). Finally, freshwater age structures will be calibrated to closely resemble empirical data from Piru Creek. This parametrization should highlight the overall contributions of the life history variants and connectivity to the long-term persistence of the DPS.

Model Implementation and Dashboard

The SCS LCM model has been implemented in R (R Core Team 2023, version 4.3.1) and only relies on well vetted packages that are available on CRAN with extensive histories of maintenance ("data.table", and "ggplot2"). The model requires little computational resources to operate and should be able to run on most modern computers. Although the code is well commented, it can be intimidating to work with as it is a somewhat complex model relying on nested loops and complex accounting structures. To make the model as user friendly and transparent as possible, we have adapted the code into an R Shiny framework to create a reactive Graphic User Interface (GUI) to run the model (Figure 15). The GUI includes options to rapidly adjust the majority of the model's parameters, and should allow novice users to explore the model, its assumptions, and results.

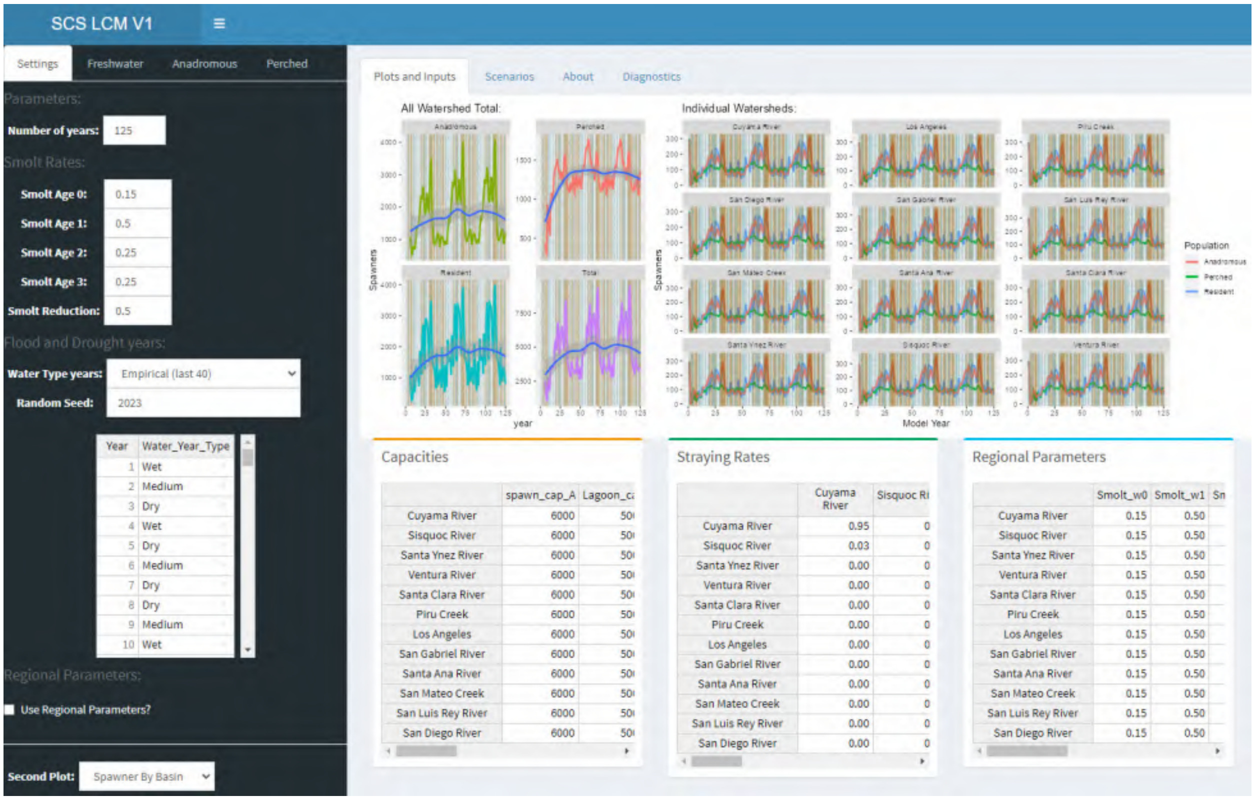

Figure 15. Screen capture of the GUI. A User guide for the model interface is under development and will be included in the 'About' tab.

Additional Scenarios

The model framework is easy to adapt and expand to consider other additional scenarios. As an example of this, we have added a “Reduction Event” scenario to the GUI (under the “Scenarios” tab in the main panel) that allows users to simulate a one-off large scale reduction event. Users have the option to select what year the reduction event starts, its total duration, and how large of a reduction in returning spawners should be applied. This sandbox scenario can help explore the effects of major unforeseen environmental impacts, and to evaluate population resiliency to these events. Moreover, this is meant to demonstrate the type of additional scenarios that can be created and evaluated using this model framework.

Concluding Remarks

- SCS show many adaptations and life history variants, many unique or emphasized for this population (e.g. Freshwater life histories, lagoon Rearing, ‘mini-jacks’, etc.). Ecological theory suggests that these adaptions are important to the population (hence their development) and should be considered in a population life cycle model to fully understand the dynamics of the population.
- Our model demonstrates how many of these adaptations can impact the long-term population dynamics, generally increasing the longevity and fitness of the population overall.

- Although the model is relatively simple and relies on many assumptions, the core dynamics demonstrate that concepts like connectivity (e.g., straying and perched population spill over) and life history variants (e.g., inclusion of both anadromous and resident spawners) can have relatively large impacts on a population's trajectories and persistence, and that omitting them may not fully capture the population's capabilities.
- By providing the GUI interface, the model can facilitate open discussion on management actions and future condition effects on the persistence of the SCS DPS at both regional and population wide scales.
- The model highlights data gaps and needs and can be updated as more information is available.

Subject: Materials for Commissioners Meeting Packet

Good Afternoon,

Attached you will find a public support letter that EnviroVoters collected in favor of fully listing Southern Steelhead under CESA.

Please let me know if there are any needed changes to ensure that these docs are included for the Commissioners' review prior to the meeting.

Thanks, Russell

Thank you,

Russell Marlow

RE: California Trout, Inc.'s Petition to list Southern California Steelhead (Oncorhynchus mykiss) as Endangered Office - Administrative Law's Notice ID #Z2021-0702-02 and Z2022-0426-01

President Murray and Commissioners:

As concerned California residents, I write to you today to express my full support for designating the Southern California steelhead as endangered under California's Endangered Species Act.

Southern steelhead are an iconic native species, but without further protections we risk losing them forever. That's not a California I want to live in. Do you? You must act immediately to put in place all precautions to prevent this species from total loss.

Recent research tells us that Southern steelhead populations are in danger of extinction within the next 25 to 50 years if current trends persist. Since their listing as an endangered species in 1997 under the federal Endangered Species Act, Southern steelhead numbers have continued to decline to precariously low levels. In the past 25 years, only 177 adult Southern steelhead were documented in their native range! Allowing this species to disappear is not acceptable, and more protections are essential.

These fish play a key role in our ecosystems, and they can give us crucial information about the greater health of the watersheds they swim in (and that our communities rely upon). We can look to them for clues on how California must work to address bigger problems in our southern rivers and streams, watersheds that provide countless societal and economic benefits for the entire state. I believe that we prosper when rivers and waterways in key locations are thriving, and in many of these places there is work to be done.

These fish may also play a role in providing resiliency for ecosystems further north along the coast. Southern steelhead are uniquely adapted to Southern California's warmer Mediterranean climate. As climate change continues to increase water temperatures and alter flow regimes along the entire West Coast, Southern steelhead could be critical to the long- term resiliency of their northern relatives.

For all these reasons, I wholeheartedly support California Trout's recommendation that Southern California steelhead be listed as endangered in all waterways within historic range below natural or man-made barriers. CalTrout chose this delineation thoughtfully, so that fishing and continued management for rainbow trout, the freshwater form of this amazing species, would still be possible above these barriers.

It's not too late to save the Southern California steelhead species from blinking out – but if you don't act urgently, we may very well miss our chance. Please make protection of these amazing and important fish a conservation priority by listing them as endangered under the state's Endangered Species Act.

Sincerely,

EnviroVoters Together as Concerned Californians and Individuals All Over

VIA EMAIL fgc@fgc.ca.gov

Ms. Samantha Murray, President & Members
California Fish and Game Commission
P.O. Box 944209
Sacramento, CA 94244

Dear President Murray and Members:

Comments on the Petition to List the Southern California Steelhead Pursuant to the California Endangered Species Act and the Department of Fish and Wildlife's Status Review Report

The Los Angeles County Sanitation Districts (Sanitation Districts) received the Notice of Final Consideration of the subject petition by the California Fish and Game Commission (Commission) for their April 17-18, 2024, meeting, and have reviewed the January 2024 California Department of Fish and Wildlife (CDFW) Status Review Report of Southern California Steelhead (2024 Status Report). The Sanitation Districts previously reviewed the June 7, 2021, Petition to List the Southern California Steelhead under the California Endangered Species Act (CESA) and the November 2021 Petition Evaluation prepared by CDFW and provided comments to the Commission on January 27, 2022 (see Attachment 1). By way of background, the Sanitation Districts are a confederation of 24 special districts serving approximately 5.4 million people in Los Angeles County (County). Our service area covers approximately 850 square miles and encompasses 78 cities and unincorporated territory within the County. The Sanitation Districts construct, operate, and maintain facilities to convey, treat, recycle, and dispose of wastewater, and generate recycled water, bioenergy, and biosolids as byproducts of the treatment process.

General Comments Related to Listing and Identification of the Upper Santa Clara and Lower San Gabriel Rivers

As indicated in our previous comment letter, the Sanitation Districts are not taking a position regarding the listing of Southern California Steelhead (SCS) under CESA. However, we hope that the information provided in that letter has allowed the Commission and CDFW to gain an understanding of our operations and the significant potential consequences of CESA listing to our operations. For the upper Santa Clara River above its confluence with Piru Creek, and the portion of the lower San Gabriel River below its confluence with San Jose Creek, we are unaware of any evidence that SCS currently use these waterbodies due to the presence of physical barriers, lack of streamflow, and/or lack of suitable habitat. Thus, the Sanitation Districts are concerned about the implications of designating these areas as currently supporting SCS, and the impact that this designation may have over time on our ability to carry out the essential public services that we provide. We are concerned about requirements and water quality objectives that may be imposed on the water reclamation plants (WRPs) that we operate by CDFW and/or the Los Angeles Regional Water Quality and State Water Resources Control Boards (collectively the "Waterboards") in order to protect purported SCS habitat. Specifically, we are concerned that, when considering requests for Streambed Alteration Agreements, CDFW may incorrectly assume the presence of SCS to impose stringent prohibitions or conditions on essential activities such as maintaining sewers (which may cross under/over these rivers), maintaining or installing retaining walls, and maintaining discharge outfalls located in the affected water bodies. Further, the Waterboards may update the Los Angeles Region Water Quality Control Plan, as well as subsequently modify National Pollutant Discharge Elimination System (NPDES) permits, to require higher-quality discharges to receiving waters to protect SCS, even if they are not and cannot be present in these locations due to the barriers (i.e., dry gaps, dams, etc.) preventing access. Finally, the Sanitation Districts' wastewater facilities operate under California Water Code Section 1211 approved petitions, which are issued by the Waterboards and govern the discharges, and these allow us to provide recycled water for municipal uses.

One possible consequence of the potential changes to water quality regulatory requirements, or imposition of other new regulatory requirements, could be a need for new types of treatment at our WRP facilities. The cost, energy, and greenhouse gas emission impacts of constructing and operating additional treatment facilities to support SCS habitat would be substantial, and all for a purported SCS distribution that is not known to occur in reaches of the upper Santa Clara River, lower San Gabriel River, and their tributaries to which the Sanitation Districts' WRPs discharge recycled water. Furthermore, the potential listing of SCS could lead to unintended consequences such as less recycled water being available for reuse due to additional discharges to the rivers that could be required, even if this habitat is not accessible or appropriate for SCS. This would affect the water supply and resiliency of this region and potentially create water shortages.

Specific Comment on 2024 CDFW Status Report Figure 7

Moreover, the Sanitation Districts are concerned that Figure 7 of CDFW's 2024 Status Report (page 43) clearly mis-identifies reaches of the Santa Clara River extending far upstream of Piru Creek as current SCS distribution areas. The Sanitation Districts own and operate two WRPs that discharge approximately 18 million gallons per day of recycled water into the upper Santa Clara River, constituting most of the surface flow in portions of that waterbody where surface flow is present. Reaches of the Santa Clara River where discharges occur are separated by a naturally occurring "dry gap" from coastal reaches (see map in Attachment 2). Piru Creek was indicated as the upper limit of potential SCS habitat identified in the National Marine Fisheries Service January 2012 Southern California Steelhead Recovery Plan. Thus, it was the Sanitation Districts' understanding that the Santa Clara River upstream of Piru Creek is not suitable SCS habitat and consequently is not a focus of the potential CESA listing. Prior discussions with CDFW staff in March 2022 had supported this understanding. Furthermore, we are currently working on receiving water temperature studies in the upper Santa Clara River with CDFW and United States Fish and Wildlife Service (USFWS) staff, and SCS have never been identified by the USFWS or any other State or federal resource agencies as a species present in this area of the watershed. Despite these facts, and without any evidentiary basis, the 2024 Status Report shows a blue line signifying actual SCS presence in these reaches.

Research by ESA Consultants (see Attachment 3 for ESA technical memorandum), including several studies conducted over the past several decades in the area, has indicated that there is no record of current SCS occupation in the upper Santa Clara River watershed (east of the Piru Creek confluence) on which to support any determination of species "presence". Despite extensive fish sampling in the area over the last few decades, no SCS have been encountered. Habitat conditions currently do not suggest suitable habitat is present for this species in the area. Furthermore, the 2024 Status Report did not reference any scientific work or publication that would support such a determination. Sanitation Districts staff recently met with CDFW staff involved with development of the 2024 Status Report, and we appreciate the cooperation of CDFW staff in discussing this matter with us. However, during this discussion, CDFW staff did not provide any new evidence or sufficient scientific justification for demarcating the upper Santa Clara River watershed as current SCS habitat. The references discussed in the 2024 Status Report have been thoroughly reviewed by ESA Consultants and incorporated into their attached report. While the Sanitation Districts recognize this is only a status report, we are very concerned about the potential for future misuse of the SCS distribution indicated in the 2024 Status Report to require or suggest unnecessary restrictions and conditions on our facilities in the upper Santa Clara River to protect the species.

Based on the above, the Sanitation Districts respectfully request that the Commission take the following actions:

1) Santa Clara River – Direct CDFW staff to remove the "Current" SCS distribution designation for the Santa Clara River upstream of Piru Creek from Figure 7 of the 2024 Status Report.

2) San Gabriel River – Direct CDFW staff to work with the Sanitation Districts to develop a Section 2084 regulation and Section 2081(d) rule that is protective of the SCS species yet allows the Sanitation Districts to continue activities necessary to support their essential function of providing wastewater treatment and related services, including but not limited to discharge, monitoring and the provision of recycled water, to County residents and businesses. This reiterates the request from our previous correspondence, which is provided again as Attachment 1.

Once again, we thank you for the opportunity to provide these comments and look forward to working with CDFW and the Commission. For any questions, please contact the undersigned at (560) 908-4288, ext. 2701 or rtremblay@lacsd.org.

Very truly yours,

Ray Tremblay

VIA EMAIL fgc@fgc.ca.gov

Mr. Peter S. Silva, President & Members
California Fish and Game Commission
P.O. Box 944209
Sacramento, CA 94244

Dear President Silva and Members:

Comments on the Petition to List the Southern California Steelhead Trout Pursuant to the California Endangered Species Act and the Department of Fish and Wildlife's Petition Evaluation

The Los Angeles County Sanitation Districts (Sanitation Districts) have reviewed the June 7, 2021, Petition to List the Southern California Steelhead (Steelhead) under the California Endangered Species Act (CESA) and the November 2021 Petition Evaluation prepared by the California Department of Fish and Wildlife (CDFW). While the Sanitation Districts are not taking a position regarding the application of CESA to Steelhead in Southern California, we wish to provide the California Fish and Game Commission (Commission) and CDFW with information about our operation to help inform the decision making processes of the Commission and CDFW as to the potential consequences of listing as related to our operations. To provide some background, the Sanitation Districts are a confederation of 24 independent special districts serving approximately 5.6 million people in Los Angeles County (County). The Sanitation Districts' service area covers approximately 850 square miles and encompasses 78 cities and unincorporated territory within the County. The Sanitation Districts construct, operate, and maintain facilities to convey, treat, recycle, and dispose of wastewater and industrial wastes and generate recycled water, bioenergy, and biosolids as byproducts of the treatment process. As such, the Sanitation Districts are requesting that if the Steelhead listing proceeds, CDFW and the Commission also develop a Section 2084 regulation and Section 2081(d) rule that is protective of the species, yet allows the Sanitation Districts to continue activities necessary to support their essential function of providing wastewater treatment and related services, including but not limited to discharge, monitoring and the provision of recycled water, to County residents and businesses.

Description of Sanitation Districts Operations Potentially Affected by Steelhead CESA Listing

Facilities

Among other facilities, the Sanitation Districts operate a network of inland water reclamation plants designed to produce high quality recycled water for municipal reuse. Not all the recycled water is currently utilized by our partner water agencies however and the remaining flows must be discharged to inland surface water bodies. A portion of the recycled water that is used is also discharged to inland rivers which are used as conveyance to downstream uses. The Sanitation Districts currently discharge over 30 million gallons per day (MGD) into the San Gabriel River and its tributaries (San Jose Creek and Coyote Creek), from five water reclamation plants (WRPs) under National Pollutant Discharge Elimination System (NPDES) permits issued by the Los Angeles Regional

Water Quality Control Board (Regional Board) (see Figure1). Conditions in the San Gabriel River are unsuitable for promotion of Steelhead under baseline conditions. For example, the portions of the San Gabriel River and tributaries in which these treatment facilities discharge are highly managed, highly modified, mostly concrete lined, and receive little flow from other sources other than stormwater runoff. The only reason there are measurable flows on a seasonal basis is due to the artificial condition of wastewater discharges. There is no affirmative duty under CESA to maintain an artificial condition. Further, the National Marine Fisheries Service January 2012 Southern California Steelhead Recovery Plan (Recovery Plan) found that restoring conditions for Southern California Steelhead in the San Gabriel River would require multiple long-term measures related to water management, recreation, and urban development. It went on to state that a fish passage barrier inventory and assessment for the watershed should be conducted as there are several operating dams that impede fish passage. It is our understanding that any use of the reaches we discharge to for Steelhead recovery would be solely for migration on a seasonal basis.

The Sanitation Districts also own and operate two additional water reclamation plants that discharge approximately 18 MGD into the Upper Santa Clara River, constituting most of the surface flow in portions of that waterbody where surface flow is present. The reaches of the Santa Clara River where discharges occur are separated by a “dry gap” from coastal reaches with surface flow and are far upstream of Piru Creek, the limit of potential Steelhead habitat identified in the Recovery Plan. Thus, it is our understanding that the Santa Clara River upstream of Piru Creek is not a focus of the potential CESA listing and our remaining comments in this letter focus on the San Gabriel River.

Recycled Water and CA Water Code Section 1211 Approved Petitions

Any listing decision should consider the current instream conditions, as well as current and future discharges of recycled water to the San Gabriel River. These discharges vary seasonally and are heavily managed by the Los Angeles County Flood Control District. The Sanitation Districts’ goal is to maximize reuse. The Sanitation Districts work with regional and local water agencies to develop these recycled water projects and are actively working on the development of several new projects in the region due to the need to develop additional local climate-resilient water supplies, which can help local and regional municipalities reduce reliance on imported water and ease the pressure on distant watersheds that support habitat for a number of threatened and endangered species. There is significant demand for the Sanitation Districts to supply additional recycled water to local water agencies to the extent to which it is available.

To this end, after numerous years of working with CDFW and the State Water Resources Control Board, the Sanitation Districts obtained approval for several California Water Code Section 1211 Petitions that allow us to reduce our combined discharge to a total of 7 MGD (5 MGD from our San Jose Creek WRP and 2 MGD from our Los Coyotes WRP) to the San Gabriel River. These approved Section 1211 Petitions allow us to provide additional recycled water for reuse to local water agencies without impacting riparian habitat or special status species. The permits require the Sanitation Districts to monitor the surrounding riparian habitat using an adaptive management approach to protect the least Bell’s vireo, an endangered avian species. Further, as part of the adaptive management plan, a habitat management committee, which includes participation by CDFW and the United States Fish and Wildlife Service, reviews the collected data collected and provides future recommendations. Because these petitions were only recently approved, the reductions in discharges to the San Gabriel River have not yet occurred. The Sanitation Districts expect to reach these levels of minimum discharge over the next decade as new recycled water projects are implemented.

In addition to minimum discharges to comply with the Section 1211 Petitions, the Sanitation Districts also use the San Gabriel River and its tributaries to convey recycled water from our WRPs to their point of use. Recycled water produced at our WRPs and not used for municipal purposes is discharged for percolation and conveyance downstream. Unlined portions of the San Gabriel River and adjacent engineered spreading basins are used as part of the Montebello Forebay Groundwater Recharge Project to capture recycled water to augment local groundwater supplies. Los Angeles County Flood Control District operates the river and spreading basins to maximize conservation of recycled water and stormwater. During most times of the year, the vast majority of the discharges from the San Jose Creek, Whittier Narrows and Pomona WRPs are captured and conserved.

Excess Recycled Water Discharge

The Sanitation Districts also wish to emphasize that, while we take our responsibility to protect the beneficial uses and habitat of the waterbodies to which we discharge very seriously, we also have a primary responsibility to provide the essential public service of wastewater treatment to approximately 5 million people residing in the Los Angeles Basin; this service must be available on a continuous basis. While supplying recycled water is also an important function, recycled water demand fluctuates diurnally (due to daily usage patterns) and seasonally. Moreover, the amount of wastewater production fluctuates over time, whether it be due to flow reductions attributable to water conservation or peak wet weather flows that occur during and immediately after storms. During winter months and during storm events, demand for recycled water is lower, and more treated wastewater must be discharged to the environment. In short, wastewater treatment and the ability to discharge must always be available, as the volume of water is significant and cannot be directly controlled by the Sanitation Districts. The variability of the flows must also be taken into account when considering the application of discharge standards. While it may be feasible to treat our recycled water to be suitable for Steelhead migration at low flows, it may be infeasible to provide that treatment for all flow after a rain event when recycled water demands are minimal. If discharges were to continue, the Sanitation Districts could be required to construct and maintain very large-scale treatment facilities that only operate a few times of year. There is likely not sufficient space available at our WRPs to provide higher levels of treatment for all the flow.

Treatment Requirements

It is our understanding that if a CESA listing is adopted, the Water Quality Control Plan, Los Angeles Region (Basin Plan) may need to be modified to reflect updated beneficial uses (e.g. for endangered species) and accompanying water quality standards for constituents such as temperature and ammonia toxicity could be adopted by the Regional Board to protect these beneficial uses. The Sanitation Districts are concerned with having to comply with far more stringent effluent limitations to support this beneficial use (potentially at all times of the year) despite the absence of Steelhead in the San Gabriel River under baseline conditions and the presence of Steelhead in the San Gabriel River in the vicinity of our discharges would only occur during migration. The cost, energy, and greenhouse gas emissions for having to construct and operate additional treatment facilities would be substantial. CDFW should consider these costs and other factors when determining if conditions in the San Gabriel River watershed are suitable for Steelhead recovery.

Monitoring Programs

The Sanitation Districts conduct extensive water quality monitoring activities in the San Gabriel River and Santa Clara River. In addition to implementation of an extensive monitoring and reporting program in and around the discharges from the WRPs to the San Gabriel and Santa Clara Rivers, the Sanitation Districts fund and participate in the San Gabriel River Regional Monitoring Program, which is a watershed-wide monitoring program that has been active for over 16 years. All of these monitoring activities are required by the Regional Board and are contained in our NPDES permits.

Request for Pre-Emptive Consultation and Accommodation for Essential Public Services

Notwithstanding our understanding that the reaches of the San Gabriel River to which our facilities discharge are not likely suitable for Steelhead recovery under the CESA listing (and dry reaches upstream of the San Jose Creek and Pomona WRPs make those reaches unsuitable as well), if CDFW decides to accept the petition for consideration, it's our understanding that the Commission can adopt regulations under Section 2084 of the California Fish and Game Code to authorize the taking of a candidate species, subject to terms and conditions it prescribes, based on the best available scientific information. Under Section 2084, CDFW may also recommend to the Commission that it authorize the taking of an endangered, threatened or candidate species. The Sanitation Districts would be glad to work with CDFW and the Commission to develop a Section 2084 regulation that is protective of the species, yet allows the Sanitation Districts to continue activities necessary to support their essential function of providing wastewater treatment services to Los Angeles County residents and businesses.

At this time, the Sanitation Districts recommend that CDFW propose and the Commission adopt a Section 2084 regulation that authorizes the exceptions to the take prohibition described below. These incidental take authorizations would support critical operations, maintenance and capital activities required to provide reliable wastewater services to protect public health, safety, and the environment. In crafting a Section 2084 regulation that accommodates these authorizations, the Sanitation Districts are ready and willing to collaborate with CDFW and the Commission to develop best management practices and other measures to provide for conservation of the species. Furthermore, if the Commission decides to ultimately list the Southern California Steelhead, the Sanitation Districts request CDFW consider adopting a rule pursuant to section 2081(d) that contemplates the same incidental take authorizations.

Incidental Take Authorizations Being Requested

1. Take authorization as it relates to the Sanitation Districts' previously approved Section 1211 permits, and any of their successors.

   As noted above, increasing recycled water supplies is urgently needed to address the State's water crisis. The Sanitation Districts spent over 5 years working with CDFW to develop an adaptive management plan to ensure riparian habitat and special status species will not be impacted by the reduction in discharge to the San Gabriel River from Sanitation Districts' WRPs. The discharge reduction enables more recycled water to be beneficially reused, thereby providing a resilient water supply source. Given the long history of Sanitation Districts' partnership with CDFW in these efforts, the Sanitation Districts believe it is appropriate to exempt actions undertaken pursuant to implementation of conditions contained in approved the 1211 petitions

2. Take authorization to allow required monitoring to be conducted per NDPES permit Monitoring and Reporting Programs and the San Gabriel River Regional Monitoring Program.

   The Sanitation Districts conduct routine monitoring for discharges into the San Gabriel and Santa Clara River watersheds as part of implementation of NPDES permit requirements. The Sanitation Districts also participate in implementation of the San Gabriel River Regional Monitoring Program (www.sgrrmp.org). If best management practices are adhered to, these water quality monitoring activities should be identified as exempt from "incidental take" as they not only help ensure that NPDES permit limits are being met, but also that public health and the environment are protected.

3. Take authorization to allow the Sanitation Districts to discharge more flow (compared to average or dry weather conditions) to the San Gabriel River and its tributaries during wet weather or due to other conditions that may periodically occur, such as maintenance or repair to a recycled water system.

   When there is a reduction in demand for recycled water from one of its WRPs in the San Gabriel River Watershed or during wet weather conditions, the water reclamation plants have historically discharged higher than average flow into the San Gabriel River. For flood control and other public health and safety reasons, the Sanitation Districts need to maintain the flexibility to be able to continue this historic practice.

4. Take authorization to allow the Sanitation Districts to adhere to the temperature compliance schedules in our NPDES permits, including any related studies.

   As mentioned previously, within the San Gabriel River, the Sanitation Districts have five WRPs with NPDES permits issued by the Regional Board. Each of those permits, which were renewed in 2021, contains a ten-year temperature compliance schedule that will allow the Sanitation Districts to identify and implement measures needed to comply with Basin Plan temperature objectives. The Sanitation Districts are also required to conduct studies as part of their compliance. Providing this exception will allow the Sanitation Districts to maintain compliance with their NPDES permits and assure compliance with Los Angeles Region Basin Plan temperature objectives. Similar activities to conduct studies and comply with Los Angeles Region Basin Plan temperature objectives are expected to be included in NPDES permit updates scheduled during 2022 for the two WRPs that discharge to the Upper Santa Clara River, and this exception should be applied there as well.

5. Take authorization to allow continued rotation of discharge from our San Jose Creek and Whittier Narrows WRPs to each of the various NPDES permitted outfall discharge locations.

   Historically, discharge from the San Jose Creek WRP rotates to various NPDES permitted outfall discharge locations. This has been done to maximize recycled water deliveries, maintain habitat, ensure public safety, and allow for system maintenance. Before, during, and after storm events, the Los Angeles County Department of Public Works may switch discharge locations for flood control purposes and to maximize stormwater capture. This flexibility and practice of rotating discharges must be allowed to continue in order to support this diverse range of public-interest goals.

Once again, we thank you for the opportunity to provide these comments and look forward to working with CDFW and the Commission. For any questions, please contact the undersigned at (560) 908-4288, ext. 2701 or rtremblay@lacsd.org.

Very truly yours,

Ray Tremblay

memorandum

date	April 2, 2024
to	Santa Clarita Valley Water Agency
cc	
from	Joel Mulder
subject	Review of Current and Historical Oncorhychus mykiss Occurrences in the Upper Santa Clara River Watershed (Los Angeles County)

Purpose

ESA has prepared this technical memorandum (memo) for Santa Clarita Valley Water Agency to review and document available information on the current and historical distribution of *Oncorhynchus mykiss (O. mykiss)*, including both the anadromous (southern California steelhead, referred to as steelhead herein) and resident (rainbow trout) life history forms of the species, in the upper Santa Clara River watershed within Los Angeles County (i.e., the watershed upstream of the Piru Dry Gap[1]). Information from a variety of sources is summarized in this memo, including biogeographic datasets, state and federal documents, peer-reviewed publications, historical source compilations, non-governmental organization information, and survey data.

Biogeographic Datasets

A query of California Department of Fish and Wildlife (CDFW) California Natural Diversity Database data (both processed and unprocessed data) found no documented occurrence of steelhead in the Santa Clara River watershed upstream of the Piru Creek confluence.

The CDFW Biogeographic Information and Observation System online mapping tool (BIOS) layers for steelhead range and distribution offer conflicting mapping of southern Steelhead distribution, as described below.

Winter Steelhead Range (ds699).

This dataset, developed by CDFW, contains all CalWater 2.2.1 Planning Watersheds where CDFW has documented winter run steelhead to be present (representing planning watersheds intersecting the known distribution, which is based on where the species has been observed and reported) during or after 1990. This

[1] Beginning about 3.5 river miles downstream of the Los Angeles - Ventura County line, the Santa Clara River surface flow is infiltrated into the underlying eastern Piru groundwater basin. Surface flow reappears approximately 6 miles downstream, past the confluence of Piru Creek. The river is dry through this reach most of the year, with water present only when rainfall events create sufficient stormwater runoff into the river (GSI 2008, LARWQCB 2007). This dry ephemeral reach of the river is informally known as the “Piru dry gap” in the Santa Clara River.

dataset does not show winter steelhead range as occurring in the Santa Clara River watershed upstream of the Piru Creek confluence.

Winter Steelhead Distribution (ds340)

This dataset, developed by CDFW, depicts observation-based stream-level geographic distribution of anadromous winter-run steelhead in California. It was developed for the express purpose of assisting with steelhead recovery planning efforts. The distributions reported in this dataset were derived from a subset of the data contained in the Aquatic Species Observation Database (ASOD), a Microsoft Access multi-species observation data capture application. Data source contributors, as well as CDFW fisheries biologists, have been provided the opportunity to review and suggest edits or additions during a recent review. Data contributors were notified and invited to review and comment on the handling of the information that they provided. The distribution was then posted to an intranet mapping application, and CDFW biologists were provided an opportunity to review and comment on the dataset. During this review, biologists were also encouraged to add new observation data. The dataset does not show steelhead distribution as occurring in the Santa Clara River watershed upstream of the Piru Creek confluence.

Southern California Steelhead Range (ds1290)

This dataset, developed by the University of California at Davis (U.C. Davis), shows a species extant range layer for steelhead by HUC12 watersheds based on datasets and interpreted by PISCES, which is software and data describing the best-known ranges for California's 133 native fish and numerous non-native fish. PISCES “models” presence, with corresponding probabilities if appropriate, based on expert opinion and observation data. PISCES biogeographic modeling outcomes reflect environmental and anthropogenic variables that “predict” where a given species may occur (Santos et al. 2014). The metadata for the layer describes the references for the datasets interpreted by PISCES as Moyle, Quinines and Bell (expert opinion) and NMFS Southern California Steelhead ESU Current Stream Habitat Distribution Table.pdf. It is not clear what the source is for the NMFS current stream habitat distribution table.

There are two primary layers in the PISCES model for steelhead. One is HUC12 watersheds with observations of *O. mykiss*. No HUC12 watersheds upstream of the Piru Creek confluence are shown as having positive observations. The other layer is a “historical expert” layer, which depicts HUC12 watersheds where steelhead occurred historically based on expert opinion. This layer shows steelhead occurring in the HUC12 watersheds containing the mainstem from Piru Creek upstream to about Soledad Canyon, and Castaic Creek, based on expert opinion but not on observational data.

Coastal Steelhead Trout Watersheds (ds962)

This dataset, developed by CDFW, provides a minimal set of watershed fields used to identify coastal steelhead management units. This data set is an extract of the California Watershed (CalWater) dataset. It has been generalized to hydrologic sub-areas for those watersheds that are considered part of the coastal steelhead range. However, the source data for the inclusion of hydrologic units in the “coastal steelhead trout range” is not cited or referenced in the dataset metadata. The dataset depicts hydrologic units in the upper Santa Clara River basin (upstream of the Piru Creek confluence) as coastal steelhead watersheds.

Federal and State Documents

Federal Endangered Species Act designated critical habitat for southern California steelhead in the Santa Clara River watershed extends from the Pacific Ocean, upstream the main Santa Clara River to the confluence with Piru Creek; critical habitat in the Santa Clara River does not extend beyond the confluence with Piru Creek (70 FR 52487).

In the NMFS population characterization for steelhead recovery planning, the discussion of the Santa Clara River states "The available evidence suggests that steelhead have been limited to the western part of the Santa Clara basin (Kelley 2004)" (Boughton et al. 2006). The document uses Boughton and Goslin's (2006) over-summering habitat model (described below) as the basis for its findings.

Boughton and Goslin (2006) developed a model of potential steelhead over-summering habitat using the method of environmental envelopes. Under the envelope method, predicted habitat is the set of stream segments falling within the same range of conditions that encapsulate the known occurrences of the species. In the discussion of results from the Los Angeles Basin, the authors note "The model predicted a distinct patch of potential habitat in the far eastern end of the Santa Clara basin (upper right quadrant, east of Newhall). This did not conform to expectations. Reports from the area suggested that steelhead were confined to the western end of the Santa Clara system. Visits to the eastern area between Newhall and Palmdale indicated that this area is drier than implied by the model, due to a rain-shadow effect from the San Gabriel Mountains (C. Swift, personal communication, Entrix). It probably did not contain potential habitat in reality". In their discussion of the model's environmental envelope outputs, the authors note that the Southern California Coast ESU[2] may have more false positives (warm areas with no potential for thermal refugia), but that these false positives may occur at a finer resolution than addressed by the model. In other words, the model may indicate suitable habitat in some areas of Southern California where in reality temperatures and lack of thermal refugia preclude steelhead occurrence.

In NMFS' 2023 5-Year Review for the species, there is no mention of areas of the Santa Clara River watershed upstream of the Piru Creek confluence (NMFS 2023). In the Southern California Steelhead Recovery Plan (NMFS 2012) discussion of current watershed conditions the only mention of the Santa Clara River watershed upstream of the Piru Creek confluence is that "Fish passage is further impacted by the operation of Castaic Dam on Castaic Creek". Table 2-1 of the Recovery Plan lists the Santa Clara River watershed as historically occupied by steelhead, citing Becker et al. 2009, Boughton et al. 2005, and Titus et al. 2010 (NMFS 2012). A discussion of those sources is provided below, with a focus on historical occurrences in the upper watershed.

Boughton et al. (2005) assessed the current occurrence of anadromous *O. mykiss* in each coastal basin of southern California in which it occurred historically. While the current and historical occurrences in the Santa Clara River are not described specifically in the memorandum, Figure 4 shows the historic distribution of spawning and rearing basins for steelhead in southern California. The figure shows the Santa Clara River basin up to approximately the Ventura-Los Angeles County line as historically occupied. The figure notes that shading of entire basins implies only that steelhead occurred somewhere, not necessarily everywhere, in a basin. The source

[2] Listed steelhead are now referred to as a ''distinct population segment'' (DPS), which is not recognized in the scientific literature. In 1991, NMFS issued a policy for delineating Pacific salmon DPS (56 FR 58612; November 20, 1991). Under this policy a group of Pacific salmon populations is considered an ''evolutionarily significant unit'' (ESU) if it is substantially reproductively isolated from other conspecific populations, and it represents an important component in the evolutionary legacy of the biological species. Further, an ESU is considered to be a DPS (and thus a ''species'') under the ESA.

for the historical occurrence data for the figure is noted as Titus et al. 2003, Stoecker et al. 2002, and a third source which was omitted from the figure description (text is cut off). Further discussion of Titus et al. is provided below. Stoecker et al. (2002) is a report on steelhead assessment and recovery opportunities in southern Santa Barbara County as is not relevant to the Santa Clara River.

The Titus et al. 2003 in preparation document cited in Boughton et al. 2005 and Titus et al. 2010 in preparation document cited in the species recovery plan (NMFS 2012) is cited as several sources under different publication years as the document has been in draft form with various updates for some time. As of April 2, 2024, the manuscript is still a draft[3]. The report provides stream-specific information on steelhead in central and southern California gathered from three main sources: (1) A literature search of pertinent journal articles, CDFW (known as California Department of Fish and Game until 2013) administrative reports and fish bulletins, and other resource agency, university, and consultant publications; (2) Resource agency files, especially CDFW stream survey files; (3) Interviews conducted with professional biologists, academicians, and representatives of sportfishing organizations and other special interest groups for information from personal files, and anecdotes based on personal observations. The report's description of the Santa Clara River Headwater Tributaries in Los Angeles County states no historical evidence of steelhead runs. San Francisquito Canyon and Soledad Canyon are noted as two streams for which there are CDFW records for rainbow trout presence and/or stocking dating back to circa 1930.

Non-Governmental Organization Resources

Becker et al. (2009) summarizes historical accounts of *O. mykiss* in streams south of San Francisco Bay based on thousands of documents in public and private collections, and interviews with biologists. Only three areas in the upper Santa Clara River watershed are described in the report as having fish observations. It is important to note that these observations are for fish in general, and not specifically steelhead.

Elizabeth Lake Canyon, tributary to Castaic Creek - Field notes from US Forest Service staff from 1947 indicate that "some fish" were caught in Elizabeth Lake Canyon Creek in the previous season (CDFG 1952). The author noted that the creek was unlikely to support fish life throughout the year, presumably due to low flow.

Fish Canyon, tributary to Castaic Creek - A 1956 CDFW stream inventory for Fish Canyon Creek states, "…some native fish reported in upper reaches" (CDFG 1956b). It adds, "This is definitely a marginal water…"

Bouquet Canyon - According to CDFW records, rainbow trout fry from the Shasta hatchery were planted in Bouquet Canyon Creek in 1943 (CDFG 1943). A 1947 stream survey indicates that *O. mykiss* including a "few fingerlings" were observed in the creek but notes, "Fishing maintained only be frequent plantings" (CDFG 1947b).

In a previous document, Becker et al. (2008) appears to acknowledge the unreliable nature of these observations in Figures 24 and 25 of the report, describing the historic and current, respectively, status of *O. mykiss* in coastal streams of southern Ventura County. In the figures, Castaic Creek and its tributaries, as well as San Francisquito and Bouquet Canyon creeks, are shown as "unknown or insufficient data". Paradoxically, the mainstem Santa Clara River upstream of the Piru Creek confluence is shown as "definite run or population" despite no

---

[3] Available at: https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=10194

documentation in the report of any observations currently or historically in that section of river. CalTrout, an organization focused on healthy waters and resilient wild fish, provides on The Southern Steelhead page of their website[4] as well as their publication “SOS II: Fish in Hot Water: Status, threats and solutions for California salmon, steelhead, and trout” a map of current and historical steelhead range. The source of the map is noted as PISCES (2017). See the discussion above under Biogeographic Datasets - Southern California Steelhead Range (ds1290) for PISCES.

The conservation group Trout Unlimited’s website[5] provides maps of the historical and current status of *O. mykiss* in coastal streams of southern Ventura County, California. Both maps show the mainstem of the upper Santa Clara River from the Piru Creek confluence up to about the N3 Angeles Forest Highway as historically and currently having a “definite run or population”. However, the cited source for these maps is Becker et al. 2009, described above, which does not appear to substantiate the steelhead historical and current distribution depicted on these figures.

Other Sources

Stoecker and Kelley (2005) analyzed the habitat conditions, population status and barriers to migration for steelhead in the lower Santa Clara River watershed from the Piru Creek tributary downstream, including significant drainages. There is no mention of steelhead resources upstream of the Piru Creek confluence.

Bowers (2008) compiled historical steelhead accounts in Ventura County, primarily from newspaper accounts, personal fishing logs, books, pamphlets, and Ventura County Board of Supervisors’ Minutes. Because the report looked at Ventura County, little mention is made of the upper Santa Clara River watershed in Los Angeles County except two articles from the Santa Paula Chronicle. The first, in 1925, noted five thousand “trout” were planted in Bouquet Canyon. The second, in 1943, described Bouquet Canyon as being “in good shape with plenty of good-sized fish left over from last year’s plant”, presumably referring to planted *O. mykiss.*

Bell (1978) described the fishes of the Santa Clara River and made collections at 46 stations from the river mouth upstream as far as water existed. In the upper watershed, this included San Francisquito Creek, Castaic Creek, Arrastre Canyon, and the mainstem river. No *O. mykiss* were encountered. Bell cites Hubbs (1946) as reporting large and consistent runs of *Salmo gairdneri* (the former scientific name for *O. mykiss*) in the Santa Clara River. However, Bell notes that at the time of his survey, *Salmo* were abundant in Sespe Creek, but Piru Creek and the Santa Clara mainstem were much less suitable habitat, and trout were restricted to a few deep holes in Piru Creek and as escapees to the mainstem from Fillmore fish hatchery. No mention is made of trout in the upper watershed.

Numerous fish sampling events have been conducted in the upper Santa Clara River, particularly the mainstem, in more recent years. Table 1 below presents a list of the sources examined. No *O. mykiss* were encountered in any of the surveys.

Discussion

In review of the available information, no verifiable or concrete observations of native *O. mykiss* in the upper Santa Clara River watershed have been described or recorded historically or currently. Observations that potentially could have been native *O. mykiss* are described in Becker et al. 2009. However, observations of "some fish" or "some native fish" in Elizabeth Canyon and Fish Canyon do not specifically mention *O. mykiss.* The references could be to other native fish in the upper watershed such as threespine stickleback (*Gasterosteus williamsoni*) which were formerly more common in the upper headwater tributaries (Bell 1978). Titus et al. (*In preparation*) also notes San Francisquito Canyon and Soledad Canyon as two streams for which there are CDFW records for rainbow trout presence and/or stocking dating back to circa 1930.

These observations may all well have been planted trout. As described in Titus et al. (*In preparation*) above and in newspaper accounts (Bowers 2008), extensive stocking was occurring in the upper watershed as early as 1925, and it would have been impossible to distinguish native resident trout or steelhead from stocked trout.

Given these unreliable historic accounts and lack of any other verifiable observations, it is of concern that Becker et al. 2008 and Titus et al. (*In preparation*) appear to be the basis for some historic and current distribution maps for southern California steelhead in the upper Santa Clara River (e.g., Boughton et al. 2005, Trout Unlimited), particularly since Becker et al. 2008 itself shows occurrence maps in upper watershed tributaries where there are questionable fish observations as "unknown or insufficient data". It is also not apparent why the upper watershed is considered to have been historically occupied by experts for the U.C. Davis PISCES model, and historically and currently occupied in Figures 24 and 25 of in Becker et al. 2008 despite the absence of observations. Perhaps the underlying assumption is that because the lower Santa Clara River had a well-documented and robust steelhead run (Hubbs 1946, Stoecker and Kelley 2005, Bowers 2008), fish would have inevitably made their way all the way up the river to the upper basin headwaters. However, an examination of habitat conditions in this area suggests that the habitat in the upper basin may have precluded or greatly limited steelhead migration in most years, and that even in particularly wet years when migration was possible, available upstream spawning and over-summering habitat was and is extremely limited or of poor quality.

The Santa Clara River is a perennial stream from Interstate 5 downstream to just west of the Los Angeles - Ventura County line. Beginning about 3.5 river miles downstream of the county line the entire surface flow is infiltrated into the underlying eastern Piru groundwater basin. Surface flow reappears approximately 6 miles downstream, past the confluence of Piru Creek. The river is dry through this reach most of the year, with water present only when rainfall events create sufficient stormwater runoff into the river (GSI 2008, LARWQCB 2007). This dry ephemeral reach of the river is informally known as the "Piru dry gap" in the Santa Clara River. Flood flows in the Upper Santa Clara River increase, peak, and subside rapidly in response to high-intensity rainfall. The "flashy" hydrograph produced by these conditions shows a rapid increase in discharge over a short time period with a quickly developed peak discharge compared to normal baseflow (Kennedy/Jenks 2014). Thus, migration opportunities through the dry gap for upstream migrating steelhead adults and downstream migrating smolts would have historically been limited to typically brief high flow events. The same is true under current conditions, though flows through the dry gap may be artificially altered in duration due to releases from or withholding in upstream reservoirs (e.g., Castaic Lake).

Habitat conditions in the upper watershed tributaries are described in historic accounts as generally poor for *O. mykiss*. For example, field notes from US Forest Service staff from Elizabeth Lake Canyon Creek in 1952 note that the creek was unlikely to support fish throughout the year "presumably due to low flow", and in 1956 regarding Fish Canyon "This is definitely a marginal water…", and in Bouquet Canyon Creek, 1943, "Fishing maintained only by frequent plantings" (Becker et al. 2009). Boughton and Goslin (2006) acknowledge that the watershed between Newhall and Palmdale is subject to a rain-shadow effect from the San Gabriel Mountains and "probably did not contain potential habitat in reality". No current information or surveys reviewed suggest that suitable habitat for *O. mykiss* is extant in the upper basin tributaries. Becker et al. (2010) analyzed information on rearing habitat to identify regionally significant watersheds, which are those offering the greatest potential for producing steelhead smolts, including over-summering opportunities and conditions favoring high growth rates. Within these watersheds the report identifies "essential" streams or reaches that offer the best habitat resources. Within the upper Santa Clara River watershed, portions of the mainstem and several tributaries are identified as “essential” stream, but no waterbodies in the upper watershed are identified as “available” or “suitable” *O. mykiss* habitat (see Figure 14 in the report).

In conclusion, there is no record of current *O. mykiss* occupation in the upper Santa Clara River watershed (east of the Piru Creek confluence) on which to support any determination of species “presence”. Despite extensive fish sampling in the area over the last few decades, no *O. mykiss* have been encountered. Habitat conditions currently do not suggest suitable habitat is present for this species in the area.

There are no verifiable or concrete historical observations of native *O. mykiss* in the upper Santa Clara River watershed, and historical descriptions of habitat conditions do not suggest suitable, perennial habitat was present for *O. mykiss* in the area.

Re: California Fish and Game Commission April 17-18, 2024 Meeting Agenda #22 – Southern California steelhead

Dear President Murray:

The California Building Industry Association (CBIA) appreciates the opportunity to comment on the petition to list the Southern California steelhead (steelhead) and the accompanying California Department of Fish and Wildlife (Department) Status Review Report. CBIA is a statewide trade association based in Sacramento representing thousands of member companies including homebuilders, trade contractors, architects, engineers, designers, suppliers and industry professionals in the homebuilding, multi-family and mixed-use development markets.

We have reviewed the petition to list the steelhead, the Department's status review report, and additional information submitted by stakeholders and believe that the petitioned action is not warranted and urge the California Fish and Game Commission (Commission) to deny the petition.

CBIA shares the concerns raised by organizations including the Association of California Water Agencies regarding both the scientific basis for a listing determination, the potential impacts on California's water agencies and their ability to reliably provide water, and the impact certain aspects of the listing will have on the state's homebuilding industry.

CBIA is concerned that part of the rationale leading the Department to recommend to the Commission that the petitioned action is warranted is based on serious deficiencies regarding population information and mapping inaccuracies. The Department's status review points out on page 40 (4.2 Sources of Information) that:

> "Data limitations and uncertainties associated with historical accounts for Southern SH/RT limits our ability to understand their complete historical abundance and distribution in their range. The majority of available historical data are in reports, technical memos, and other documents that have not undergone a formal peer-review process."

The report goes on to state that the data constraints "may limit the power of statistical analyses to assess trends in viability criteria. Therefore, the results of the analyses conducted in subsequent portions of this chapter should be interpreted in the context of these limitations."

CBIA believes that the data limitations has produced flawed analyses and speculation as to what is the current and historical range of the species to the point that several figures contained in the report – for example Figure 7 located on Page 43 and Figure 11 located on Page 58) – could lead a person to believe that Southern California steelhead should be found in certain watersheds where in reality none have been observed.

CBIA believes that if such types of maps are necessary then the Department should utilize the data developed by the U.S. Fish and Wildlife Service in order to provide a level of consistency instead of relying on information and data that is at its core limited and full of uncertainty.

Based on these issues and those raised by organizations including the Association of California Water Agencies, we urge the Commission to find that the petitioned action is not warranted.

Sincerely,

Nick Cammarota
Senior Vice President & General Counsel
California Building Industry Association

Subject: Evaluation of Additional References Received for the Status Review of southern California steelhead (Oncorhynchus mykiss)

Summary

The California Department of Fish and Wildlife (Department) has prepared this supplemental information for southern California steelhead (*Oncorhynchus mykiss*) memo for the California Fish and Game Commission (Commission). The Department created the memo in response to references the Department received in February 2024 after the Department transmitted its final status review report on southern California steelhead (Status Review) to the Commission in January 2024. The Department reviewed each reference, assessed its relevance to the Status Review, and compiled the information in this memo. Of the 39 references, we determined that 17 contained information that is directly relevant to the Status Review, 14 contained useful background information but were determined to not be directly relevant to the Status Review, and 8 were already cited in the Status Review. Collectively, the 39 references either support or are consistent with the analysis, conclusions, and recommendations in the Status Review.

If you have any questions or need additional information, please contact Jay Rowan, Branch Chief, Fisheries Branch, at (916) 212-3164 or by email at fisheries@wildlife.ca.gov.

Information directly relevant to the Status Review

1. Allesio, P., M. H. Capelli, S. D. Cooper, B. Keller, E. A. Keller, H. A. Loaiciga, C. McMahon, and J. M. Melack. 2023. Upper Mission and Rattlesnake Creeks: Hydrogeologic and Biologic Investigation, Santa Barbara, California with Special Reference to Mission Tunnel Effects on Creek Flows. Prepared for Urban Creek Council, Santa Barbara.

   This reference reports the key findings and recommendations resulting from a hydrologic, geomorphologic, geologic, and aquatic, and riparian study of the upper, non-urban, watershed of Mission Creek (including its tributary, Rattlesnake Creek). It includes a detailed summary of the history of southern California steelhead populations in the watershed as well as an assessment of suitable habitat. The discussion on abundance and trends in this report is consistent with the Status Review analysis results in Chapter 4, Section 4.4.1.2, Page 63.

2. Boughton, D. A. and M. Goslin. 2006. Potential Steelhead Over-Summering Habitat in the South-Central/Southern California Coast Recovery Domain: Maps Based on the Envelope Method. NOAA Technical Memorandum NMFS-SWFSC-391.

   This report discusses the results of a modeling exercise to map and visualize potential over-summering habitat in the federal South-Central/Southern California Coast recovery domain. The Department evaluated this report during the development of the Status Review. Even though a significant area of over-summering habitat is located above barriers to anadromous migrations, the findings provide useful information about the life-history and habitat of southern California steelhead and is consistent with Chapter 2, Section 2.4, and Chapter 5 of the Status Review.

3. Capelli, M. H. 2023. The role of wildfires in the recovery strategy for the endangered southern California steelhead. In: J. L. Florsheim, A.P. O'Dowd, and A. Chin (eds.). *Biogeomorphic Responses to Wildfire in Fluvial Ecosystems*. Geological Society of America. Special Paper 562

   This research article discusses the role of wildfires in the recovery strategy for the endangered southern California steelhead. It supports and provides additional useful information related to Chapter 6, Section 6.2.7, Pages 101-102 of the Status Review.

4. Cooper, S. D., H. H. Page, S. W. Wiseman, K. Klose, D. Bennett, T. Even, S. Sadro, C. E. Nelson, and T. L. Dudley. 2015. Physicochemical and biological responses of streams to wildfire in riparian zones. *Freshwater Biology* 60(12): 2600–2619.

   This academic journal article documented wildfire impacts on stream food webs resulting from wildfires in the riparian zones of streams in Santa Barbara County. This study was conducted within the range of southern California steelhead and provides post-fire vegetation recovery management implications, and the results support Chapter 6, Section 6.2.7, pages 101-102 of the Status Review.

5. Cooper, S. D., K. Klose, D. B. Herbst, J. White, S. M. Drenner, S.M., and E. J. Eliason. 2021. Wildfire and drying legacies and stream invertebrate assemblages. Freshwater Science 40(4): 659–680 https://doi.org/10.1086/717416.

This academic journal article examines the effects of drought and wildfire on stream invertebrate communities. Stream reaches in Southern California were sampled at sites that have been either burned or unburned during both wet and dry years. The findings highlight the importance of protecting water supplies and riparian vegetation, and support Chapter 6, Section 6.2.7, pages 101-102 of the Status Review.

6. Florsheim, J. L., A. Chin, A. M. Kinshita, and S. Nourbakhshbeidokhti. 2017. Effect of storms during drought on post-wildfire recovery of channel sediment dynamics and habitat in the southern California chaparral, USA. Earth Surface Processes and Landforms 42(10):1482-1492.

   This research article investigated post-wildfire geomorphic responses from storms during a prolonged drought period following a large wildfire in southern California. The study emphasizes the complex, dynamic, and substantial effects of multi-year drought on geomorphic processes following wildfire, with implications for post-fire riparian ecosystem recovery. The study provides useful insight on the complex interactions between storms, wildfires, and drought in southern California streams and supports Chapter 6, Section 6.2.7, pages 101-102 of the Status Review.

7. Douglas, P. L. 1995. Habitat Relationships of Over summering Rainbow Trout (*Oncorhynchus mykiss*) in the Santa Ynez Drainage. M.A. Thesis. University of California Santa Barbara.

   This master's thesis examined the relationship between trout density and habitat characteristics in streams throughout the Santa Ynez watershed. The results indicate that fry density is associated with instream cover and negatively associated with water temperature. Adult trout were found to be positively correlated with instream cover and negatively associated with stream temperature, aquatic vegetation, and the density of non-salmonid fish species. Although this study was conducted above the major barrier to anadromy in the Santa Ynez watershed, it provides useful information and supports Chapter 5, Sections 5.3 through 5.5 of the Status Review.

8. Hemmert, J. 2018. Coldwater Canyon Creek Rainbow Trout (Oncorhynchus mykiss) Rescue Summary. Fisheries Heritage and Wild Trout Program, Inland Deserts Region. California Department of Fish and Wildlife, Region 6.

   This memo describes rescue actions to relocate rainbow trout from the Coldwater Canyon Creek to the Mojave River hatchery in response to the 2018 Holy Fire. This effort included the capture and transportation of 241 rainbow trout from Coldwater Canyon by the Department. While this rescue effort occurred far upstream of the artificial barrier to anadromy in the Santa Ana River watershed, it provides additional information to support Chapter 6, Section 6.2.7, Page 101 of the Status Review.

9. Jacobson, S. 2021. Southern California Native Rainbow Trout Sub-Population Expansion Plan. Prepared for California Trout, Inc. June 15, 2021.

   This management plan describes a proposal by Cal Trout Inc. and partners to increase the abundance, distribution, and genetic diversity of native rainbow trout through a network of subpopulations in its range through embryonic translocation. This information may contribute in the future to the Influence of Existing Management Efforts (Chapter 7).

10. Pareti, J. 2021. Bobcat Fire Fish Rescue: West Fork San Gabriel River and Bear Creek. Fall 2020. California Department of Fish and Wildlife, Region 5.

    This report details fish rescue efforts on the West Fork San Gabriel River and Bear Creek following the Bobcat fire. A total of 1,374 rainbow trout fish were rescued for this effort. Although this report is not cited in the Status Review, a subsequent report (cited as Pareti 2020 but should be Pareti 2021) is cited that describes how the rescued fish were then translocated to the Arroyo Seco and East Fork San Gabriel Rivers.

11. Stillwater Sciences, R. Dagit, and J. C. Garza. 2010. Lifecycle Monitoring of *O. mykiss* in Topanga Creek, California. Final Report to California Department of Fish and Game Contract No. P0750021. Resources Conservation District of the Santa Monica Mountains.

    This report provides the results of nine years of lifecycle monitoring of steelhead rainbow trout in Topanga Creek. We evaluated this report during the development of the Status Review and opted to instead reference Dagit et al. 2019, which includes a comprehensive summary of lifecycle monitoring efforts in Topanga Creek from 1994 to 2019.

12. Stillwater Sciences. 2020. Conceptual Ecological Model and Limiting Factors Analysis for Steelhead in the Los Angeles River Watershed. Final Technical Memorandum. Prepared by Stillwater Sciences, Los Angeles, California for the Council for Watershed Health, Pasadena, CA. September 2020.

    This technical memorandum describes the ecological basis (i.e., life-history, LA River watershed description, limiting factors analysis, conceptual ecological model) for the steelhead passage and habitat improvements central to the Los Angeles River Fish Passage and Habitat Structures project. This pilot project aims to restore fish passage and habitat within a 4.8-mile section of the concrete-lined Los Angeles River. While this project is still in its pilot phase, it provides additional information that informs the influence of existing management measures described in Chapter 7.3.5 and 7.3.6 of the Status Review.

13. Taylor, J. B., E. D. Stein, M. Beck, K. Flint, and A. Kinoshita. 2019. Vulnerability of Stream Biological Communities in Los Angeles and Ventura Counties to Climate Change Induced Alterations of Flow and Temperature. Southern California Coastal Water Research Project. Southern California Coastal Water Research Project Technical Report 1084.

    The authors of the report used models to relate streamflow and temperature to the probability of six species occurrences (including southern California steelhead) to map out future species distributions. The authors note that the results of their analysis could be used to support a variety of future management and monitoring decisions. The findings specific to southern California steelhead provide additional information and support for the Status Review in Chapter 5, "Habitat That May Be Essential to the Continued Existence of southern California steelhead rainbow trout".

14. Ventura County Fish and Game Commission. 1973. *The Ventura River Recreational Area and Fishery: A Preliminary Report and Proposal*. Prepared for the Ventura County Board of Supervisors. March 1, 1973.

    This draft report describes the Ventura River recreational area and fishery during the early 1970s. The fisheries section of the report characterizes the watershed as an especially productive trout fishery during the pre-1940s. An estimated 4,000-5,000 adult steelhead were observed to have entered the Ventura River to spawn in 1946. The post-1946 fishery was marked by a significant alteration to the watershed, which resulted in the decline of the fishery. However, angling for trout and steelhead was still considered to be productive. This preliminary report provides additional useful background information and support for Chapter 4, Section 4.3.1.3, pages 46-48 in the Status Review.

15. Capelli, M. H. 1997. Ventura River steelhead survey, Ventura County, California. Prepared for California Department of Fish and Game, Region 5. UC Santa Barbara Library: Special Collections, University of California, Santa Barbara, USA.

    This report summarizes the results of a sampling survey conducted on the lower Ventura River below the Robles Diversion. The effort captured a total of 52 rainbow trout across a total of 4.25 stream miles. The fish ranged in size from 7.5 to 16 inches. Five individuals were hatchery fish, while the remaining were determined to be natural residents or anadromous individuals. This survey provides additional relevant information and support for Chapter 4, Section 4.3.1.3, Pages 46-48 of the Status Review.

16. Harrison, L., E. Keller, and M. Sallee. 2005. Santa Monica Mountains Steelhead Habitat Assessment: Watershed hydrologic analysis. University of California, Santa Barbara.

    This watershed analysis aimed to identify which basins in the Santa Monica Mountains are most capable of supporting steelhead trout populations. The study examined the relationship between baseflow and geology and modeled predictions of rainfall-runoff between important watersheds. Larger basins with higher flows were ranked as having the highest potential to support steelhead. These basins include Malibu, Topanga, Arroyo Sequit, Trancas, Zumas, and Las Flores Creek. This study provides an important contribution to our understanding of habitat potential for steelhead trout in the Santa Monica Mountains. However, more recent reports were reviewed during the development of the Status Review, such as the federal Recovery Plan of 2013, which includes updated information on core recovery watersheds in the Santa Monica Mountains and southern California.

17. Nielsen, J., C. Zimmerman, J. Olsen, T. Wiacek, E. Kretschmer, G. Greenwald, J. Wenburg. 2002. Population Genetic Structure of Santa Ynez Rainbow Trout - 2001 Based on Microsatellite and mtDNA Analyses.

    This study examined the genetic diversity of 8 rainbow trout subpopulations in the Santa Ynez River. The relevant findings of the study are that most subpopulations sampled do not appear to be significantly influenced by hatchery fish, despite the considerable amounts of hatchery supplementation that had occurred up until the end of the 1990s. These results provide further support for information provided in Chapter 2, Section 2.5.7, Page 32-33 on the genetic impacts of historical stocking in the Status Review.

Background Information Not Directly Relevant to the Status Review

18. Barabe, R. M. 2021. Population estimates of wild rainbow trout in a remote stream of southern California. *California Fish and Wildlife* 107(1):21-32.

    This reference reports a CDFW-led study on the distribution and abundance of wild Rainbow Trout in Pauma Creek, a tributary to the San Luis River in northern San Diego County. A total of 854 fish were captured during this two-year seasonal survey. Pauma Creek is currently located above multiple barriers to anadromous migration and is therefore not directly relevant to the Status Review.

19. Cooper, S. D., P. Sam, S. Sabater, J. M. Melack, J.M., and J. L. Sabo. 2013. The effects of land-use changes on streams and rivers in Mediterranean climates: Hydrobiologia 719(1): 383–425 https://doi.org/10.1007 /s10750-012-1333-4.

    This academic journal article reviewed literature on the effects of land use changes on Mediterranean river ecosystems, including those in Chile, South Africa, and California. While the information is informative, it is not directly relevant to the Status Review.

20. HDR Engineering, Inc. 2013. Los Padres National Forest Steelhead Monitoring, Tracking and Reporting Program. Final Plan. Prepared for the U.S. Forest Service, Los Padres National Forest. Santa Maria, CA.

    This report provides guidance on monitoring, tracking, and reporting of rainbow trout populations and habitat conditions within the Los Padres National Forest. While informative, watershed specific monitoring programs for streams occurring outside the scope of the Petitioner’s listing definition are not directly relevant to the Status Review.

21. Keller, E. A., G. Bean, and D. Best. 2015. Fluvial geomorphology of a boulder-bed, debris-flow- dominated channel in an active-tectonic environment. Geomorphology 243(2015):14-26.

    This scientific research article describes the fluvial geomorphic processes of Rattlesnake Creek in the Santa Ynez Range in Southern California. The authors hypothesize the mechanisms that drive the underlying step-pool morphology of the creek. While the study was conducted within the geographic range of southern California steelhead, its results are not directly relevant to the Status Review.

22. McMahon, C., S. D. Cooper, and S. W. Wiseman, S.W. 2023. Postfire stream responses to spatial fire patterns in riparian and upland zones. In: J. L. Florsheim, A. P. O’Dowd, and A. Chin, A. (eds.). *Biogeomorphic Responses to Wildfire in Fluvial Ecosystems*. Geological Society of America. Special Paper 562.

    This book chapter examined differences in burn patterns in riparian versus upland zones and their implications for stream characteristics. The authors studied fire patterns and postfire vegetation trajectories for the two habitat types across 26 stream sites in coastal southern California over a period of 12-years. There are many interesting and informative findings from this long-term study; however, the findings are not directly relevant to the Status Review.

23. Nielsen, J. L., D. J. Scott, and J. L. Aycrigg. 2001. Endangered species and peripheral populations: cause for conservation. *Endangered Species Update* 18(5):194-197.

This letter to the editor of the School of Natural Resources and Environment at the University of Michigan advocates for the value of peripheral populations in endangered species conservation. The letter is a rebuttal to a previous article supporting the opposite claim that peripheral populations dilute the effectiveness of species conservation. Southern California steelhead are referenced to support the authors' claim that peripheral populations have intrinsic population value. However, this letter is not directly relevant to the Status Review.

24. Hemmert, J. 2020. 2019 Coldwater Canyon Creek Rainbow Trout (*Oncorhynchus mykiss*) Relocation Summary Report – Mojave River Hatchery to Marion Creek. Fisheries Heritage and Wild Trout Program, Inland Deserts Region. California Department of Fish and Wildlife, Region 6. June 8, 2020.

This report describes the relocation of Coldwater Creek rainbow trout from the Mojave River hatchery. Of the 241 individuals rescued from Coldwater Creek in response to the Holy Fire, 149 perished at the Mojave River Hatchery, and 92 were translocated to Marion Creek. While these actions serve to inform future management efforts, they are not directly applicable to the Status Review because the watersheds in question are far above natural barriers to anadromy and are thus not directly relevant to the Status Review.

25. White, J., L. Takata, and M. Rieck. 2017. Final Los Padres National Forest 2017 Steelhead Monitoring Report. U.S. Forest Service, Los Padres National Forest. Challenge Cost Agreement between the University of California, Santa Barbara and USFS-LPNF (Agreement No. CS-11050700-007).

This report assessed the physical, chemical, and biological conditions of streams affected by three major fires that occurred in the Los Padres National Forest. Rainbow trout were observed at 6 of 8 unburned sites but were not observed at sites impacted by fire. This report provides insight on the impact of fire on resident rainbow trout populations and their habitat above major barriers to anadromy. However, the survey sites were all outside the scope of the Petitioner's definition of the species and thus not directly relevant to the Status Review.

26. Bean, G. S. 2007. Geologic controls on channel morphology and low-flow habitat in Rattlesnake Creek, Santa Barbara, California. M.S. Thesis. University of California Santa Barbara.

This master's thesis examined whether geologic and hydrogeologic properties control channel morphology and low-flow habitat for southern California steelhead in Rattlesnake Creek. The study found that rock strength and joint strength of the underlying geology did not significantly affect the channel morphology of the creek. This study is not directly relevant to the Status Review.

27. Capelli, M.H. 1999. Dam Sand Rights: Removing Rindge and Matilija Dams. Proceedings, Sand Rights 1999: Bringing back the beaches, Ventura, CA. September 23-26, 1999.

    This article discusses the many benefits of removing the Rindge and Matilija dams, including the establishment of natural sediment transport, beach restoration, and shoreline armoring. The article advocates for inland sources of beach material, such as sediment trapped behind outdated dams, to be used to restore the beaches of southern California. While this article provides useful background information on the history of Matilija and Rindge dams, it is not directly relevant to the Status Review.

28. Capelli, M.H. 2004. Removing Matilija Dam: Opportunities and challenges for Ventura River restoration. Proceedings U.S. Society on Dams. St. Louis Missouri. March 29-April 2, 2004.

    This article discusses the opportunities, benefits, and challenges of removing Matilija Dam from the Ventura River watershed. Matilija Dam traps 213,000 to 230,000 cubic yards of sediment annually since it was constructed in 1946. The article summarizes the benefits to the southern California steelhead population in the Ventura River if it was removed. Although this article provides detailed background information on the potential for dam removal on the Ventura River, it is not directly relevant to the Status Review.

    This scientific research article modeled the interactions among pool-riffle sequences in Rattlesnake Creek in Santa Barbara County. The authors found that pool-riffle sequences in boulder-bed streams are maintained by flows at or near bankfull discharge due to variability in velocity and tractile force. This research article is not directly relevant to the Status Review.

30. Rich, A. & E. Keller. 2013. A hydrologic and geomorphic model of estuary breaching and closure. Geomorphology. 191. 64–74. 10.1016/j.geomorph.2013.03.003.

This scientific research article modeled the hydrology of bar-built estuaries to better understand breaching and closing patterns. The study site used was the Carmel Lagoon in Monterey County. The results demonstrate that the model could accurately predict the breaching and closing of Carmel Lagoon. While the results of the study contribute many interesting findings to estuary hydrology, they are not directly relevant to the Status Review.

31. Cooper, S.D., S.W. Wiseman, B. DiFiore, and K. Klose. 2024. Trout and invertebrate assemblages in stream pools through wildfire and drought. Freshwater Biology (69): 300-320.

    This scientific research article examines how climate change (i.e., drought and fire) influences top predators and their impacts on lower trophic levels. The study examined relationships among the distribution of trout, environmental factors, and stream invertebrate assemblages across sample sites that both contained and did not contain trout. The results indicate that the impact that trout have on invertebrate communities depends on environmental conditions and bottom-up and top-down trophic pressures. While this information contributes to the growing body of science on stream trophic food web impacts due to climate change, the results are not directly relevant to the Status Review.

PETITION TO THE STATE OF CALIFORNIA FISH AND GAME COMMISSION SUPPORTING INFORMATION FOR

Agassiz's desert tortoise or Mojave desert tortoise (*Gopherus agassizii*)
Common Name **Scientific Name**

EXECUTIVE SUMMARY

Based upon a scientific review of its distribution and status, this petition requests that the Agassiz's desert tortoise (*Gopherus agassizii*; Mojave desert tortoise or desert tortoise) be moved from listed as Threatened to Endangered by the California Fish and Game Commission (Commission). Despite federal and state protections, the desert tortoise is closer to extinction than it was in 1989 and 1990 when it was listed by the Commission and U.S. Fish and Wildlife Service (USFWS), respectively. A change in listing from Threatened to Endangered will reflect the current dire situation facing California's state reptile and is necessary to generate substantially increased attention and efforts to reverse the very real likelihood that desert tortoise will become extinct in California.

The Commission listed the desert tortoise as Threatened under the California Endangered Species Act (CESA) in 1989. The Mojave population of the desert tortoise was listed as Endangered under a federal emergency listing rule under the Endangered Species Act (ESA) by the USFWS that same year. In 1990, the Mojave population of the species was listed by the USFWS under a final ESA rule as Threatened (USFWS 1990). A recovery plan prepared by the USFWS for this federally-listed species was adopted in 1994 (USFWS 1994a), with Critical Habitat concurrently designated (USFWS 1994b). A revised recovery plan for the species, noting problems in implementing certain previous recovery plan actions, was adopted in 2011 (USFWS 2011).

The initial California listing of the desert tortoise as threatened was based on a severe decline of tortoises throughout California, Nevada, Utah, and northwest Arizona – with California populations considered the most endangered.

Recent genetic analysis has concluded that the Mojave population of the desert tortoise is a distinct species, not a population, with a range that includes southeastern California, southern Nevada, northwest Arizona, and southwest Utah (Murphy et al. 2011). Those tortoises occurring in the rest of Arizona and northwest/west Sonora, Mexico, have recently been described as a separate species, Morafka's desert tortoise (*Gopherus morafkai*), and those in southwest Sonora and Sinaloa, Mexico, as Goode's thornscrub tortoise (*Gopherus evgoodei*) (Edwards et al. 2016). The species occurring in California is best described as Agassiz's desert tortoise (*Gopherus agassizii*).

Thirty-years after its listing as Threatened under provisions of the CESA and ESA, Agassiz's desert tortoise is in worse condition with the species on a path to extinction due to an increase in the number and severity of threats. Similarly, while Critical Habitat was designated for this species in 1994 and several federal resource management plans have been adopted by the Bureau of Land Management (BLM) and designed to improve habitat conditions, the sobering reality is that conditions on the ground have worsened for Agassiz's desert tortoise habitat over the long term, especially in California. More development and increased human uses have occurred in the California desert since listing, resulting in substantial loss of individuals, reduced recruitment, and substantial loss/degradation of habitat. Further, these threats are amplified by the effects of climate change on tortoise habitat. As a result, tortoise populations throughout **all** Recovery Units in California continue to decline.

Reversing the trend towards extinction and putting Agassiz's desert tortoise on a path towards recovery is difficult because the tortoise is a long-lived reptile, requiring up to 20 years to reach sexual maturity, and has a low reproductive rate over a long period of reproductive potential. The combination of a late breeding age and a low reproductive rate makes accomplishing desert tortoise recovery very challenging (USFWS 1994a). In addition, the continued, ongoing loss and degradation of the species' last remaining occupied habitat from a variety of authorized and unauthorized land uses, in an area of increasing human population growth, renewable energy development and generation, motorized vehicle recreation, and other human impacts, only makes the conservation and recovery of the desert tortoise even more challenging.

Threats to the species at the time of the 1990 federal listing as Threatened have not abated. Instead, they are more widespread and intense. The relatively recent expansion of military testing and training installations (United States Army National Training Center, Fort Irwin; United States Navy, Marine Corps Air Ground Combat Center, Twentynine Palms); development of large-scale renewable energy projects throughout the range of Agassiz's desert tortoise; and increased human population growth and activities in the California desert have resulted in concurrent tortoise mortality and habitat degradation/loss, both adjacent to human communities and at appreciable distances. Notably, tortoise populations located immediately adjacent to expanding human communities have disappeared.

Tortoises and their habitats are impacted by a myriad of authorized and illegal human activities that degrade or eliminate suitable creosote bush scrub and other vegetation communities needed as habitat. In particular, off-highway vehicle use, especially widespread, unregulated use on lands that are supposed to be protected, destroys and fragments habitat, injures and kills tortoise, and crushes tortoise burrows and eggs. Human activities also subsidize predators whose increased numbers prey on tortoises and facilitate invasion of non-native species of plants that degrade habitat quality and displace native forbs and grasses needed for adequate nutrition and reproduction/recruitment (Brooks and Berry 2006). Invasive, non-native plants also increase flammable fuel load to the point where wildfire, when it occurs, results in catastrophic megafires that kill tortoises outright. Recovery from fire in Mojave and Colorado desert vegetation communities is extremely slow because these communities are not adapted to wildfire and non-native plants outcompete native species during the post-fire period (Brooks and Esque 2002).

Climate modeling predicts that California's deserts will experience longer and more frequent drought and increased temperatures. These climate conditions will impact tortoise habitat and food supply, the species' ability to reproduce and recruit tortoises, and its sensitivity as a cold-blooded reptile to increasing temperature extremes. These impacts combined with the ongoing impacts from human activities are endangering Agassiz's desert tortoise throughout California.

The USFWS has repeatedly identified high adult tortoise survivorship as a key factor in meeting tortoise recovery objectives (USFWS 1994a, 2011). However, science-based surveys (line distance sampling) extending over a 10-year period throughout the species' range in California and data from permanent study plots indicate this key factor is not being achieved (USFWS 2015). These surveys demonstrate that desert tortoise numbers are declining significantly and resulting in all three Recovery Units experiencing reduced numbers and densities that reflect a species on a trajectory toward extinction.

Based on systematic USFWS-designed line distance sampling conducted by the USFWS's Desert Tortoise Recovery Office (DTRO), from 2004 through 2014, adult tortoises in the three California Recovery Units (Western Mojave, Colorado Desert, Eastern Mojave) declined 51.3 percent from 119,029 individuals to 65,726 (USFWS 2015). It is noteworthy and troubling for the future survival and recovery of desert tortoise that these losses occurred within federally designated Critical Habitat Units for tortoises, which, in theory, receive a higher level of protection under provisions of the federal ESA and land use plans prepared by federal agencies, primarily by the BLM for public lands in the California Desert Conservation Area.

Adult tortoise densities in Critical Habitat within the Western Mojave Recovery Unit averaged 5.7 per square kilometer in 2004, in contrast with an average density of 2.8 per square kilometer in 2014. This serious reduction is consistent with the substantial decreases in tortoise population densities documented within all three Recovery Units in California (Allison and McLuckie 2018). Unfortunately, this current decline is a continuation of the downward population trends documented in the Western Mojave by BLM wildlife biologists using a series of one square-mile study plots beginning in 1979 and extending to 2002. Initial surveys on these plots documented adult desert tortoise densities ranging from 29 to 147 per square kilometer in much of the western Mojave Desert (Tracy et al. 2004). Using the available scientific survey data, **adult tortoise densities in the Western Mojave Recovery Unit declined by 85 to 95 percent between 1980 and 2014** and continue to decline to the present time.

According to Allison and McLuckie (2018), adult tortoise densities in the three California Recovery Units of Agassiz's desert tortoise declined at the following annual rates during the period 2004 through 2014: Colorado Desert –4.5%; Eastern Mojave –11.2%; and Western Mojave –7.1%.

Allison and McLuckie (2018) also concluded that:

- *Overall this threatened species is **experiencing large, ongoing population declines**, and **adult tortoise numbers have decreased by over 50% in some recovery units** since 2004*;

- ***Declining adult densities through 2014 have left the Western Mojave adult numbers at 49% and in the Eastern Mojave at 33% of their 2004 levels**. Such steep declines in the density of adults are only sustainable if there were suitably large improvements in reproduction and juvenile growth and survival. However, the proportion of juveniles has not increased anywhere since 2007, and in these two recovery units **the proportion of juveniles in 2014 has declined to 91% and 77% of their representation in 2004,** respectively*;

- *Recent attention has focused especially on increased predation risk in the Western Mojave, Eastern Mojave, and Colorado Desert recovery units due to prey-switching during droughts by* Coyotes *(Canis latrans) and especially by increasing abundance of* Common Ravens *(Corvus corax), which typically prey on smaller tortoises rather than on adults*;

- *The negative population trends in most of the* [Tortoise Conservation Areas] *TCAs for Mojave Desert Tortoises indicate that **this species is on the path to extinction under current conditions.** This may reflect inadequate recovery action implementation, slow response by tortoises and their habitat to implemented actions, or new and ongoing human activities in the desert that have not been mitigated appropriately. It may also be a result of stochastic or directional climatic events that impact large expanses of tortoise habitat (e.g., drought, fire, climate change) and are largely beyond the realm of local land management activities. **Our results are a call to action to remove ongoing threats to tortoises from TCAs, and possibly to contemplate the role of human activities outside TCAs and their impact on tortoise populations inside them.***

(Emphasis added).

The USFWS (1994a) has determined that the minimum viable density of adult tortoises is 3.9 tortoises per square kilometer (10 tortoises per square mile), and that populations with densities below this size are in danger of extinction. The USFWS (2015) has reported that the density of adult desert tortoises in the three

Desert Tortoise Recovery Units in California are less than the minimum viable density and are experiencing a declining trend.

In addition to the startling population declines, this species is also facing significant uncertainty regarding protections on federal land. The California Desert Conservation Area (CDCA) Plan is the primary document guiding management on BLM land and was amended by the Desert Renewable Energy Conservation Plan (DRECP) in 2016 and the West Mojave Plan Route Network and Livestock Grazing Project in 2019. The most recent West Mojave Plan provides for a continuation of excessive vehicle use and livestock grazing, which are two of the most important threats to the desert tortoise and its critical habitat. Further, there is a currently pending plan amendment to the DRECP that is anticipated to contain further reductions in protections to desert tortoise.

Based on the best available scientific information presented in this petition, naturally-occurring populations of Agassiz's desert tortoise are on the verge of extirpation in California from a variety of human-caused threats and warrant a change in their listing status from Threatened to Endangered. Defenders of Wildlife, Desert Tortoise Council and Desert Tortoise Preserve Committee (Petitioners) believe changing the status of the species from Threatened to Endangered under provisions of the California Endangered Species Act will result in improved conservation and management outcomes for this species because it will (1) accurately reflect its status under CESA, (2) better inform project proponents that the tortoise is in danger of extinction and they should move their projects out of tortoise habitat/linkage areas to avoid extinction in California, (3) result in fully mitigation/compensation for the direct, indirect, and cumulative impacts to the tortoise, (4) provide for the implementation of more recovery actions to prevent its extinction in California, and (5) result in a higher-level of analysis of impacts to this species by the California Department of Fish and Wildlife (CDFW) from proposed land use activities on both federal, state, local, and private lands. If California is going to have any hope of avoiding the extinction of its state reptile, Agassiz's desert tortoise, and reverse the current decline of the tortoise to move toward recovery, the Commission must act by changing the listing status of this species from Threatened to Endangered.

1. **POPULATION TRENDS**

Describe current population trends (with numbers and rate) and relate these to viable population numbers. Explain survey methodology used to arrive at numbers or estimates and what assumptions, if any, were involved.

Background:

Population Sampling Methodologies

Permanent Study Plots: In the late 1970s, the Bureau of Land Management implemented a sampling methodology to collect demographic data on desert tortoises at 47 study plots in the spring. The method was to survey the sites intensively, locating all living tortoises and shell remains (BLM 2002). From these 47 plots, BLM selected and established 15 permanent one square mile study plots at various locations in the three Recovery Units (Figure 1) for the desert tortoise in the California Desert Conservation Area – Western Mojave, Colorado Desert, and Eastern Mojave (BLM 2002, Berry 2003) (See Tables 1a and 1b below). One hundred percent of each plot was surveyed twice for live desert tortoises and tortoise sign (e.g., burrows, scat, tracks, etc.). Surveys occurred in spring for 60 days. Density estimates were determined using mark-recapture sampling methods. Abundance, sex ratio, mortality, size distribution, and other population attributes were determined from the data collected. Most study plots were surveyed from every year to every 10 years (Berry 2003). The results of the surveys were applied to adjacent areas.

From the data collected, BLM reported the abundance of all size classes of desert tortoises (e.g., hatchlings, juveniles, immatures, subadults, and adults), mortality, population density and trend, size-specific sex ratios, age structure, survivorship rates, and causes of mortality at the size class and population levels in the California desert when compared to prior surveys at each plot. BLM in Nevada and Utah implemented this methodology in 1981 and Arizona in 1987 (USFWS 2010). BLM surveyed these study plots until 1995 when the U.S. Geological Survey assumed the task in California (BLM 2002; BLM et al. 2005).

The permanent study plot method had its downsides and assumptions. These include:

- Because of the intensive search effort needed to survey 100 percent of each plot, most study plots were not surveyed annually.
- Placement of permanent study plots was not random.
- Generally, plots were located where densities of tortoises were found to be high. This placement was done to get an adequate sample size to determine density using mark-recapture calculations. Thus, density estimates from study plots when applied to adjacent areas could be greater or less than the actual densities.
- The assumption that tortoises do not enter or leave the study plot during the entire 60-day spring survey period is not likely being met for the mark-recapture method.
- Tracy et al. (2004) concluded that it was not appropriate to extrapolate data from these plots to serve as a range-wide population baseline from which to assess recovery.

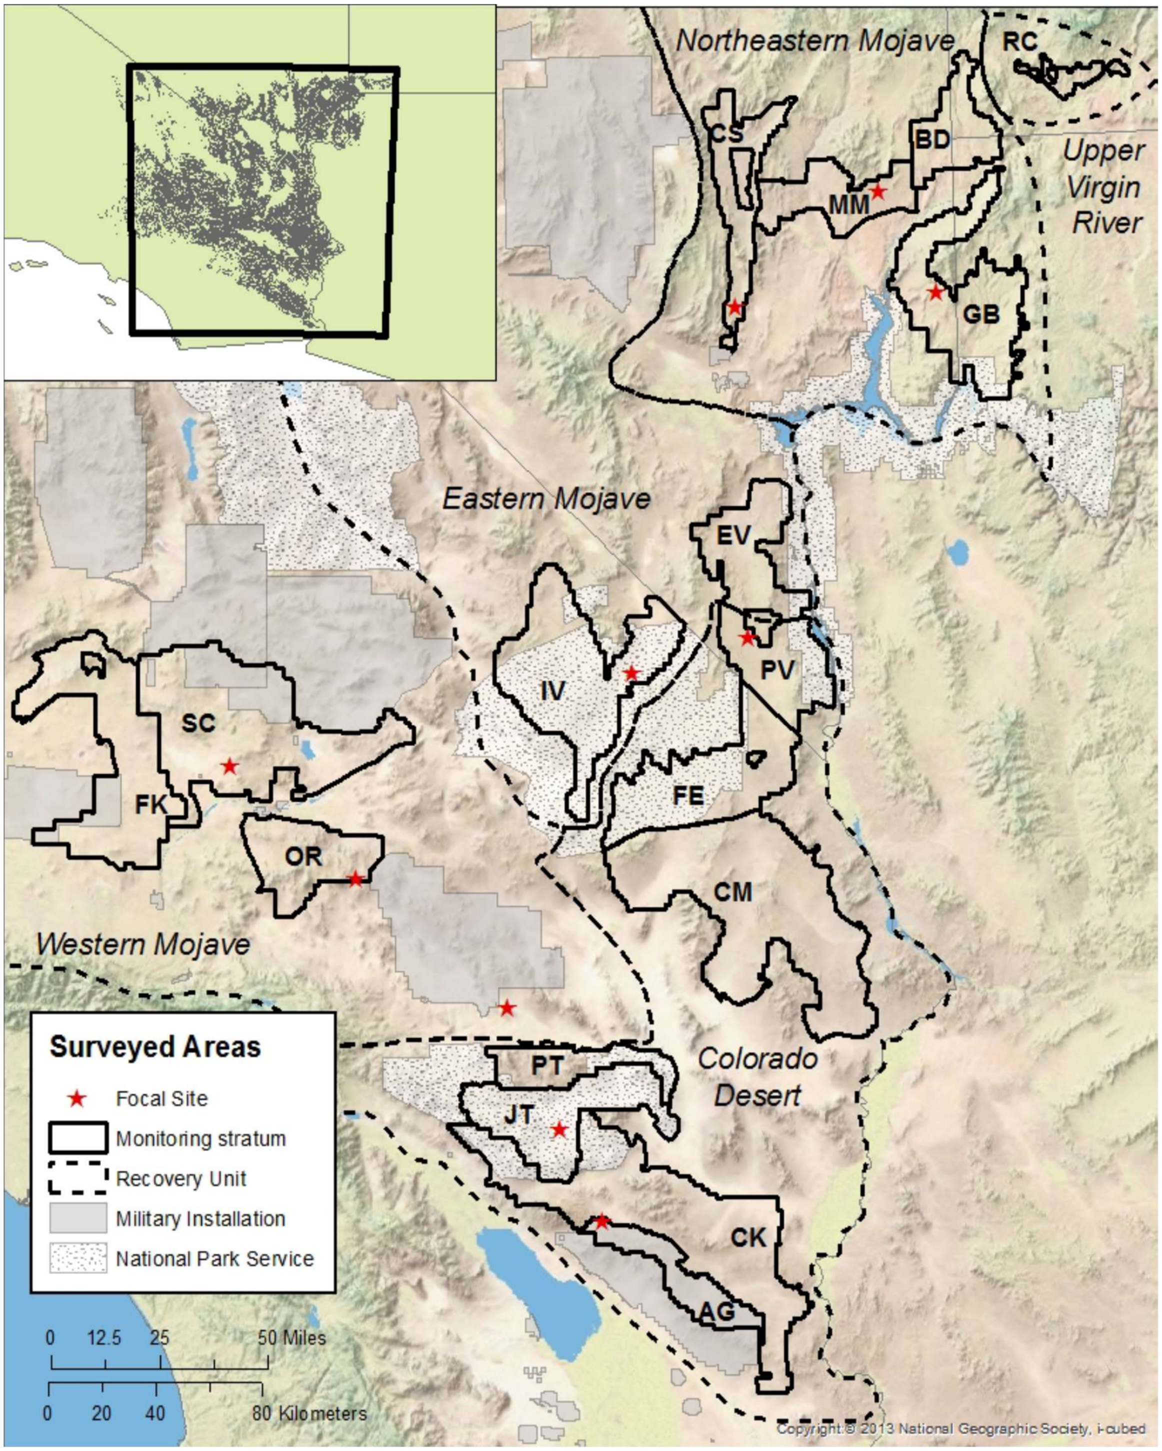

Figure 1. Map of the Recovery Units and Critical Habitat Units (CHUs) for Agassiz's desert tortoise. The CHUs in California are: FK = Fremont-Kramer, SC = Superior-Cronese, OR = Ord-Rodman, PT = Pinto Mountains, JT = Joshua Tree, CK = Chuckwalla, AG = Chocolate Mtns Aerial Gunnery Range, CM = Chemehuevi, FE = Fenner, IV = Ivanpah.

Line Distance Sampling: In June 1999, the interagency Desert Tortoise Management Oversight Group (DTMOG) adopted line distance sampling as the method for estimating adult desert tortoise abundance and density on a rangewide basis, and to detect long-term population trends (Anderson and Burnham 1996). This sampling method is intended to document rangewide population trends for adult desert tortoises over time and to determine whether the goals and objectives in the Recovery Plan regarding tortoise densities are being met. This monitoring strategy uses annual surveys on randomly placed line distance transects, with effort levels designed to detect long-term population trends (e.g., 10-year trends) in adult tortoises. This method was used beginning in 2001 by experienced survey crews under the direction of the USFWS DTRO, who publishes annual reports of line distance survey result reports (e.g., USFWS 2019a, 2020).

The downsides and assumptions of line distance sampling include:

- Line distance sampling collects data only to estimate the density of live adult tortoises. No systematic methodology is used to collect data on other population attributes (e.g., sex ratio, carcasses (mortality), cause of death, abundance or density of hatchling or juvenile tortoises, or short-term changes to population characteristics such as a catastrophic decline or remarkable increase) (USFWS 2006).
- Transects are not located randomly throughout the range of the desert tortoise. Rather, they are located randomly within CHUs, due to funding constraints and logistical issues. This methodology leaves occupied tortoise habitat outside these areas and areas needed for connectivity between CHUs/TCAs/Desert Wildlife Management Areas (DWMAs) unsurveyed.
- There are no trend data for tortoise populations outside CHUs.
- CHUs are more likely to be managed for the tortoise and its habitat than habitat outside CHUs and more likely to have greater densities of tortoises than areas outside CHUs. Therefore, the density estimates for adult tortoises in CHUs obtained from line distance sampling would likely be greater than for areas outside the CHUs in tortoise habitat and greater than rangewide density estimates. Thus, the line distance sampling does not provide a rangewide density estimate; it provides a density estimate for CHUs.
- Like permanent study plots, CHUs are not surveyed annually but about once every 3 years.
- Results from the range-wide line distance sampling survey program for population monitoring in CHUs/TCAs/DWMAs are intended to provide a baseline from which recovery criteria for stable populations within recovery units may be measured (USFWS 2006). However, collection of this baseline data was started in 2001. This is 12 years after listing Agassiz's desert tortoise as under CESA and ESA. Desert tortoise densities and abundance continued to decline from 1989/1990 (date of listings) to 2001. Using tortoise densities obtained from 2001 and later implies that although

listed as threatened, the densities of tortoises could decline further and still achieve recovery. A more appropriate approach would have been to use densities at the date of listing as the baseline.

CHUs for Agassiz's desert tortoises receive, in theory, greater protection under ESA provisions for federal actions because of the prohibition of adversely modifying or destroying Critical Habitat under ESA Section 7(a)(2). In spite of this prohibition, recent programmatic plans by the BLM in the California deserts have designated Extensive Recreation Management Areas (ERMAs) and Special Recreation Management Areas (SRMAs) in hundreds of thousands of acres of Critical Habitat for the tortoise (BLM 2016). BLM has also opened Cuddeback and Coyote dry lake beds within Critical Habitats in the Western Mojave Desert to unrestricted motorized vehicle use (BLM 2019).

With greater protection afforded to desert tortoise habitat within designated Critical Habitat, one would assume that tortoise populations occurring in Critical Habitat would have higher densities, a higher probability of recovery, and upward population trends over time with implementation of developed recovery plan actions. However, when analyzing the data from multiple years of line distance sampling, this assumption, has proven incorrect (Berry et al. 2014, USFWS 2015), and exactly the opposite. (See "Line Distance Sampling Results.")

Population Viability for Agassiz's Desert Tortoise

In the 1994 Recovery Plan for the Mojave Population of the Desert Tortoise, the USFWS determined that the minimum viable tortoise population density is 3.9 adults per square kilometer, or approximately 10 per square mile. In calculating this detailed population viability analysis, many assumptions were factored into this analysis, including a male-female ratio of 1:1 (i.e., the number of female tortoises should not be less than the number of male tortoises) (USFWS 1994a), and certain minimum areas of conserved habitat (reserves) would be established and managed, with most of these areas geographically linked by adjacent borders or corridors of suitable tortoise habitat. Populations of Mojave desert tortoises with densities below this amount are not viable and in danger of extinction (USFWS 1994a).

At the time the 1994 Recovery Plan was written, there was less consideration of the potentially important role of drought and climate change in the desert ecosystem, and with regard to desert tortoises and tortoise habitats in particular. In the meantime, studies have documented vulnerability of juvenile (Wilson et al., 2001) and adult tortoises (Peterson 1994, 1996; Henen 1997; Longshore et al., 2003) to drought (USFWS 2006).

The analysis of population viability for the desert tortoise used (1) population densities as of the early 1990s and size of reserves (i.e., areas managed for the desert tortoise), and (2) the population numbers (abundance) as of the early

1990s and size of reserves. As population densities for the Mojave desert tortoise decline, reserve sizes must increase, and as population numbers (abundance) for the Mojave desert tortoise decline, reserve sizes must increase (USFWS 1994a).

Reserve design (USFWS 1994a) and designation of Critical Habitat were based on the population viability analysis from numbers (abundance) and densities of populations of the Mojave desert tortoise in the early 1990s. Inherent in this analysis is that the lands be managed with reserve level protection (USFWS 1994a) or ecosystem protection as described in section 2(b) of the federal ESA, and that sources of mortality be reduced so recruitment exceeds mortality (that is, lambda >1)(USFWS 1994a).

Permanent Study Plot Results

Since the permanent study plots were first established in the late 1970s to 2002, tortoise populations have experienced declines both in numbers of tortoises registered during the surveys and in densities of live tortoises (Berry and Medica 1995, Brown et al. 1999, Berry et al. 2002). Declines of >50% and up to 96% have occurred regardless of initial densities (Berry 2003). Declines in numbers and densities of live tortoises were confirmed by corresponding increases in carcasses, including remains of marked tortoises (Berry 2003).

Beginning in the 1980s, high tortoise mortality associated disease was documented throughout the western Mojave Desert, and shortly thereafter, in populations within the eastern Mojave Desert in California and Nevada. Disease outbreak was first detected in surveys at the Desert Tortoise Research Natural Area (DTRNA) study plot (Brown et al. 1999) on the west edge of what is now the Fremont-Kramer CHU and subsequently in populations in adjacent Critical Habitat Units (i.e., Fremont-Kramer and Superior-Cronese).

Table 1a. Estimated annual densities of adult Agassiz's desert tortoises (midline carapace length (MCL) >180 mm) during 60-day spring surveys using mark-recapture methodology at one square-mile permanent study plots in two of the three Agassiz's Desert Tortoise Recovery Units and Critical Habitat Units (CHUs)/Tortoise Conservation Areas (TCAs)/Desert Wildlife Management Areas (DWMAs) in California. Density is in adult tortoises/square-kilometer. DTRNA = Desert Tortoise Research Natural Area.

In the Western Mojave Recovery Unit, between 1982 and 1992, the overall tortoise population at the DTRNA declined by 86% with the adult population declining by about 94%, primarily due to *Mycoplasmosis* disease mortality (Brown et al. 1999). Juvenile tortoise mortality occurred primarily from Common raven (*Corvus corax*) predation. Tracy et al. (2004) concluded that the apparent downward trend in desert tortoise populations in the western portion of the range (Western Mojave Recovery Unit) that was identified at the time of listing from permanent study plot data was valid and ongoing from several threats including disease.

In the Colorado Desert Recovery Unit, BLM and CDFG (2002) reported that populations of desert tortoises "have declined precipitously in some parts of the range, such as the Chuckwalla Bench….Population estimates of permanent study plots at Chemehuevi Valley and Chuckwalla Bench have shown declines as high as 90 percent over the past decade" (i.e., early 1990s to 2000s).

Surveys in the eastern Mojave Desert (i.e., Goffs, California) (Colorado Desert Recovery Unit) have found high levels of Agassiz's desert tortoise mortality attributable to tortoise shell (*dyskeratosis*) and respiratory tract (*mycoplasmosis*) diseases (Berry 2000). Surveys performed in 2000, eleven years after state listing of the desert tortoise as Threatened, revealed that all tortoise size classes in sampled eastern Mojave Desert Critical Habitats had declined by as much as 76-80% from previous tortoise population estimates. The decline rate in larger tortoise size classes, which have a greater reproductive contribution to the population [i.e., larger females produced larger clutch sizes (Wallis et al. 1999)], was estimated to have declined by as much as 90% from previous estimates (Berry 2000, BLM 2002).

Lovich (2016) reported on the trend of desert tortoise densities in Joshua Tree National Park (Colorado Desert Recovery Unit). He noted tortoise populations "decreased in size during droughts." And, "What was once a robust and large population of tortoises in the early 1990s declined precipitously by 2012."

In the Eastern Mojave Recovery Unit in California, surveys performed in 2000, eleven years after state listing of the desert tortoise as Threatened, revealed that all tortoise age classes sampled in the CHUs of the Eastern Mojave Recovery Unit had declined by as much as 76-80% from previous tortoise population estimates. The decline rate in larger tortoise size/age classes, which have a greater reproductive contribution to the population, was estimated to have declined by as much as 90% from previous estimates (Berry 2000).

Line Distance Sampling Results

The USFWS Desert Tortoise Recovery Office has published reports of annual line distance sampling results since 2001 (e.g., USFWS 2019a, 2020). The first multi-year report was issued in 2006 for years 2001-2005.

Below are the results of line distance surveys by year (2001-2019) and change in estimated abundance of adult tortoises by Recovery Unit and Critical Habitat Unit in

California (Table 2) (USFWS 2006, 2009, 2010, 2011, 2012b, 1012c, 2013, 2014, 2015, 2016a, 2018, 2019, 2020).

Table 2. Density of adult Agassiz's desert tortoises (>180 mm MCL) per km^2 by year (2001-2018) in Critical Habitat Units designated for the species within California.

*Density of 2.5 adult tortoises per km^2 in the Ord-Rodman CHU is for resident tortoises only. The 3.4 adult tortoises per km^2 includes the tortoises translocated from the expansion area of the Marine Corps Air Ground Combat Center to Ord-Rodman CHU that were found during transect sampling.

USFWS (2006) reported low tortoise densities across recovery units from 2001-2005 and are indicative of a continuing long-term decline of tortoise abundance and population densities throughout the Mojave and Colorado deserts in California. This decline was first reported in the 1980s and resulted in the Commission listing the desert tortoise as Threatened in 1989 and USFWS following in 1990.

In their 2015 report, the USFWS provides an aggregate analysis of the data from 2004 through 2014 to determine the trend of adult desert tortoise (>180 mm midline carapace length) densities and abundance from rangewide sampling in CHUs/TCAs/DWMAs (Table 3).

Table 3. Summary of 10-year trend data (from 2004 to 2014) for Recovery Units and Critical Habitat Units (CHU)/Tortoise Conservation Areas (TCA)/Desert Wildlife Management Areas (DWMAs) for Agassiz's desert tortoise, *Gopherus agassizii* (=Mojave desert tortoise*)* in California The table includes the area of each Recovery Unit and CHU/TCA/DWMA, percent of total habitat for each Recovery Unit and CHU/TCA/DWMA, density (number of breeding adults/km^2 and standard errors = SE), and the percent change in population density between 2004-2014. Populations below the viable level of 3.9 breeding individuals/km^2 (10 breeding individuals per mi^2) (assumes a 1:1 sex ratio (i.e., number of adult females equal to or greater than adult males) and showing a decline from 2004 to 2014 are in red (USFWS 2015).

Recovery Unit Designated Critical Habitat Unit/Tortoise Conservation Area/Desert Wildlife Management Area	Surveyed area (km^2)	% of total habitat area in Recovery Unit & CHU/TCA	2014 density/km^2 (SE)	% 10-year change (2004–2014)

Ivanpah, CA	2,447	9.53	2.3 (0.9)	**–56.05 decline**

Using line distance sampling data, Defenders of Wildlife prepared a series of graphs showing the population trend of adult desert tortoises from 2001 within CHUs in California, including a line showing the minimum viable density threshold of 3.9 adults per square kilometer, and a projected date of extirpation or extinction (Attachment 1).

An analysis of these data indicate:

- The aggregate adult tortoise densities in the Western Mojave Recovery Unit, Colorado Desert Recovery Unit, and Eastern Mojave Recovery Unit in

California were below the population viability density of 3.9 adult tortoises per km^2.

- At the CHU/TCA/DWMA population level, 9 of the 10 populations in these Recovery Units in California were below this viability density.
- For percent change in population abundance between 2004 and 2014, all populations in the three CHUs/TCAs/DWMAs except one (Joshua Tree National Park) experienced a decline.
- For percent change in population abundance in 2014 using 2004 data as a baseline, the aggregate change in all Recovery Units in California experienced declines ranging from 36 to 67 percent.
- In the Western Mojave Recovery Unit at the population level, the three populations experienced 50 to 61 percent declines.
- In the Colorado Desert Recovery Unit in California, five of six populations experienced 29 to 64 percent declines.
- In the Eastern Mojave Recovery Unit in California, the Ivanpah population experienced a 56 percent decline.
- Only the Joshua Tree population in the Colorado Desert Recovery Unit had an increase in population abundance. Despite this 178 percent increase, its population density was below the 3.9 tortoises per km^2 population viability level.

The population viability analysis in the 1994 Recovery Plan assumed a 1:1 male - female sex ratio and used the estimated densities of tortoises in the early 1990s in the analysis to calculate the population viability density. Unfortunately, we were unable to find information in the USFWS reports on the sex ratios of these populations. Therefore, we are unable to determine if this assumption is being met. A male - female sex ratio that favors males would require a greater population density than 3.9 adult tortoises per square kilometer for a population to be viable.

In addition, the density and abundance of desert tortoises has declined substantially in the Western Mojave Recovery Unit, Colorado Desert Recovery Unit, and Eastern Mojave Recovery Unit since the population viability analysis was published in the 1994 Recovery Plan. Consequently, the minimum viable density for tortoise populations may now be greater than the 3.9 adult tortoises per km^2 (10 adult tortoises per m^{i2}) because population density estimates in the 1990s were used to calculate the population viability density along with other parameters.

In their analysis of the USFWS's 2015 Line Distance Survey Report, Allison and McLuckie (2018) reported:

"*Populations of the Mojave Desert Tortoise (Gopherus agassizii) experienced severe declines in abundance in the decades leading up to 1990, when the species was listed as threatened under the U.S. Endangered Species Act. Prevailing declines in the abundance of adults overall and in four of the five recovery units indicate the need for more aggressive implementation of recovery actions and more critical evaluation of the suite of future activities and projects in tortoise habitat that may exacerbate ongoing population declines. Adult densities in the* [California recovery units] *declined at different annual rates: Colorado Desert (-4.5%, Eastern Mojave*

(-11.2%), and Western Mojave (-7.1%). Of the four recovery units in which we used two-pass surveys, the probability of encountering a juvenile was consistently lowest in the Western Mojave Recovery Unit.

Overall this threatened species is experiencing large, ongoing population declines, and adult tortoise numbers have decreased by over 50% in some recovery units since 2004. Declining adult densities through 2014 have left the Western Mojave adult numbers at 49% and in the Eastern Mojave at 33% of their 2004 levels. Such steep declines in the density of adults are only sustainable if there were suitably large improvements in reproduction and juvenile growth and survival. However, the proportion of juveniles has not increased anywhere since 2007, and in these two recovery units the proportion of juveniles in 2014 has declined to 91% and 77% of their representation in 2004, respectively.

Throughout our assessment, we describe tortoise status based on adult densities, which is useful for comparison of areas of different sizes. However, if the area available to tortoises is decreasing, then trends in tortoise density no longer capture the magnitude of decreases in abundance. Some of the area of potential habitat (68,501 km^2) has certainly been modified in a way that decreases the number of tortoises present.

We used area estimates that removed impervious surfaces created by development as cities in the desert expanded. However, we did not address degradation and loss of habitat from recent expansion of military operations (753.4 km^2 so far on Fort Irwin and the MCAGCC [in addition to training/bombing lands expanded at China Lake Naval Weapons Center]*… the current range-wide distance sampling program provides fairly coarse but clear summaries of patterns in tortoise density and abundance, definitive because they sample regionally and range-wide.*

The negative population trends in most of the TCAs for Mojave Desert Tortoises indicate that this species is on the path to extinction under current conditions. This may reflect inadequate recovery action implementation, slow response by tortoises and their habitat to implemented actions, or new and ongoing human activities in the desert that have not been mitigated appropriately.

It may also be a result of stochastic or directional climatic events that impact large expanses of tortoise habitat (e.g., drought, fire, climate change) and are largely beyond the realm of local land management activities. Our results are a call to action to remove ongoing threats to tortoises from TCAs, and possibly to contemplate the role of human activities outside TCAs and their impact on tortoise populations inside them."

Combining Permanent Study Plots and Line Distance Sampling Results

By the time formal line distance sampling of adult tortoise populations in California began in 2001, high levels of tortoise mortality had been documented and already reduced these populations by up to approximately 90%, such as in the Fremont-Kramer CHU in the Western Mojave Recovery Unit (USFWS 1994a).

As mentioned above, beginning in the 1980s, high tortoise mortality was reported in the three Recovery Units in California. Combining the adult density data from permanent study plots and line distance sampling for these three Recovery Units indicates a substantial long-term downward trend in the density of these desert tortoise populations (Attachment 2).

Agassiz's desert tortoise is a "K-strategist" (MacArthur and Wilson 1967, USFWS 1994a), with delayed maturity and long life under normal conditions. Its survival strategy is to live a long time and recruit a small number of individuals into the population to replenish the loss of adults or slowly increase the population size. However, given the numerous, increasing, and compounding threats to the desert tortoise (see Section 6 "Factors Affecting Ability to Survive and Reproduce") and the long-term downward trend in the density of reproducing adults, these data indicate that adults are not living a long time and recruitment is much lower than mortality. With most population densities in California below the minimum viable density, this long-term downward trend indicates the survival strategy of the desert tortoise has not been working for several decades. Agassiz's desert tortoise is on a path to extirpation in California.

Analyzing the line distance sampling data that spans 19 years, population declines of desert tortoises have been documented since 2001, currently resulting in a breeding adult tortoise density generally below the minimum population viability level of 3.9 tortoises per square kilometer in all but one of the tortoise Critical Habitat Units in California (USFWS 2020). Twenty-five years after the publication of the 1994 Recovery Plan, the USFWS has confirmed that the densities of the 10 tortoise populations in CHUs/TCAs/DWMAs in California are below this minimum viable density, except for the Chocolate Mountains. If the density estimates from line distance sampling in CHUs is below the minimum viable density, it is likely that the occupied habitats outside the CHUs have lower population densities, as Critical Habitat receives an additional regulatory level of management. This would mean that rangewide the density and abundance of the tortoise may not be as great as reported from line distance sampling.

In summary, the permanent study plots data and long-term monitoring data from the USFWS's line distance sampling show a multi-decadal decline in the density of adult desert tortoises in California. The line distance sampling shows the density of 9 of 10 populations of Agassiz's desert tortoise in the CHUs of the California desert are below the population viability density of 3.9 adult tortoises per km^2. All populations have experienced steep declines in abundance since 2004 except the Joshua Tree population. Between 2004 and 2014, nine populations continue to decline at substantial rates. If these rates of decline continue, the trajectory for extirpation of the tortoise in California will likely occur within the foreseeable future. This assumes that factors such as drought and climate change do not become worse and that human uses of desert lands do not increase substantially in the future. Based on past history and regional climate models, we know this is unlikely.

2. RANGE AND DISTRIBUTION

In the text, indicate the percentage of historic distribution that is in existence and the rate of loss. If appropriate, indicate the number of extant occurrences, populations or portions of populations in California. Indicate whether the rate of loss is accelerating, and estimate when extinction would occur if current trends continue. Discuss the relationship between historic and current acreage and degree of habitat fragmentation. Describe the quality of the existing habitats in terms of ability to maintain viable populations with or without enhancement.

The following information is from the report published by the USFWS DTRO, entitled "Status and Trend of the desert tortoise and its Critical Habitat in 2019" (USFWS 2019b):

Beginning in the 1970s *"the range and distribution of the Desert tortoise in California was initially mapped using observations of live individuals and their sign collected by the Bureau of Land Management during development of the California Desert Conservation Area Plan. Over 1,000 triangular transects were surveyed between 1978 and 1983 and were used to build a Desert tortoise occurrence map based on five classes of estimated abundance (0-20, 21-50, 51-100, 101-250, > 250 tortoises/mile. Further refinement of the occurrence and relative abundance of Desert tortoises in the Western Mojave Desert was completed by the Bureau of Land Management from 1998-1999 in support of the West Mojave Plan. Approximately 1,800 transects were performed*. *Within its range in California, habitat degradation and loss due to land-use practices include development (urban and rural), military training activities, habitat fragmentation from roads and utility corridors, recreational activities, and livestock grazing."*

In 2009, the US Geological Survey looked at the distribution of the desert tortoise by focusing on available habitat for the species (USFWS 2019b): *"Typical habitat of the desert tortoise in the Mojave Desert is characterized as Creosote Bush Scrub ranging in elevation from approximately 1,000 to 5,500 feet. A key habitat component within this habitat is a reliable food source in the form of annual forbs and grasses, which rely on annual precipitation ranging from approximately 2-8 inches. Based on an evaluation of environmental variables associated with occupied Desert tortoise habitat, U.S. Geological Survey researchers developed a habitat suitability model in 2009* (Nussear et al. 2009), *which provided the first accurate map of predicted occupied habitat for the species.*

The most apparent threats to the desert tortoise are those that result in mortality and permanent habitat loss across large areas, such as urbanization and large-scale renewable energy projects and those that fragment and degrade habitats, such as proliferation of roads and highways, off-highway vehicle (OHV) activity [including military training], wildfire, and habitat invasion by non-native invasive plant species.

Prior to 1994, desert tortoises were extirpated from large areas within their distributional limits by urban and agricultural development (e.g., the cities of Barstow and Lancaster, California; Las Vegas, Nevada; and St. George, Utah; etc.; agricultural areas south of Edwards Air Force Base and east of Barstow), military training (e.g., Fort Irwin, Leach Lake Gunnery Range), and off-highway vehicle use (e.g., portions of off-road management areas managed by the BLM and *unauthorized use in areas such as east of California City, California). Since 2010, the U.S. Fish and Wildlife concluded that the distribution of the Desert tortoise had not changed substantially in terms of the overall extent of its range, although desert tortoises have been removed from several thousand acres because of solar development, military activities, and other project development (USFWS 2010). In 2014, the U.S. Fish and Wildlife Service accounted for acres of non-habitat for the species (i.e., impervious surfaces that included paved and developed areas and other disturbed areas that have zero probability of supporting desert tortoises. Within California, impervious surfaces totaled 3,325,979 acres, or 19.2% of the total acres of modeled habitat for the species.*

Other anthropogenic factors affect the physical and biological features of critical habitat in more subtle ways. Surface disturbance from OHV vehicle activity can cause erosion and large amounts of dust to be discharged into the air. Recent studies on surface dust impacts on gas exchanges in Mojave Desert shrubs showed that plants encrusted by dust have reduced photosynthesis and decreased water-use efficiency, which may decrease primary production during seasons when photosynthesis occurs.

Sharifi et al. (1997) also showed reduction in maximum leaf conductance, transpiration, and water-use efficiency due to dust. Leaf and stem temperatures were also shown to be higher in plants with leaf-surface dust. These effects may also impact [native] desert annuals, an important food source for desert tortoises.

Invasion of non-native plants can affect the quality and quantity of plant foods available to desert tortoises. Increased presence of invasive plants can also contribute to increased fire frequency. Proliferation of invasive plants is increasing in the Mojave and Sonoran deserts and is recognized as a substantial threat to desert tortoise habitat."

Substantial alteration of Agassiz's desert tortoise Critical Habitat occurred with the expansion of the U.S. Army's National Training Center at Fort Irwin in 2002, 13 years after listing of the species as Threatened by the California Fish and Game Commission. This federal action resulted in the transfer of approximately 99,000 acres of public land managed by the BLM in the Superior-Cronese Critical Habitat Unit of the Western Mojave Recovery Unit in California to the U.S. Army. (Charis 2005). The Army is now conducting mechanized warfare training, which directly impacts tortoise habitat, on approximately 18,000 of these acres in the Southern Expansion Area, and indirectly impacts additional habitat by creating large amounts of dust that are deposited in adjacent and downwind areas. The dust covers plants and reduces their ability to photosynthesize. It also reduces maximum leaf conductance, transpiration, and water-use efficiency (Sharifi et al. 1997). Thus, plant survival, growth, and reproduction are reduced. This reduces the availability of important forage plants (USFWS 2010) and cover for the tortoise from predators and temperature extremes. Military training activities spread the seeds and plant propagules of nonnative plant species in the tracks and tires of their vehicles and in their equipment. The remaining 62,000 acres of Critical Habitat in the Western Expansion Area have not been used for mechanized training to date, but the Army intends to utilize them at some future date (USFWS 2012a).

Prior to use of the 18,000 acres in the Southern Expansion Area, the Army in 2002 captured a total of 650 adult and sub-adult desert tortoises and translocated them to specific non-training lands within and adjacent to the installation. Roughly half of tortoises translocated died during or immediately after translocation. To date, tortoises have only been removed from the Southern Expansion Area where mechanized warfare training takes place (USFWS 2012a). Surveys in the 62,000 acre Western Expansion Area revealed that approximately 1,100 individuals would have to be captured and translocated before mechanized training could commence.

A second significant impact to Agassiz's desert tortoise habitat occurred in 2013, when the U.S. Navy expanded the U.S. Marine Corps Air Ground Combat Center (MCAGCC) into the eastern Johnson Valley by acquiring 154,000 acres of public land managed by the BLM and 13,971 acres of non-federal land (U.S. Marine Corps et al. 2016). Approximately 1,000 desert tortoises were captured and translocated from the area planned for active mechanized warfare training exercises into the adjacent Ord-Rodman CHU. The same direct and indirect impacts to tortoises and tortoise habitat from the National Training Center's expansion also occurred on the expansion lands of MCAGCC.

Between 2009 and 2019, ten solar energy generation projects were also approved on public lands supporting Agassiz's desert tortoise habitat in California, 20 years following state listing of the species as Threatened. As a result, a total of 31,578 acres of Agassiz's desert tortoise habitat on public land has been removed during this time, although none of these projects are located in Critical Habitat. Additional private land with significant tortoise habitat have also been developed for renewable energy projects. The estimated incidental take of Agassiz's desert tortoises for these projects total over 2,298 individuals to date, based on USFWS biological opinions and CESA Section 2081 incidental take permits. Authorization for additional incidental take in the future is anticipated due to continued development of solar energy facilities, primarily on federal land managed by the BLM.

Roads have been described as the single most destructive element in the process of habitat fragmentation (Noss 1993) and their ecological effects are considered "the sleeping giant of biological conservation" (Forman 2002:viii, as cited in van der Ree et al. 2011). Though roads comprise only 1% of surface area, an estimated 19% of the total land within the United States is ecologically affected by roads due to indirect effects that extend beyond the physical footprint of the road (Forman, 2000, as cited in Nafus et al. 2013).

There are approximately 15,000 miles of paved and maintained roads within the range of the Agassiz's desert tortoise in California (BLM 1999); and 5,997 miles of authorized off-highway vehicle routes within the western Mojave Desert (BLM 2005, 2019). These roads and routes and their use by vehicles have numerous adverse impacts on the desert tortoise and its habitat. They include (1) wildlife mortality from collisions with vehicles, collecting, and vandalism (McLellan and Shackleton 1988, Kilgo et al. 1998) (2) hindrance/barrier to animal movements thereby reducing access to resources and mates [fragmentation], (3) degradation of habitat quality [spread of non-native invasive plant species] (Parendes and Jones 2000), (4) habitat loss caused by disturbance effects in the wider environment and from the physical occupation of land by the road, and (5) subdividing animal populations into smaller and more vulnerable fractions (at higher risk of localized extirpation from stochastic events or from inbreeding depression) (Jaeger et al. 2005a, 2005b, Roedembeck et al. 2007) (USFWS 1994a, Boarman 2002). A summary of the miles of routes and disturbed areas associated with motorized vehicle use within CHUs in the Western Mojave Recovery Unit is provided in Attachment 3.

For a herbivorous species such as the desert tortoise, roadside vegetation is often more robust and diverse because water that becomes concentrated along roadside berms promotes germination. This attracts tortoises and puts them at higher risk of mortality as road-kill (Boarman et al. 1997).

LaRue (1993) and Boarman et al. (1997) reported observing depauperate desert tortoise populations along highways. Subsequent research shows that populations may be depressed in a zone at least as far as 0.4 kilometers (0.25 miles) from the roadway on each side (Boarman and Sazaki 1996). The greater the distance from the road, the more desert tortoise sign is observed (LaRue 1993; Boarman et al. 1997; von Seckendorff Hoff and Marlow 2002; Boarman and Sazaki 1996). Similarly, the cover and richness of non-native plant species decreases as distance from the road increases (Boarman and Sazaki 1996).

In summary, the distribution of Agassiz's desert tortoise has been shrinking since its listing as threatened because of the myriad of land use projects throughout much of the tortoise's range in California. The larger individual projects (e.g., the expansion of the National Training Center at Fort Irwin and MCAGCC, and numerous large-scale renewable energy projects) and collectively, smaller development projects in/near the growing cities/communities of Palmdale-Lancaster, Victorville-Hesperia-Adelanto-Apple Valley, and Barstow-Lenwood continue to reduce the distribution of the tortoise near these communities. Thousands of miles of roads and routes of travel crisscross desert tortoise habitat effectively eliminating tortoises from thousands of acres of habitats adjacent to their corridors and fragment tortoise populations.

3. **ABUNDANCE**

Provide available historic and current population estimates/trends, densities, vigor, sex and age structures, and explain population changes relative to human-caused impacts or natural events. Compare current and historic abundance in terms of overall population size or size of occurrences, populations or portions of populations, as appropriate. Describe current population trends (with numbers and rate) and relate these to viable population numbers. Explain survey methodology used to arrive at numbers or estimates and what assumptions, if any, were involved.

As stated above in the Executive Summary and Section 1 (Population Trends), adult tortoise populations in Recovery Units in California have declined by 51.3% from 2004 through 2014 (i.e., from 119,029 tortoises in 2004 to 65,726 tortoises in 2014) (USFWS 2015). These declines were within tortoise Critical Habitat Units where there is a higher level of habitat protection expected to occur compared to lands outside these areas.

Densities of adult tortoises in CHUs within the Western Mojave Recovery Unit were estimated in 2004 to average 5.7 tortoises per square kilometer, in contrast to an average density of 2.8 tortoises per square kilometer estimated in 2014 – a decline similar to those occurring in all three Recovery Units in California (USFWS 2015). Historical survey data from permanent study plots in the Western Mojave Recovery Unit in the late 1970s and early 1980s were used to estimate adult tortoise densities in the 1994 Recovery Plan, which ranged from 2 to 96 per square kilometer at that time (USFWS 1994a) – indicating that adult tortoises in the Western Mojave Recovery Unit may have declined by as much as 85-95% from roughly 1980 to 2014. During this time Agassiz's desert tortoise had been state-listed as Threatened for 15 years.

These trend data indicate that under current management, Agassiz's desert tortoise populations within Critical Habitat Units in California continue to decline rapidly, which is inconsistent with the goals in the Recovery Plans of stabilizing and recovering depleted tortoise populations and halting habitat degradation – a situation that endangers the continued viability of wild tortoise populations in California. Still higher tortoise population declines, and greater degrees of habitat degradation, are known to occur outside of these Critical Habitat Units, possibly due to less restrictions placed on various public land use activities and private land development through regional and county land use plans [e.g., California Desert Conservation Area (CDCA) Plan (BLM 1980), as amended by the Desert Renewable Energy Conservation Plan (DRECP)].

Darst et al. (2013) developed a tortoise threats assessment that ranked the relative importance of threats to Agassiz's desert tortoise and its populations. These researchers determined that urbanization, human access, military operations, disease, and illegal use of off-highway vehicles were, and continue to be, the most significant threats on a range-wide basis.

In the 1994 rule designating Critical Habitat for the Mojave population of the desert tortoise, the USFWS (1994b) stated:

"*OHV use in the desert has increased and proliferated since the 1960s. As of 1980, OHV activities affected approximately 25 percent of all desert tortoise habitat in California*."

Various researchers have studied threats to tortoises and their populations. Tuma et al. (2016) conducted a detailed analysis of threats present in the Superior-Cronese Critical Habitat Unit in the Western Mojave Recovery Unit in California. These researchers concluded human presence was associated with significantly greater declines in tortoise populations because it was associated with habitat degradation and higher animal mortality on a continuous basis. This conclusion was reached even though human presence had a patchy distribution in the study area. Land use activities, such as vehicle use on/off authorized roads/trails, camping, mining, and livestock grazing; as well as habitat loss associated with housing subdivisions, freeways, transmission lines and railroads were identified in this study as a current suite of threats to Agassiz's desert tortoise. The second highest-ranked threat was subsidized predators, which contribute to tortoise mortality on a continuous, widespread basis but without causing habitat loss or degradation.

The USFWS (2011) concluded in its revised recovery plan for the Mojave Population of the Desert Tortoise that:

"*The vast majority of threats to the desert tortoise or its habitat are associated with human land uses. The threats identified in the 1994 Recovery Plan formed the basis for listing the tortoise as a threatened species and continue to affect the species today*."

As stated in Section 1 ("Population Trends"), the USFWS (1994) has determined the minimum viable density of adult tortoises is 3.9 tortoises per square kilometer, and that populations with densities below this number are in danger of extirpation. Based on extensive (2001-2014) line distance sampling, the USFWS (2015) determined that the estimated density of adult tortoises within Critical Habitat within the Western Mojave Recovery Unit in California in 2014 had declined to 2.8 tortoises per square kilometer, which is below the minimum density to ensure population viability or persistence. For the Colorado Desert Recovery Unit, the estimated density of adult tortoises was 4.0 tortoises per square kilometer. Although just above the minimum viable density of 3.9 calculated for desert tortoises in 1994, this CHU had a declining trend of 36.25 % from 2004 to 2012. This declining trend likely means that the density of adult tortoise will be below the minimum viable density in the foreseeable future. The Eastern Mojave Recovery Unit in California had an estimated adult tortoise density of 2.3 tortoises per square kilometer and the estimated density for the entire Recovery Unit in California and Nevada was 1.9 tortoises per square kilometer. Like the Colorado Desert Recovery Unit, the Western Mojave and Eastern Mojave Recovery Units had declining trends of 50.7% and 63.7%, respectively (see Table 3 in Section 1 – "Population Trends"). Tortoise densities in 8 of 10 Critical Habitat Units in California are also below minimum viability (see Table 3 in Section 1 – "Population Trends").

In addition to these threats, there is the overarching threat of climate change. Regional climate change models for the southwest United States show that the area is already experiencing the effects of climate change. The average daily temperatures for the 2001–2010 decade were the highest in the southwestern United States from 1901 through 2010 (Overpeck et al. 2012) with temperatures almost 2.0 degrees Fahrenheit (1.1 degrees Celsius) higher than historic averages, with fewer cold snaps and more heat waves (Overpeck et al. 2012). Climate change models for the southwestern United States for the 21st century predict seasonal air and surface temperatures in all seasons will increase (Overpeck et al. 2012), with greater warming in summer and fall than winter and spring. Droughts in parts of the southwestern United States are projected to become greater in intensity (Overpeck et al. 2012) (i.e., more frequent and/or longer in duration) with a precipitation decrease westward through the Sonoran and Mojave Deserts. With precipitation decreasing as one moves farther west in the southwest U.S., this would mean that the western portion of the range of Agassiz's desert tortoise (i.e., the tortoises in California) would be most affected by this decrease in precipitation from climate change.

Perennial vegetation is being impacted by prolonged drought conditions in the Mojave Desert. The negative effects of long-term drought on Sonoran, Great Basin, and Mojave Desert perennial plants are well documented (Goldberg and Turner 1986; Turner 1990; Bowers 2005; Hereford et al. 2006; Miriti 2006; Hamerlynck and McAuliffe 2008; Hamerlynck and Huxman 2009; Ralphs and Banks 2009, as cited in Huggins et al. 2010), and include high shrub mortality, shrub canopy deterioration, and low plant recruitment.

In a portion of the Superior-Cronese CHU, die-offs of desert shrubs have been documented. Data from plant transects reveal that total shrub cover and volume have decreased significantly by roughly 10% between 2000 and 2009 (Huggins et al. 2010). Mortality of these long-lived shrubs has been high (48%), and the recruitment of new shrubs (5%) has been too low to maintain their populations at previous levels (Huggins et al. 2010).

If the climate models for the Southwest and Mojave and Colorado deserts are correct, as the westernmost deserts in the southwest, their drought periods will become longer and more frequent. These climatic conditions will result in reduced reproduction and recruitment and elevated mortality of native woody perennial vegetation needed by the desert tortoise for shelter from extreme weather conditions and cover from predators. It also means that the frequency and quantity of native annual and herbaceous perennial plants needed by the tortoise for adequate nutrition (see Section 5 “Kind of Habitat Necessary for Survival”) would be reduced further. Reductions in precipitation and availability of forage plants for tortoises would result in reduced tortoise survival, reproduction, and recruitment (Henen 1997; Henen 2002a; Henen 2002b; and Wallis et al. 1999) and reduced tortoise densities and abundance). Because 9 of the 10 tortoise populations in the three Recovery Units in California are below the population viability threshold, the tortoise cannot persist if its survival, reproduction, or recruitment will be reduced. The tortoise’s downward trend toward extirpation will continue.

Based on the best available scientific information (presented above), Agassiz’s desert tortoise is in danger of extirpation in Critical Habitat Units in California from a variety of human-related threats. Because line distance sampling represents estimates of desert tortoise densities and abundance rangewide, the data and analysis from line distance sampling shows that Agassiz’s desert tortoise is in danger of extirpation in the three Recovery Units in California - the Western Mojave Recovery Unit, the Colorado Desert Recovery Unit, and the Eastern Mojave Recovery Unit.

Defenders of Wildlife, the Desert Tortoise Council and the Desert Tortoise Preserve Committee believe changing the regulatory status of Agassiz’s desert tortoise from Threatened to Endangered under CESA provisions will result in a higher level of impact analyses for proposed land use activities and greater long-term protection of occupied habitats. Mitigation requirements to avoid, minimize, and compensate for adverse impacts under Endangered vs. Threatened status would likely be greater and more effective in halting population declines and habitat loss/degradation, and in contributing to recovery of the species. Funding available for conservation projects for recovery of Endangered vs. Threatened species would also likely be greater.

4. LIFE HISTORY (SPECIES DESCRIPTION, BIOLOGY, AND ECOLOGY)

Include pertinent information that is available on species identification, taxonomy and systematics, seasonal activity or phenology, reproductive biology, mortality/natality, longevity, growth rate, growth form, food habits, habitat relationships and ecological niche or ecological attributes, interactions with other species or special habitat requirements that may increase vulnerability of the species to certain natural or human-caused adverse impacts (e.g., obligate wetland or riparian habitat species, low birthrate, colonial species).

This information is available in the supporting documents for the 1989 listing of the desert tortoise as Threatened by the Commission, as well as in the supporting documents for federal listing as Threatened by the USFWS. Additional information is available in the 1994 Recovery Plan (USFWS 1994a) and the 2011 Revised Recovery Plan (USFWS 2011). A summary is provided below from the Status of the Desert Tortoise (USFWS 2019b) and Andersen et al. (2000), and the two desert tortoise recovery plans.

The desert tortoise is a large, herbivorous reptile that reaches 20 to 38 centimeters (8 to 15 inches) in carapace (upper shell) length and 10 to 15 centimeters (4 to 6 inches) in shell height. Hatchlings emerge from eggs at about 5 centimeters (2 inches) in length. During the first 5 to 7 years of life, the tortoise shell is incompletely ossified; it is soft and easy to puncture and rip open (Boarman 2002). This makes small tortoises highly vulnerable to predation by a variety of mammals and birds. Adult desert tortoises weigh 3.6 to 6.8 kilograms (8 to 15 pounds). The forelimbs have heavy, claw-like scales and are flattened for digging. Hind limbs are more elephantine (Ernst et al. 1994).

Desert tortoise behavior is well adapted to living in a highly variable and often harsh desert environment. They spend much of their lives in burrows that they excavate, even during their seasons of activity. Burrows are made under rocks or in soil and may be as much as 5 m in length but are usually 1 m deep (Burge 1978, Bulova 1994). Patterns of burrow use are sex specific (Bailey et al. 1995) and may reflect complex social interactions among individual tortoises (Bulova 1994). Burrow living can make tortoises difficult to find, particularly in drought years when the animals seal themselves behind a wall of dirt and stay underground to conserve water.

In late winter or early spring, they emerge from overwintering burrows and typically remain active through fall. Activity decreases in summer, but tortoises often emerge after summer rain storms to drink (Henen et al. 1998). During activity periods, desert tortoises eat a wide variety of herbaceous vegetation, particularly perennial grasses and the flowers of annual plants (Berry 1974; Luckenbach 1982; Esque 1994). Tortoises are selective in the plant species and plant parts that they eat. Oftedal et al. (2002) reported that plant species and plant parts of species eaten by desert tortoises were higher in water, protein, and potassium excretion potential (PEP), and lower in potassium than uneaten species and parts. During periods of inactivity, they reduce their metabolism and water loss and consume very little food by remaining in their burrows. Adult desert tortoises lose water at such a slow rate that they can survive for more than a year without access to free water (obtaining it from their food, if available) and can apparently tolerate large imbalances in their water and energy budgets (Nagy and Medica 1986; Peterson 1996; Henen et al. 1998) at least for a limited time.

Desert tortoises are essentially “K-strategists” (MacArthur and Wilson 1967), with delayed maturity and long life. Eggs and hatchlings are quite vulnerable, and pre-reproductive adult mortality averages 98% (Wilbur and Morin 1988, Turner et al. 1987). Adults, however, are well protected against most predators (other than humans) and other environmental hazards and consequently can be long-lived (Germano 1992, Turner et al. 1987). Their longevity helps compensate for their variable annual reproductive success, which is correlated with environmental conditions.

Mating occurs both during spring and fall (Black 1976; Rostal et al. 1994). In drought years, the availability of surface water following rains may be crucial for desert tortoise survival (Nagy and Medica 1986). During these unfavorable periods, desert tortoises decrease surface activity and remain mostly inactive or dormant underground (Duda et al. 1999), which reduces water loss and minimizes energy expenditures (Nagy and Medica 1986). Duda et al. (1999) showed that home range size, number of different burrows used, average distances traveled per day, and levels of surface activity were significantly reduced during drought years.

The size of desert tortoise home ranges varies with respect to location and year (Berry 1986) and also serves as an indicator of resource availability and opportunity for reproduction and social interactions (O’Connor et al. 1994). Females have long-term home ranges that may be as little or less than half that of the average male, which can range to 80 or more hectares (200 acres) (Burge 1977; Berry 1986a; Duda et al. 1999; Harless et al. 2009). Core areas used within tortoises’ larger home ranges depend on the number of burrows used within those areas (Harless et al. 2009). Over its lifetime, each desert tortoise may use more than 3.9 square kilometers (1.5 square miles) of habitat and may make periodic forays of more than 11 kilometers (7 miles) at a time (Berry 1986).

Tortoises are long-lived and grow slowly, requiring 13 to 20 years to reach sexual maturity, and have low reproductive rates during a long period of reproductive potential (Turner et al. 1984; Bury 1987; Germano 1994). Growth rates are greater in wet years with higher annual plant production (e.g., desert tortoises grew an average of 12.3 millimeters [0.5 inch] in an El Niño year compared to 1.8 millimeters [0.07 inches] in a drought year in Rock Valley, Nevada (Medica et al. 1975). The number of eggs as well as the number of clutches that a female desert tortoise can produce in a season is dependent on a variety of factors including environment, habitat, availability of forage and drinking water, and physiological condition (Turner et al. 1986, 1987; Henen 1997; McLuckie and Fridell 2002). The success rate of clutches has proven difficult to measure, but predation, while highly variable (Bjurlin and Bissonette 2004), appears to play an important role in clutch failure (Germano 1994).

Although Agassiz's desert tortoise occurs from the western Mojave Desert in California east to southwestern Utah, it consists of populations that show differences in genetics, morphology, ecology, and behavior (USFWS 2011). The USFWS used differences in genetic, ecological, and physiological characteristics to help delineate boundaries or other differences between Recovery Units. The designation of Recovery Units ensures that local adaptation as well as critical genetic diversity are maintained for Agassiz's desert tortoise (USFWS 2011). Hence, there are three Recovery Units for the desert tortoise in California.

5. KIND OF HABITAT NECESSARY FOR SURVIVAL

Describe habitat features that are thought to be important to the species' ability to maintain viable population levels. Any or all of the following features may be included, as appropriate:

Plant community; edaphic conditions; climate; light; topography/microtopography; natural disturbance; interactions with other plants or animals; associated species; elevation; migration or movement corridors; wintering habitat; breeding habitat; foraging habitat; other habitat features.

Suitable habitat for the species has been previously described in a U.S. Geological Survey (USGS) tortoise habitat model, as cited above in this Petition. However, we are providing a description of habitat characteristics below (from Nussear 2009, USFWS 1994a, USFWS 1994b, and USFWS 2011).

The habitat requirements of Agassiz's desert include sufficient suitable quantity and quality of plants for forage and cover, suitable substrates for burrow and nest sites, and low occurrence of predators. Throughout most of the Mojave region, desert tortoises occur primarily on flats and bajadas with soils ranging from sand to sandy-gravel, characterized vegetationally by scattered shrubs and abundant inter-shrub space for growth of herbaceous plants. Desert tortoises are also found on rocky terrain and slopes in parts of the Mojave region, and there is significant geographic variation in the way desert tortoises use available resources.

In the Mojave Desert, annual precipitation within known habitat ranges from 100 to 210 mm (Germano et al. 1994), mostly occurring during the winter months (> 50-75%) and infrequently as snow below 1,200 m. The temperature range within known habitat is extreme, with average daily low temperatures in January typically at or slightly below 0 ºC and average daily high temperatures in July ranging from 37 to 43 ºC (Germano et al. 1994).

In California, the desert tortoise uses the following vegetation communities:

- In the Colorado Desert Recovery Unit, vegetation communities include Succulent Scrub *(Fouquieria, Opuntia, Yucca),* Blue Palo Verde-Smoke Tree Woodland, Creosote Bush Scrub (lava flows), Blue Palo Verde-Ironwood-Smoke Tree Woodland, and Creosote Bush Scrub (rocky slopes).
- In the Eastern Mojave Recovery Unit, vegetation communities include Big Galleta-Scrub Steppe, Succulent Scrub *(Yucca, Opuntia* species), Creosote

Bush Scrub, Cheesebush Scrub (east Mojave type), and Indian Rice Grass Scrub-Steppe.

- In the Western Mojave Desert, vegetation communities include Mojave Saltbush- Allscale Scrub (endemic), Indian Rice Grass Scrub-Steppe, Hopsage Scrub, Big Galleta Scrub Steppe, Cheesebush Scrub (west Mojave type), Desert Psammophytes, and Blackbush Scrub.

The USFWS has determined that the physical and biological features (referred to as the primary constituent elements) of critical habitat that support nesting, foraging, sheltering, dispersal, and gene flow are essential to the conservation of the desert tortoise. The specific physical and biological features of Mojave desert tortoise critical habitat are:

- sufficient space to support viable populations within each of the recovery units and to provide for movement, dispersal, and gene flow;
- sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species;
- suitable substrates for burrowing, nesting, and overwintering; burrows, caliche caves, and other shelter sites; sufficient vegetation for shelter from temperature extremes and predators; and
- habitat protected from disturbance and human-caused mortality.

Forage quantity and quality is limited in the range of the Mojave desert tortoise. In the Mojave and Colorado deserts, many food plants are high in potassium (Minnich 1979), which is difficult for desert tortoises to excrete due to the lack of salt glands that are found in other reptilian herbivores such as chuckwallas (*Sauromalus obesus*) and desert iguanas (*Dipsosaurus dorsalis*) (Minnich 1970; Nagy 1972). Reptiles are also unable to produce concentrated urine, which further complicates the ability for desert tortoises to expel excess potassium (Oftedal and Allen 1996). Oftedal (2002) suggested that desert tortoises may be vulnerable to disease as a result of physiological stress associated with foraging on food plants with insufficient water and nitrogen to counteract the negative effects of dietary potassium. Only high quality food plants (as expressed by the Potassium Excretion Potential, or PEP, index) allow substantial storage of protein (nitrogen) that is used for growth and reproduction, or to sustain the animals during drought. Non-native, annual grasses have lower PEP indices than most native forbs (Oftedal 2002; Oftedal et al. 2002). Oftedal et al. (2002) found that foraging juvenile tortoises favored water-rich, high-PEP, native forbs. Much of the nutritional difference between available and selected forage was attributable to avoidance of abundant, non-native split grass (*Schismus* spp.) with mature fruit, which is very low in water, protein, and PEP. Of the species eaten, *Camissonia claviformis*, a native Mojave desert primrose, accounted for nearly 50 percent of all bites, even though it accounted for less than 5 percent of the biomass encountered, and was largely responsible for the high PEP of the overall diet. Impacts to vegetation (such as livestock grazing, invasion of non-native plants [from use of roadways], and soil disturbance) that reduce the abundance and distribution of high PEP plants may result in additional challenges for foraging desert tortoises (Oftedal et al. 2002).

Non-native grasses are not as nutritious as native forbs. Recent studies have shown that calcium and phosphorus availability are higher in forbs than in grasses and that desert tortoises lose phosphorus when feeding on grasses but gain phosphorus when eating forbs (Hazard et al. 2010).

As previously stated in Section 1 "Population Density," for the desert tortoise to survive and recover, its habitat should be managed with reserve level protection (USFWS 1994a). A reserve has a primary goal of protecting biodiversity from harmful activities and processes, both natural and anthropogenic. Thus, reserve level protection for Agassiz's desert tortoise requires substantially reducing the direct and indirect impacts to the tortoise and its habitats that cause/contribute to its mortality and its recruitment if lambda is less than 1. Section 6 "Factors Affecting the Ability to Survive and Reproduce" includes a figure of the human-caused impacts to the habitat of the desert tortoise that results in mortality.

6. **FACTORS AFFECTING ABILITY TO SURVIVE AND REPRODUCE**

Discuss the basis for the threats to the species or subspecies, or to each population, occurrence or portion of range (as appropriate) due to one or more of the following factors:

(1) present or threatened modification or destruction of its habitat;
(2) overexploitation;
(3) predation;
(4) competition;
(5) disease; or
(6) other natural events or human-related activities.

Identify the direct, indirect, and cumulative adverse impacts and discuss how these are contributing to the decline of the species. Indicate whether the species is vulnerable to random catastrophic events.

Information on these factors (e.g., habitat modification/destruction, predation, disease, etc.) has been provided in the above responses. A summary of these anthropomorphic threats and their interactions is provided in Figure 2 (below).

In addition, the desert tortoise is vulnerable to catastrophic events such as wildfire and flooding. Wildfire threat has increased dramatically over the past 100 years due to colonization of tortoise habitat by invasive, non-native species such as cheatgrass (*Bromus tectorum*), red brome (*Bromus madritensis* ssp. *rubens*) and Mediterranean splitgrass (*Schismus barbatus*). These annual grasses germinate early, compete with and displace native species of forbs and grasses for moisture and nutrients (Brooks 1999a, Brooks 1999b).

These non-native plants also form a dense and expansive layer of dry plant material in shrub communities at the end of the growing season that is highly flammable – substantially contributing to an area's wildfire fuel load. Affected native plant communities can sometimes recover from wildfire over an extensive time period; but many become type-converted to a flammable grass community following intense fire, resulting in a modified tortoise habitat of generally low quality which generally lacks constituent elements of this species' native habitat (Brooks and Esque 2002, Brooks and Matchett 2003).

While flooding due to intense monsoon thunderstorms is relatively common in the eastern half of the species range in California, and rare in the western half, recent climate models predict that more frequent and intense thunderstorms are anticipated over time as a result of climate change. Overall rainfall is expected to decrease, but intense storms will likely become more common. Three climate model projections for the California Desert region show increased precipitation during winter months over the entire area, but one model predicts the greatest rainfall increase in winter and also a large increase in summer precipitation. One climate change model projects increasing precipitation throughout the 21st century with a much wetter future overall despite a decline in spring and, to a lesser extent, fall rains (Bachelet et al. 2016).

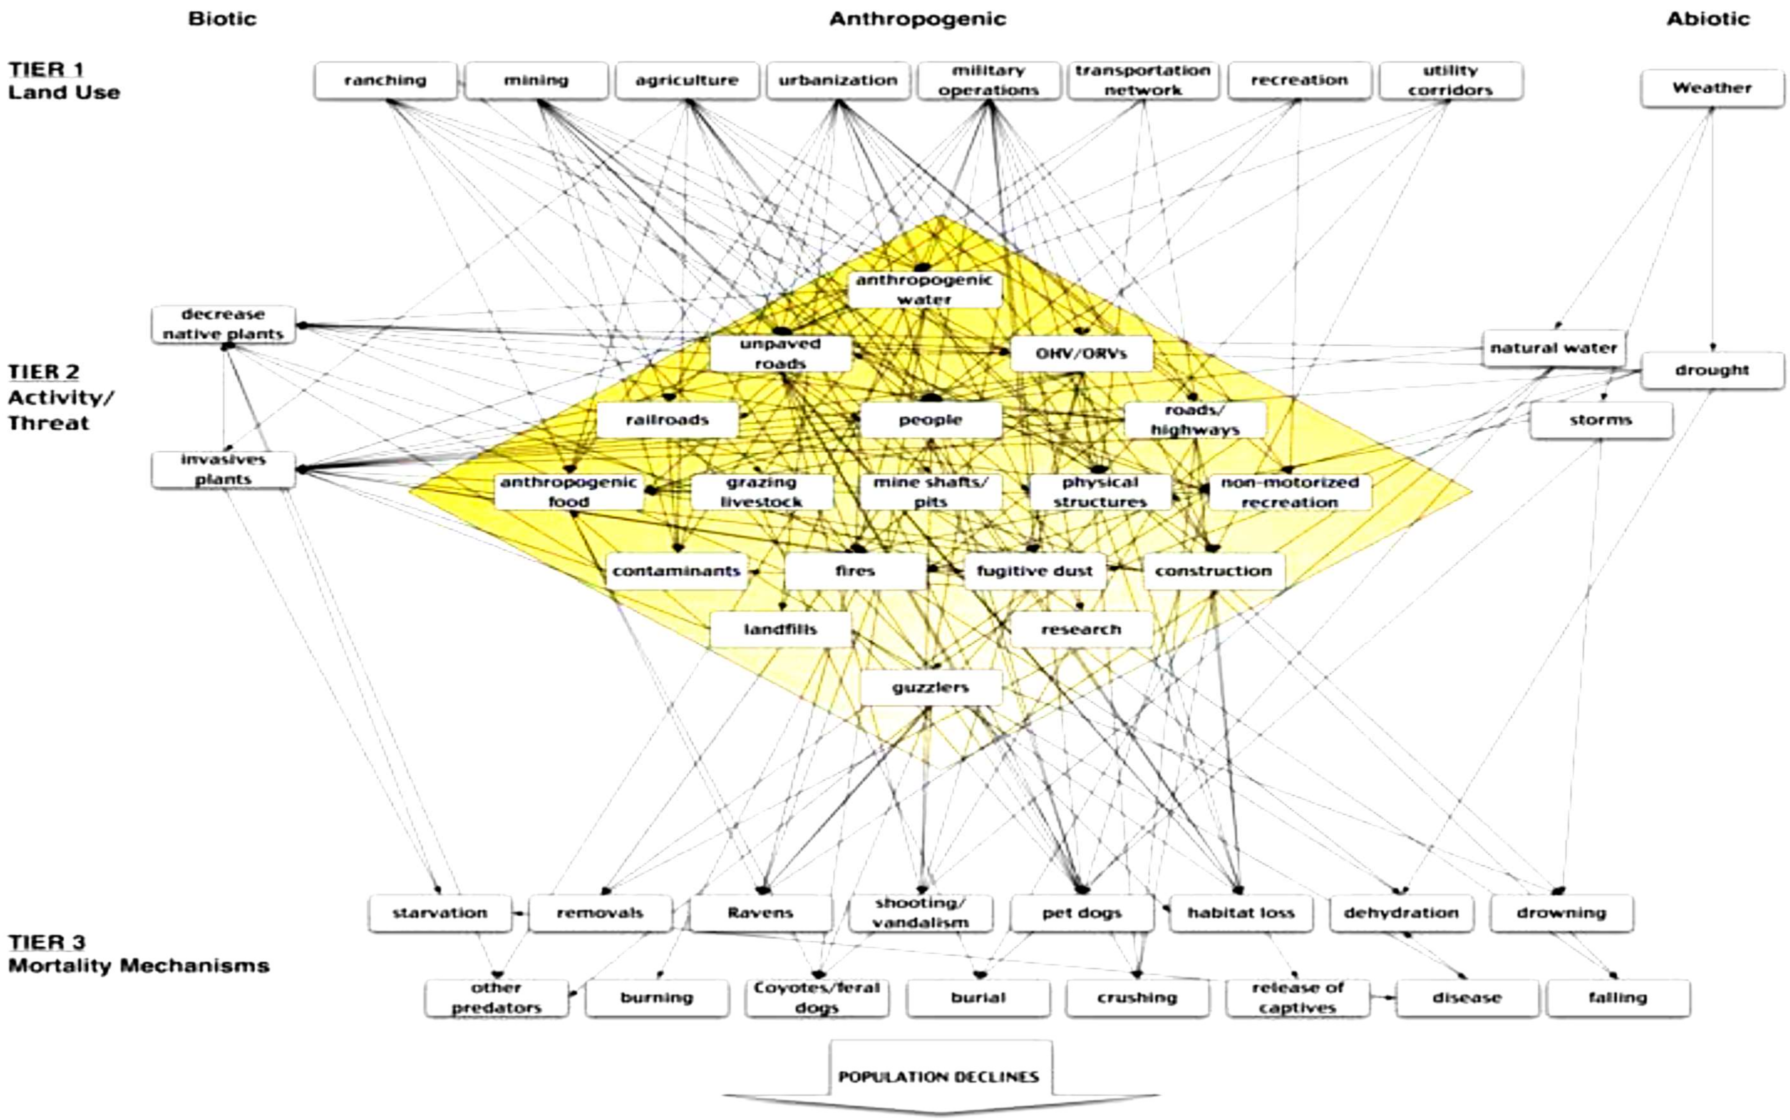

Figure 2. Network of threats demonstrating the interconnectedness between multiple human activities that interact to adversely impact tortoise populations. Tier 1 includes the major land use patterns that facilitate various activities (Tier 2) that impact tortoise populations through a suite of mortality factors (Tier 3). (From Tracy et al. 2004)

7. **DEGREE AND IMMEDIACY OF THREAT**

Indicate the immediacy of the threat and the magnitude of loss or rate of decline that has occurred to the present or is expected to occur without protective measures.

Desert tortoise populations in California have declined by approximately 90% since surveys were initially conducted starting in 1975, and also declined by over 50% since line-distance sampling began in 2004. Nine out of 10 populations in critical habitat units are now below the minimum viable density of adult tortoises ($3.9/km^2$ or $10/mi^2$), and the steep population declines are continuing. This situation results in populations that have little or no resilience to stochastic events (e.g., drought, disease, fire, etc.) and are likely to become extinct in the foreseeable future.

Additional protective measures need to be implemented immediately to prevent desert tortoise populations from becoming extinct in California. Conservation and recovery actions funded and implemented to date have proven ineffective as demonstrated through line-distance sampling and the annual reports published by the Desert Tortoise Recovery Office. There is an urgent need to ensure the survival of adult tortoises, and especially reproductive females, so that populations can slowly recover; and to drastically reduce loss of hatchling and immature individuals due to predation by excessive raven populations.

Detailed information on threats to Agassiz's desert tortoise are described above in Sections 1 ("Population Trends"), 2 ("Range and Distribution"), 3 ("Abundance") and 6 ("Factors Affecting Ability to Survive and Reproduce").

8. **IMPACT OF EXISTING MANAGEMENT EFFORTS**

Describe any ongoing protective measures or existing management plans for the species or its habitat. Information on species or land management activities that are impacting populations or portions of the range and information on proposed land-use changes should be included. This may be best accomplished by discussing populations or portions of the range, where a chart display may be useful.

Include available information on any or all of the following:

(1) property ownership/jurisdiction for known populations or portions of the range;

The following information on property ownership/jurisdiction for populations of the desert tortoise in California is from the USFWS Federal Register Notice on designation of critical habitat (USFWS 1994B) and additional land acquisition and jurisdictional changes occurring after 1994:

4,754,000 acres of critical habitat was designated in California with the following ownership/jurisdictions and acreage:

- BLM: 2,968,300 acres
- National Park Service: 828,000 acres

- Department of Defense: 450,200 acres
- State of California: 132,900 acres
- Private: 1,051,500 acres

Current and historic desert tortoise habitat loss, deterioration, and fragmentation is largely attributable to urban development, military operations, and multiple-uses off public land, such as off-highway vehicle (OHV) activities and livestock grazing.

(2) current land use;

Federal land managed by the BLM: These federal lands are managed by BLM under provisions in the CDCA Plan, most recently amended by the DRECP and the West Mojave Plan, and are managed to provide a variety of multiple uses including livestock grazing, utility rights of way, livestock grazing, OHV use, wildlife habitat management, wilderness and wild and scenic rivers. The CDCA Plan prohibits or restricts some lands uses within desert tortoise conservation areas, such as renewable energy projects and pipelines, but the plan has been amended many times to allow for these uses to occur. We anticipate that the BLM will propose to significantly diminish biological resources conservation lands and conservation actions in the near future when it releases an amended DRECP.

Federal land managed by the National Park Service: These federal lands are located within the Mojave National Preserve and Joshua Tree National Park. They are managed under provisions of General Management Plans, which emphasize natural and cultural resources protection.

Lands managed by the State of California: These lands are managed primarily by the California Department of Parks and Recreation and state parks and preserves, and by the California Department of Fish and Wildlife as State Wildlife Areas and State Ecological Reserves. High quality habitat for the desert tortoise occurs in the Western Mojave and Fremont Valley Ecological Reserves. The are managed for conservation with limited public use allowed, but unauthorized OHV use frequently occurs due to limited law enforcement capability.

Federal land managed by the Department of Defense: These federal lands are located within four large installations (China Lake Naval Air Weapons Station, Edwards Air Force Base, Fort Irwin, the Marine Corps Air Ground Combat Center, and the Chocolate Mountains Gunnery Range). They are used primarily for weapons development and testing, aircraft testing and research, and military training. Natural resources within these installations, including the desert tortoise, are managed under provisions of Integrated Natural Resource Management Plans.

Private lands: Private lands designated as critical habitat are typically interspersed among federal lands managed by the BLM and National Park Service. They are managed by local agencies under county General Plans for a variety of land uses that include residential development, agriculture, open space, mining, etc. Activities that would impact the desert tortoise or adversely modify critical habitat would require the project proponent to obtain an incidental take permit from the

CDFW and USFWS, the latter of which would require preparation and implementation of a Habitat Conservation Plan.

(3) protective measures being taken, if any, and effectiveness of current management activities;

Federal lands have a variety of protective measures in place to minimize or compensate for adverse impact to the desert tortoise and its habitat. The most protective measures are associated with National Park Service General Management Plans for the Mojave National Preserve and Joshua Tree National Park where conservation of natural and cultural resources is paramount. However, with high public visitation, these park units have experienced loss of desert tortoises due to mortality due to vehicle strikes. Speed limit signing and law enforcement patrols have had little effect in reducing threats due to vehicle strikes.

Department of Defense lands have a wide range of effects on the desert tortoise and its habitat. Installations used for large-scale mechanized training and live-fire of weapons (e.g., Fort Irwin and the Marine Corps Air Ground Combat Center) have resulted in loss and fragmentation of habitat and loss of tortoise hatchlings and juveniles that were not detected during capture and translocation operations. However, activities at the China Lake Naval Air Weapons Station and Edwards Air Force Base typically do not disturb significant amounts of habitat because their weapons development and testing activities occur within designated military airspace, with very limited use of habitat for weapons impact sites.

In order to minimize direct mortality of desert tortoises from large-scale projects, such as solar energy generation facilities, the CDFW and USFWS typically require that desert tortoises be captured and translocated to secured habitat as close to the site as possible, and that the project site be fenced to prevent tortoises from entering the facility. Translocation is considered an experimental technique to minimize mortality, but it has undergone improvements over time, resulting in higher levels of tortoise survival following translocation in the short-term. Long term effects are being studied. Short-term adverse impacts documented through field studies include mortality due to environmental exposure, elevated predation, dehydration and lower reproductive activity.

FGC - 670.1

(4) current research on the species;

Current research on the desert tortoise includes:

1) annual population estimates in Critical Habitat Units using line distance sampling;

2) disease occurrence and related mortality;

3) toxic elements in blood and liver tissue;

4) experimental translocation,

5) captive breeding and survival of young individuals into natural settings; and

6) existing management/recovery plans and the extent of their implementation.

The initial and subsequent recovery plans include recommendations for management of the species and its habitat that will contribute to the goal of recovery and eventual delisting, provided recovery goals are met.

With regard to the 1994 recovery plan, the USFWS stated in its 1994 rule (USFWS 1994b) for designation of Critical Habitat, that "*Desert tortoise populations have declined substantially throughout the Mojave Region in the last 2 decades, primarily due to habitat loss. These populations grow slowly, and significant improvement in the status of the Mojave population will be a very long process, measured in decades or centuries in most parts of the Mojave Region*."

Although the USFWS designated Critical Habitat for the Mojave population of the desert tortoise in 1994, it stated in the final rule (USFWS 1994b):

"*Designating critical habitat does not create a management plan, it does not establish numerical population goals, it does not prescribe specific management actions (inside or outside of critical habitat), nor does it have a direct effect on areas not designated as critical habitat. Specific management recommendations for critical habitat are more appropriately addressed in recovery plans, management plans, and section 7 consultations*."

Of the 4,754,000 acres of Critical Habitat in California, 2,968,300 acres are public lands managed by the BLM. Recovery of the species is largely dependent on provisions in that agency's CDCA Plan that protect Critical as well as non-Critical Habitat (e.g., linkage habitats between CHUs) through effective and timely implementation of specific management actions that reduce threats, and protect and restore elements of the habitat that Agassiz's desert tortoise requires for survival, growth and reproduction.

Subsequent to the federal listing of the desert tortoise as threatened in 1990, the CDCA Plan was amended through several regional plan amendments that added goals and objectives and specific management actions intended to contribute to the recovery of the species. A few of these regional plan amendments included:

1) Northern and Eastern Mojave Plan (BLM 2002);
2) Northern and Eastern Colorado Desert Plan (BLM and CDFG 2002);
3) Western Colorado Desert Plan (BLM 2003):
4) West Mojave Plan (BLM et al. 2006); and
5) Desert Renewable Energy Conservation Plan (BLM 2016)

BLM's 2002, 2003 and 2006 regional plan amendments to the CDCA Plan established Areas of Critical Environmental Concern (ACECs) and associated land use restrictions to protect tortoise habitat; largely corresponding to Critical Habitat designated for the species in 1994. These amendments allowed off-highway vehicle use to continue on designated open routes, as well as livestock grazing with limitations on season of use and forage utilization.

These plan amendments did not envision renewable energy development demand on public lands, an issue that emerged in approximately 2007 when right-of-way applications for large-scale solar energy and wind energy projects were filed with the BLM on over 100,000 acres of public land. As a result, 10 large-scale solar energy projects were approved in occupied tortoise habitat, outside of Critical Habitat in the Ivanpah Valley, Chuckwalla Valley, Blythe Mesa and the central Mojave of California, totaling 31,578 acres.

Off-highway vehicle routes were also designated in these regional plan amendments within Agassiz's desert tortoise habitat as open, closed or, in rare instances, as limited to certain types of vehicles. BLM's route designation on 3 million acres of public land in the West Mojave Plan (WEMO) area was found to have violated the provisions of the National Environmental Policy Act, Executive Orders, and regulations governing the use of off-highway vehicles on public land, and the CDCA Plan.

Subsequently, BLM (2019) revised the WEMO Plan route designation to address these legal deficiencies. Defenders of Wildlife urged the CDFW to review and comment on this plan when it was being developed, but that did not happen. Unfortunately, the final plan established open routes and livestock grazing in Critical Habitat that were largely the same as in the 2006 WEMO Plan, with a few deleterious additions, including promoting unrestricted motorized vehicle use on

FGC - 670.1

dry lake beds in Critical Habitat and introducing competitive event corridors through Critical Habitat.

In its request for formal consultation with the USFWS, the BLM determined the DRECP amendments of 2016 to the CDCA Plan would adversely affect both Agassiz's desert tortoise and its Critical Habitat. It is noteworthy that the DRECP established "development caps" within tortoise ACECs ranging from 0.1% - 0.5%; the latter of which applies to all Critical Habitat Units. However, these development caps do not include the effects of livestock grazing or indirect effects of off-highway vehicle use and development projects whose impacts extend beyond the direct footprint of the projects and vehicle routes. Standardized compensatory mitigation ratios were also established at 5:1 in Critical Habitat and 1:1 outside of Critical Habitat; and 2:1 within mapped tortoise habitat linkages that connect conservation areas (i.e., ACECs).

Although these various amendments to the CDCA Plan were intended to contribute to the recovery of Agassiz's desert tortoise (e.g., BLM 2016, BLM et al. 2005), the results of line distance sampling conducted by the USFWS DTRO show those intentions have not been met. They show tortoise populations in all Critical Habitat Units within California as continuing to decline rapidly, with most below the minimum viable density of 3.9 adults per square kilometer.

In its biological opinion for the DRECP adopted by the BLM in 2016, the USFWS (2016b) stated:

"*Despite the implementation of these actions, disturbance and human-caused mortality continue to occur in many areas of critical habitat (which overlap the desert wildlife management areas for the most part and are the management units for which most data are collected) to the extent that the conservation value and function of critical habitat is, to some degree, compromised*."

And that,

"*Unauthorized off-road vehicle use continues to disturb habitat and result in loss of vegetation within the boundaries of critical habitat (e.g., Coolgardie Mesa in the Western Mojave Recovery Unit); although we have not documented the death of desert tortoises as a direct result of this activity, it likely occurs. Additionally, the habitat disturbance caused by this unauthorized activity exacerbates the spread of invasive plants, which displace native plants that are important forage for the desert tortoise, thereby increasing the physiological stress faced by desert tortoises*."

The USFWS (2016b) also concluded that under the DRECP amendments:

(3/94)

FGC - 670.1

"…*development of renewable energy facilities …would remove or degrade up to 11,290 acres of desert tortoise habitat within the action area*."

Of these, 4,734 acres are within Critical Habitat. However, the biological opinion does not address the effects of future renewable energy projects that may be proposed outside of Development Focus Areas (DFAs) for renewable energy; namely public lands now termed General Public Lands and Variance Process Lands.

The only documented exception to these ongoing declines is in the DTRNA in the Western Mojave Recovery Unit. The USFWS did not designate Critical Habitat for Agassiz's desert tortoise in this area because the existing reserve-level protection provisions largely eliminated threats to the species and its habitat, including:

1) closure to all off-highway vehicle use;
2) closure to all livestock grazing;
3) closure to mineral development; and
4) a protective perimeter fence to prevent trespass of vehicles and livestock.

Recent field research has confirmed that these protective actions have been effective in reversing ongoing declines in the Agassiz's desert tortoise population within the DTRNA compared to adjacent areas lacking these protective measures.

Berry et al. (2014) surveyed 260 km^2 in the Western Mojave Desert to evaluate relationships between condition of tortoise populations and habitat on lands that have experienced three different levels of management and protection. The DTRNA was most protected; Critical Habitat designated for the desert tortoise in the Western Rand Mountains Area of Critical Environmental Concern was considered moderately protected; and private lands were considered to have no protection.

The researchers found that live tortoise density was:

1) Six-times greater inside the DTRNA compared to adjacent Critical Habitat where intensive off-highway vehicle use occurs on a designated route network; and
2) Four-times greater than on adjacent private lands.

The crude annual death rates for adult tortoises was lowest in the DTRNA (2.8% per year), followed by private lands (6.3% per year) and Critical Habitat (20.4% per year). The high death rates in Critical Habitat were of particular concern. When causes of death could be determined, they included vehicle crushing, gunshot, and predation by ravens and mammals.

(6) *Proposed land-use changes (include knowledge of forthcoming California Environmental Quality Act documents that may or should address impacts, and lead agencies involved);*

On 2/1/2018, the BLM issued a notice it intended to amend the DRECP in response to President Trump's executive orders requiring federal agencies to review regulations that unnecessarily impede energy development and deployment of broadband telecommunication facilities. We anticipate that BLM will propose amendments to the DRECP that reduce conservation lands designated in 2016, allow renewable energy development in ACECs and eliminate compensatory mitigation for land uses that adversely impact habitat for various focal species, including the desert tortoise. Proposed amendments to the DRECP are expected to be released for public review and comment in the spring of 2020. The BLM's notice is available here: https://www.blm.gov/california/BLM-to-consider-changes-desert-renewable-energy-conservation-plan.

(7) *County general plans, federal and State agency plans/actions or other plans/actions that address or should address the species*.

At this time, we are aware of only one local agency plan that places restrictions on development of renewable energy projects on private land, the Renewable Energy and Conservation Element of the San Bernardino County General Plan. That element of the General Plan restricts utility-scale solar energy development to private lands within DFAs designated by the BLM.

9. SUGGESTIONS FOR FUTURE MANAGEMENT

Describe activities that may be necessary to ensure future survival of the species after listing or delisting. Include recommendations for any or all of the following:

Although the desert tortoise is currently listed as threatened under the CESA and ESA, we provide recommendations for additional management actions that would promote its recovery under applicable items, below.

(1) *activities that would protect existing populations (site maintenance, preserve design establishment, etc.);*

While a majority of Agassiz's desert tortoise Critical Habitat in California has been designated as ACECs by the BLM for habitat protection and to promote recovery of the species, the types and intensity of land use activities allowed and

FGC - 670.1

authorized on a regular basis within these areas continue to adversely impact the species. These ACECs should be managed as biological reserves in a manner similar to the DTRNA, where activities that adversely impact the species are largely prohibited (e.g., off-highway vehicle use, use of unlicensed motorized vehicles, and livestock grazing). This management level was stated in the 1994 Recovery Plan as a recovery action. However, this is not occurring.

Fencing highways and roads with tortoise exclusion fence would eliminate these linear features as population sinks and greater reduce the “road effect zone.” This action would reduce tortoise mortality. Fencing highways is occurring in Nevada.

(2) *monitoring programs and studies;*

Science-based systematic monitoring of the impacts of off-highway vehicle use and livestock grazing is needed to assess the magnitude and extent of impact these activities have on Agassiz’s desert tortoise, which would be used to develop additional protective measures or restrictions through the adaptive management process. Such systematic monitoring has not been initiated in California.

However, the BLM and others have developed an extensive bibliography of reliable information on the known adverse impacts of both recreational vehicle use and livestock grazing upon Agassiz’s desert tortoise, some of which follows:

D.S. Ouren, et al. 2007. Report prepared for U.S. Geological Survey. Environmental Effects of Off-highway Vehicles on Bureau of Land Management Lands: A Literature Synthesis, Annotated Bibliographies, Extensive Bibliographies, and Internet Resources. (3/94)

FGC - 670.1

(3) *needed amendments to existing management and land-use plans, including county general plans;*

The CDCA Plan is the primary document guiding management of public lands and was initially adopted in 1980 and amended many times over the past 39 years, such as by the DRECP in 2016 and by earlier regional plan amendments, identified above. The BLM finalized the West Mojave Plan Route Network and Livestock Grazing amendments to the CDCA Plan in 2019. (https://www.blm.gov/programs/planning-and-nepa/plans-development/california/west-mojave-plan-route-network).

Based on a thorough review of the CDCA Plan, we recommend that it be further amended to:

- eliminate livestock grazing in desert tortoise Critical Habitat and habitat linkages;
  restrict the use of unlicensed or non-street legal off-highway vehicles to BLM-designated Open Areas;
- close and restore all redundant vehicle routes in desert tortoise Critical Habitat and habitat linkages;
- establish a 15 mile per hour vehicle speed limit in all desert tortoise Critical Habitat;
- establish seasonal and/or temporary closure of motorized vehicle routes to off-highway vehicle use during the spring season and during precipitation events when standing water is on dirt roads and trails; and
- enforce existing restrictions and the restrictions suggested above in Critical Habitat areas.

(4) *agencies/organizations that should be involved in planning and implementing management and recovery actions;*

BLM (California Desert District and Field Offices); Department of Defense (Fort Irwin, MCAGCC, China Lake, Edwards Air Force Base, Chocolate Mountain Aerial Gunnery Range); California Department of Parks and Recreation; CDFW; Caltrans; respective planning departments in Kern County, San Bernardino County, Riverside County, Imperial County, and Inyo County.

(5*) other activities that would help protect existing habitat or ensure survival of the species;*

Plan for and implement effective and timely control of common raven populations within all Desert Tortoise Recovery Units with priority given to Critical Habitat Units within the Western Mojave Recovery Unit.

(6) *how other sensitive species (listed and unlisted) may benefit from protection of this species*; and

(7); *how other species/habitats may be impacted by management and recovery activities for this species*.

The state-listed Threatened Mohave ground squirrel would benefit because its declining range overlaps with the Agassiz's desert tortoise in large portions of the Western Mojave Recovery Unit. In addition, several federal and state-listed and sensitive plant species would benefit, such as the Barstow woolly sunflower, Desert cymopterus, Lane Mountain milk-vetch, Mojave monkeyflower, Mojave tarplant, Parish's daisy, and Triple-ribbed milk-vetch.

(8*) at what point this species would be considered stable and sustainable.*

The U.S. Fish and Wildlife established recovery criteria for the desert tortoise in its 1994 and Revised 2011 Recovery Plans. Recovery criteria include the management or elimination of threats, and addressing the five statutory delisting factors. However, at the time the Revised Recovery Plan was finalized, the USFWS considered the following three criteria applicable due to lack of information on the degree of threat posed by certain activities.

<u>Recovery Objective 1 (Demography)</u>. Maintain self-sustaining populations of desert tortoises within each Recovery Unit into the future.

> *<u>Recovery Criterion 1</u>. Rates of population change (λ) for desert tortoises are increasing (i.e., λ > 1) over at least 25 years (a single tortoise generation).*

<u>Recovery Objective 2 (Distribution)</u>. Maintain well-distributed populations of desert tortoises throughout each Recovery Unit.

> *<u>Recovery Criterion 2</u>. Distribution of desert tortoises throughout each tortoise conservation area is increasing over at least 25 years (i.e., ψ [occupancy] > 0).*

<u>Recovery Objective 3 (Habitat)</u>. Ensure that habitat within each Recovery Unit is protected and managed to support long-term viability of desert tortoise populations.

> *<u>Recovery Criterion 3</u>. The quantity of desert tortoise habitat within each desert TCA is maintained with no net loss until tortoise population*

viability is ensured. When parameters relating habitat quality to tortoise populations are defined and a mechanism to track these parameters established, the condition of desert tortoise habitat should also be demonstrably improving.

The Revised Recovery Plan estimated that if all the recovery actions were implemented and were successful, desert tortoise recovery would be expected to occur by the year 2025. However, since none of the recovery criteria have been met, especially positive rates of change in populations over at least 25 years, recovery will take much longer, likely multiple decades or perhaps over 100 years.

10. **AVAILABILITY AND SOURCES OF INFORMATION**

Cite literature, available specimen collection records, and other pertinent reference materials. Attach documents critical to the recommended action. Be sure to include recent status surveys. List names, addresses, and telephone numbers of persons providing unpublished information and list those supporting the recommended action.

All cited literature used in this petition are identified above and full citations are included in Attachment 4 (Literature Cited), with many having website links to documents. Additional sources of information in support of this petition include:

11. **DETAILED DISTRIBUTION MAP**

Delineate on appropriate maps the historic and present distribution (estimated if not known). Include one map of California showing general distribution, and U.S. Geological Survey topographical maps (or equivalent) of appropriate scale, for more detailed distribution information, including locations of occurrences, populations or portions of populations, as appropriate. Include historic and current distribution as documented by literature, museum records, California Natural Diversity Data Base and other California Department of Fish and Wildlife records, and testimony of knowledgeable individuals. All maps must be suitable for black and white reproduction and fully labeled, including borders, base map name, map scale and species name, and should not exceed 11" x 14" in size.

Distribution maps of the desert tortoise are available on the following website links:

CONCLUSION

Thirty years after its listing as Threatened under provisions of the California and federal Endangered Species Acts, Agassiz's desert tortoise is in much worse condition than it was in 1990, and the number and severity of threats have increased. Threats to the species at the time of the 1990 federal listing as Threatened have not abated; they are becoming more widespread and intense.

Tortoises and their habitats are impacted by a myriad of authorized and illegal human activities that degrade or eliminate suitable creosote bush scrub and other vegetation communities needed as habitat, subsidize predators whose increased numbers prey on tortoises, and facilitate invasion of non-native species of plants that degrade habitat quality and displace native forbs and grasses needed for adequate nutrition and reproduction/recruitment.

Based on systematic USFWS-funded line distance sampling conducted by the Service's Desert Tortoise Recovery Office, from 2004 through 2014, adult tortoises in the three California Recovery Units declined by 51.3 percent over 10 years; and 9 of the 10 populations in these Recovery Units in California were below viability density. This decline is a continuation of an ongoing decline since the 1980s as documented by the data from permanent study plots on the CHUs and Recovery Units for the tortoise in California.

Based on the best available scientific information, as identified and summarized in this petition, naturally-occurring populations of Agassiz's desert tortoise are on the verge of extirpation in California from a variety of human-related threats. Defenders of Wildlife,

(3/94)

Desert Tortoise Council and Desert Tortoise Preserve Committee believe changing the status of Agassiz's desert tortoise from threatened to endangered under provisions of the California Endangered Species Act will more accurately reflect the status of the species under CESA; result in a higher-level of analysis of impacts from land use activities by CDFW; will result in more effective measures to avoid and minimize incidental take; and will result in higher levels of compensatory mitigation for unavoidable impacts. Combined, these outcomes will contribute to halting the decline of Agassiz's desert tortoise in California and provide conditions conducive to its recovery.

State of California
Department of Fish and Wildlife

Original on file, received January 9, 2024

Memorandum

Date: December 29, 2023

To: Melissa Miller-Henson
Executive Director
Fish and Game Commission

From: Charlton H. Bonham
Director

Subject: Status Review Report for the Mojave Desert Tortoise (Gopherus agassizii)

The California Department of Fish and Wildlife (Department) has prepared the attached status review for the Mojave Desert Tortoise (Gopherus agassizii) for the California Fish and Game Commission (Commission) pursuant to the California Endangered Species Act, Fish and Game Code section 2050 et seq. The Commission published the Notice of Candidacy Findings on October 19, 2020, directing the Department to prepare a status review. On October 14, 2021, the Commission approved a Department request for a 6-month extension to further analyze the petition and complete its status review in accordance with Fish and Game Code section 2074.6.

The Department completed the attached status review as required by Fish and Game Code section 2074.6. The status review contains the Department's review of the best scientific information available to the Department on the status of the Mojave Desert Tortoise and serves as the basis for the Department's recommendation to the Commission that the petitioned action to list the Mojave Desert Tortoise as endangered is warranted. The Department finds that the Mojave Desert Tortoise is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease.

If you have any questions or need additional information, please contact Scott Gardner, Branch Chief, Wildlife Branch at (916) 801-6257 or by email at wildlifemgt@wildlife.ca.gov.

ACKNOWLEDGMENTS

This status review was prepared by Department scientific and technical staff, with substantial contributions from Anne Hilborn, Katrina Smith, and Wendy Campbell. Laura Patterson, Madeline Weiland, Neil Clipperton, and Pete Figura provided valuable feedback on a draft version of the status review. The Department is extremely grateful for the valuable comments provided on this status review by the following peer reviewers: Jeffery Lovich, Kristina Drake, Kerry Holcomb, Corey Mitchell, and Kenneth Nussear. The conclusions in this status review are those of the Department and do not necessarily reflect those of the reviewer

EXECUTIVE SUMMARY

This status review contains the most current information available on the Mojave Desert Tortoise (*Gopherus agassizii*) and serves as the basis for the California Department of Fish and Wildlife's (Department) recommendation to the California Fish and Game Commission (Commission) on whether to change the status (i.e., uplist) of the species from threatened to endangered under the California Endangered Species Act (CESA).

The Mojave Desert Tortoise was designated a threatened species under CESA in 1989 and designated as threatened under the federal Endangered Species Act (ESA) in 1990. On March 23, 2020, Defenders of Wildlife, Desert Tortoise Council, and Desert Tortoise Preserve Committee submitted a petition to the Commission to change the status of the Mojave Desert Tortoise from threatened to endangered. At its public meeting on October 14, 2020, the Commission considered the petition, and based in part on the Department's petition evaluation and recommendation, found sufficient information exists to indicate the petitioned action may be warranted and accepted the petition for consideration. The Commission's decision initiated this status review to inform the Commission's decision on whether the change in status is warranted. The Department's recommendation is that uplisting the Mojave Desert Tortoise is warranted.

Species Description, Biology, and Ecology

The Mojave Desert Tortoise is a long-lived, desert-dwelling reptile that uses behavioral and physiological adaptations to avoid extreme temperatures and dehydration, and to budget stored energy. Mojave Desert Tortoises primarily regulate their temperature by using underground burrows where the air is cooler and higher in humidity in summer, and warmer in winter. They can spend more than 90% of their lives underground.

Females become sexually mature at 12–20 years old and typically lay one or two clutches of eggs (about 6 eggs per clutch) per year. Nest predation is common, with 12–47% of nests lost to predators annually. Incubation time in the wild varies from 67 to 104 days and incubation temperatures determine the sex of the hatchlings, with hotter temperatures producing female-skewed clutches.

In California, the range of the Mojave Desert Tortoise includes the Mojave Desert and portions of the Sonoran and Great Basin deserts. Desert tortoise habitat typically consists of alluvial fans and plains that facilitate the digging of burrows. Tortoises need sufficient forage plants as well as larger shrubs and bushes for shade and protection of burrows. Tortoises feed on annual forbs, annual and perennial grasses, herbaceous perennial plants, and some cacti. Tortoises occur in very low densities or are absent where shrub cover is sparse, precipitation is low, and annual food plants are available only intermittently (e.g., lower elevations of Death Valley). They also occur at low densities in areas that are moderately to severely disturbed by human activity.

Status and Trends

The most robust estimates of densities come from annual systematic surveys done in the USFWS-designated Tortoise Conservation Areas (TCAs) which are grouped into Recovery Units. These surveys began in 2001 and cover large areas of the best habitat for tortoises. The 1994 USFWS Recovery Plan for desert tortoise identified 3.9 adult tortoises/km^2 as the minimum density necessary for population viability. Only two of the ten TCAs in California had mean densities above that threshold in 2001, and all the TCAs were below the threshold in 2020. Between 2001 and 2020, densities declined an average of about 1% per year in the Colorado Desert and Eastern Mojave Recovery Units (17% decline over 19 years), and about 4% per year in the Western Mojave Recovery Unit (54% decline over 19 years). In 2001, the Western Mojave was the area with the highest densities of tortoises, but experienced the steepest decline in abundance, losing >50% of adults from 2001 to 2020. However, there is still a large amount of available habitat in California and there were estimated to be more than 90,000 adult tortoises in the Western Mojave Recovery Unit in 2020.

The available population data indicate that there were widespread sharp drops in density before the tortoise was listed as threatened, and those losses have continued to the point where most surveyed areas no longer support viable tortoise populations. Despite 30 years of state and federal protection as a threatened species, tortoise populations do not show consistent signs of recovery.

The slow maturation and low reproductive rates of tortoises means that if past and current management is successful at addressing threats and stemming the decline of tortoise populations, it would still take at least 25 years of positive population growth to reach the USFWS Recovery Criteria. For example, the USFWS 1994 Recovery Plan estimates that when adult survivorship is 98%, population growth would be less than 0.5% per year, and would take 140 years to double in size. Annual survival rates for both adults and juveniles are much lower than 98% in most areas, and since the late 1970s, the number of juveniles detected on surveys has also fallen sharply, to the point that in some recent surveys in the western Mojave Desert almost no juveniles were found.

Threats

The declines of Mojave Desert Tortoise populations are likely due to extensive and interconnected threats. The important threats fall into two categories, those that directly kill adults and juveniles, and those that cause longer-term changes to habitat availability and quality.

In long-lived species that are slow to reproduce, decreased survival has long lasting impacts on population viability and can alter demographic rates for decades. Predation pressure from ravens and coyotes reduces the survival of juvenile and adult tortoises. Development within the tortoise range often creates or increases traffic on paved roads, and extensive networks of unpaved roads and trails for off highway vehicles occur on public land. Tortoises are killed by vehicles on paved and unpaved roads and trails. Moreover, road infrastructure increases the amount of roadkill and garbage available, creating food subsidies for ravens and coyotes which encourages their presence near tortoises. Well-designed fences and culverts can help prevent tortoises and other wildlife from being killed by vehicles along major roads, but little fencing has been built in California tortoise habitat since 2011.

Habitat modification, fragmentation, and destruction reduces the amount of habitat that can support tortoises in the long-term and reduces the size of remaining habitat patches. Although a large proportion of desert tortoise range is under federal control, renewable energy, housing, offroad vehicle use, and other types of development reduce the amount of habitat available. Concerningly, predators like the raven and coyote that receive food subsidies in fragmented and disturbed habitats can also occur at higher densities in nearby "undisturbed" habitats.

Additional factors have direct and indirect impacts on tortoises and their habitat. Climate change is likely to cause hotter and periodically drier conditions in the desert tortoise range that will increase their physiological stress and change activity patterns. The nutritious native vegetation tortoises feed on is being outcompeted by nutritionally poor invasive grasses, which can lower tortoise survival rates. Fires fueled by invasive grasses decrease the amount of native vegetation available for tortoises to feed on and remove other important vegetation components of tortoise habitat. In combination, the impacts of climate change will likely result in less available suitable habitat.

Some threats appear to be declining since the species was listed. Upper respiratory tract diseases were a major concern when tortoises were listed as threatened. Encouragingly, the prevalence of diseased tortoises is lower than in previous decades, and these diseases do not currently appear to be an acute threat to wild populations. The prevalence of gunshot deaths has also decreased in the past several decades.

Historical and current conservation and management efforts such as the prohibition on take, creation of land use plans, required mitigation, and translocation and head-starting efforts have not proven sufficient to halt the population declines of desert tortoise. Given that there are multiple interacting threats that are reducing the amount and quality of viable habitat and lowering survival rates of adults and juveniles, the available information suggests that tortoises populations will continue to decline for the foreseeable future. However, several of the major threats like raven predation on juveniles and the lack of tortoise exclusion fencing on highways are issues that can be addressed with appropriate resources and policy changes. Implementing these actions where appropriate to improve survival in the short term is critical to give desert tortoises populations the resilience to weather longer term habitat and climactic effects.

Several recommended management actions are described in this status review. Improved coordination and communication between the Department and other state and federal agencies would help the implementation of these actions. We also point to several needs for increasing capacity at the Department to better track the impact of threats and conservation actions on tortoise populations.

Recommendation—In consideration of the scientific information contained herein, the Department has determined that listing the Mojave Desert Tortoise as endangered under CESA is warranted at this time.

1. REGULATORY SETTING

1.1 Petition Evaluation Process

On March 23, 2020, the Commission received a petition from Defenders of Wildlife, the Desert Tortoise Council, and the Desert Tortoise Preserve Committee to change the status of Mojave Desert Tortoise from threatened to endangered. On April 13, 2020, the Commission referred the petition to the Department for evaluation pursuant to Fish and Game Code section 2073 and published a formal notice of receipt of the petition (Cal. Reg. Notice Register 2020, No. 18-Z, p. 693). At its meeting on April 16, 2020, the Commission officially received the petition.

A petition to list, delist, or change the status of a species under CESA must include "information regarding the population trend, range, distribution, abundance, and life history of a species, the factors affecting the ability of the population to survive and reproduce, the degree and immediacy of the threat, the impact of existing management efforts, suggestions for future management, and the availability and sources of information. The petition shall also include information regarding the kind of habitat necessary for species survival, a detailed distribution map, and any other factors that the petitioner deems relevant" (Fish & G. Code, § 2072.3).

The Department's charge and focus in its advisory capacity to the Commission is scientific, and it evaluates petitions based on the best scientific information available regarding potential listing factors including those listed above. At its meeting on August 20, 2020, the Commission received the Department's petition evaluation report, which is intended to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5 & 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & I). Focusing on the information available to the Department relating to each of the required information categories listed above, the Department recommended to the Commission that the petition be accepted.

At its public meeting on October 14, 2020, the Commission considered the petition, the Department's petition evaluation and recommendation, and comments received. The Commission found that sufficient information existed to indicate the petitioned action may be warranted and accepted the petition for consideration. Upon publication of the Commission's notice of its findings, the Mojave Desert Tortoise was designated a candidate species on October 19, 2020 (Cal. Reg. Notice Register 2020, No. 44-Z, p. 1445).

The Commission's decision to designate the Mojave Desert Tortoise as a candidate species triggered the Department's process for conducting a 12-month status review to inform the Commission's decision on whether the change in status is warranted (Fish & G. Code, § 2074.6

and Cal. Code of Regs., title 14, § 670.1). At its meeting on October 14, 2021, the Commission granted the Department a six-month extension to complete the status review and facilitate external peer review.

1.2 Status Review Overview

This status review is based upon the best scientific information available to the Department and serves as the basis for the Department's recommendation to the Commission on whether the petitioned action to list the Mojave Desert Tortoise as endangered is warranted. It is not intended to be an exhaustive review of all published scientific literature on Mojave Desert Tortoise; rather it is intended to summarize key points relevant to the status of the species and address regulatory report requirements.

All of the required elements in Fish and Game Code sections 2072.3 and 2074.6, as well as in California Code of Regulations Title 14 section 670.1, are included and addressed in this status review. These elements include "information regarding the population trend, range, distribution, abundance, and life history of a species, the factors affecting the ability of the population to survive and reproduce, the degree and immediacy of the threat, the impact of existing management efforts, suggestions for future management, and the availability and sources of information. The petition shall also include information regarding the kind of habitat necessary for species survival, a detailed distribution map" (Fish & G. Code, § 2072.3; see also Cal. Code Regs., tit. 14, § 670.1, subd. (d)(1)). Sections are named and organized according to each of the required petition components and the listing factors that the Commission must consider in making its determination. However, in some instances, the Department has renamed and grouped similar elements to create a more cohesive and readable report.

A species shall be listed as endangered or threatened "if the Commission determines its continued existence is in serious danger or is threatened by any one or any combination of the following factors: present or threatened modification or destruction of its habitat, overexploitation, predation, competition, disease, or other natural occurrences or human-related activities" (Cal. Code Regs., tit. 14, § 670.1, subd. (i)(1)(A)).

An endangered species under CESA is one "which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish & G. Code, § 2062). A threatened species under CESA is one that "although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by [CESA]" (id., § 2067).

Receipt of this report is to be placed on the agenda for the next available meeting of the Commission after delivery. At that time, the report will be made available to the public for a 30-day public comment period prior to the Commission taking any action on the petition.

2. BIOLOGY

2.1 Taxonomy

Desert tortoises are members of the order Testudines, family Testudinidae, genus *Gopherus*. When the Commission listed Desert Tortoise as threatened in 1989, *Gopherus agassizii* was understood to range from southeastern California, across southern Nevada, through western Arizona, and south into Sonora and Sinaloa, Mexico. In 2011, studies of tortoise genetics, morphometrics, and ecology led experts to conclude that the species complex formerly known as “Desert Tortoise” in fact consists of two separate species, Mojave Desert Tortoise and Sonoran Desert Tortoise (*Gopherus morafkai*) (Murphy et al. 2011, Iverson et al. 2017). Mojave Desert Tortoise, also known as Agassiz’s Desert Tortoise or Mohave Desert Tortoise, retains the binomial *G. agassizii*, and ranges across the deserts of southeastern California, southern Nevada, and small areas of Arizona and Utah north of the Colorado River as well as southwestern Utah. There is an “anomalous" population of *G. agassizii* east of the Colorado River in the Black Mountains of Arizona (Edwards et al. 2015). Apart from that population, desert tortoises east of the Colorado River in Arizona and in northern Mexico are now classified as Sonoran Desert Tortoise, also known as Morafka’s Desert Tortoise. More recent work by Edwards et al. (2016) separates desert tortoises living in the thorn scrub and tropical deciduous forests of southern Mexico into another species, *Gopherus evgoodei*. Only the Mojave Desert Tortoise occurs in California. This status review uses the common name Mojave Desert Tortoise when referring to *G. agassizii* as the species is currently understood. Any reference to Agassiz’s or Mohave Desert Tortoise in this document should be considered synonymous with Mojave Desert Tortoise.

2.2 Species Description and Life History

Much of the information in this section is summarized from a Berry and Murphy (2019) monograph on *Gopherus agassizii*. The Mojave Desert Tortoise is a long-lived, desert-dwelling reptile. The upper shell or carapace of adults ranges in size from 178mm to over 370mm in length. Shell color varies from light yellow to dark charcoal in hatchling tortoises and from light to dark brown in adults (Berry and Murphy 2019). Generally, males are larger than females (Ernst and Lovich 1994) but the largest measured wild individual was a female in 1986 whose carapace length was 374 mm (Berry and Murphy 2019). The largest male measured in the wild had a 330 mm carapace length (Berry and Murphy 2019).

Figure 1. Mojave Desert Tortoise. Pictures by Dana Wilson BLM (left) and Roy Averill-Murray USFWS (right).

Desert tortoises make extensive use of underground burrows to regulate body temperature and as protection from predators. Temperatures in burrows can be up to 20°C (36°F) cooler than summer air temperatures, especially very deep in the burrows (Berry and Murphy 2019). Home range size depends on sex, age, and environmental conditions. Over a 2-year study in the western Mojave Desert, male home range size was 39–47 ha and female home range size was 14–17 ha (Harless et al. 2009). Home ranges of individuals can overlap (O'Connor et al. 1994) and in the western Mojave Desert Harless et al. (2009) found that males overlap more with other tortoises than do females. They also found that the overlap of an individual's home range from one year to the next was about 35% and did not vary significantly by sex. Individuals tend to have fidelity to home ranges and activity centers, even after a fire (Drake et al. 2015, Lovich et al. 2018).

Tortoises are long-lived and females are thought to become sexually mature at 12–20 years old (mean 18.8; Medica et al. 2012), depending on locality (Woodbury and Hardy 1948, Turner et al. 1986, Curtin et al. 2009). Generation time is estimated to be around 25 years (U. S. Fish and Wildlife Service 1994). Mating occurs in late summer and fall, and females can mate with multiple males (Davy et al. 2011). Female tortoises store sperm/delay implantation so that nesting and egg laying occurs in April–July depending on the region (Berry and Murphy 2019). Females typically lay one or two clutches of eggs (about 6 eggs per clutch) per year; however, some females have been documented to lay more than two clutches (Ennen et al. 2012, Mitchell et al. 2021). Tortoise nests are typically placed near entrance to the burrow or within suitable soil (Ennen et al. 2012), and there is no parental care once eggs have hatched (Berry and Murphy 2019). Reported incubation time in the wild varies from 67–104 days (McLuckie and Fridell 2002) and incubation temperatures determine the sex of the hatchlings. Sex ratios were 1:1 at an incubation temperature of 31.3°C (88.3°F), while eggs incubated at under 30°C (86°F) produced only male hatchlings and those incubated at over 32.5° (90.5°F) produced only females (Rostal et al. 2002). Nest predation is common, with 12–47% of nests destroyed by predators annually (Bjurlin and Bissonette 2004, Ennen et al. 2012). When nests are not depredated, hatchling success is about 80% (Bjurlin and Bissonette 2004). Newly hatched tortoises are about 4–5 cm in length (Bjurlin and Bissonette 2004) and their shells do not fully ossify until they are 5–7 years old.

Tortoises feed on annual and perennial forbs, grasses, and will consume cacti during droughts (Berry and Murphy 2019). Much of the range of the desert tortoise is highly invaded by nonnative plants, including grasses like red brome (*Bromus rubens*) and cheatgrass (*Bromus tectorum*). Experimental studies found that grass diets that included no forbs were detrimental to tortoises, leading to weight loss, poor body condition, or even death (Hazard et al. 2009, Drake et al. 2016). This was the case even when the diet included native grasses (Drake et al. 2016). In addition, the seeds of *B. rubens* can cause injury to the oral mucosa of juveniles (Drake et al. 2016). According to Berry and Murphy (2019), tortoises "favored species of forbs or herbaceous perennials from several plant families: Asteraceae, Boraginaceae, Cactaceae, Fabaceae, Malvaceae, Nyctaginaceae, Onagraceae, and Plantaginaceae (Burge and Bradley 1976; Avery and Neibergs 1997; Jennings and Berry 2015)."

Tortoises are ectotherms whose body temperature is closely linked to the temperature in the environment around them. Mojave Desert Tortoises live in places that can fluctuate up to 40°C (104°F) seasonally and they primarily regulate their temperature by using underground burrows or rock shelters (Cummings et al. 2020) where the air is cooler and moister than the outside air in summer and warmer in winter (Ernst and Lovich 1994). Depending on the type, length, and depth of burrow, average temperatures inside vary from 33.7–36.6°C (92.6–97.8°F) in the summer and 8.9–13.5°C (48–56.3°F) in the winter (Mack et al. 2015). Berry and Murphy (2019) reported that desert tortoises spend >90% of their lives underground. Tortoises are active when their body temperatures are between 19.0°C and 37.8°C (66.2–100°F), they retreat to shade when body temperatures are 35–38°C (95–100.4°F), and body temperatures of 43°C (109.4°F) are deadly (Brattstrom 1965, Zimmerman et al. 1994). However, tortoises can be active above ground at any time of year, especially if it has rained and they can drink, or if they need to move between shelters (Ernst and Lovich 1994). They generally are underground or in rock shelters in late fall and winter, and in late spring through the hot summer. In early spring and fall they are more active above ground, feeding, travelling, and interacting with other tortoises (Berry and Murphy 2019). In the cooler late winter and spring, they are active late morning to mid-afternoon. In the hotter summer and fall, if activity occurs, it tends to be in the cool of the morning and late evening. Smaller juvenile tortoises can be active at cooler temperatures than larger tortoises so tend to be active more days per year (Berry and Murphy 2019). Available water and forage have an impact on activity and movement. Tortoises moved less, used fewer burrows, and had smaller home ranges during drought years as compared to wet years in the mid-1990s (Duda et al. 1999). However, at a different site in the late 1990s, the relationships between precipitation and activity area, rate of movement, and burrows used were less clear (Ennen et al. 2012), suggesting that there are many interacting forces that determine tortoise activity and movement levels.

Tortoises also have additional behavioral and physiological strategies to deal with extremes of temperature and resource availability. During droughts, tortoises can lose up to 40% of their body mass. They can resorb water from their bladders and store sodium, chloride, and urea in their blood and in the bladder. When it rains, they drink, void their bladders, and rapidly increase their body weight (Ernst and Lovich 1994, Peterson 1996, Berry and Murphy 2019).

2.3 Habitat Associations

Figure 2. Mojave Desert Tortoise in the Mojave Desert. Photo by Rachel London via USFWS

Mojave Desert Tortoises in California can be found in part of the southern Great Basin, Mojave, and western Sonoran deserts in southeastern California (Berry and Murphy 2019, Figure 2). Due to their dependence on burrows, they require soils, topography, geological features, and vegetation that facilitate the creation of burrows or dens (Andersen et al. 2000). Therefore, desert tortoise habitat typically consists of alluvial fans and plains, but they can be found on rocky hillsides (Germano et al. 1994). Tortoises also need appropriate vegetation communities for forage and shelter. Most burrows are found beneath shrubs, though they can also be dug into the sides of ephemeral streams.

The vegetation types that tortoises use vary across their range and by altitude. As Berry and Murphy (2019) put it:

> "Within the Mojave Desert ecosystem, tortoises occur in several vegetation associations. At lower elevations or adjacent to dry lake beds, saltbush associations (*Atriplex* spp.) and other members of the Chenopodiaceae provide habitat. The most common associations contain creosote bush (*Larrea tridentata*), usually with white bur-sage (*Ambrosia dumosa*) or cheesebush (*A. salsola*) and several other species of shrubs, cacti, and perennial grasses. With increasing elevation, multiple species of woody shrubs and tree yuccas (Joshua tree, *Yucca brevifolia,* and Mojave yucca, *Y.*

schidigera) become more common, with blackbrush (*Coleogyne ramosissima*) associations present in higher elevations.

The western Sonoran Desert is a warmer, hotter desert with a higher proportion of precipitation occurring in summer. This desert is also characterized by creosote bushes, but a major difference is the presence of microphyll woodlands of blue palo verde (*Parkinsonia florida*), smoke tree (*Psorothamnus spinosus*), and ironwood (*Olneya tesota*) in ephemeral stream channels separated by desert pavements or open desert with ocotillo (*Fouqueria splendens*) mixed with creosote bush, other shrubs, and cacti (Berry 1984).

Tortoises occur in very low densities or are absent where shrub cover is sparse, precipitation is low and timing erratic, and annual food plants are available only intermittently (e.g., the lower elevations in Death Valley). They are also in low densities in moderately to severely disturbed areas, regardless of desert or region (e.g., Bury and Luckenbach 2002; Keith et al. 2008; Berry et al. 2013)."

2.4 Range and Distribution

Range is the general geographical area in which a species occurs. For purposes of CESA and this status review, we are describing and evaluating the tortoise's range in California. Distribution describes the sites where individuals and populations of the species occur, and the spatial arrangement of individuals within the species' range.

In California, the range of the Mojave Desert Tortoise includes the Mojave Desert and portions of the Colorado subunit of the Sonoran and Great Basin Deserts from the southern end of the Owens Valley south of the town of Lone Pine in Inyo County to the Mexican border near the southeastern corner of the state, and from the Colorado River in the east to the lower slopes of the Sierra Nevada, Transverse, and Peninsular mountains in the west (Berry and Murphy 2019).

The distribution of desert tortoises within California is uneven, and portions of the range no longer provide suitable tortoise habitat due to agriculture, development, and military activity. Data on tortoise occurrences from the California Natural Diversity Database (CNDDB) and the Global Biodiversity Information Facility (GBIF) were used to plot the distribution of observations in California (Figure 3). These datasets do not represent exhaustive and comprehensive inventories of desert tortoises in California and are largely presence-only datasets. While caution should be used in using these types of data, there appear to be fewer occurrences in the northern part of the range and in the Death Valley/Mojave Central Trough (see grey area on Figure 3), and few occur in low areas near the Salton Sea (Lovich et al. 2020).

Desert Tortoise distribution has been dynamic due to the release of captive tortoises and potential immigration into areas from which they were previously extirpated. For example, tortoises were largely extirpated from the area of Anza Borrego Desert State Park by the 1940s (Manning 2018). In the early 1970s, taking tortoises from the wild became illegal, and people began turning in their captive tortoises to the Department. Between 1970 and 1972 the

Department released about 65 previously captive tortoises into the park. There were occasional sightings in the decades since, with more sightings since 2010. The tortoises there today could be descendants of released tortoises, however natural immigration to the park may also have occurred as there is a tenuous corridor of suitable habitat that connects the park to habitat occupied by tortoises to the north. In 2016, park staff began surveying for tortoises and formally collecting incidental observation data, and subsequent genetic analysis of tortoise blood and scat suggested "evidence of a naturally reproducing Mojave desert tortoise population in Anza Borrego Desert State Park" (Manning 2018). These tortoises extend "the distribution of reproducing Mojave Desert Tortoises greater than 60 km south of Palm Springs and beyond the southern edge of the Colorado Desert Recovery Unit boundary depicted in the recovery plan (Service 2011a)" (USFWS 2022*a*). We show this reoccupation of historical range in Figure 3, delineated using suitable ecoregion boundaries.

Figure 3. Map of the California range of the Mojave Desert Tortoise, occurrence locations, and Ecoregions. CNDDB data are sightings from 1935 to 2011. The GBIF occurrences are from 1978 to 2022, and only include sightings that are confirmed by a photograph. The pink dots are the locations of tortoises in the reoccupied historical range as reported in USFWS (2022a). Range boundary is from the California Wildlife Habitat Relationship System (CDFW 2014).

2.5 Population Genetic Structure

For imperiled species, understanding the genetic structuring of their populations is important for effective management. Head-starting and translocation are two actions used in desert tortoise conservation (see section 9.1 for more details), and the efficacy of both depends on knowledge of genetic boundaries to avoid the potentially negative impacts of artificially mixing individuals from different genetic populations (Sánchez-Ramírez et al. 2018).

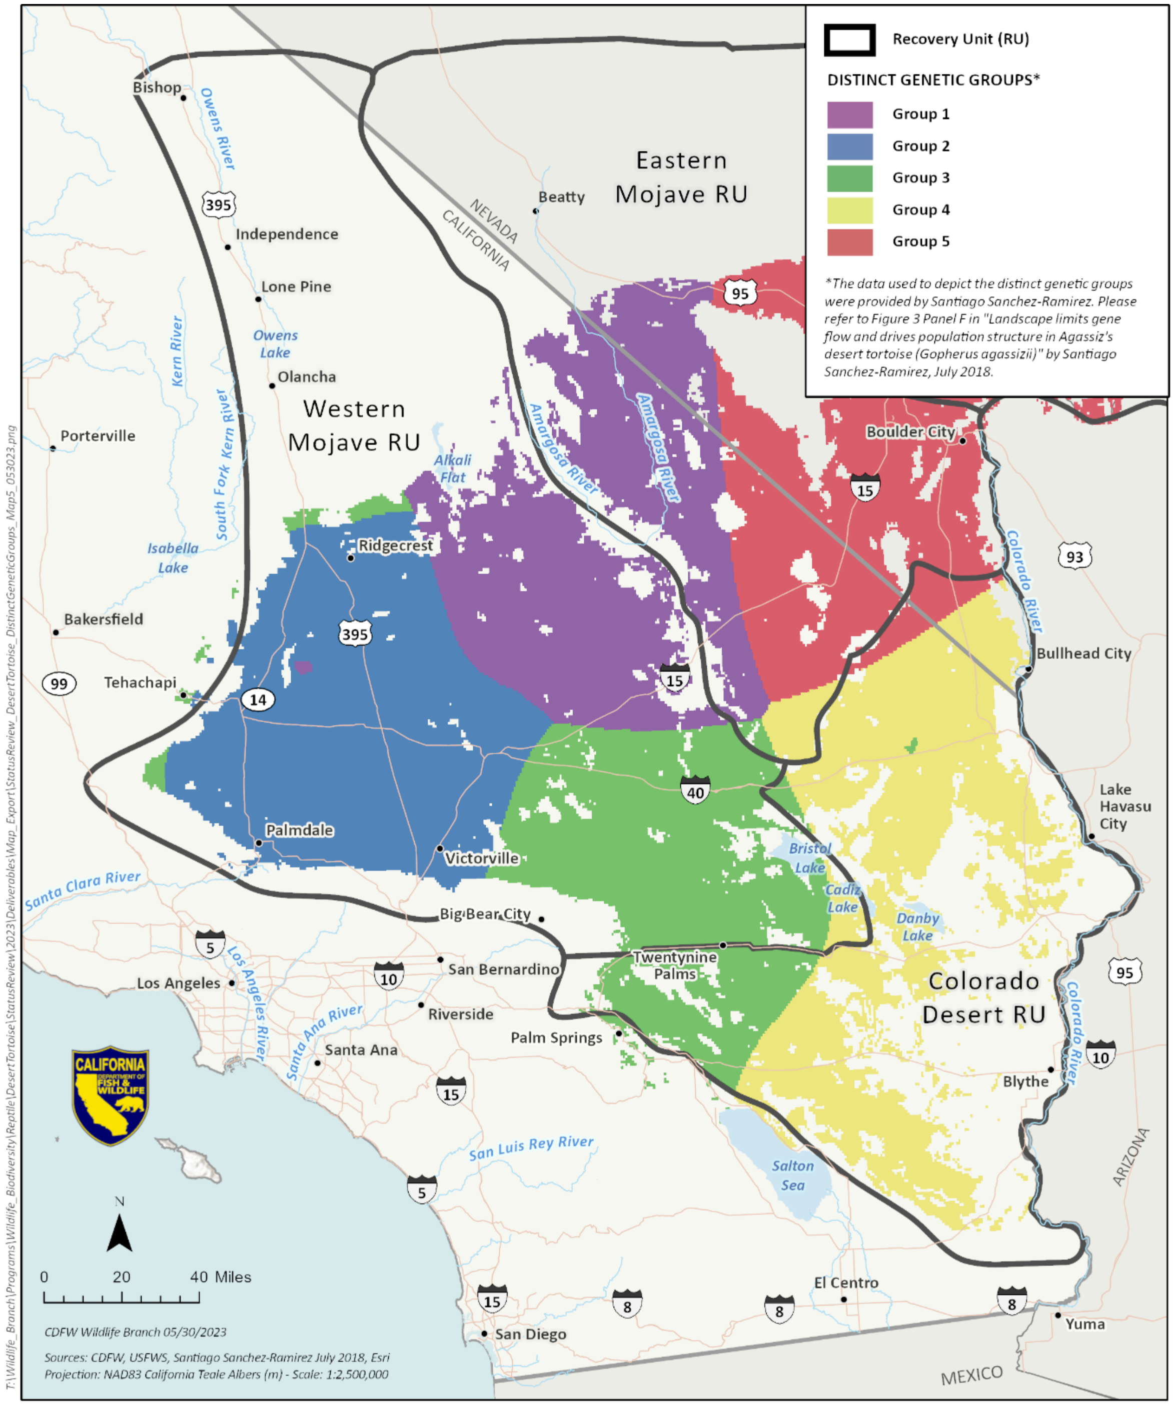
The 1994 U.S. Fish and Wildlife Service (USFWS) Recovery Plan outlined recovery units consisting of "evolutionarily distinct" populations, with three recovery units occurring in California: Western Mojave, Eastern Mojave, and Colorado Desert Recovery Units (see section 3.1 for details). However, a recent study found that the best supported number of genetic clusters in California was five, with the Western Mojave Recovery Unit in the northern and western part of the tortoise range in California containing three genetic groups (Sánchez-Ramírez et al. 2018) (Figure 4). This differs from the earlier work of Hagerty and Tracy (2010) which found the Western Mojave Recovery Unit to be one genetic group. This means that populations within 200–300 km of each other which were previously considered genetically similar and a single genetic unit for management purposes may actually be several genetically identifiable populations. Outbreeding depression has not been well studied in *G. agassizii*; however, the potential negative impacts of outbreeding are expected to occur at long time scales (~600 years; Averill-Murray and Hagerty 2014). This suggests that habitat quality and predator numbers are more important than outbreeding depression when evaluating suitable recipient sites for translocation. Despite this, Sánchez-Ramírez et al. (2018) advise caution when moving tortoises long distances for translocation or population augmentation. For more details about translocations see section 5.2.

3. STATUS AND POPULATION TRENDS IN CALIFORNIA

3.1 Administrative Status

The Mojave Desert Tortoise has been protected as a threatened species under the California Endangered Species Act (CESA) (Title 14, §670.5) since 1989 and under the federal Endangered Species Act (ESA) since 1990. Unauthorized "take" of threatened and endangered species is prohibited. "Take" is defined under CESA as hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill (*Id.*, § 86).

The 1994 USFWS Desert Tortoise Recovery Plan designated six federal recovery units that cover desert tortoise range in California, Arizona, Nevada, and Utah. The recovery units were based on genetics, morphology, behavior, ecology, and habitat use, and each was considered an "evolutionarily distinct" population. These recovery units were revised in the 2011 Recovery Plan with better information and mapping tools. Of the six, all the Western Mojave, the majority of the Colorado Desert, and the western portion of the Eastern Mojave (formerly the Northeastern Mojave) Recovery Units are within California (Figure 4).



Disclaimer: Information presented on this map is for visual reference only. Consult primary data sources to ascertain the usability of this information for any use other than visual reference.

Figure 4. Map of genetic groups of the Mojave Desert Tortoise. Superimposition of the boundaries of the Recovery Units over Figure 3 panel F in Sánchez-Ramírez et al. (2018). The base map is the "spatial interpolation of ancestry coefficients of Agassiz's desert tortoises using Krig modeling…combines areas of maximal ancestry proportion for each of the five genetic groups".

The Western Mojave Recovery Unit is differentiated from the other recovery units by rainfall and vegetation (USFWS 2011). Summers are warm and winters are cold, with most rainfall occurring in fall and winter. Tortoises in the Western Mojave Recovery Unit dig deep burrows (usually located under shrubs on bajadas) for winter hibernation and summer estivation. Above-ground activity occurs primarily in spring when winter annuals provide food (USFWS 2011).

The Colorado Desert Recovery Unit receives about 1/3 of its annual rainfall in summer and supports distinct summer and winter annual plants that tortoises feed on. The climate is somewhat warmer than in other recovery units, with very few freezing days per year. Tortoises are found in the valleys, on bajadas, desert pavements, rocky slopes, and in the broad, well-developed washes (USFWS 2011).

The Eastern Mojave Recovery Unit is separated from the Western Mojave Recovery Unit by a mostly inhospitable barrier created by the Saline Valley, Death Valley, and Silurian Valley. Desert tortoises in the Eastern Mojave Recovery Unit are generally found in creosote bush scrub communities of flats, valley bottoms, alluvial fans, and bajadas. They are often active in spring, late summer, and early fall, as this region receives up to about 40% of its annual rainfall in summer and there are two distinct annual floras on which tortoises can feed (USFWS 2011).

Each recovery unit contains one or more Critical Habitat Units (CHUs). Under section 4 of the ESA, the Department of the Interior is directed to designate the specific areas supporting those physical and biological features that are essential for the conservation of the species. The Department of Interior designated critical habitat areas for the Mojave Desert Tortoise in early 1994 (59 FR 5820) that encompass over 24,281 km^2 in the Mojave and Colorado deserts (USFWS 2011). The critical habitat units are administrative areas managed to give reserve-level protection to desert tortoise populations while maintaining and protecting other sensitive species and ecosystem functions (USFWS 1994). According to USFWS (2019a):

> "The specific physical and biological features of desert tortoise critical habitat are (1) sufficient space to support viable populations within each of the six recovery units and to provide for movement, dispersal, and gene flow; sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species; (2) suitable substrates for burrowing, nesting, and overwintering; (3) burrows, caliche caves, and other shelter sites; (4) sufficient vegetation for shelter from temperature extremes and predators; and (5) habitat protected from disturbance and human-caused mortality."

In California, federal critical habitat designation totals 19,239 km^2. Of this, 13,465 km^2 are Bureau of Land Management (BLM) land, 980 km^2 are military land, 538 km^2 are state land, and 4,255 km^2 are private land (USFWS 1994) (Figure 5).

Figure 5. Landownership, RUs, and CHUs in the Mojave Desert Tortoise range in California.

Tortoise Conservation Areas (TCAs) are areas that mostly align with CHUs that the USFWS has designated for surveys to evaluate tortoise population status and recovery (see Figures 5, 6 and Table 1). They include "designated critical habitat as well as contiguous areas with potential tortoise habitat and compatible management" (USFWS 2019*b*). The TCAs have the same name as the CHU they encompass, with a few exceptions where there are multiple TCAs within a CHU

(USFWS 2015). Additionally, the Joshua Tree TCA is not within a CHU. See Figure 6 for boundaries of CHUs and TCAs, and Table 1 for overall size and amount of habitat within the CHUs and size of TCAs.

Table 1. Area of modeled desert tortoise habitat within California CHUs, and size of associated TCAs (USFWS 2019a). Note that there are two TCAs within the Chuckwalla CHU. Modeled habitat is suitable desert tortoise habitat per Nussear et al. (2009).

Recovery Unit	Critical Habitat Unit	Size (km^2)	Modeled Habitat (km^2)	Tortoise Conservation Area	Size (km^2)
Western Mojave	Fremont-Kramer	2,096	2,028	Fremont-Kramer	2,417
Western Mojave	Ord-Rodman	1,025	745	Ord-Rodman	1,124

3.2 Trends in Density and Abundance

Tortoises are long lived, reach sexual maturity late, and may have decades of reproductive life. These life history characteristics make it difficult to assess trends in tortoise populations. For such species, short- and medium-term studies (1–10 years) may not be long enough to adequately understand population trends (Tracy et al. 2004). Also, studies that cover only very small, localized portions of the tortoise's range have limited value in assessing the overall population status. This makes long-term studies with consistent methodology that cover large portions of the range in California key to understanding the extent to which tortoise populations are declining or recovering over time.

Since the species was listed as threatened under CESA in 1989, the most robust estimates of density over time come from long-term surveys of TCAs within each CHU using line distance sampling. In 2001–2003, two person teams surveyed TCAs using line transect surveys. Transects were searched out to 8–10 m from the centerline. The shape and length of the transect changed year to year (USFWS 2006). Starting in 2004, square transects with 3 km sides were set up to provide good coverage of each TCA, and a random selection of these transects are surveyed each year. Two surveyors walk line transects along the boundary of the square or as close to it as is feasible. The lead surveyor walks in a straight line on a specified compass bearing, trailing 25 m of cord, and the second crew member follows at the end of the cord. They record the distance and bearing from the survey line to all tortoises seen and live tortoises are measured and sexed. In addition, data from tortoises carrying radio transmitters are used to estimate the proportion of tortoises that are above ground and detectable during the transects. Transects are scheduled in mid-March to May to maximize the chance tortoises will be active and above ground. Standard models are used to calculate density for the TCA from the line transect data in each sampling stratum. Funding for these efforts has varied, but in most years from 2001 to 2021 the USFWS has coordinated the distance sampling monitoring program for desert tortoises in the three recovery units that cover tortoise range in California (USFWS 2015, 2019b, 2020a, 2022a, b). The estimated densities in each TCA from 2004 to 2021 are presented in Appendix A.

Creating reliable estimates of density for desert tortoise is challenging not only due to their life history traits but also because "spatial variation in environmental features influences both population densities and the ability of observers to detect individuals" (Zylstra et al. 2023). Until recently, the best estimates of density and trends in density were the yearly estimates generated by USFWS and Allison and McLuckie (2018). However, the most up to date modelling comes from Zylstra et al. (2023) who used the line transect data to generate spatially explicit estimates of density and regional trends for desert tortoises in the three recovery units from 2001 to 2020. Their results differ from the earlier ones because their modelling framework is better able to account for sources of uncertainty in the estimates, and we use their results in the discussion below.

Despite the protections afforded though the federal ESA and CESA, tortoise populations have declined in recent decades. The 1994 USFWS Recovery Plan for desert tortoise identified 3.9 adult tortoises/km^2 as the minimum density necessary for population viability (U. S. Fish and Wildlife Service 1994, USFWS 2011). Only two of the ten TCAs in California had mean densities above that threshold in 2001, both of which were in the Western Mojave RU (Zylstra et al. 2023; Table 2). Despite the low densities in 2001, the estimated densities continued to decline across all California TCAs through 2020. Over this period, densities declined about 1% per year in the Colorado Desert and Eastern Mojave RUs, and about 4% per year in the Western Mojave RU (Zylstra et al. 2023; Figure 7). These rates of decline correspond to decreases in population density of 17% and 54% over 19 years, respectively. By 2020, all TCAs had densities that were below the population viability threshold.

Table 2. Predicted density of Mojave Desert Tortoises (number of adults/km^2) in each of the Tortoise Conservation Areas (TCAs) in the recovery units in California in 2001 and 2020. Total estimated area excludes impervious surfaces (which increased by <25 km^2 between 2001 and 2019 across all TCAs). Modified from Zylstra et al. (2023).

Recovery Unit	**TCA**	**Area (km^2)**	**Mean Density 2001**	**Min Density 2001**	**Max Density 2001**	**Mean Density 2020**	**Min Density 2020**	**Max Density 2020**
Colorado Desert	Chocolate Mountain Aerial Gunnery Range	866	3.74	2.18	5.52	3.1	1.81	4.58
Colorado Desert	Chuckwalla	3768	2.84	0.12	7.39	2.37	0.1	6.15
Colorado Desert	Chemehuevi	4281	2.7	1.01	4.9	2.24	0.84	4.1
Colorado Desert	Fenner	2009	3.56	0.47	4.77	2.95	0.39	3.96
Colorado Desert	Joshua Tree	1714	3.07	0.11	7.07	2.55	0.09	5.82
Colorado Desert	Pinto Mountains	848	3.59	0.61	5.35	2.99	0.52	4.47
Eastern Mojave	Ivanpah Valley	2755	1.75	0.16	2.94	1.59	0.15	2.68
Western Mojave	Fremont-Kramer	2590	7.29	0.51	12.4	3.33	0.23	5.24
Western Mojave	Ord-Rodman	1223	3.8	0.05	8.7	1.74	0.02	3.97
Western Mojave	Superior Cronese	3508	5.45	0.53	9.44	2.5	0.24	3.99

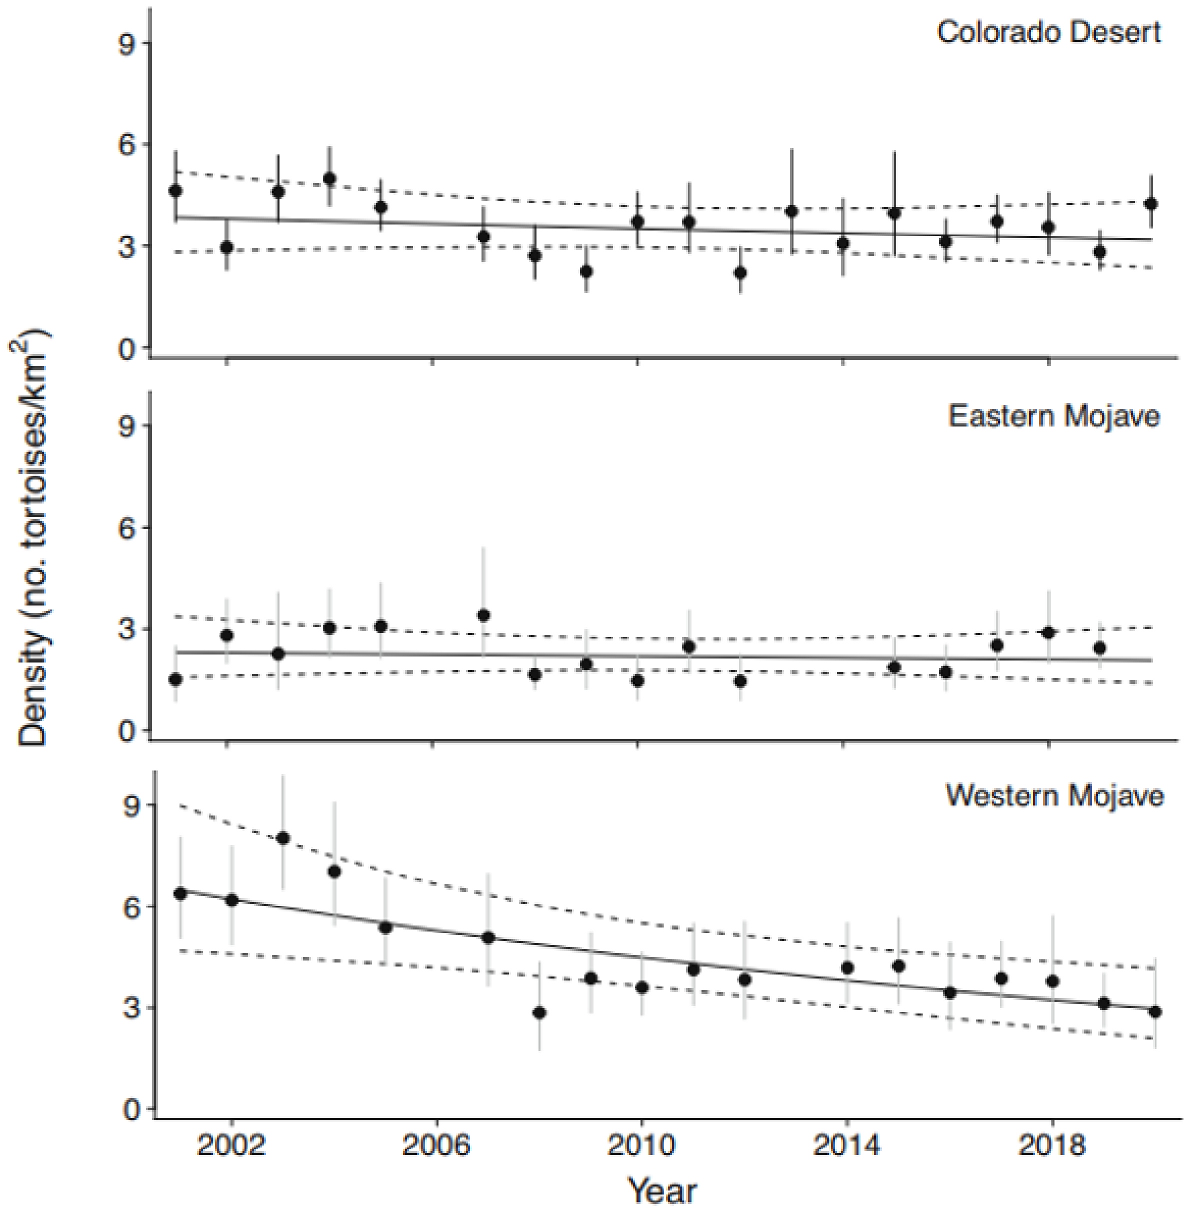

Figure 7. Estimates of density for adult Mojave Desert Tortoises (posterior medians [circles] and 95% credible intervals [CIs]) in each year a recovery unit was surveyed, with fitted log-linear trends (solid line) and 95% CIs for trends (dashed lines) in each recovery unit relevant for California. Modified from Zylstra et al 2023.

In 2001, the Western Mojave RU had the highest densities in California, but it has experienced the steepest decline in abundance since then, losing >50% from 2001 to 2020 (Zylstra et al. 2023; Table 3). The losses in abundance in the Colorado Desert and Eastern Mojave RUs were not as steep (with declines of about 17% and 9%, respectively), but overall, the three recovery units lost an estimated 130,000 tortoises over 19 years (Table 3). The Colorado Desert and

Eastern Mojave RUs each have one TCA outside of California, so the abundance estimates in Table 3 are likely an over-estimate for California.

Table 3. Predicted abundance (with associated standard error in parentheses) of adult Mojave Desert Tortoises in 2001 and 2020, and the difference between the two years, in the three California recovery units. For reference, the estimated areas within each recovery unit in 2001 and 2020 are included. The change in area between years is due to exclusion of areas with >40% impermeable surfaces. Modified from Zylstra et al. 2023.

Recovery Unit	Area (km²) 2001	Abundance (2001)	Area (km²) 2020	Abundance (2020)	Difference in Abundance
Colorado Desert	30,815	75,918 (12,458)	30,723	62,820 (9,862)	-12,782 (17,774)
Eastern Mojave	39,778	53,564 (10,784)	39,567	48,692 (9886)	-5,081 (16,925)
Western Mojave	50,623	206,540 (35,443)	50,444	94,433 (16,737)	-112,020 (42,490)

Predictions are based on a model that allowed for independent log-linear trends in each of the four recovery units. Differences in abundance between 2001 and 2020 were computed for each Markov chain Monte Carlo iteration and then summarized. Thus, calculated differences in the rightmost column do not equal the differences between summarized values in the Abundance columns.

Allison and McLuckie (2018) used different methods to estimate densities and declines in abundance from 2004 to 2014. Their density and abundance estimates were higher than those in Zylstra et al. (2023) but they also estimated a decline in abundance of about 50% in the Western Mojave RU in 2004–2014. Regardless, both techniques indicate broad scale, long-term declines in density and abundance for desert tortoise across their range in California. Currently all TCAs are estimated to be below the density necessary for population viability and have suffered declines for decades. These declines in the TCAs occurred despite state and federal listing and most of the land falling under federal land management agency ownership (Figure 5).

The long-term surveys in the TCAs provide robust data on declines in density since 2001. However, tortoise populations had been in decline for decades previously, and estimates of densities from before the species was listed under CESA in 1989 are important for understanding the scale of longer-term decline. While there were no large scale or frequent systematic population monitoring programs in the 20th century, multiple regional or short-term surveys gave snapshots of density in certain areas pre and post listing. These early monitoring programs sometimes relied on tortoise sign (tracks, scats, burrows, or carcasses) as well as observations of live tortoises, or employed mark-recapture methods to obtain estimates of abundance or density. It should be noted that survey methods that rely on sign to estimate numbers of live tortoises are not reliable. In addition, mark recapture methods contain several assumptions that are violated in surveys of tortoises (Corn 1994), and the lack of spatial information in conventional mark recapture analysis leads to inflated estimates of density (Mitchell et al. 2021*b*). Therefore, estimates of density before 2001 must be approached with caution and direct comparisons between density estimates from mark recapture and line transect density methods are not advised. However, we can use these studies to give a rough picture of the state of tortoise populations in the late 20th century.

Broad estimates of tortoise densities in California before the species was listed under CESA can be found in Berry (1986*a*):

> "Berry and Nicholson (1984a) developed a more detailed map of relative tortoise abundance throughout an area of over 100,000 km^2 using data from 1,808 strip transects. Transects, which were 2.4 km by 9.1 m, provided counts of tortoise signs (live individuals, carcasses, scats, cover sites, tracks, drinking sites, and courtship rings). Counts of signs were calibrated against counts along transects in areas where tortoise densities had been estimated by repeated censuses. The map prepared by this method showed five relative density classes: 0–8, 9–19, 20–39, 40–97, and >97 tortoises/km^2. Four major tortoise population centers or crucial habitats with densities of >77 tortoises/km^2 were identified: (1) Fremont-Stoddard in the western Mojave Desert (4,864 km^2), (2) Ivanpah in the eastern Mojave Desert (918 km^2), (3) Fenner-Chemehuevi in the eastern Mojave and northeastern Colorado deserts (3,881 km^2), and (4) Chuckwalla (1,333 km^2) in the southern Colorado Desert."

In addition, in the 1970s the BLM established 27 2.6 km^2 (1 $mile^2$) survey sites in California (Berry and Turner 1986). Using mark recapture methods, researchers surveyed the plots over 60-day periods in the spring every 2–10 years (Berry and Medica 1995). Berry (1986*a*) reported that of those 27 sites, "eight had estimated densities of $\leq$8 tortoises/km^2, six had 8–39 tortoises/km^2, and 13 sites supported 42–184 tortoises/km^2", though the years those estimates come from are not reported. Several of these sites are located within the current Ivanpah, Chuckwalla, Fenner, and Chemehuevi TCAs. The Desert Tortoise Natural Area overlaps with the northern border of the Fremont-Kramer TCA. Comparing the density estimates in Berry and Medica (1995) to the USFWS estimates in 2001–2021 is not appropriate due to the differences in methodology described above. However, comparing the mark recapture density estimates between 1979 and 1992 can give us a sense of the general scale of decline even if the estimates themselves are biased high (Berry and Medica 1995, Mitchell et al. 2021*b*). Estimates of densities in 1979–1980 vary from 36 adults/km^2 in Chemehuevi to a high of 73 adults/km^2 in Fenner and Chuckwalla (Figure 8). By the early 1990s, densities of adults had not fallen particularly dramatically except in Chuckwalla which had a 57% decline from about 73 adults/km^2 to about 31 adults/km^2, and the Desert Tortoise Natural Area which saw a 93% decline to 3.7 adults/km^2 (Figure 8).

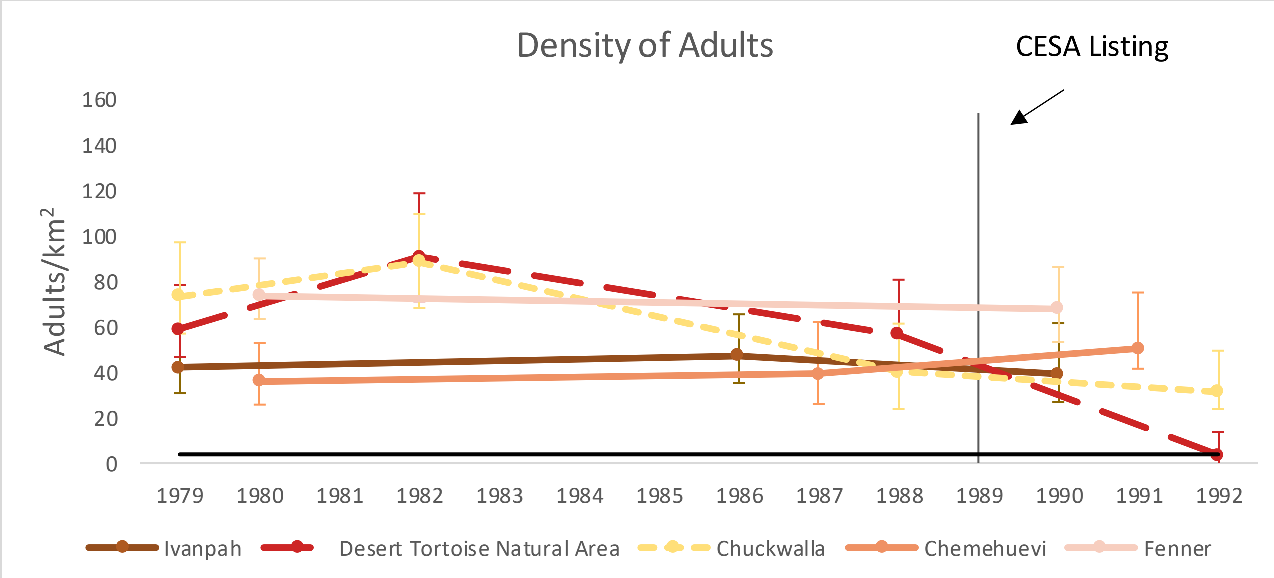

Figure 8. Estimated densities of adults/km^2 in plots surveyed 1979–1992 using mark recapture methods. Each dot represents the midpoint of the density estimate for a given year, bars are 95% confidence intervals. Black horizontal line represents 3.9 adults/km^2, the estimated minimum density needed for population viability. Redrawn from figures in Berry and Medica (1995).

Berry et al. (2020b) continued the work of surveying tortoises at Desert Tortoise Research Natural Area in the western Mojave Desert for decades. Part of the site was fenced to keep out sheep, vehicles, and humans but allow movement of tortoises, and surveys were done both inside and outside the fence. In 1979 when they started the surveys, estimated densities of tortoises were 103/km^2 inside the fence and 79/km^2 outside the fence. In 2002, densities had declined to 10.2/km^2 inside the fence and 4.17/ km^2 outside the fence. By 2012, densities had increased to 15.6/km^2 inside the fence, and to 4.9/km^2 outside the fence. Counts of tortoises (from which densities were estimated) followed an estimated overall linear decline of 9.1% per year over the 30+ years of the study.

Other studies give rough estimates of historical density in other parts of the range. In the Pinto Basin of Joshua Tree National Park in 1991–1996, Freilich et al. (2000) used mark recapture methods to resurvey a 1 mi^2 (2.59 km^2) plot that had been surveyed in the 1970s. Their methods were designed to estimate abundance rather than density; however, their estimate for the early 1990s was 42 adults/km^2. They reported that the density estimates were 29–31 adults and juveniles/km^2 in the 1970s. However, Lovich et al. (2014) reported that surveys in the Pinto Basin in 1987–1988 provided density estimates as high as 77 tortoises/km^2.

Medium-term tracking of densities occurred in four study sites in California at various times between 1977 and 1985 (Berry et al. 1986). At one site in the western Mojave Desert, Fremont Peak, sampling occurred three times (1977, 1980, and 1985) and the population density declined from 27/km^2 in 1980 to 15/km^2 in 1985 (Berry et al. 1986). However, at three other sites there were no significant changes in density during those years. At the Kramer Hills site in the Western Mojave Desert there were an estimated 42 adults/km^2 in 1980 and 44 adults/km^2 in 1982. The Chemehuevi Wash site in the Colorado Desert was surveyed in 1979 and 1982 and saw a nonsignificant increase from 18 adults/km^2 to 22 adults/km^2. The Chuckwalla Bench study site in the Colorado Desert had a non-significant increase in density from 75 adults/km^2 in 1979 to 87 adults/km^2 in 1982 (Berry et al. 1986); see Figure 8.

Although the density estimates from mark recapture surveys in the 1970s and 1980s only cover small areas and are biased high (Mitchell et al. 2021*b*), they provide a general picture of long-term decline and give context for more recent density estimates.

Juveniles

Juvenile tortoises are easier to overlook during surveys than adults, and the U.S. Fish and Wildlife Service does not include densities of juveniles in their yearly reports on density in the TCAs (but see Figure 10). However, Berry and Medica (1995) report on the density of adults and of all tortoises (including juveniles) using mark recapture surveys in BLM plots from 1979 to 1992. From those survey results, we can roughly calculate historical density of juveniles (density of all tortoises minus density of adult tortoises) in those specific plots to determine broad patterns of decline through 1992 (Figure 9).

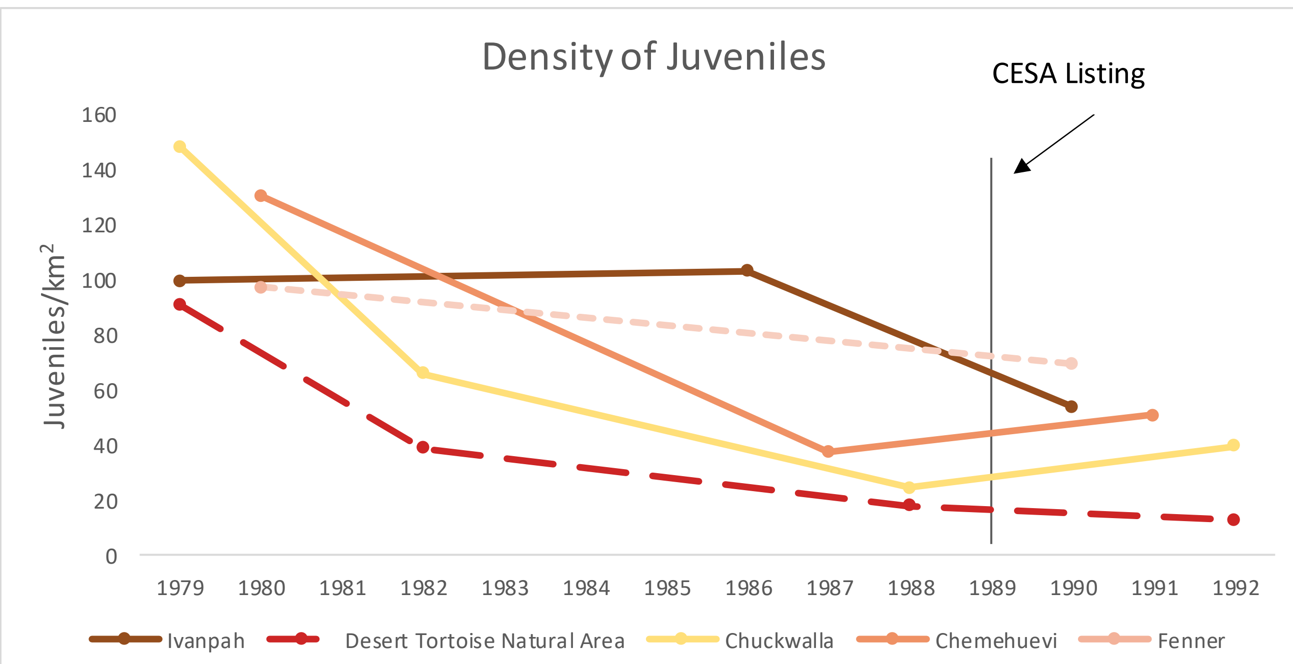

Figure 9. Density of juvenile tortoises in plots in California from 1979 to 1992. Juvenile density was calculated by subtracting density of adults from density of all tortoises presented in Berry and Medica (1995).

Between the late 1970s and early 1990s, the density of juveniles declined roughly 46% in Ivanpah, 86% in the Desert Tortoise Natural Area, 73% in Chuckwalla, 62% in Chemehuevi, and 29% in Fenner (Figure 9). While juvenile tortoises are expected to have low survival rates, this long-term loss of juveniles from the landscape is concerning, and there is evidence that it is continuing into recent years. In 2014 in the Western Mojave RU, the density of adult tortoises was 49% of what it had been in 2004, and the proportion of juveniles in the population declined by 9% (Allison and McLuckie 2018). In the yearly transect surveys done in the TCAs, the median midline carapace length did not change significantly between 2001 and 2015 (Figure 10). However, fewer juveniles small enough to be classified as outliers (the small circles below the lower 'whisker' in the box and whisker plot of Figure 10) were found in 2007–2015 compared to 2001–2005. In 2011, only one juvenile (midline carapace length <180 mm) was found, and in 2012 none were found. In some areas, the youngest tortoises found in recent years were at least 30 years old (Holcomb 2022*a*). Despite a steady median carapace length across 2001–2015, the range of carapace lengths decreased, with most of that change due to fewer smaller individuals found. Even with thousands of adults in a population, if sufficient juvenile tortoises are not surviving to breeding age, the population will decline without interventions like head-starting, although that decline may take decades to manifest (Lovich et al. 2018).

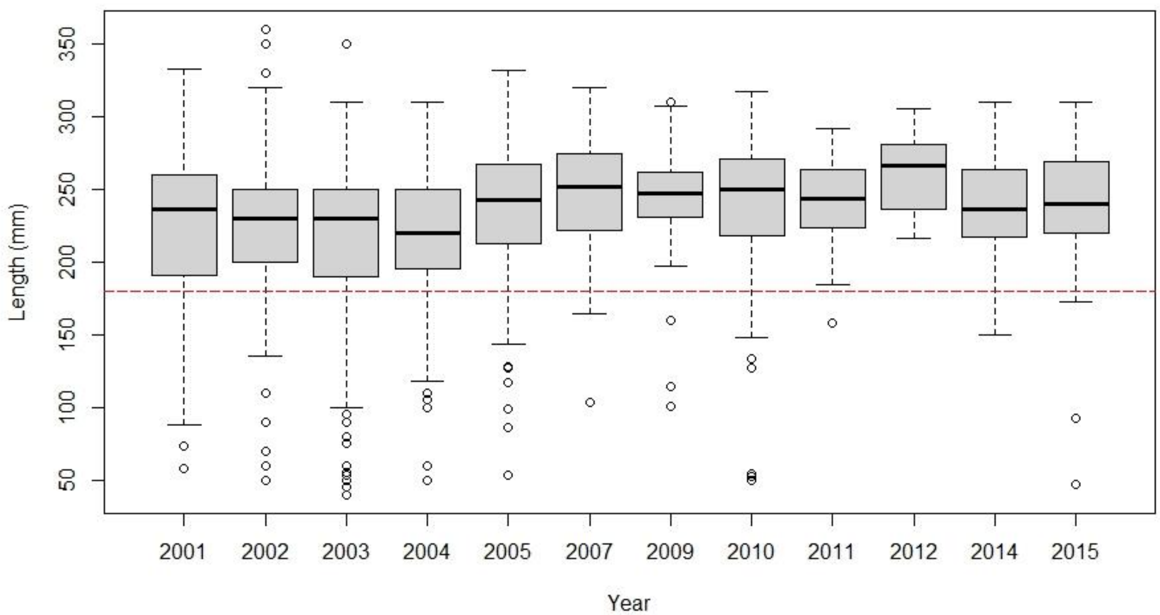

Figure 10. Midline carapace length of tortoises surveyed within the Western Mojave Recovery Unit Tortoise Conservation Areas, showing a reduction in observations of tortoises smaller than 180mm after about 2005. Described in Alison and McLuckie (2018), and figure made with USFWS unpublished data provided by K. Holcomb and used with permission. The horizontal dashed line at 180 mm represents the size over which tortoises are considered to be adults.

3.3 Mortality and Survival Rates

Adult and juvenile survival rates are important demographic factors that can affect whether a population is increasing, stable, or declining. Desert tortoises generally have low survival rates (i.e., high mortality rates) as hatchlings and juveniles, and relatively high adult survival rates (Berry and Murphy 2019). The adult survival rate needed for population stability depends on a number of factors, including population reproduction and/or recruitment rates, but the USFWS 1994 Recovery Plan estimated that an adult survival rate of 98% per year is needed for population growth of 0.5% per year. A more recent estimate that incorporated current adult densities and juvenile survival rates found that an adult survival rate of 93% per year was necessary for desert tortoise population stability (no growth or decline) (Holcomb 2022*a*). Estimates of survival/mortality rates come from a variety of studies within California, most of which were quite limited in geographic scale. When comparing survival rates to mortality/death rates, a broad rule of thumb is that mortality or death rate ≈ 1-(survival rate).

Adult tortoises are much easier to survey than juveniles and consequently most of the information about survival and mortality in the wild relates to adults. In the late 1970s and early 1980s, a study from four sites provided some limited information on annual mortality rates in stable and declining populations (Berry et al. 1986). At Fremont Peak in an area that later became the Fremont-Kramer TCA, densities of adults and subadults declined significantly between 1973 and 1985, and the estimated annual mortality rate of adults and subadults was 4.8% per year. In contrast, three other sites surveyed during that period that did not see significant declines in density had annual mortality rates of 2.2–2.9% (Berry et al. 1986). Berry et al. (2020b) estimated survival rates (1979–2012) of adults and juvenile tortoises inside and outside of the fenced portion of the Desert Tortoise Research Natural Area in the Western Mojave. As mentioned previously, in 1979 the estimated density of all tortoises was 103/km^2 inside the fence and 79/km^2 outside the fence. By 2012 densities had decreased to 15.6/km^2 inside the fence and to 4.9/km^2 outside the fence. During those years the population suffered an estimated 87.6% decline. Median annual survival probability (converted into percentages for ease of comparison) for adults inside and outside of the fenced area ranged from 79%–83% in 1979–1989, 71%–78% in 1989–2002, and 94%–96% in 2002–2012. These estimates are all well below the necessary survival rate identified in the USFWS 1994 Recovery Plan to achieve modest population growth. Juveniles had lower survival - their estimated median annual survival probability was 66%–73% in 1979–1989, 57%–65% in 1989–2002, and 90%-93% in 2002–2012.

In Eastern Joshua Tree National Park, tortoises were surveyed intermittently from 1978 to 2012 (Lovich et al. 2014). The authors tested the impact of rainfall on survival, and the best model of survival was based on the average estimated winter precipitation over the preceding three winters. They estimated a mean annual (apparent) survival rate of 0.87 (87%). Values below the mean occurred in 1991, 1997–2004 and 2008, which were years of lower rainfall (Lovich et al. 2014). Estimated survival was above the mean in 2010–2011. It should be noted that other factors that impact survival, such as predation, roadkill, and disease were not tested independently.

Between 2002 and 2004, Berry and Keith (2008) evaluated the status of desert tortoise populations in Red Rock Canyon State Park in Kern County. In the 1970s the population density had been estimated to be <8 tortoises/km^2. They estimated that 67% of the adult and subadult tortoise alive in 2000 were dead in 2004, and densities were between 2.7 and 3.6 tortoises/km^2.

In 2007–2008, Berry et al. (2020c) evaluated the status of a population of tortoises in the El Paso Mountains close to the Fremont-Kramer Critical Habitat Unit. Estimated density of adults was 4.8/km^2 and the annual death rate of adults in 2003–2008 was 6.9% (Berry et al. 2020*c*). The top causes of known death were mammalian and avian predators, gunshots, and vehicles. The authors concluded that "the high death rate of adults, low population density, high human visitor use, and ongoing decline in the adjacent critical habitat unit indicate that a viable population is unlikely to persist in the study area" (Berry et al. 2020*c*).

Esque et al. (2010) tracked several hundred adult tortoises before and after translocations from Fort Irwin National Training Center to neighboring public land in the Superior-Cronese Critical Habitat Unit. They monitored translocated tortoises, tortoises resident at the release sites, and control tortoises in nearby areas that were not affected by the translocations. In the first year (2008), 19% of control tortoises, 20% of resident tortoises, and 25% of translocated tortoises died. Most of the mortalities were thought to be due to coyote (*Canis latrans*) predation. As a comparison, at a different reference site in the Superior-Cronese Critical Habitat Unit, 8.3% of tracked tortoises died in 2008. At reference sites in other critical habitat units in California, percent mortality in 2008 ranged from 0% in Ivanpah and Ord-Rodman to 28–30% in Chemehuevi and Chuckwalla. Esque et al. (2010) also showed that mortality can vary greatly year to year in the same site. For example, at Soda Mountain outside of the Superior-Cronese Critical Habitat Unit, in 2006 there was no mortality, in 2007 mortality was 17%, and in 2010 mortality was 43%.

In 2009, Berry et al. (2020a) surveyed about 93 km^2 of BLM land within the eastern Chemehuevi Valley, adjacent to the Chemehuevi Critical Habitat Unit. Based on the number of live and dead tortoises found and the estimated age of the carcasses, they concluded that the density of adults was 2.0/km^2 (+/- 1.0), and that the annual death rate in the four years prior to the survey was 13.1%/year. These data led them to conclude that the population was probably nonviable (Berry et al. 2020*a*).

Collectively, these data suggest that adult survival rates in most recently surveyed areas are too low to support stable populations and have been below the thresholds established by the USFWS 1994 Recovery Plan and by Holcomb (2022a) for some time (Table 4). Although survival rates have not been estimated systematically across the tortoise's range in California, rates appear to be particularly low outside of CHUs.

Table 4. Survival and mortality rates of adult and subadult tortoises in various studies.

Life stage	Survival vs Mortality	Rate	Location	Time scale	Reference
Adults	Median annual survival probability	79%-83%	Desert Tortoise Research Natural Area	1979-1989	Berry et al. 2020b
Adults	Median annual survival probability	71%-78%	Desert Tortoise Research Natural Area	1989-2002	Berry et al. 2020b
Adults	Median annual survival probability	94%-96%	Desert Tortoise Research Natural Area	2002-2012	Berry et al. 2020b
All	Mean annual survival	87%	Eastern Joshua Tree National Park	1978-2012	Lovich et al. 2014
Adults & subadults	Annual mortality	4.5%	Fremont -Kramer TCA	1977-1985	Berry et al. 1986

Juvenile Survival

In long-lived species like the tortoise, if adult survivorship drops, reproductive rates or juvenile survival would have to increase dramatically to keep populations stable. Analysis by the USFWS (1994) estimated that "a 10% increase in adult mortality can require a 300% increase in juvenile survivorship" to maintain a stable population. Many of the threats to adult survival also affect juveniles, making it unlikely that juvenile survivorship can naturally increase to the levels needed to compensate for the decreasing adult survival documented above.

Several factors limit the number of hatchlings that are produced in the wild each year. Temperature, precipitation, and body size influence the number eggs females lay (Henen 2002, Mitchell et al. 2021*a*), with the maximum being 12-18 eggs a year (J. Lovich Pers comm 2023). Incubation success depends on temperature, and nest predation is common (see section 2.2 for more detail) (Berry and Murphy 2019). In the Ivanpah Valley between 2011 and 2014, Tuberville et al. (2019) compared survival and growth of free ranging hatchlings to those reared in pens under different rainfall scenarios. Both groups were hatched from eggs laid by wild females and brought into captivity for the study. Free ranging hatchlings were released into the wild between 0 and 18 months old. Estimated annual survival rates for the free ranging hatchlings was 48%–49% compared to 94% of those reared in pens.

We have little information on historical juvenile survival rates, but the impact of recent low survival rates can be seen in demographic information. As mentioned previously, in the yearly surveys performed in the Western Mojave TCAs, many fewer tortoises with midline carapace length <180 mm were found in 2007–2015 compared to 2001–2005 (Figure 10). One factor influencing juvenile mortality is raven (*Corvus corax*) predation. Holcomb et al. (2021) estimated that annual survival rates for 1–10-year-old tortoises in 5 CHUs averaged 63% when within 500 m of a raven's nest, and ~76% when the median distance to a nest was 1.72 km. See section 4.4 for more detail on predation.

One strategy to improve juvenile survival is to raise tortoises in captivity and then release them once they reach a certain size (referred to as head-starting; for more details see section 5.2). A study at the Fort Irwin National Training Center on head-started juvenile tortoises (Nagy et al. 2015*b*) found that in the two years after release, survivorship was 76–79%, but in the third-year survivorship dropped to 53%, resulting in an overall three year survival rate of 32%. Survival was generally higher amongst tortoises with a carapace length of at least 100 mm (9 years old). Another study on head-starting found no significant difference in the survival rate of hatchlings released vs. those reared indoors for 7 months vs. those reared in outdoor pens for 7 months (Daly et al. 2019). Although the head-started tortoises grew quickly, the combined annual survival of the three groups was 44%, with the odds of survival increasing 51% for every 100 m away from a raven nest. They predicted that survival would be near 100% if the nearest nest was more than 1.6 km away (Daly et al. 2019).

Even with head-starting, juvenile survival rates can be lower than the 59% average annual juvenile survival rate estimated by Holcomb (2022a) to be necessary for population stability if adult annual survival rates are 93% (Table 5; see Table 4 for adult annual survival rates). The available information suggests that low juvenile survival is a likely contributor to widespread declines in density.

Table 5. Survival rates of juvenile tortoises in various studies.

Life stage	Survival rate estimated	Rate	Location	Time scale	Reference
Juveniles	Median annual survival probability	66%-73%	Desert Tortoise Research Natural Area	1979-1989	Berry et al. 2020b
Juveniles	Median annual survival probability	57%-65%	Desert Tortoise Research Natural Area	1989-2002	Berry et al. 2020b
Juveniles	Median annual survival probability	90%-93%	Desert Tortoise Research Natural Area	2002-2012	Berry et al. 2020b
Head started juveniles	Survivorship after 2 years	76-79%	Fort Irwin	2005-2007	Nagy et al. 2015
Head started juveniles	Survivorship after 3 years	53%	Fort Irwin	2005-2008	Nagy et al. 2015
Wild Hatchlings	Survival rate	48%-49%	Ivanpah Valley	2011-2014	Tuberville et al 2019
Head started juveniles	Annual survival after release	44%	Mojave National Preserve	2015	Daly et al. 2019
Juveniles	Annual survival close to ravens' nest	63%	Mojave Desert	2020	Holcomb et al. 2021
Juveniles	Annual survival far from a raven nest	76%	Mojave Desert	2020	Holcomb et al. 2021

For species like tortoise with slow growth, delayed maturation, and low reproduction rates Shine 2005), factors that lower adult survival rates can have long-term negative impacts on abundance/density. Snapping turtles have similar life history traits as desert tortoises, and in a population in Ontario Canada, river otters killed about 50% of the adults over three years in the late 1980s (Keevil et al. 2018). Female annual survival rates fell from 94% to 76–86% during those years, and the population was reduced by about 40% (Keevil et al. 2018). Twenty-three years later, survival rates had returned to early 1980s level, but abundance did not rebound. This suggests that even if threats are removed, and survival rates increase, for a long-lived species like the desert tortoise, populations may not recover for several decades. The problem is magnified if juvenile survival is very low as occurs in multiple survey areas in California. Having breeding adults on the landscape is vital for population viability, and low rates of juvenile recruitment create an unstable demographic structure that will make it less likely for populations to recover and makes them vulnerable to any additional sources of mortality (Holcomb 2022b).

4. FACTORS AFFECTING THE ABILITY TO SURVIVE AND REPRODUCE

This section considers the factors affecting the ability of the population to survive and reproduce, and the degree and immediacy of threat (Fish & G. Code, § 2072.3; see also Cal. Code Regs., tit. 14, § 670.1, subd. (d)(1)). In addition, this section addresses the six listing factors identified in title 14 of the California Code of Regulations section 670.1, subdivision (d)(1): present or threatened modification or destruction of habitat, overexploitation, predation, competition, disease, or other natural occurrences or human-related activities. This section reviews the best available scientific information regarding each of these factors and assesses the degree of threat of each.

Desert tortoise life history traits, including delayed reproductive maturity, relatively low annual fecundity, and low survival rates of juvenile tortoises cause populations to be vulnerable to a multitude of threats (Berry et al. 2020*b*). Their vulnerability is increased because many of the threats are interactive and amplify each other. This document focuses on individual threats, but also recognizes that many of them are fundamentally intertwined. Many of the threats described in the initial desert tortoise status review and the USFWS Recovery Plans (U. S. Fish and Wildlife Service 1994, USFWS 2011) continue to affect the species.

4.1 Habitat Modification and Destruction

The Mojave Desert Tortoise range in California includes a variety of public and private land jurisdictions, the top three being BLM (39,251 km^2), National Park Service (NPS) (17,035 km^2), and Department of Defense (DoD) (13,018 km^2). Habitat management and allowable modification varies by jurisdiction. BLM land can be officially designated as Wilderness where mechanical transport is not allowed and there are many restrictions on use. In other areas BLM land is managed for a wide range of uses and stakeholders, and permitted activities that may impact tortoises include off-highway driving, mining, and renewable energy projects. On NPS land off-highway driving, mining, and renewable energy projects are not allowed. DoD land is not generally open to the public and uses range from extremely low impact to high impact live artillery use. See Figure 5 for more details on land ownership.

In the large majority of tortoise habitat, at least some alteration is allowed which can impact tortoises. Across all states, an estimated 66% of Mojave Desert Tortoise habitat has some development within 1 km, where development is defined as “urban development, cultivated agriculture, energy development (e.g., oil and gas well pads, solar energy facilities), surface mines and quarries, pipelines and transmission lines, and transportation (e.g., roads and railroads” (Carter et al. 2020). The direct impacts of development include removal of soil and vegetation, destruction of burrows, and creation of roads and other infrastructure that can kill tortoises or hinder their movements (Boarman and Sazaki 1996, 2006). An important indirect impact of development is subsidization of predators (see section 4.4) (Boarman et al. 2006).

Tortoises are less likely to occur in areas that have even a low level of development. Carter et al. (2020) found that “encounter rates of both live and dead Mojave Desert Tortoises combined decreased significantly with development levels” and that when “10% of the area within 1 km of that location has been altered by development” (10% development), it was rare to find live or dead tortoises at a location. The authors estimated that encounter rates for both live and dead Mojave Desert Tortoises decreased an average of 4% for every 1% increase in the development index (Carter et al. 2020).

While there is some development within 1 km of the majority of desert tortoise habitat range-wide, the three Recovery Units partially or wholly within California generally include little development. In the Western Mojave Recovery Unit (which is wholly within California) 47% of tortoise habitat has almost no development (<1% within 1 km), and 5% of habitat has >10% development (USFWS 2022*a*). For the Eastern Mojave Recovery Unit, the proportion of habitat with <1% development within 1 km is 58%, and 5% is at 10% development. In the Colorado Desert Recovery Unit, it is 65% and 4% respectively (USFWS 2022*a*). However, those two units extend outside of California (see Figure 6), and it is unclear whether those percentages are representative of the range in California. In their 2022 5-year review, the USFWS concluded that "space does not appear to be a limiting factor to tortoise recovery". However, these categories of development used above do not include unpaved roads and tracks for off-highway vehicles (OHVs) which are allowed on BLM land (see section 4.2). And given continued desert development, the conclusions may be less applicable in the future.

The human population in the inland deserts of California has increased significantly in the past 30 years. Between 1990 and 2022, the number of housing units increased 58% in Imperial County, 79% in Riverside County, and 37% in San Bernardino County (numbers calculated from State of California Department of Finance 2023). Not all of this growth happened in the desert portions of the counties, and the more urbanized areas tend to be in western parts of the counties that contain less desert habitat. Urban or suburban development typically expands along the edges of previously impacted habitats which generally contain few tortoises. Therefore, we focus discussion on other types of projects that are more likely to have large-scale impacts on areas with desert tortoise populations.

Department of Defense

The Department of Defense is a major landholder in the desert tortoise range. Military bases in California deserts include Fort Irwin, Naval Air Weapons Station China Lake, Edwards Air Force Base, George Air Force Base, Chocolate Mountain Aerial Gunnery Range, Marine Corps Air Ground Combat Center Twentynine Palms (MCAGCC), and Marine Corps Logistics Base Barstow. In total, these bases encompass over 3 million acres (14.78% of the total tortoise range in California, see Figure 5). A wide variety of land uses occur on DoD property, and some of those uses are compatible with desert tortoises while others are not. For example, MCAGCC has Restricted Use Areas, at least one of which (Sandhills TA) is 11,801 acres and "protects the installations water supply, archeological resources, and the desert tortoise" (Marine Air Ground Task Force Training Command and Center 2018). In contrast, active training areas are generally high impact and tortoises in those areas are translocated to other sites. For example, according to the USFWS (2022*a*), the "Department of the Army (Army) expanded training onto 18,197 acres (73.6 km^2) of designated critical habitat on the southern area of Fort Irwin that had previously been off-limits to training, thus requiring the translocation of approximately 650 adult desert tortoises. In addition, the Army plans to expand activities onto and displace tortoises from up to 62,045 acres (~250 km^2) of its western training area in the near future, which is designated critical habitat and currently off limits to training. The Department of the Navy (Navy) expanded training for the Marine Corps Air Ground Combat Center (MCAGCC) at Twentynine Palms into approximately 167,982 acres (680 km^2) of public and private land, which required translocating approximately 1,000 adult tortoises." Around 700 of the tortoises from Twentynine Palms were translocated into the Ord-Rodman TCA (see section 5.2 on Translocation).

Along with translocation of tortoises, other strategies used by the DoD to offset the impact of converting large areas of habitat into training grounds include acquiring land within a CHU (making it federal), buying out grazing allotments, increased law enforcement in tortoise habitat, predator monitoring and targeted control within translocation sites, rehabilitation of closed routes, installation of off-highway vehicle barriers and desert tortoise exclusion fencing, and constructing perimeter fences to prevent public trespass into tortoise habitat (USFWS 2022*a*). For more discussion of efforts to conserve tortoises, see section 5.2 Current Management Actions.

Given the relatively large amount of DoD land with land use practices that require translocation of tortoises, it is of interest whether and how quickly habitats might become suitable again for tortoises if they are no longer used for training. Recovery from disturbance can take a long time in desert ecosystems (Lovich and Bainbridge 1999). This has been documented in soils and vegetation of the Desert Training Center which spans parts of southern California, southern Nevada, and western Arizona. This area was used for military training exercises in the 1940s and 1960s, and 40–60 years later the soil in tank tracks remained compacted and rain infiltration rates were low (Prose and Wilshire 2000). These soil differences led to increased plant density in the tracks, but those plants had restricted growth. In addition, grass species with shallow fibrous root systems increased in density in the tracks while species with long tap roots had reduced density and cover (Prose and Wilshire 2000). USFWS (1994) estimated that areas where camps, roads, and parking lots were built would take "decades or centuries to recover."

Other documented direct negative impacts to tortoises on military property include "vandalism, predation, mycoplasmosis, and shell diseases" with "significantly more tortoises with shell disease…found on plots with current and recent military use than on plots with no history of military use" (Berry et al. 2006). For more detail on shell disease see section 4.7.

In the past 10 years, approximately 150,000 acres of the ~3,000,000 acres (~607 km^2 of ~12,140 km^2) of viable desert tortoise habitat under DoD jurisdiction in California have been eliminated (USFWS 2022*a*).

Renewable Energy Projects

Renewable energy projects, including solar farms and wind energy facilities, are a major source of development in desert tortoise habitat. These facilities are regarded as key to reducing CO_2 emissions, and their development has been prioritized on public land (e.g., American Reinvestment and Recovery Act 2008; National Energy Policy Act 2005, Infrastructure Investment and Jobs Act 2021, Inflation Reduction Act 2022). Unlike urban or suburban development, energy projects tend to be sited in mostly undeveloped public land, thus leading to the potential degradation and fragmentation of relatively high-quality tortoise habitat (Lovich and Ennen 2011).

Development of a wind power project results in a variety of disturbances that are classified as temporary or permanent. Permanent impacts include land occupied by wind turbine pads, access roads, substations, and transmission lines. Temporary direct impacts include temporary roads, staging areas, and substation/transmission construction (Denholm et al. 2009). However, in desert ecosystems, 'temporary' disturbances may have decades-long impacts if sites are not actively rehabilitated. Denholm et al. (2009) collated data on the size of several wind projects in California including total size (land associated with the complete wind plant project) and area of direct (permanent and temporary) impact. Of the four projects with complete data, direct impacts accounted for 1.5–7% of the total area of the project.

Data specifically evaluating the impacts of wind energy facilities on desert tortoises remains limited, however two studies suggest that tortoise survival rates on project sites are relatively high. A study near Palm Springs in Riverside County estimated tortoise survival rate within a wind energy facility (WEF) and a nearby wilderness area (NWA) using data from 1997–2000 and 2009–2014 (Agha et al. 2015). They found "long-term tortoise survivorship within the WEF (96.7%) was significantly higher than in the nearby NWA (92.1%)" (Agha et al. 2015). This counter intuitive result may have been due to tortoises at the WEF benefiting from "edge enhancement of vegetation (food resources), turbine pads (artificial rain catchments), reduced subsidized predators and low traffic." (Agha et al. 2015). Lovich et al. (2011) tracked tortoises at a wind energy facility near Palm Springs for six field seasons (1997–2000 and 2009–2010). The facility contained turbines, electrical transformers, and an extensive network of roads. Their estimated annual survivorship rate of 91.6% (confidence interval 90.5–93.5%) was based only on adult females, which is a much higher survival rate than has been reported in many areas across the range in California (see section 3.3). The authors suggested a few characteristics of the site that might have led to high survival rates including very restricted public access and fewer ravens. However, they cautioned that without before-and-after studies of the impact of wind energy facilities, of which there are very few, it is hard to draw conclusions about the long-term impacts of wind energy facilities on desert tortoise. A study in southern California compared windfarms with nearby areas and found that species richness, evenness, and diversity was lower on the farm sites for reptiles, birds, mammals, arachnids, and plants (Keehn and Feldman 2018). Renewable energy facilities are not sited within tortoise CHUs, however they can be close enough that the impacts listed above spill over into critical habitat (K. Berry USGS, pers. comm 2022).

Solar power plants have a different design and land use than windfarms. However, similar types of impact classifications occur. Direct impacts occur where land is cleared and occupied by solar arrays, access roads, substations, service buildings, and other infrastructure (Ong et al. 2013). Three types of solar power plants were evaluated in one study, and the percentage of total land that was directly impacted was between 38% and 100% of the project site (N=12 projects) (Ong et al. 2013). The impact of infrastructure to wildlife extends beyond the habitat that is directly modified, including fragmentation and barriers to gene flow, effects due to noise, vibration, and shadow flicker, electromagnetic field generation, macro- and micro-climate change, predator attraction, dust and dust suppressants, and increased fire risk (Lovich and Ennen 2011, 2013).

Renewable energy projects that could potentially cause 'take' of desert tortoises must apply for incidental take permits (ITPs) from the Department or from the USFWS depending on jurisdiction (see section 5.1 for more detail). Between 2010 and 2021, the Department issued

ITPs for desert tortoise for 49 renewable energy projects, the majority of which are solar farms. In 2022, the Department completed ITP permitting for six renewable energy projects within San Bernardino and Riverside counties that would have a total footprint of about 10,600 acres (43 km^2). As of October 2022, the Department was in the process of reviewing or issuing ITPs for 14 more renewable energy projects in Riverside and San Bernardino counties that could potentially have footprints of up to 20,750 acres (84 km^2). For solar farms in particular, CDFW assumes these sites will lose all of their biological resources. Not all of these projects are necessarily sited within the recovery units or will end up receiving permits from the Department. However, it does show that there is increasing demand to use land within the Mojave Desert for renewable energy projects, specifically high impact solar farms (for more information about ITPs, see Section 5.2).

Cannabis Operations

Illegal cannabis farms are an emerging threat to tortoises and their habitat in California's deserts. Habitat is destroyed to put up greenhouses, and there are potential associated spillover effects like chemical leakage into stream beds, trash dumps, and other land disturbances beyond the footprint of the greenhouses. In addition, water and trash may attract and increase densities of predators like coyotes and ravens, and guard dogs (*Canis familiaris*) are thought to kill tortoises (Holcomb 2022*a*, USFWS 2022*a*). In the Department's Region 6, which includes the majority of desert tortoise range, as of 2022 there had been 3,065 acres (~12 km^2) of illegal cannabis cultivation visited by law enforcement. However, the Department acknowledges that there are vastly more illegal sites within tortoise range for which a law enforcement response has not been possible, therefore these numbers likely underestimate the true impacts. The presence of illegal cannabis farms can have additional indirect impacts on tortoise conservation. For example, according to USFWS (2022a), "illegal cannabis farms have already led to the cessation of raven monitoring and management efforts in the Fremont-Kramer Critical Habitat Unit in 2021, with the likelihood that tortoise monitoring in the same unit scheduled for 2022 will be cancelled due to safety concerns for field workers."

Legal cannabis cultivation also occurs within the desert tortoise range. Currently in Region 6 there are 2,394 acres (~9.5 km^2) of legal cannabis cultivation that have Streambed Alteration Agreements. The Department evaluates each development project individually for the purposes of the California Environmental Quality Act, and there has not been a robust analysis of the cumulative impacts to the species resulting from cannabis development in the area. Due to the newness of the threat, the overall impact on tortoises from illegal and legal cultivation has not been quantified. However, it is a matter of increasing concern, and the current tools of permitting and law enforcement resources may not be sufficient to lessen the negative impacts on tortoises.

Summary

While the long-term impact of habitat modification and destruction resulting from the land uses described above, along with any associated mitigation measures, is not fully known, the USFWS (2019*a*) states the impacts of large-scale land use conversions are "unlikely to be positive, despite the numerous conservation measures that have been (or will be) implemented as part of the actions." Although there are multiple science-based measures enacted to manage and mitigate threats, USFWS (2019*a*) warns that they "have been unable, to date, to determine whether the expected benefits of the measures have yet been realized, at least in part because of the low reproductive capacity of the desert tortoise. Therefore, the conversion of habitat into areas that are unsuitable for this species continues the trend of constricting the desert tortoise into a smaller portion of its range".

Across the entire species range, it has been estimated that 7.4% of modelled tortoise habitat is now unsuitable for tortoise survival due to development and recent fire (Holcomb 2022*a*). Additionally, habitat is degraded in many additional areas by factors such as off-highway vehicle use, wildfire, invasive plant species, and increased temperature due to climate change. Therefore, focusing solely on the proportion of direct habitat loss in the desert tortoise range may be misleading and create an overly optimistic picture. With more than 90% of historical habitat still accessible, tortoise populations have declined severely in the past two decades.

4.2 Vehicle Strikes, Roads, and Fencing

Development of all types creates roads and other transport corridors that impact tortoises directly through vehicle strikes and as barriers to movement. Indirect impacts of transport corridors include habitat degradation including the spread of invasive species (Boarman et al. 1997, Brooks and Lair 2005).

Tortoises are often attracted to roads within their home ranges because the rain runoff collects and appropriate forage plants often grow along their edges (Boarman et al. 1997). However, impacts from direct mortality and increased access for predators near roads can result in the creation of reduced occupancy zones of variable width along roads (Boarman et al.1997). Two-lane paved roads in Mojave National Preserve had reduced occupancy up to 400 m away from the road (Hughson and Darby 2013). Boarman and Sazaki (1996) studied Highway 58 in California and found reduced occupancy up to 800 m away. If the roads occur at a sufficient density, these zones could impact enough habitat to affect tortoise density across large scales. Although these results are only correlative, the TCAs that have road densities above 0.75 km/km^2 all had declines in tortoise densities between 2004 and 2014, while TCAs with less dense roads had both increases and declines in tortoise density (USFWS 2022*a*).

Desert tortoises are particularly susceptible to being killed on roads due to their slow rate of travel. Human behavior also plays a role. Boarman et al. (1997) anecdotally reported drivers intentionally swerving to hit turtles and tortoises. Even if most drivers are not intentionally hitting tortoises, speeding on all types of roads can lead to deadly strikes on tortoises (A. Ellsworth pers. comm. Nov 2022). Boarman and Sazaki (1996) estimated a kill rate of one tortoise per 2.4 km of road per year on Highway 58 in the western Mojave Desert, but warned their estimate was likely low because carcasses disappear quickly in the desert (likely due to scavenging). Juvenile dispersing tortoises are more likely to be killed on roads compared to adults (Boarman and Sazaki 1996). Anecdotal evidence from the Mojave Desert Preserve indicates an average of 5.3 tortoises per year are found dead on the 216 km of paved road in the Preserve. Using 2008–2010 data from the Preserve, Hughson and Darby (2013) estimated that the loss of ~60 tortoises per year (on top of the low rates of natural adult mortality for such a long-lived species) would be unsustainable. They concluded that road mortalities could account for ~9% of this excess mortality per year.

Keeping tortoises off roads is a conservation priority (USFWS 2022*a*). Well-constructed fencing designed to stop tortoises from accessing roads can lead to 93% fewer tortoise carcasses along highways as well as reducing road kills of other small vertebrates (Boarman and Sazaki 1996). Properly designed culverts under roads facilitate tortoise movements and help prevent fences from fragmenting tortoise populations (Boarman and Sazaki 1996). However, proper design is key, as culverts can become death traps for tortoises if not properly designed and implemented (Lovich et al. 2011).

While fences are an important conservation measure, the pace of construction has slowed in recent years. According to the USFWS (2022*a*):

> "Through 2011 approximately 1,660 km of highway roadside (including both sides of roads for those fenced on each side) had tortoise exclusion fencing installed to prevent road mortalities. Unfortunately, only approximately 43 km of roadside have been fenced in the decade since 2011. Almost 500 km of roadside have been identified as priorities for fencing based on our current understanding of road-effect zone area, relative habitat potential, and locations of extant populations (Holcomb 2019)."

Considerations that can slow or prevent fence building include cost, maintenance, visual disruption of the landscape, and loss of habitat during construction. At the October 2022 Desert Tortoise Management Oversight Group Meeting, the BLM reported that 3.5 miles of I-40 in the Ord-Rodman CHU will be fenced and 5 miles of fence will be built in Mojave National Preserve. Other strategies to reduce tortoise mortalities on roads such as lowering speed limits, installing warning signs, and driver education have not been shown to be particularly effective (Hughson and Darby 2013).

Off-highway vehicles

Off-roading is a popular pastime in California's deserts. According to the BLM, in 2008 there were four times the number of off-highway vehicles in western states than in 1998 (Bisson 2008). In Desert Wildlife Management Areas and CHUs, OHVs are legally required to stay on established roads and trails, while on the remainder of BLM land they can travel cross-country, although local BLM offices can enact further restrictions. OHVs and their associated unpaved trails lead to habitat degradation, but the impacts are thought to be generally less severe than paved roads.

OHV trails are typically <4 m wide with a dirt surface, and are unimproved (i.e., they have never been bladed or filled) (Brooks and Lair 2005). When the trails are created, soils and vegetation are altered, and some types of wildlife may potentially be killed. Tortoises can be struck by OHVs on and off these trails. OHVs can crush burrows, depriving tortoises of refuge from extreme temperatures and drought. In areas of very frequent OHV use, multiple routes may merge into broad areas devoid of perennial vegetation 10–100 m or more across. These extremely high impact areas are rare, however there are large networks of OHV trails across the Mojave Desert which collectively can significantly change local habitat and soils (Brooks and Lair 2005). OHV trails change water runoff patterns (especially on slopes) and can lead to greater erosion (Brooks and Lair 2005). In addition, roads of all kinds can serve as pathways for invasive species. Inholdings of private parcels within BLM land are often set aside for conservation, and OHV trails formally stop and restart at the boundaries. However, drivers often trespass across those private parcels, creating negative impacts for the tortoises even in areas that are designated as protected (A. Ellsworth, CDFW pers. comm. Oct 2022). The ecosystem or landscape-wide impact of OHV use can be hard to tease out in areas like the Mojave Desert that have multiple land uses, and Brooks et al. (2005) warned that "dispersed landscape effects … should be generalized very cautiously".

The extent of OHV trails in desert tortoise habitat is hard to quantify, however the recent expansion of the Spangler, El Mirage, and Johnson Valley off-highway vehicle recreation areas under the 2019 John D. Dingell, Jr. Conservation, Management, and Recreation Act opened up an additional 60,000 acres (~242 km^2) of public land to OHV use (USFWS 2022*a*).

Closing and restoring illegal OHV routes can improve habitat for tortoises. At the October 2022 Desert Tortoise Management Oversight Group Meeting, the BLM reported that there is a multi-year restoration project in Fremont-Kramer CHU to monitor and restore OHV routes.

4.3 Impacts from Invasive and Non-Native Species

Like many of the processes threatening desert tortoise, the impacts of invasive species are often tied to and synergistic with other factors such as livestock grazing, drought, and wildfire. Invasive Mediterranean grasses have spread through much of the Mojave Desert. These grasses create fuel for wildfires (Drake et al. 2015) and outcompete native annual plants (DeFalco et al. 2003). In 1995, 34 plots in the Mojave Desert near Barstow had frequencies of occurrence of 17% for *Bromus* and 38% for *Schismus* (both invasive grasses) (Brooks 1999). A more recent study sampled 718 plots across the Mojave Desert in 2009–2013 to investigate invasive grasses (*Bromus* spp. and *Schismus* spp.) and an invasive forb *(Erodium cicutarium*). At least one of the invasive taxa occurred in 91% of the plots with herbaceous cover, and two or more of the species co-occurred in 77% (Underwood et al. 2019). Berry et al. (2020b) summarized the impacts of invasive grasses on desert tortoise:

> "Grasses are high in fiber, contain less digestible energy, and little protein (Hazard et al. 2009), causing juveniles to lose phosphorus and potentially shell volume (Hazard et al. 2010). Because of numerous human activities, invasive, non-native, and fire-prone grasses became established in tortoise habitat and now contribute substantially to the biomass of annual plants in late winter and spring, the principal feeding time for the tortoise (Brooks and Berry 2006, Brooks and Matchett 2006, Brooks et al. 2006, Minnich 2008). These grasses compete with native forbs for nutrients (Brooks 2000a). A diet of grasses is insufficient in

> nutrients and leads to water loss during digestion (Hazard et al. 2009, 2010). In experimental studies, 32–37% of neonates and yearlings did not survive on a diet of grasses, whereas individuals in these size groups fed native forbs or a mix of native forbs and grasses had better body condition, immune functions, growth, and survival rates exceeding 95% (Drake et al. 2016)."

In contrast to grasses, the alien forb *Erodium* provided sufficient nitrogen and is of similar nutritional quality as a native forb (Nagy et al. 1998), allowing juvenile tortoises fed on forbs to gain weight (Hazard et al. 2009).

4.4 Competition

Grazing by livestock is a major part of the recent history of the desert. While grazing on BLM lands was historically permitted in tortoise range (Berry et al. 2014) after federal listing in 1990 it was halted in the CHUs. However, grazing is allowed on private inholdings within the CHUs, which are often unfenced. The documented impacts of livestock on tortoises include competition for food, trampling to death, and causing the collapse of burrows (see Berry and Murphy (2019)). Livestock also degrade habitat by creating or expanding trails which reduces annual plant cover and can (but does not always) promote wind erosion and compaction (Webb and Stielstra 1979, Lovich and Bainbridge 1999). Livestock increase browsing pressure on the trees and shrubs that tortoises require for shade and for establishing burrows (Berry et al. 2020a). Artificial watering sites concentrate activity of wild and domesticated large herbivores, potentially modifying soil nutrients, compaction, seedbanks, and density of invasive species nearby. In a grazing allotment on BLM land in the west central Mojave Desert, cover of native plants decreased with increasing proximity to a water site, while cover of alien (but not necessarily invasive) species increased (Brooks et al. 2006). This change in plant composition was observed up to 800 m away from the watering site. Ninety-six percent of the alien plant cover was made up of three species, including the forb *Erodium cicutarium* and the alien grass *Schismus* spp. (Brooks et al. 2006).

4.5 Predation

Desert tortoises are preyed upon by several native species, with different predators targeting different tortoise age classes. The number and distribution of certain predators in tortoise habitats have increased in tandem with human development.

The best studied tortoise predators in California are ravens and coyotes. These species are generalist predators which utilize a variety of habitats including those modified by humans. Human residence and activity in tortoise habitat provide food resources such as unsecured trash, water, and road-killed carcasses, and buildings and other structures provide shelter (Boarman et al. 2006, Kristan and Boarman 2007). These 'resources bonanzas' (Kristan and Boarman 2007) allow predator populations to flourish, potentially increasing predation pressure on native prey.

Raven populations have drastically increased in the Mojave Desert in the past 50–100 years and ravens have become a major predator of juvenile tortoises. This contrasts with population trends for many other bird species. Between the early 20th century and 2013–16, survey sites in the Mojave Desert lost 43% of their bird species on average (Iknayan and Beissinger 2018). Ravens were the only bird species to substantially increase across survey sites. The probability that ravens would be detected at a survey site was on average 35% in the first half of the 20th century and 76% in 2013–2016 (Iknayan and Beissinger 2018). Between 1970 and 2020, the index of abundance of ravens inside Mojave Desert Tortoise range increased by a factor of 6 (Harju et al. 2021). In 2020, surveys in Fenner, Ivanpah, Fremont-Kramer, Ord-Rodman, and Superior-Cronese CHUs found average densities of 0.63 ravens/km^2 in Fenner in the east to 2.44 ravens/km^2 in Fremont-Kramer in the west (Holcomb et al. 2021). This expansion of raven presence in extent and abundance is due at least in part to increased anthropogenic subsidies (Boarman and Berry 1995). Ravens spend time near these subsidies (Boarman and Berry 1995, Boarman et al. 1995, 2006), which is one of the factors that leads to higher mortality for tortoises near human infrastructure than in open desert (Berry et al. 2006, Esque et al. 2010). As human infrastructure has increased in the Mojave Desert, the impact of raven predation on desert tortoise populations has likely increased.

Ravens are more likely to target juvenile tortoises rather than adults. Nagy et al. (2015b) released 53 tortoises on Fort Irwin National Training Center in 2005, and 78% of the mortality of smaller tortoises (carapace 45–80 mm) was due to ravens, while coyotes were a major source of mortality for larger (111–175 mm) tortoises. High levels of raven predation on juveniles are thought to have led to far fewer juveniles being observed in the annual TCA surveys. In an area with a raven density of 2.4/km^2, the USFWS estimated survival of 0–12-year-old tortoises at 51%, which is much lower than in areas without ravens (Holcomb 2022*b*). Distance to the nearest raven nest impacts the survival rates of 0–10-year-old tortoises. Using decoy tortoises, Holcomb et al. (2021) found that juvenile tortoises had an average annual survival rate of 63% at 500 m from a raven nest, while juvenile tortoises 1.72 km from a nest had an annual survival rate of about 76%. They estimated that in areas where there were more than 0.89 ravens/km^2, and tortoises were less than 1.72 km from a nest, high rates of juvenile mortality would lead to population decline. If these criteria were applied to the Fremont-Kramer CHU, raven predation alone would likely have caused “inadequate” recruitment of juvenile tortoises across the majority of the CHUs over the past 20 years (Holcomb et al. 2021).

Predation pressure by ravens is not even across the tortoise range. In a study in the El Paso Mountains east of Bakersfield between 2008 and 2009, avian predators (mostly ravens) accounted for only 2.5% (on plot) and 3.7% (off plot) of observed mortalities (Berry et al. 2020*c*). Ivanpah and Fenner CHUs are in the eastern part of the range and have fewer anthropogenic subsidies for ravens and therefore lower raven densities. However, the densities in those CHUs are high enough that predation pressure combined with drought, road mortality, and invasive species together permit sustained recruitment of juvenile tortoises only in a few places (Holcomb et al. 2021).

Coyotes are thought to be a major predator of adult tortoises. In a study of translocated tortoises in the Superior-Cronese CHU, between 2008 and 2018 an estimated 60% were killed by predators, likely coyotes based on nearby tracks and scat (Esque et al. 2010, Mack and Berry 2023). In an examination of the dead tortoises found in the El Paso Mountains east of Bakersfield between 2008 and 2009, 20% of the carcasses found on the survey plots and about 52% of those found off plots were killed by mammalian predators including coyote, kit fox (*Vulpes macrotis arsipus)*, and badger (*Taxidea taxus)* (Berry et al. 2020*c*). Lovich et al. (2014) surveyed tortoises in a plot in Joshua Tree National Park, and in 2012, about 30% of tortoise carcasses had signs of predation or scavenging, likely by coyotes or kit foxes.

There is some evidence that canid predators focus more on females than males. In the Superior-Cronese CHU in 2008, Esque et al. (2010) found that females were more likely to be predated than males. They also looked at reference sites across the Mojave Desert and found that coyote predation on tortoises was strongly associated with the size of nearby human populations (Esque et al. 2010). Like ravens, coyotes receive food subsidies from human populations, and according to scat surveys, are widespread in some areas (Cypher et al. 2014). However, there is not much data on coyote population trends in the Western Mojave (Cypher et al. 2014) so it is unclear if their numbers have increased in the past few decades or were particularly high in years of high tortoise mortality like 2008.

During periods of suppressed rodent and prey populations following dry years, it has been suggested that coyotes will switch to preying on tortoises (Esque et al. 2010). This may help explain the widespread high mortality rates due to predation in 2008 (Esque et al. 2010). However, work by Cypher et al. (2018) did not necessarily support that hypothesis. In a study following the 2008 translocation of tortoises to an area south of Fort Irwin, they collected data on the relative abundance of rodents and rabbits, as well as the contents of coyote scats in 2009–2014. The years 2011–2014 were very dry compared to the wetter years of 2009–2010. While the frequency of occurrence of rodents in scat was lower in dry years (24.3%–46.3%) than in the wet years (53%–65%), the frequency of tortoises in scat was also lower in dry years (2.4%–2.6%) compared to wet years (5.6%–5.8%). These results suggest that it is unlikely coyotes switched to tortoise prey because of lack of rodents. Instead, as coyotes ate fewer rodents in the dry years, their amount of anthropogenic food sources increased (Cypher et al. 2018). While 2008 may have been an anomalous widespread pulse in predation pressure (Esque et al. 2010), there is a lack of rigorous evidence that coyotes regularly prey switch to tortoises when rodent or lagomorph populations are low because of drought.

Badgers are thought to be partially responsible for high levels of mortality of tortoises in 2012-2013 on and near Ft. Irwin, and may be important predators in certain locales (Emblidge et al. 2015). Other predators of tortoises include fire ants, white-tailed antelope squirrels (*Ammospermophilus leucurus*), bobcats (*Lynx rufus*) (Nagy et al. 2015*a, b*), red-tailed hawks (*Buteo jamaicensis*) (Anderson and Berry 2019), rattlesnakes (*Crotalus* spp.) (Berry et al. 2016), and domestic dogs (Berry and Murphy 2019).

Summary

Predation, especially by ravens and coyotes, is a significant factor in desert tortoise population decline. Ravens (and to a lesser extent coyotes) are subsidized by the infrastructure, water, and food around human development, and raven populations have dramatically increased in recent decades. Ravens preferentially target juvenile tortoises, and since clutch sizes are low and tortoises can take 12–20 years to become sexually mature, decreased juvenile survival is likely an important factor in many areas with declining tortoise densities. Given the slow life history traits of tortoises, lower juvenile survival will be a long-term issue for the population, impacting populations for decades. Coyotes can kill older tortoises, and in some areas are a significant cause of death. Reducing raven and coyote predation is likely to be challenging and predation is likely to remain a significant challenge for rapid tortoise population recovery.

4.6 Climate Change and Drought

Anthropogenic climate change has led to higher annual average air temperatures in general as well as increased volatility of California's climate. Extreme events like drought and heat waves are more frequent, rainfall is increasingly variable, and flow regimes of rivers are changing (Bedsworth et al. 2018). These changes have led to observable shifts in species distributions and timing of life history events (OEHHA 2018). In California, Mojave Desert Tortoises inhabit the relatively cooler high Mojave Desert, and the hotter low Sonoran Desert. The western part of the tortoise range in the Mojave Desert gets most of its precipitation in the winter with only about 15% from summer monsoons, whereas the monsoons account for about 30% of yearly precipitation in the eastern deserts (Hopkins 2018).

Impacts of Increased heat

In the inland deserts of California, daily maximum temperatures warmed by 0.4–0.7°F (0.2–0.38°C) when 1976–2005 was compared to a historical base line of 1961–1990 (Hopkins 2018). Those temperatures are projected to see increases of up to 8–14°F (4.4–7.7°C) by 2070–2100, depending on the future emission levels of greenhouse gases (Hopkins 2018). It is projected that by 2070–2100 there will be up to 141 days a year in the Mojave Desert when the temperature exceeds 95°F (35°C), up from an average of 90 days per year in 1981–2000. Minimum daily temperatures are projected to rise 4–7°F (2.2–3.8°C) by 2070–2100 (Hopkins 2018).

Under warming scenarios described above, desert tortoises will have fewer areas where they can stay within their physiological limits. As habitat area shrinks, tortoises are already heading upslope in some areas to escape the heat of the valley bottoms (W. Campbell pers. comm. May 2022). This type of movement may become more difficult as temperatures increase and suitable upslope areas shrink. Sadoti et al. (2017) found that tortoises restrict their movements when it is hotter. While this is not necessarily surprising, if there are more days when it is too hot for tortoises to move, they might find it harder to move to avoid those hot temperatures and will have limited opportunities to disperse or find mates. However, the degree to which increased heat in the summer will shift mating season or impact reproductive success is unknown. Increased temperatures will make burrows as refugia from the heat more critical.

Since only certain types of soils and substrates allow for creation of adequately long tunnels, available tunnel sites may become a critical habitat concern in the future and should be taken into consideration in conservation efforts Mack et al. 2015).

As mentioned in the section on life history, the sex of the hatchling is heavily influenced by incubation temperature. As temperatures rise and heat extremes become more common due to anthropogenic climate change, it is likely that sex ratios at hatching will skew to be more female dominated, however the degree to which this will impact adult sex ratios is unknown, especially if drought increases adult female mortality.

Impacts of drought

Desert tortoises are adapted to drought and heat. However, increasing levels of both are likely to cause physiological stress and alter the availability of edible vegetation. Barrows (2011) lists some of the physiological and behavioral impacts of drought:

> "Drought conditions result in reduced tortoise activity (Duda et al., 1999) and lower metabolic and reproductive rates (Peterson, 1996a; Henen, 1997; Henen et al., 1998) although some breeding activity occurs even during periods of water stress (Henen, 1997). Despite these behavioral and physiological adaptations, during droughts tortoises experience as much as 40% loss of body mass and a 60% loss of water volume relative to body mass as well as large variations in blood osmolarity (Peterson, 1996b) and can have higher levels of mortality (Turner et al., 1984)."

California has undergone extreme drought recently with the 2000–2021 span being the driest in the southwestern U.S. in the past 1,200 years (Williams et al. 2022). Although there is significant uncertainty regarding projected precipitation changes, current models show that winter precipitation is likely to increase in the inland deserts, but the summer monsoon precipitation could decrease up to 40% if atmospheric CO_2 concentrations double (Pascale et al. 2017). Precipitation events are likely to be more intense and at the same time soils are predicted to be drier, leading to more flash flooding (Hopkins 2018). The projected warmer and periodically drier conditions during the 21st century may increase the risk for more severe drought (Hopkins 2018).

Long-term drought has caused die offs of perennial plants in desert tortoise habitat, likely driven by lack of winter rain (McAuliffe and Hamerlynck 2010). Die offs were extensive but not homogenous, and soil conditions likely played a role (McAuliffe and Hamerlynck 2010). Tortoises are selective herbivores that will feed from a wide variety of available plants if necessary but primarily focus their observed foraging effort on a small set of species, many of which are relatively uncommon (Jennings and Berry 2015). Given predictions that winters may become wetter but summers drier (Hopkins 2018), the impacts of future droughts on the vegetation that tortoises rely on is unclear. Some invasive species of *Bromus* grasses are successful in disturbed habitats, and their presence in desert habitat has helped alter the fire cycle (Brooks 1999, Bradley et al. 2016). However, germination, growth, and reproduction are limited by temperature and rainfall which makes it difficult to predict the relative success of invasive grasses vs. native forbs under predicted climate changes (Bradley et al. 2016). It is possible that tortoises will also face increased nutritional stress if preferred plants die off and more nutrient poor grasses like *Bromus* remain available.

Lovich et al. (2014) used intermittent surveys in Joshua Tree NP from 1979 to 2012 to estimate the impact of persistent and recurrent drought on tortoise survival. Estimated population size decreased dramatically from 1996 to 2012, with high survival in 1978–1996, and lower survival in 1997–2002. The lower survival rates were concurrent with persistent drought, and estimated survival rates were best explained by winter precipitation. Being in a national park, tortoises in Joshua Tree should be sheltered from many anthropogenic impacts including large scale habitat modification and degradation and direct killing by humans. In addition, in 2012, many of the dead tortoises showed signs consistent with death by dehydration and starvation. Therefore, the authors concluded the decline was likely the result of reduced survival rates due to drought (Lovich et al. 2014). Other populations of desert tortoises have also shown a negative impact of drought on survival and abundance. Populations in Arizona of *G. agassizii* and *G. morafkai* were surveyed multiple times between 1990 and 2017 and experienced very low survival (30% in the Black Mountains and 34% in the Hualapai Mountains) during a drought, which led to a drop in adult abundances of about 50% (USFWS 2022*a*).

There is some evidence that drought is affecting sex ratios of adult tortoises. Unequal sex ratios are thought to lower effective population size, which in small populations with limited connectivity could exacerbate inbreeding (Frankham 1995). In 2015–2016, Lovich et al. (2023) surveyed two sites in Shaver's Valley about 70 km southeast of Palm Springs along the boundary of the Joshua Tree and Chuckwalla TCAs. At both sites there was a male bias in live tortoises. At the cooler, wetter site there was an even sex ratio in tortoises found dead, but in the hotter and drier Chuckwalla site, more females were found dead. It is possible that the energetic requirements required for reproduction make females less likely to survive long-term drought conditions (Lovich et al. 2023). However, there is limited evidence that there is a widespread and long-term skew in sex ratios. In a 2.6 km^2 (1 mi^2) study plot in Joshua Tree NP, data from intermittent surveys from 1978–2012 showed that "sex ratios, defined as the number of live males divided by the number of females, ranged from unity, to male biased (5:1), to female biased (0.22:1) across years with no trend in any one direction" (Lovich et al. 2014). On a wind energy facility near Palm springs in 1997–2010, the "adult sex ratio was not significantly different from unity" (Lovich et al. 2011).

A major question is how much desert tortoise habitat will become unsuitable in the future due to heat and drought. Species have shifted altitude and/or latitude as climate has changed (VanDerWal et al. 2013, Wolf et al. 2016), but species that are not nimble dispersers may have trouble accessing new areas, and those areas may not contain the full suite of conditions necessary for survival. However, within current habitats, local refugia may persist in future climatic conditions and allow species to persist. Barrows et al. (2016) evaluated potential habitat refugia on MCAGCC and found that 33% of the study area (283,900 ha) supported desert tortoise habitat at the time. With a simulated 1°C (1.8°F) of warming, the amount of habitat shrunk by 25%, with remaining habitat occurring at higher elevation. Under a simulated

3°C warming, habitat area shrunk by 56% (to 127,650 ha). Of the remaining available habitat, 91% overlapped with current tortoise habitat, suggesting that climate refugia would be relatively easy for tortoises to access. However, it should be noted that while Barrows et al. (2016) considered 3°C (5.4°F) to be an end of century level of warming, California's 4th Climate Change Assessment from 2018 predicts that level of warming to occur in the inland deserts by 2039 (Bedsworth et al. 2018). In Joshua Tree National Park, desert tortoises are found in both the Mojave and Sonoran desert portions. Modelling by Barrows (2011) predicts that under 2°C (3.6°F) of warming with 50 mm decrease in precipitation, habitat area will decrease by about 88% in the Sonoran Desert portion and by about 66% in the Mojave Desert portion.

4.7 Fire

Desert tortoise habitat historically experienced few fires due to low plant productivity and sparse fuel loads, and those that did occur tended to burn in a patchy mosaic pattern (Esque et al. 2003). Consequently, desert tortoises are not well adapted to fire, although use of burrows can prevent mass casualties in fires (Esque et al. 2003). The expansion of invasive plants (primarily grasses like *Bromus*) has increased fuel loads in the Mojave Desert (Brooks 1999), and fire frequency in the California portion of the Mojave Desert increased between 1980 and 1995 (Brooks and Esque 2002). However, longer term studies looking at fires from 1980–2004 (Brooks and Matchett 2006) and 1992–2011 (Hegeman et al. 2014) in the Mojave Desert show no clear increase in numbers of fires or acres burned per year. However, 2005 stood out as the amount of area burned in the Mojave Desert was 385,357 ha (952,238 acres) (M. Brooks unpublished data), representing 132% of the total area that burned during the previous 25 years (Brooks and Matchett 2006). In recent years large fires have burned in Mojave National Preserve including the 2020 Dome Fire (43,273 acres /175 km^2) of higher elevation tortoise habitat) (USFWS 2022*a*), or the 2023 York Fire (93,078 acres/377 km^2). Fire-caused tortoise death is summarized in Berry and Murphy (2019):

> "Woodbury and Hardy (1948) reported deaths of about 14 tortoises from a fire covering ca. 5.2 km^2 on part of the Beaver Dam Slope south of Bunkerville in 1942. In a post-fire study, Lovich et al. (2011c) described a fire in the western Sonoran Desert that killed an adult female tortoise and injured five other adult tortoises. Nussear et al. (2012) reported that three of 30 tortoises died from fire during a comparative study of translocated and resident tortoises. In the Red Cliffs Desert Reserve and critical habitat in Utah, 687 tortoises died in 2005 in a fire that burned ca. 23% of the approximately 251 km^2 habitat (A. McLuckie, pers. comm.). Drake et al. (2012) described a tortoise recovering from burns three years post-fire."

The effects of wildfire on vegetation can impact tortoises in several ways. A study in low elevation Mojave Desert shrubland found that invasive *Bromus* cover increased after one fire but did not continue increasing after additional fires (Brooks 2012). However, native vegetation cover decreased with multiple fires, with percentage cover dropping from about 25% to about 1% when fire frequency increased from one every ten years to three every ten years. Given the poor nutritional content of *Bromus*, increasing fire frequency threatens tortoises' ability to find sufficient and adequate food. Tortoises tend to remain in same areas after fire (Lovich et al. 2018), and one study found that tortoises used burned and unburned areas nearly equally, starting the first year after the fire (Drake et al. 2015). Tortoises moved into the burned areas seasonally to forage for preferred annuals and herbaceous perennials (Drake et al. 2015). The use of burned habitats did not appear to affect their health or reproduction in the short term. However, the expansion of red brome grass in burned areas and the injuries that fire can cause tortoises remained concerns (Drake et al. 2015).

The effects of a changing climate on wildfire size and frequency in desert tortoise habitat are uncertain. Increased winter rain could promote biomass growth that dries out in the hotter summers and increases fuel load (Tagestad et al. 2016). Alternately, the predicted increase in drought like conditions may keep fuel loads low. Another variable is the cause of ignitions. In the past 40 years, human caused fires were more prevalent in areas with high visitation levels such as low to mid elevation and desert montane zones, while lightning caused fires were more common in the central and eastern areas that get summer monsoons (Brooks and Matchett 2006). There are widespread campaigns and regulations aimed at reducing the chances that visitors will cause fires in the desert, and the efficacy of these campaigns may influence fire frequency and spatial distribution in the future. Overall, Hopkins (2018) suggests that strong temporal and spatial variability in precipitation and fuel load across the desert makes long-term and widespread trends in fire regime hard to predict.

4.8 Disease and Parasites

Desert tortoises are susceptible to a variety of diseases, some of which are likely to have caused or contributed to population declines. Upper respiratory tract disease (URTD) has been cited as a cause of population declines in desert tortoise and was a reason for listing under the ESA in 1990 (USFWS 1990).

URTD can be caused by the bacteria *Mycoplasma agassizii* and *Mycoplasma testudineum*, while herpesviruses can cause similar symptoms (Johnson et al. 2005, Jacobson et al. 2014). The disease presents as lesions in the nasal cavity and inflammation of mucosa of the upper respiratory tract, muchoid discharge from the nares, damaged nasal scales due to chronic muchoid discharge, wheezing breath, swollen and watery eyes, and extreme lethargy (Jacobson et al. 1995, 2014, Johnson et al. 2005, Sandmeier et al. 2013). Tortoises that do not show clinical signs of infection can still serve as a reservoir for the disease and likely can transmit it to healthy tortoises (Jacobson et al. 1995). Transmission is most likely through direct contact that happens during courtship, mating, and fighting, and aerosol transmission is not likely (USFWS 1990, Jacobson et al. 2014). The disease both directly kills tortoises and can potentially interfere with their sense of smell and therefore their ability to forage for food and can potentially negatively affect their reproductive fitness (Germano et al. 2014, Jacobson et al. 2014). Sandmeier et al. (2013) found evidence that longer and colder winters correlated positively with the proportion of tortoises exhibiting URTD, possibly because time spent underground depresses the tortoise immune system or allows the bacteria to flourish.

A significant URTD outbreak occurred in the Desert Tortoise Natural Area in Kern County in 1989 when 627 dead tortoises were recovered during a survey, and 43% of 468 live tortoises had signs of the disease (Jacobson et al. 1991). The population declined by 90% between 1979 and 1992 (Berry and Medica 1995). In 1990–1995, Christopher et al. (2003) sampled tortoises at three sites in the Mojave Desert:

> "Of 108 tortoises, 68.5% had clinical signs of upper respiratory tract disease consistent with mycoplasmosis at least once during the study period. In addition, 48.1% developed moderate to severe shell lesions consistent with cutaneous dyskeratosis. Ulcerated or plaque-like oral lesions were noted on single occasions in 23% of tortoises at Goffs and 6% of tortoises at Ivanpah. Tortoises with oral lesions were significantly more likely than tortoises without lesions to have positive nasal cultures for *Mycoplasma agassizii* (P=0.001) and to be dehydrated (P=0.0007)".

More recent studies have found much lower prevalence of URTD. In the central Mojave Desert in 2005–2008, Berry et al. (2015) found only 1.49% of sampled tortoises were antibody positive. It is thought that the high prevalence of the disease in wild populations in the 1970s–1990s was due in part to infected captive tortoises being released into the wild. Several factors are correlated with outbreaks of the disease, mainly factors that increase physiological stress in tortoises such as drought, heavy metal pollution, and human disturbance (Jacobson et al. 2014). Berry et al. (2015) pointed out that many of the stressors that increase tortoise vulnerability to URTD, especially drought and proximity to human populations, are increasing in desert tortoise range. However, there have not been any large outbreaks documented in California recently, and in the Desert Tortoise Natural Area the disease has "evolved from an acute, epizootic disease with high mortality to a chronic endemic disease with variable morbidity, low mortality" (Jacobson et al. 2014). Reflecting the decreased level of threat currently posed by the disease, in their 2022 5-year review the USFWS stated that "direct disease management of wild tortoise populations is less important (other than in translocations of tortoises between populations) than managing factors that affect their habitat and its capacity to support healthy tortoises" (USFWS 2022*a*).

Official handling protocols include strict guidelines to minimize human mediated transfer of pathogens and stress (USFWS 2020*b*). In addition, translocating sick individuals runs the risk of spreading URTD, so translocation protocols include health assessments and quarantine to minimize disease transfer between populations (USFWS 2020*b*). However, disease can be transferred by tortoises naturally dispersing, and reservoirs of the disease in populations outside of California should be considered in discussions of connectivity (Burgess et al. 2021).

Shell diseases like cutaneous dyskeratosis also affect tortoises and present as "abnormal conformation and loss of normal integrity of the horny layer (scute) of the shell and cutaneous scales. Deep shell defects may expose dermal bone" (Homer et al. 2001). Shell lesions were correlated with high mortality rates of desert tortoises in Chuckwalla Bench in 1982–1988 (Figures 8 and 9, Jacobson et al. 1994) . In 1979, 56% of the tortoises surveyed had shell lesions.

The proportion of effected tortoises increased to 65% in 1982, to 90% in 1988, and remained high in 1990 at 87%. During those years the density of all tortoises (adults and juveniles) fell from 221/km^2 to 71/km^2, a 68% decline (Berry and Medica 1995). While the declines in population cannot be definitively tied to shell lesions, they could be a sign of a deficiency disease or toxicosis (Jacobson et al. 1994). There has been very little reported on shell disease in wild tortoises in California since the mid-1990s.

4.9 Overexploitation

Under the California Fish and Game Code, desert tortoises have had some legal protection from take or collection since 1961 (Fish & G. Code, § 5000: *It is unlawful to sell, purchase, harm, take, possess, transport, or shoot a projectile at, a tortoise* (Gopherus)). However, vandalism (gunshots) and collecting for pets were listed as reasons for population declines in the USFWS's 1990 decision to list the desert tortoise as threatened (USFWS 1990). Before tortoises were listed, Berry (1986*b*) found that percentage of tortoise deaths from gunshots in California deserts (1972–1982) ranged from a low of 1.8% at Chuckwalla Bench to a high of 28.9% in the Fremont Valley. Overall, 14.3% of carcasses found had evidence of gunshots, with the areas with the highest percentage in the Western Mojave. In a 2008–2009 study in the El Paso Mountains in Kern County, 6 of 67 carcasses had evidence of gunshots (Berry et al. 2020*c*). Berry and Murphy (2019) reported gunshot deaths in Fort Irwin National Training Center (1997–2003), Red Rock State Park (2002–2004), and the Desert Research Natural Area (2011).

While the actual number of California tortoises collected from the wild is unknown, Berry et al. (1996) (reported in Berry and Murphy (2019)) estimated that more than 2,000 tortoises were removed from four study areas over a 10-year period from the mid-1980s to the mid-1990s. It is likely some tortoises are still being taken from the wild, with those near roads most vulnerable. A study in the Sonoran Desert of Arizona in 2008–2009 placed decoy tortoises on roads and found 1.4% of drivers stopped and tried to collect the decoy by placing it in their vehicle. Drivers were more likely to notice the tortoises on maintained gravel roads compared to paved roads or unmaintained gravel roads. However, road type did not influence the probability a driver would try to collect the tortoise (Grandmaison and Frary 2012).

4.10 Other Human-related Activities

Mining and pollution

Although Spanish colonizers panned for gold in the Chocolate Mountains in the late 1700s, commercial mining in California deserts began in the 1800s. Prospectors and miners dug shafts to extract gold, tungsten, silver, copper, and other valuable materials (Shumway et al. 1980). Some of these shafts remain open and unfenced, and tortoises can fall in and become trapped (Berry and Murphy 2019). Mining also leaves behind pollutants of various types including mercury, arsenic, and lead that impact soil and plants (including those favored by tortoises) up to 15 km from mining sites (Chaffee and Berry 2006). These pollutants can enter tortoises via breathing, ingestion of impacted plants, or absorption through skin, and there is some concern that exposure to these toxins may make tortoises more susceptible to disease (Berry et al. 2015, Berry and Murphy 2019). Tortoises collected from the Kelly Rand Mining District northeast of California City and from Edwards Airforce Base had bioaccumulated arsenic in their shell plates compared to tortoises from areas with minimal land disturbance (Foster et al. 2009). However, Cohn et al. (2021) analyzed the blood of tortoises in the Ivanpah Valley and found that heavy metal levels in the blood were generally low (0%–7%), heavy metal levels in the soil did not exceed soil health guidelines, and there was no relationship between metal concentrations and body health or disease prevalence, suggesting that tortoises were not negatively impacted by mining pollution in that area.

Deliberate Releases

Based on public comments received by the Department, well-meaning individuals may release captive tortoises, believing it will help wild populations. People may also release animals they no longer wish to keep as pets. The deliberate release of captive tortoises presents several issues. Captive tortoises can have high prevalence of respiratory diseases which could be passed on to wild tortoises if they are released (Berry et al. 2015). Releasing animals of unknown genetic origin, or even different species like *G. morafkai* or the Texas tortoise (*G. berlandieri*), could result in hybridization with wild *G. agassizii* (USFWS 1994). The release of diseased captive tortoises was a large enough concern to be mentioned as reason for population declines in the 1994 Recovery Plan (USFWS 1994), but we lack robust recent data on the current prevalence of releases and their effects. A public education campaign highlighting the downsides to freeing captive tortoises may help address this threat. Translocations of captive tortoises into the wild are also discussed in section 5.2.

5. EXISTING MANAGEMENT

5.1 Regulatory Status and Legal Protections

Federal

Federal Endangered Species Act

In August 1989, the USFWS listed the Mojave population of desert tortoise as endangered on an interim basis. Eight months later in April 1990, it issued a final rule to list it as threatened (USFWS 1990). In July 2002, the USFWS received a petition to reclassify the species from threatened to endangered. In 2017, the USFWS announced a 90-day finding that the petition did not present substantial scientific or commercial information indicating that reclassifying the Mojave population of the desert tortoise may be warranted, and no status review was initiated in response to the petition. The USFWS has published status reviews in 2010 and 2022, both recommending that the threatened status be retained (USFWS 2010, 2022*a*). The 2022 status review uses much of the same data presented here and acknowledges that “the status of the Mojave Desert Tortoise had not improved by 2014 and most threats to the species persist at or above 2010–2011 levels. These conditions portend further status deterioration in the absence of concerted efforts by land managers to meaningfully reduce predator subsidies, vehicle-caused tortoise mortalities, and invasive annual plants in important tortoise habitats” (USFWS 2022*a*). The recommendation to retain the threatened status was based on finding about a dozen *G. agassizii* in Arizona, east of the Colorado River making the “range of the species slightly larger than the currently listed entity”, recognition that the range-wide population of tortoises is in the hundreds of thousands, and optimism that conservation actions will eventually result in population improvements (USFWS 2022*a*).

National Environmental Policy Act

The National Environmental Policy Act (NEPA) requires federal agencies to assess the environmental effects of their proposed actions prior to making certain decisions. Using the NEPA process, agencies evaluate the environmental and related social and economic effects of their proposed actions. Agencies also provide opportunities for public review and comment on those evaluations. Title I of NEPA contains a Declaration of National Environmental Policy. This policy requires the federal government to use all practicable means to create and maintain conditions under which man and nature can exist in productive harmony. Section 102 in Title I of the Act requires federal agencies to incorporate environmental considerations in their planning and decision-making through a systematic interdisciplinary approach. Specifically, all federal agencies are to prepare detailed statements assessing the environmental impact of and alternatives to major federal actions significantly affecting the environment. These statements are commonly referred to as Environmental Impact Statements and Environmental Assessments.

State

California Law/Fish and Game Code

California law has long included protections for Mojave Desert Tortoise. In 1939, California state law prohibited purchase or sale of the species. In 1961, an additional law was passed to prohibit "*to sell, purchase, harm, take, possess, transport, or shoot a projectile at, a tortoise*" (Fish & G. Code, § 5000). In 1972, the Fish and Game Code was amended to allow possession of tortoises as long as the tortoise was legally acquired (Fish & G. Code, § 5001).

California Endangered Species Act

On August 3, 1989, the Commission listed the desert tortoise as a threatened species under CESA. CESA prohibits the import, export, take, possession, purchase, or sale of Mojave Desert Tortoise, or any part or product of Mojave Desert Tortoise, except as otherwise provided by the Fish and Game Code, such as through a permit or agreement issued by the Department (Fish & G. Code, § 2080 *et seq.*). For example, the Department may issue permits that authorize the incidental take of listed and candidate species if the take is incidental to an otherwise lawful activity, the impacts of the authorized take are minimized and fully mitigated, the activity will not jeopardize the continued existence of the species, and other conditions are met (Fish & G. Code, § 2081, subd. (b).). The Department may also authorize incidental take through voluntary local programs and safe harbor agreements (Fish & G. Code, §§ 2086 and 2089.2 et. *Seq.*) and for scientific, educational, or management purposes (Fish & G. Code, § 2081, subd. (a).). If the species is listed under both the federal ESA and CESA, a project that has received a federal incidental take statement or incidental take permit that is consistent with CESA can receive a consistency determination (CD) from the Department (Fish & G. Code, § 2080.1).

Given the predominance of federal land in desert tortoise range, it should be noted that federal agencies undertaking federal projects on federal land are usually not subject to CESA and instead must typically consult with the USFWS to "ensure that actions they fund, authorize, permit, or otherwise carry out will not jeopardize the continued existence of any listed species or adversely modify designated critical habitats" (USFWS 2022*d*). However, non-federal entities working on federal lands are subject to CESA. For example, timber companies with permission to harvest timber on U.S. Forest Service lands must comply with both federal and state wildlife laws.

In 2000 and 2005, the Department prepared summary reports pursuant to CESA describing the status of desert tortoise as declining (CDFW 2000, 2005). The 2005 report described the desert tortoise as severely threatened by population losses and further stated that tortoise populations were extremely low in some areas and may not have been viable (CDFW 2005).

<u>California Environmental Quality Act</u>
State and local agencies must conduct environmental review under the California Environmental Quality Act (CEQA) for discretionary projects proposed to be carried out or approved by the public agency unless the agency properly determines the project is exempt from CEQA (Pub. Resources Code, § 21080). If a project has the potential to substantially reduce the habitat, decrease the number, or restrict the range of any rare, threatened, or endangered species, the lead agency must make a finding that the project will have a significant effect on the environment and prepare an environmental impact report (EIR) or mitigated negative declaration as appropriate before proceeding with or approving the project (Cal. Code Regs., tit. 14, §§ 15065(a)(1), 15070, and 15380.). An agency cannot approve or carry out any project for which the EIR identifies one or more significant effects on the environment unless it makes one or more of the following findings: (1) changes have been required in or incorporated into the project that avoid the significant environmental effects or mitigate them to a less than significant level; (2) those changes are in the responsibility and jurisdiction of another agency and have been, or can and should be, adopted by that other agency; or (3) specific economic, legal, social, technological, or other considerations make infeasible the mitigation measures or alternatives identified in the EIR (Pub. Resources Code, § 21081; Cal. Code Regs., tit. 14, §§ 15091 and 15093.). For (3), the agency must adopt a statement of overriding considerations finding that the overriding benefits of the project outweigh the significant effects on the environment. CEQA establishes a duty for public agencies to avoid or minimize such significant negative effects where feasible (Cal. Code regs., tit. 14, § 15021.). Impacts to Mojave Desert Tortoise, as a CESA-threatened species, must be identified, evaluated, disclosed, and mitigated or justified under the Biological Resources section of an environmental document prepared pursuant to CEQA.

Nonregulatory Status

<u>Natural Heritage Program Ranking and IUCN Red List</u>
Natural heritage ranking does not provide any regulatory protections but is often considered during the CEQA process (Hammerson et al. 2008). All Natural Heritage Programs, such as the CNDDB, use the same ranking methodology originally developed by The Nature Conservancy and now maintained by NatureServe. This ranking methodology consists of a global rank describing the rank for a given taxon over its entire distribution, and a state rank describing the

rank for the taxon over its state distribution. Both global and state ranks reflect a combination of rarity, threat, and trend factors. The ranking methodology uses a standardized calculator that uses available information to assign a numeric score or range of scores to the taxon, with lower scores indicating that a taxon is more vulnerable to extinction, and higher scores indicating that a taxon is more stable (Faber-Langendoen et al. 2012). The rank calculation process begins with an initial rank score based on rarity and threats, with rarity (multiplied by 0.7) factored more heavily into the calculator than threats (multiplied by 0.3). The combined rarity and threat rank is then either raised or lowered based on trends. When there is a negative trend, the rank score is lowered, and when there is a positive trend the rank score is raised. Short-term trends are factored more heavily into the calculator than long-term trends. International Union for Conservation of Nature (IUCN) and NatureServe assess extinction risk for species using a time period of 10 years or 3 generations, whichever is longer, up to a maximum of 100 years (Faber-Langendoen et al. 2012).

The Mojave Desert Tortoise has been assigned a global rank of G3 indicating the species is "vulnerable and at moderate risk of extinction or collapse due to a fairly restricted range, relatively few populations or occurrences, recent and widespread declines, threats, or other factors." This species has been assigned a state rank of S2 indicating the species is locally imperiled and "at high risk of extirpation in the jurisdiction due to restricted range, few populations or occurrences, steep declines, severe threats, or other factors." The factors cited for this rank include widespread habitat loss, degradation, and fragmentation, and human-associated factors that cause mortality (NatureServe 2022).

The IUCN Red List provided a global scope assessment of Mojave Desert Tortoise in October 2021 (Berry et al. 2021) resulting in a designation of critically endangered. This Red List category represents the highest risk of extinction and is assigned when a taxon has been evaluated against the ranking criteria and is not yet designated Extinct in the Wild, but qualifies above endangered, vulnerable, and near threatened. The species was originally assessed as vulnerable in 1996 and its designation has steadily increased in severity (Berry and Murphy 2019).

5.2 Management Efforts

Due to its large range and the decades since it was formally protected under the ESA and CESA, a diverse suite of government and other entities are involved in land ownership and management within the range of Mojave Desert Tortoise (Table 7). The majority of land is managed by federal agencies, but the range also includes a substantial portion of private land. The BLM is responsible for managing nearly 11,000 km^2 of Mojave Desert Tortoise critical habitat and is the largest landowner within the species range. The NPS is responsible for the next largest portion of the range, most of which is congressionally designated Wilderness where motorized vehicles are prohibited. Private lands and DoD lands comprise most of the remaining land ownership within the species range.

Table 6. Land ownership within the entire range of Mojave Desert Tortoise and within designated critical habitat.

Land Management Entity	Landownership in Species Range (Km^2)	Percent of Landownership in Species Range (%)	Landownership in Critical Habitat (Km^2)	Percent of Landownership in Critical Habitat (%)
United States Bureau of Land Management	37,960	42.5	10,917	56.6
United States National Park Service	18,418	20.6	3,702	19.2
Private Lands	15,147	17	1,730	9.0
United States Department of Defense	13,018	14.6	2,270	11.8
State of California	2,018	2.3	485	2.5
Cities, Counties, Non-Profits, Special Districts	995	1.1	114	0.6
Other Public or Private Lands	391	0.4	30	0.2
Other Federal	79	0.1	19	0.1
United States Bureau of Indian Affairs	689	0.8	NA	NA
United States Forest Service	242	0.3	NA	NA
United States Bureau of Reclamation	181	0.2	NA	NA
United States Fish and Wildlife Service	89	0.1	NA	NA

Partnerships and Working Groups

The Desert Tortoise Management Oversight Group (MOG), formed in 1994, is comprised of senior managers from USFWS, BLM, state transportation agencies, state wildlife agencies, county governments, and non-governmental organizations (NGOs) that work in the tortoise range in Arizona, Nevada, Utah, and California. This group identifies regional recovery priorities, addresses issues common to multiple agencies, and shares information and updates about tortoise status and their recovery activities.

The Recovery and Sustainment Partnership (RASP) is comprised of DoD and Department of Interior agencies and is intended to provide increased flexibility for the use of land for military operations (i.e., make it easier to conduct training in areas with tortoise populations) in return for developing recovery initiatives. Under this partnership, agencies fund recovery actions such as raven management in California. Pooled funding and the Memorandum of Understanding between RASP partners allows for increased flexibility and reduced regulatory hurdles for implementation of broad, regional scale recovery actions.

The California Desert Conservation Act (Fish & G. Code, § 1450 et seq.) became effective on January 1, 2022, and establishes a California Desert Conservation Program within the California Wildlife Conservation Board with the goals of protecting habitat in California's Mojave and Colorado deserts by planning and implementing land acquisition and restoration projects. The California Desert Conservation Program could result in increased conservation or restoration of Mojave Desert Tortoise habitat in California.

United States Fish and Wildlife Service

The USFWS has developed and revised range-wide Recovery Plans for Mojave Desert Tortoise that encourage collaboration, identify research priorities, and encourage management actions for the benefit of the species. In 1994, the USFWS published the first Recovery Plan and designated more than 25,000 km^2 of critical habitat, most of which is in California (USFWS 1994). The plan identified Desert Wildlife Management Areas and included management recommendations such as landscape-level management and monitoring, public education, and habitat protection (USFWS 1994). In 2011, the USFWS published revisions to the Revised Recovery Plan which identified research priorities and recovery actions, including facilitation of recovery partnerships, protection of existing populations and habitat, supplementing populations, and implementing adaptive management (USFWS 2011). In 2010, the USFWS published its first 5-year review for Mojave Desert Tortoise across its multi-state range, in which they assigned a recovery priority number indicating that the species faces a moderate degree of threat, has a low potential for recovery, and faces conflict with construction or other development projects or other forms of economic activity. The USFWS recommended no change in status from threatened to endangered, in part because implementation of the at-the-time draft Revised Recovery Plan was expected to resolve key uncertainties and improve recovery potential (USFWS 2010). In 2022, the USFWS published another 5-year review reporting the continuing declines in density in all the California Tortoise Conservation Areas (see Table 2), but also recommended no change in the listing status of the Mojave Desert Tortoise (USFWS 2022*a*). For more detail see section 5.1.

As part of the 2011 Revised Recovery Plan revision, Recovery Implementation Teams were developed, which are "composed of representatives from government agencies and non-profit organizations. Participants in these teams prepare proposals for recovery actions, seek funding to support the proposals, and assist with implementation when funding becomes available" (Berry and Murphy 2019). Recovery Implementation Teams have focused on restoration of habitat burned and/or denuded by livestock, trash management to mitigate predator subsidies, invasive plant control, roadway fencing, and other conservation and management actions (Berry and Murphy 2019).

Bureau of Land Management

The 2016 Desert Renewable Energy and Conservation Plan (DRECP) Land Use Plan Amendment (LUPA) to the California Desert Conservation Act Plan of 1980 guides management of 10.8 million acres (43,706 km^2) of BLM lands in California. The plan "identifies priority areas for renewable energy development while setting aside areas for conservation and recreation" (BLM 2022). Phase I of the DRECP focused on the BLM lands and was released as a LUPA. Phase II will focus on county-level planning designed to work in conjunction with the LUPA. Along with many other agencies and stakeholders, the Department provided input on the development of the DRECP.

Under the DRECP, 11,290 acres (~46 km^2) of modeled desert tortoise habitat would eventually be developed for renewable energy, with a streamlined permit review process (BLM 2016). The LUPA contains numerous conservation and management actions, including establishment of a cumulative limit (no more than 1%) on ground-disturbing activities within BLM-owned portions of TCAs and mapped linkages. The plan amendment further prohibits long-term habitat removal in high density tortoise areas (more than five tortoises at least 160 mm carapace length per square mile, or more than 35 individuals in total), but gives an exception for transmission projects. Although the LUPA allows some renewable energy project development in tortoise habitat, other lands will be managed "according to numerous conservation and management actions that are more protective of desert tortoises than direction contained in the previous land use plan "(USFWS 2022*a*).

National Park Service

Management of the Mojave Desert Tortoise on NPS lands is guided by the NPS Organic Act of 1916, the ESA, the Wilderness Act of 1964, the 2006 NPS Management Policies, each unit's General Management Plan (GMP) and Superintendent's Compendium, and Resource Stewardship Strategies.

The NPS Organic Act of 1916 (39 Stat. 535, 16 U.S.C. 1, as amended), states that the NPS "shall promote and regulate the use of the Federal areas known as national parks, monuments, and reservations…to conserve the scenery and the national and historic objects and the wildlife therein and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations."

In desert tortoise range, the NPS administers Joshua Tree National Park, Death Valley National Park, and Mojave National Preserve. The majority of lands across these three units are congressionally designated Wilderness, including nearly 50% of lands in Mojave National Preserve, approximately 85% of lands in Joshua Tree National Park, and roughly 93% of lands in Death Valley National Park. The Wilderness Act is intended to preserve places "where the earth and its community of life are untrammeled by man, where man himself is a visitor who does not remain" (Wilderness Act section 2, subd. I). Use of offroad vehicles and motorized equipment is prohibited in Wilderness areas.

The NPS Management Policies indicate that Parks will "meet its obligations under the National Park Service Organic Act and the Act to both pro-actively conserve listed species and prevent detrimental effects on these species." This includes working with other agencies and partners to implement management programs which inventory, monitor, restore, and maintain listed species habitats. The Mojave Desert Inventory & Monitoring Network of the NPS regularly implements monitoring programs at all three NPS units focused on desert spring riparian vegetation and water quality as well as upland vegetation and soil characteristics that might influence the survival of Mojave Desert Tortoise.

Broad conservation actions are outlined in GMPs and specific closures and updates to prohibited actions are contained in the Superintendent's Compendium. Examples include prohibitions on use of Unmanned Aircraft Systems (drones), limits on use of artificial lights to view wildlife, requirements for food storage and trash management, and commitments for restoration of disturbed areas and/or mitigation of direct vegetation impacts.

United States Department of Defense

The Sikes Act was established in 1960 to ensure conservation and protection of natural resources used by the DoD. The U.S. Congress amended the Sikes Act in 1997 requiring the DoD to develop and implement Integrated Natural Resources Management Plans (INRMPs). These plans outline how each military installation will manage its significant natural resources holistically while maintaining military readiness. Since these lands are often protected from access and use by the general public, they sometimes contain significant large tracts of plant and animal habitat and play important roles for species conservation and habitat connectivity.

Under the ESA, the DoD is responsible for managing and protecting the threatened and endangered species found on its installations. DoD is required to consult with the USFWS and National Oceanic and Atmospheric Association (NOAA) Fisheries to manage its threatened and endangered species efforts (Dalsimer 2016).

DoD facilities within the Mojave Desert Tortoise range include Naval Air Weapons Station China Lake, Edwards Air Force Base, Fort Irwin, Marine Air Ground Task Force Training Command and Marine Corps Air Ground Combat Center Twentynine Palms, Marine Corps Logistics Base Barstow, and the Chocolate Mountain Aerial Gunnery Range. DoD is an active collaborator in the MOG and RASP partnerships and contributes funding to many recovery actions. Unlike most other federal land, tortoise habitat under DoD jurisdiction is "subject to more dramatic changes in management or use than other federal lands depending on the changing national security situation" (USFWS 2011). This means that large tracts of desert tortoise habitat can relatively quickly be converted to uses that are incompatible with desert tortoise, requiring translocation of large number of tortoises (see section 4.1 for more details). To offset these losses of tortoise habitat, the DoD undertakes a variety of actions such as purchasing land in critical habitat units, increasing law enforcement, predator control and monitoring, rehabilitation of closed roads, and installation of fencing.

California Department of Fish and Wildlife

CESA prohibits the unauthorized take of desert tortoise, but the Department may permit take that is incidental to otherwise lawful activities if the impacts of the take are minimized and fully mitigated. These permits are commonly called incidental take permits.

The Department is required to determine what qualifies as "full mitigation" for each permit on a case-by-case basis. As a practical matter, full mitigation has frequently required the perpetual protection and management of habitat mitigation lands. In addition, projects may have to implement a variety of measures to minimize take of tortoises including but not limited to surveying and monitoring for their presence, fencing to keep tortoises out of the project site, relocating nests to safe offsite locations, translocating tortoises from the project site, and managing ravens on the site.

Since 1989, the Department has issued 192 ITPs and 49 CDs covering incidental take of Mojave Desert Tortoise; the most common project types include renewable energy, transportation, and utility infrastructure (for locations of permitted projects see Figure 11). The Department's records are not complete; however, at minimum these permits authorize 62,131 acres (~250

km^2) of permanent impacts and 14,672 acres (~59 km^2) of temporary impacts (based on data available on temporary acres from 36% of ITPs and on permanent impacts from 79% of ITPs). The ratio at which projects must protect and manage mitigation habitat varies on a project-by-project basis, however projects sited in federally designated critical habitat are generally mitigated at a 5:1 ratio and other habitats at around a 3:1 ratio, depending on quality. Permit holders have multiple options when choosing mitigation lands but must typically provide permanent protection and perpetual management of habitat for the listed species either on the project site or at another location approved by the Department. This requires transfer of fee-title and/or recordation of a conservation easement, to which the Department must be at least a third-party beneficiary, funding of short-term management practices and a long-term management endowment, and monitoring to ensure compliance with the conservation easement. Alternatively, permittees may purchase credits at conservation and mitigation banks.

The desert tortoise is addressed in several Natural Community Conservation Plans (NCCPs) and Habitat Conservation Plans (HCPs) in California, including the West Mojave Plan, the Coachella Valley Multi Species Habitat Conservation Plan (MSHCP), and the California Energy Commission's Habitat and Species Protection Research Project. The Coachella Valley MSHCP area supports a small but significant population of desert tortoises in Riverside County (CDFW 2005). This MSHCP includes all federally designated critical habitat within the plan area as part of the Desert Tortoise and Linkage Conservation Area.

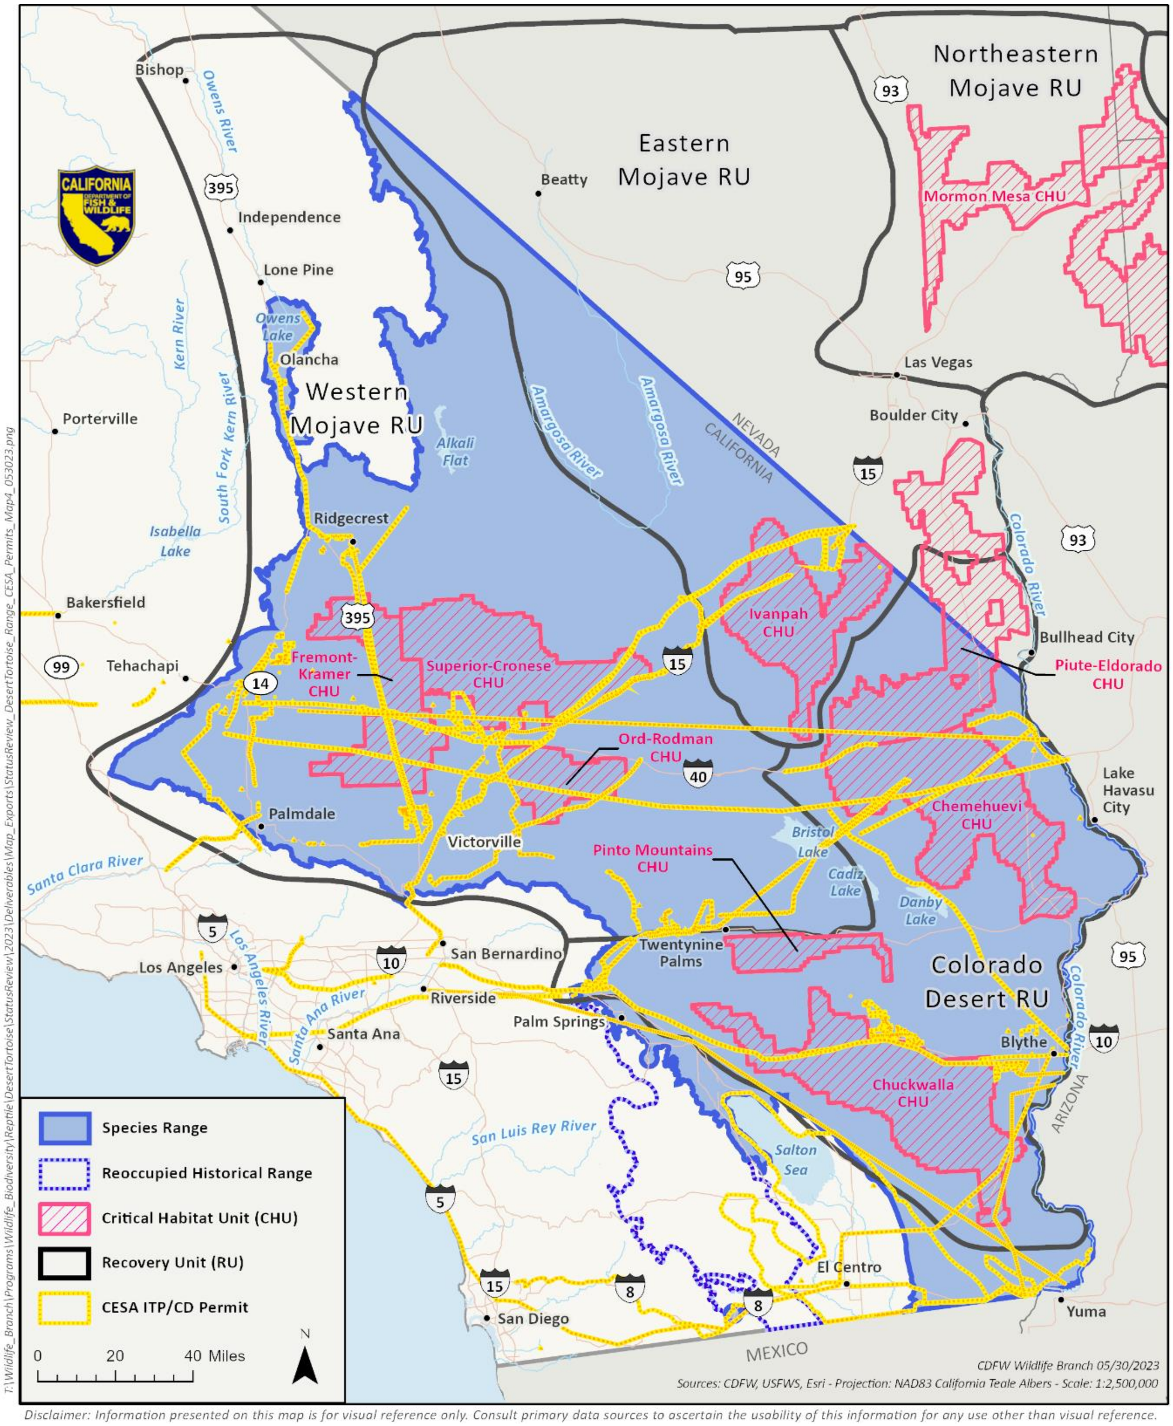

Figure 11. Map of Incidental Take Permits (ITPs) and Consistency Determinations (CD) in the general area of Mojave Desert Tortoise range in California. The linear permit areas are for energy transmission lines, pipelines, fiber optic lines, and other linear features. Other types of projects are represented as polygons.

Population Augmentation

Multiple agencies have coordinated on active management to augment and stabilize populations of desert tortoise. The two primary management strategies to increase the survival rates of individual tortoises are mitigation-driven translocation and release of head-started juveniles. Mitigation-driven translocation involves moving tortoises from a site where they would be harmed and into an appropriate recipient site. Head-starting is a strategy to reduce predation mortality on juvenile tortoises by hatching and rearing juveniles in captivity until they are large enough to avoid most predators.

Translocation

Mitigation driven translocation happens when a proposed project could result in incidental take of tortoises. As part of the minimization measures set forth in an ITP issued by the Department pursuant to CESA or an ITP or Incidental Take Statement issued by the USFWS pursuant to the ESA, tortoises in the project area can be translocated to preapproved recipient sites. The main purpose of translocations is to remove tortoises from project areas where they would otherwise not survive; however, bolstering the population at the recipient site is also a goal. There are several factors that need to be considered when tortoises are translocated, such as the habitat suitability of potential translocation sites and disease prevalence of both tortoises being moved and at the recipient site. The specific guidelines used by the USFWS are laid out in the USFWS Plan Development Guidelines (USFWS 2020*b*).

The Department requires that ITP holders monitor any tortoises translocated, and has teams carefully examine recipient sites for soil and vegetation communities that are suitable for all life stages of the tortoise, evaluate the presence and abundance of predators, and make sure there are sufficient burrows of appropriate size so that translocated tortoises can quickly find shelter. Most of the tortoises translocated under ITPs granted by the Department are placed within 4 miles of the donor site (although distance is only one of many considerations when choosing a recipient site) and the number of tortoises translocated for any project is usually less than 50. It should be noted that these common ITP requirements do not necessarily fully overlap with those of the USFWS. Due to the consistent efforts to find suitable recipient sites, deaths from translocation via dehydration or predation are rare (CDFW unpublished data, W. Campbell pers comm Jan 2023). However, the longer-term survival of translocated tortoises is not known.

Larger scale translocations face the challenge of finding recipient sites that are suitable for larger numbers of tortoises. If donor sites are chosen where resident populations are depleted or have low densities, they may not have the capacity to maintain higher densities of tortoises in general and might not be able to support large numbers of translocated animals (USFWS 2011). For example, sites with a depleted population due to habitat modification or degradation may currently be at a low carrying capacity and not be able to support many transplants because the site lacks sufficient food or shelter to support more individuals, thermal conditions are suboptimal, or predation pressure is high.

An additional consideration is how far to translocate individuals. When tortoises must be translocated from large tracts of land such as military bases, translocating individuals close to their home ranges may not always be feasible. Long distance translocation involves potential mixing of genetic subunits and possible maladaptation to the environment, and investigations into the genetic makeup of the source and recipient populations can help mangers make appropriate decisions (Weeks et al. 2011). Averill-Murray and Hagerty (2014) evaluated genetic variation of tortoises using microsatellite loci and concluded that "releasing tortoises at recipient sites within a straight-line distance of 200 km from the source population would most conservatively maintain historic genetic population structure." However, more recent work by Sánchez-Ramírez et al. (2018) using Single Nucleotide Polymorphisms (SNPs) suggests that there are three genetic subunits within the Western Mojave Recovery Unit and translocating them at distances of 200 km away could mix individuals from different genetic units.

In the spring of 2008, 570 tortoises (184 females, 293 males, 93 juveniles) were translocated from the southern edge of Fort Irwin National Training Center to neighboring public land in the Superior-Cronese Critical Habitat Unit. Esque et al. (2010) tracked the survival of translocated tortoises, resident tortoises (from areas near the release sites), and control tortoises (from areas more distant from release sites). In the first year, 19% of control tortoise, 21% of resident tortoises and 25% of translocated tortoises were found dead, with the majority of deaths attributed to predation. Esque et al. (2010) also reported higher mortality rates of tortoises in 2008 compared to the previous two years at sites across California and Nevada. Looking at the same translocation event, Mulder et al. (2017) found that four years later, the translocated males that survived were not fathering hatchlings. Even though translocated males made up 46% of the males in the population, all hatchlings that could be assigned fathers were sired by resident males.

Mack and Berry (2023) monitored 158 of the adult tortoises translocated from Fort Irwin in 2008 for ten years. Thirty-nine percent died in the first year, more than 50% were dead by the end of the third year, and after 10 years about 66% were confirmed dead and another 15% missing. Most of the deaths were attributed to coyote predation. However, they did not report survival rates of resident or control tortoises, so it is unclear the role translocation played in these death rates.

In the Ivanpah Valley near the Nevada border, the probability of mortality of translocated, resident, and control tortoises after translocation from a solar energy facility into nearby sites did not differ significantly either three (Brand et al. 2016) or five years (Dickson et al. 2019) after translocation.

Beyond the survival of tortoises involved in large scale translocations, there have been many studies looking at how body condition and temperature (Brand et al. 2016), environmental conditions (Nafus et al. 2017, Dickson et al. 2019), physiological stress (Drake et al. 2012), proximity of anthropogenic resources (Esque et al. 2010), movement and space use (Nussear et al. 2012, Farnsworth et al. 2015, Hinderle et al. 2015), and water availability (Field et al. 2007) affect the outcomes of translocations. These results are critical to improving and refining decision making around translocations.

Head starting

Head-starting is a strategy to try to circumvent the high mortality of juvenile tortoises in the wild (see sections 3.3 Mortality and Survival Rates and 4.5 Predation). Population modeling suggests that increased juvenile survival can improve population growth rates. Eggs are hatched in captivity and juveniles are reared until they reach a certain size and then released. There is some evidence that this strategy is effective at least in the short term (Nagy et al. 2015*a,b*, Tuberville et al. 2019), however, mortality is high for juveniles smaller than 100 mm in length. When Daly et al. (2019) monitored head started tortoises after release in the Mojave National preserve, annual survival was 44% and short-term survival was better if tortoises were more than 1.6 km from a raven's nest. Nagy et al. (2015) recommends not releasing head-started tortoises until they are over 100 mm, which requires keeping them in captivity for about 9 years and is a considerable investment of time and resources.

There is currently a head-starting program at the Ivanpah Desert Tortoise Head-starting Facility in Mojave National Preserve, a joint project between the University of Georgia and UC Davis. They have produced more than 675 hatchlings, released 324 which have been radio-tracked following release, with another approximately 275 for upcoming releases (Tuberville 2022). Another head-start program is on Edwards Air Force Base and involves San Diego Zoo, the U.S. Geological Survey, Cadiz Inc., and the BLM (SDZWA 2018).

6. SUMMARY OF KEY FINDINGS

CESA's implementing regulations identify key factors relevant to the Department's analyses and the Commission's decision on whether listing a species as threatened or endangered is warranted. A species will be listed as endangered or threatened if the Commission determines that the species' continued existence is in serious danger or is threatened by any one or any combination of the following factors: (1) present or threatened modification or destruction of its habitat; (2) overexploitation; (3) predation; (4) competition; (5) disease; or (6) other natural occurrences or human-related activities (Cal. Code Regs., tit. 14, § 670.1, subd. (i)).

The preceding sections of this status review describe the best scientific information available to the Department, with respect to the key factors identified in the regulations. This section considers the significance of any threat to the continued existence of Mojave Desert Tortoise for each of the factors.

Historical and current conservation efforts have not proven sufficient to halt the population declines of desert tortoises. The most robust tortoise density estimates come from annual systematic surveys begun in 2001 in the Tortoise Conservation Areas, which include the critical habitat units and contiguous areas with potential tortoise habitat and compatible management. Taken as a whole, these surveys provide strong evidence that most tortoise populations in California have declined rapidly over the past decades. Estimated rates of annual decline in density in the Recovery Units from 2001 to 2020 were about 4% in the Western Mojave (54%

decline over 19 years) and about 1% in the Eastern Mojave and Colorado Desert Recovery Units (17% decline over 19 years). In 2001, 80% of the TCAs had estimated densities below 3.9 adult tortoises/km^2, which is the density considered necessary for population viability. By 2020, all TCAs had estimated densities below that threshold. While we do not have estimates of density in all the TCAs prior to the desert tortoise being listed as threatened, densities in the early 1980s in select TCAs varied between 35 and 90 adults/km^2, and between 35 and 70 adults/km^2 when they were listed as threatened under CESA in 1989. Since the late 1970s, the number of juveniles detected on surveys has fallen to the point that in recent surveys in the Western Mojave almost no juveniles were found. Overall, population data indicate that the Mojave Desert Tortoise has experienced long-term, large population declines throughout its range in California. Data from the last 20 years show that this decline is ongoing. Populations in the TCAs, which represent much of the best habitat, are no longer considered viable.

Due to the slow components of tortoise life history, if past and current management is successful at mitigating threats and adverse impacts to tortoises, it will still take at least 25 years of positive population growth to reach the USFWS Recovery Criteria (USFWS 2022*a*). For example, the USFWS 1994 Recovery Plan estimates that when adult survivorship is 98%, population growth would be less than 0.5% per year, and would take 140 years to double in size. Annual survival rates for both adults and juveniles in many areas are much lower than 98%, making population stability, let alone growth, unlikely. Collectively, the available data show that despite 30 years of state and federal protection, in the critical habitat units (which were established to encompass the best tortoise habitat), most tortoise populations have continued to decline and do not show consistent signs of recovery. In regularly surveyed areas, tortoise densities are below the thresholds considered to represent population viability.

The dramatic declines in Mojave Desert Tortoise populations have likely resulted from the extensive number and interconnected nature of the threats facing tortoises in California. The important threats fall in two categories, those that directly kill adults and juveniles, and habitat modifications that make it less likely to support healthy populations.

Particularly in long-lived species that are slow to reproduce, decreased survival has long lasting impacts on the population and can alter demographic patterns for decades. Human created subsidies can increase predator densities, and predation pressure from ravens and coyotes reduce the survival of juvenile and adult tortoises, respectively. Increasing development removes or reduces habitat suitability and creates roads and increased traffic that can directly kill tortoises. Well-designed fences and culverts can help prevent tortoises and other wildlife being killed by vehicles along major roads, but many primary roads remain unfenced and little fencing has been built since 2011. Extensive networks of trails for off-highway vehicles on public lands add to the risk of tortoise roadkill. Development in the desert will likely continue and possibly speed up given California’s need for housing and renewable energy (Office of Governor Gavin Newsom 2021). Additional factors have direct and indirect impacts on tortoises and their habitat. Climate change is likely to make desert tortoise range hotter and drier and alter the vegetation communities. This will increase tortoise physiological stress, change activity patterns, and reduce and shift the locations of suitable tortoise habitat. Increased frequency or severity of drought can further degrade habitat and increase stress on tortoise populations. The nutritious native plants tortoises preferably feed on are being outcompeted by nutritionally poor invasive grasses, which can lower tortoise survival rates.

Some threats appear to be declining. Upper respiratory tract diseases were a major concern when tortoises were listed as threatened. Encouragingly, the prevalence of diseased tortoises is lower than in previous decades, and it does not currently appear to be an acute threat to wild populations. The prevalence of gunshot deaths also decreased in the past several decades, but it is unclear if this is due to change in human behavior or simply reflects a lower tortoise encounter rate due to declining tortoise density.

Given that there are multiple interacting threats that are reducing the amount and quality of viable habitat and declining survival rates of adults and juveniles, available information suggests that tortoise populations will continue to decline for the foreseeable future. However, several major threats like raven predation on juveniles and the lack of fencing on highways can be minimized with the appropriate resources and policy changes. Implementing these actions where appropriate to improve survival in the short term is critical to give desert tortoises the resilience to be able to weather longer term habitat and climactic effects.

7. PROTECTION AFFORDED BY LISTING

It is the policy of the state to conserve, protect, restore, and enhance any endangered or threatened species and its habitat (Fish & G. Code, § 2052). If listed as an endangered rather than a threatened species pursuant to CESA, unauthorized "take" of Mojave Desert Tortoise will remain prohibited and its conservation, protection, and enhancement will remain a statewide priority. As the Mojave Desert Tortoise is already listed as threatened, public agency environmental review is required under the California Environmental Quality Act (CEQA) and its federal counterpart, the National Environmental Policy Act (NEPA). There are no changes in legal protections under CESA for species uplisted from threatened to endangered.

However, if the status of the Mojave Desert Tortoise is changed to endangered under CESA, it may increase the likelihood that state and federal land and resource management agencies will prioritize and allocate more funds towards protection and recovery actions. The federal and state listings of the desert tortoise as threatened stimulated a great deal of interest and funding in addressing basic questions about the species, with expanded research into status and distribution of populations, ecology, genetics, and diseases, as well as collaborations to minimize conflict among the many users of desert tortoise habitats. It also triggered the creation of a USFWS Recovery Plan and the numerous conservation and management measures outlined in section 5 (Existing Management). However, funding for species recovery and management is limited, and there is a growing list of threatened and endangered species. Therefore, while a status change pursuant to CESA will highlight the urgency of tortoise conservation needs, the management effects of such a change are uncertain.

8. RECOMMENDATION FOR THE COMMISSION

CESA requires the Department to prepare this status review regarding the status of Mojave Desert Tortoise in California based upon the best scientific information available to the Department (Fish & G. Code, § 2074.6). CESA also requires the Department to indicate in this status review whether the petitioned action is warranted (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)). Based on the criteria described above, the best scientific information available to the Department indicates that Mojave Desert Tortoise is in serious danger of becoming extinct in California due to one or more causes including present or threatened degradation and loss of habitat, predation, and other natural occurrences and human-related activities.

The Department recommends that the Commission find the petitioned action to change the status of Mojave Desert Tortoise from threatened to endangered to be warranted.

9. MANAGEMENT RECOMMENDATIONS

CESA directs the Department to include in its status review recommended management activities and other recommendations for recovery of Mojave Desert Tortoise (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f).). The USFWS created a Recovery Plan for desert tortoise in 1994 which was revised in 2011. This is currently the most comprehensive framework of actions needed to recover the desert tortoise, and many of the recommendations are still very relevant. For our recommendations we borrow heavily from the framework in the 2011 revised Recovery Plan, include examples of recent progress, and point out specific areas where the Department could engage more.

9.1 Actions

This document is not a Recovery Plan; however, it is useful to identify the conservation goals that the management recommendations are meant to achieve.

In brief, the USFWS Recovery Plan includes the following objectives:

1. Maintain self-sustaining populations of desert tortoises within each recovery unit into the future.
    - Criteria: Rates of population change for desert tortoises are increasing over at least 25 years (a single tortoise generation)
2. Maintain well-distributed populations of desert tortoises throughout each recovery unit.
    - Criteria: Distribution of desert tortoises throughout each tortoise conservation area is increasing over at least 25 years
3. Ensure that habitat within each recovery unit is protected and managed to support long-term viability of desert tortoise populations.

The major elements of the USFWS Recovery Plan strategy to achieve these objectives are:

1. Develop, support, and build partnerships to facilitate recovery.
2. Protect existing populations and habitat, instituting habitat restoration where necessary.
3. Augment depleted populations in a strategic manner.
4. Monitor progress toward recovery.
5. Conduct applied research and modeling in support of recovery efforts within a strategic framework.
6. Implement a formal adaptive management program.

For each element in the Recovery Plan strategy, the USFWS includes specific measures to contribute to the strategy. We do not list all these specific measures here, but instead discuss the elements and measures that are most relevant and important to recovery in California and highlight those which the Department may have a role in implementing.

1. Develop, support, and build partnerships to facilitate recovery

There are multiple existing partnerships to facilitate recovery of desert tortoise (see section 5.2 Management Efforts). The Department could become more active in the MOG, participate in Recovery Implementation Teams, and strengthen relationships with state and federal agencies to collaboratively address priorities such as highway fencing and translocation.

2. Protect existing populations and habitat, instituting habitat restoration where necessary

a. Conserve intact desert tortoise habitat

The majority of land (63.1%) in the tortoise range is under stewardship of the BLM or the NPS and receives some level of protection (see Table 7). Future habitat conservation efforts should consider how habitat suitability will change in the coming decades under predicted climate change and ways in which habitat can be restored and made more resilient and/or habitat degradation can be ameliorated.

b. Secure lands/habitat for conservation

Projects that will potentially result in incidental take of tortoises may apply for an ITP from the Department. As a condition of the ITP, the Department must require any impacts to the desert tortoise to be fully mitigated. This requirement is most often met through the perpetual protection and management of off-site habitat. The Department should continue to focus on securing high quality habitats through the ITP process and through other means (e.g., facilitating recovery land acquisitions through grants, facilitating conservation easements). The USFWS also issues take authorizations that ask for mitigation in the form of land protection. For more detail see section 5.2 Management Efforts.

Other agencies are actively involved in securing habitat. As mentioned previously, “the Army acquired approximately 100,000 acres (~405 km^2) of nonfederal land within the Superior-Cronese Critical Habitat Unit for conservation management of desert tortoises. It also purchased the base property of three cattle allotments on which the Bureau subsequently re-allotted the forage to wildlife" (USFWS 2022*a*).

c. Connect functional habitat

Low genetic differentiation among desert tortoise populations in California (Hagerty and Tracy 2010) suggests that historically there were few barriers to movements and mixing, aside from large mountain ranges and other significant climatic or vegetative barriers. However, this is effectively no longer the case, and habitat patches are separated by roads, housing, agriculture, industry, energy projects, and military activities.

The strategy outlined in the 1994 Recovery Plan suggests that habitat patches of at least 2,590 km^2 (1,000 mi^2) are needed in each recovery unit to "contain a viable population of desert tortoises that is relatively resistant to extinction processes" (USFWS 1994). Multiple TCAs are smaller than 2,590 km^2, therefore protecting corridors between TCAs so that tortoises can disperse is important for conservation. Tortoises within isolated patches are at higher risk of extirpation due to the usual risks to small populations—stochastic catastrophes like drought and fire, reduction in genetic variation, and potential associated losses of fitness (Boarman et al. 1997, Berry and Murphy 2019, USFWS 2022*a*). While many of the patches share the same threats, given the differences in land use and management across the desert tortoise's range, individual patches should be managed to minimize the most severe threats for that patch. The USFWS (2019a) points out that the current fragmented nature of desert tortoise habitat (e.g., urban and agricultural development, highways, freeways, military training areas) will make "recolonization of extirpated areas difficult, if not impossible."

Land is not equally protected across CHUs, creating potential barriers between areas of functional habitat. We recommend focusing compensatory habitat purchases and other types of land acquisitions on connecting functional habitat. The BLM is acquiring several thousand acres of checkerboard inholding in Chuckwalla Critical Habitat Unit which will improve connectivity to Joshua Tree National Park.

d. Fence, restrict, designate, close roads and routes

For functional habitat to be connected, tortoises need to be able to move and not be isolated in patches. A major action to achieve this is to establish safe tortoise road crossings and fence nearby areas along roads.

Erecting well designed tortoise exclusion fencing along major roadways and funneling them into appropriate crossings is a key recovery action. There are 500 km (~310 mi) of road identified as priority for fencing (USFWS 2022*a*). Currently, the regulations for highway fencing have made it extremely difficult and expensive to install tortoise fencing and are a major reason that there was very little tortoise exclusion fencing installed between 2011 and 2022. Under current practice, when an applicant applies for an ITP for a road project that includes tortoise exclusion fencing and culverts for crossing, the area of land inside the fence including the median between lanes of traffic is counted as impacted habitat that must be fully mitigated through land acquisition. The costs of procuring land adds substantial costs to fencing projects, to the point that much needed fencing is not being built. To speed up the building of fences, the

Department can work with Caltrans and other agencies to reduce cost and administrative burden of building tortoise exclusion fencing and can potentially broaden the measures considered to fully mitigate the impacts of road projects. In late 2023, there are some fencing projects in process, including the first phase of a BLM effort to build 3.5 miles of fencing along I-40 in the Rod-Ordman Critical Habitat Unit. In the Mojave National Preserve there is a road rebuilding project that includes 5 miles of tortoise fencing.

In addition to fencing paved roads, closing unauthorized OHV routes in CHUs is an important step to prevent further habitat degradation.

e. Minimize excessive predation on tortoises

Implementing multiple actions simultaneously is necessary to slow the expansion of predator populations. The DoD and the USFWS have active programs to reduce anthropogenic subsidies to ravens and coyotes by securing trash and water sources and reducing the number of raven nesting and roosting sites created by infrastructure. The USFWS has a program to reduce raven populations via egg oiling with a goal of no raven nests in priority areas for tortoise recruitment (K. Holcomb, USFWS Raven Management in CA. MOG April 16, 2022).

f. Restore desert tortoise habitat

Restore closed and unauthorized OHV trails and work to reduce non-native invasive grasses from desert tortoise habitat. Areas degraded by off road vehicles in Fremont Kramer Critical Habitat Unit are being restored by the BLM, and Marine Corps Air Ground Combat Center Twentynine Palms is restoring habitat as part of implementing the RASP.

g. Minimize factors contributing to disease (particularly upper respiratory tract disease)

Continue to discourage the release of pet tortoises into the wild. Monitor and quarantine translocated tortoises to make sure they are not diseased before relocation following recommendations in USFWS (2020).

h. Establish/continue environmental education programs

Environmental education is a preventative action that has been shown to effectively change learned behavior and can be used to reduce stakeholder conflict before it happens (Hungerford and Volk 1990). Educated citizens are more likely to be aware of the consequences they can have on desert tortoises and to be more willing to take responsibility for their actions than those with less knowledge (Vaske and Donnelly 2007). Widespread efforts in museums, hunting clubs, and in BLM and NPS visitor centers and interpretive sites are needed to inform the public about the status of the desert tortoise and its recovery needs (USFWS 2011).

Interpretive kiosks or visitor centers should be used to disseminate information about the desert tortoise and the need to minimize impacts on their habitat. Education programs should include such subjects as husbandry and adoption programs for captive tortoises, the importance of discouraging unauthorized breeding of captive tortoises, and state laws related to the release of captive tortoises. Education efforts should be focused on groups that use the desert on a regular basis, such as rock-hounds and off-highway vehicle enthusiasts. Additional educational tools include public service announcements, news releases, informational videos, brochures and newsletters, websites, and volunteer opportunities (USFWS 2011).

Mojave National Preserve has a "Drive Like a Tortoise" campaign to promote drivers to slow down both to decrease the number of vehicle collisions and road killed tortoises. Organizations like the Living Desert Zoo and Garden have billboards to promote the covering of trash to reduce subsidies to ravens.

i. Increase law enforcement
Increase efforts to enforce off-roading rules in Desert Wildlife Management Areas and CHUs.

3. Augment depleted populations through a strategic program

a. Translocation
The outcomes of translocation actions discussed in section 5.2 suggest that well designed translocation projects can result in short- and medium-term survival rates for translocated tortoises that are similar to resident tortoises. However, given the continuing decline of tortoise populations in general, translocations may often not be an effective conservation strategy without addressing the drivers of declines within the subject populations. At best, augmentation of populations through translocations can buy time and keep tortoises present on the landscape while the threats causing declines are addressed. In addition, given the long-term decline of tortoise populations, understanding the population impacts of translocation is critical so that they can be effectively incorporated into larger scale long-term strategic conservation goals (Germano et al. 2015). Projects that hold ITPs from the Department monitor translocated tortoises for 5 years and submit reports to the Department. These data should be organized and analyzed in order to understand medium-term survival rates of translocated individuals, and the impacts of potential population fragmentation (see section 9.3). Increased collaboration should occur between agencies that perform translocations to understand the landscape and population impacts of short- and long-range translocations and coordinate research on disease dynamics, recruitment rates, and gene flow (USFWS 2020*b*).

b. Head-starting
Head-starting is a strategy to try to circumvent the high mortality of juvenile tortoises in the wild. Population modeling suggests that increased juvenile survival can improve population growth rates. There is some evidence that this strategy is effective at least in the short term, however, mortality is high for juveniles smaller than 100 mm in length. Daly et al. (2019) points out that by itself, head-starting is unlikely to lead to population recovery if larger issues that depress survival such as raven density and habitat degradation are not addressed. Another consideration is that unless factors that depress adult survival are also addressed, focusing on putting more juveniles in a "degraded environment in which their parents have already demonstrated that they cannot flourish" is not an effective long-term solution (Frazer 1992).

Head-starting programs should continue to monitor the survival of juveniles and the effectiveness of the programs as a population augmentation measure.

4. Monitor progress toward recovery

The USFWS conducts surveys of the Tortoise Conservation Areas to generate estimates of density, abundance, and annual rates of change (see section 3.2 Trends in Density and Abundance). The USFWS (2011) also has detailed recommendations regarding population monitoring at the Recovery Unit scale.

The Department collects a variety of data on tortoises from holders of ITPs and Scientific Collecting Permits. Improving the capacity of the Department to summarize and analyze these data to identify the cumulative impacts of permitted projects on tortoise populations will help expand the geographic scope of monitoring and is key to developing criteria for decisions on potential limits to take for desert tortoise. Sharing this information with other state and federal agencies through the MOG will help bring a broader and more comprehensive understanding of the state of tortoise populations in California. In addition, the Department should continue to engage with the USFWS and other partners to address high priority monitoring needs through the Cooperative Endangered Species Conservation Fund (Traditional Section 6) Grant Program See sections 9.2 and 9.3 for more detail.

5. Conduct applied research and modeling in support of recovery efforts within a strategic framework

The 2011 USFWS Revised Recovery Plan includes many specific research and modeling actions needed to address desert tortoise recovery. Funding for continued long-term monitoring at sites outside of TCAs such as the Desert Tortoise Natural Area would expand our understanding of long-term trends in areas with different types of management. The Department should continue to engage with the USFWS and other partners to address high priority research needs through the Cooperative Endangered Species Conservation Fund (Traditional Section 6) Grant Program and other funding opportunities.

6. Implement a formal Recovery Plan

The Department has authority to develop and implement non-regulatory Recovery Plans and recovery criteria for CESA-listed species with the goal of improving the status of species and managing threats to the point where CESA listing may no longer be appropriate or necessary. The Department should consider whether adoption of the USFWS Recovery Plan, potentially with amendments, is warranted.

9.2 Regulations and Policy

Due to the number of interacting threats facing the desert tortoise, mitigation measures developed to mitigate impacts in ITPs could address a broader suite of conservation activities. Acquiring mitigation land is an important measure, but it only addresses a few of the recovery actions for the desert tortoise. The Department should consider all available actions that meet the “fully mitigated” standard for offsetting project impacts. All measures that support and improve populations should be considered as mitigation, including installing tortoise fencing along highways, habitat enhancement, management and control of raven populations, and measures that improve connectivity. Focusing on land acquisition at the expense of other measures could result in the protection of high-quality habitat but limited reductions in broader factors causing direct mortality or restricting movement between protected areas.

Another useful step would be to review the implementation and effectiveness of all ITPs issued since CESA listing. The Department may not issue an ITP if “issuance would jeopardize the continued existence of the species” (Fish & G. Code, § 2081, subd. (c).). Given the long-term decline of desert tortoise populations, a Department evaluation of prior mitigation measures would help it assess the impacts, both direct and cumulative, of subsequent projects proposing to incidentally take desert tortoises.

9.3 Capacity Building within CDFW

Personnel

For these Management Recommendations to be most consistently implemented and successful, staffing and/or funding capacity that can be devoted to developing, supporting, and building partnerships to facilitate recovery of the Mojave Desert Tortoise is needed. Adequate staffing facilitates internal coordination and knowledge-building, as well as regular coordination and collaboration with other agencies and organizations. Dedicated Department tortoise recovery staff could serve as a primary point of contact for desert tortoise permitting and facilitate better coordination internally and externally with those working on tortoise conservation and management.

Upgrading Systems

Currently, much of the Department review and issuance of ITPs for Mojave Desert Tortoise is done on a project-by-project basis, with some take permitted through Natural Community Conservation Plans and Habitat Conservation Plans like the Coachella Valley Multi Species Habitat Conservation Plan. Projects that apply for ITPs are required to collect data and submit compliance reports to the Department. Likewise, translocation projects are required to monitor results for five years and submit reports to the Department. There is currently no central location in the Department for those types of data and reports. Much of the old data, reports, and information is in paper form and is stored in various Department offices and is functionally inaccessible. Data on project locations, recipient sites, release points, disease testing locations with test results, and mitigation lands need to be stored digitally and made available in compliance with relevant Department scientific data policies. Without a central repository for data and platforms where it can be accessed and used by staff it is difficult to understand the scope and extent of impacts of development on tortoises. Consequently, the Department does not have a complete view of how many acres have been impacted, or the amount and location of habitat that has been conserved as mitigation and the success of that mitigation. However, a permitting system is currently in development that is intended to centralize and streamline the issuing of ITPs and other permits that will make it easier for the Department to make informed decisions on future incidental take permits and jeopardy determinations.

Colorado Desert	Joshua Tree	1.9 (0.53)	2.7 (0.79)	3.0 (1.94)	2.3 (1.75)	2.3 (1.56)	2.8 (1.56)	3.5 (1.33)	3.4 (1.63)	NA	3.7^{α}	NA	2.6 (34.7)	3.6 (22.5)	NA	3.1 (20.2)	3.9 (23.3)	NA

*724 adults were translocated into the Ord-Rodman TCA in 2017–2019 due to expansion at Twentynine Palms Marine Corps Air Gunnery Command Center. These are included in these density estimates. In 2014, the density estimates for the Western Mojave TCAs and Chocolate Mountain are estimated from line distance sampling (Allison and McLuckie 2018).

α= Estimates from Ivanpah and the Colorado Desert TCAs (excluding Chocolate Mountain) in 2014 are not based on line distance sampling in that year; they are mean densities based on trend data from previous years (USFWS 2022*a*)

APPENDIX B. PUBLIC NOTIFICATIONS

Pursuant to Fish and Game Code 2074.4, the California Department of Fish and Wildlife (Department) and the California Fish and Game Commission (Commission) notified affected and interested parties and solicited data and comments on the petitioned action to list Mojave Desert Tortoise as endangered under the California Endangered Species Act (CESA). Requests for information were distributed by several methods:

- On October 19, 2020, the Commission published a Notice of Findings regarding the candidacy and status review of the Mojave Desert Tortoise in the California Regulatory Notice Register (Cal. Reg. Notice Register 2020, No. 44-Z, p. 1445).
- On May 27, 2022, the Department distributed by email and mail the attached public notice to approximately 130 people and offices of state and federal agencies, industry, and non-governmental organizations, notifying them of the Mojave Desert Tortoise's candidacy and to request information and comments on the petitioned action.
- On May 10, 2022, the Department distributed the attached press release to an email listserv maintained by the Department's Office of Communication, Education and Outreach, and posted the press release to the Department's News Room website, notifying the public of the Mojave Desert Tortoise's candidacy and to request information and comments on the petitioned action.

Public Notice

May 27, 2022

SUBJECT: NOTIFICATION OF STATUS REVIEW FOR MOJAVE DESERT TORTOISE UNDER THE CALIFORNIA ENDANGERED SPECIES ACT

To Whom It May Concern:

The California Department of Fish and Wildlife (Department) has initiated a status review for the Mojave desert tortoise (*Gopherus agassizii*), pursuant to Fish and Game Code section 2074.6, and is providing this notice pursuant to Fish and Game Code section 2074.4 to solicit data and comments on the petitioned action from interested and affected parties.

The Department has initiated this status review following the Fish and Game Commission's (Commission) decision at its October 14, 2020 meeting to accept for consideration the petition to up-list the species from threatened to endangered under the California Endangered Species Act (CESA). Having provided public notice (Cal. Reg. Notice Reg. 2020, No. 44-Z, p. 1445; Fish & G. Code, § 2074.2), the Mojave desert tortoise is a candidate species under CESA, and as such, retains the same legal protection afforded to an endangered or threatened species (Fish & G. Code, §§ 2074.2 & 2085). The listing petition and the Department's petition evaluation report are available at: https://fgc.ca.gov/CESA#adt

Take (hunt, pursue, catch, capture, or kill, or attempt to do so) of the Mojave desert tortoise remains prohibited (Fish & Game Code § 86). However, Incidental Take may be authorized with appropriate permits (Fish & G. Code §§ 2081(b), 2080.1, 2089.2 et. seq., 2086). Activities conducted for scientific, educational, or management purposes including research and restoration, which may result in take of this species, can be authorized through permits or memorandums of understanding (Fish & G. Code § 2081(a)). For more information on take authorizations, visit https://wildlife.ca.gov/Conservation/CESA/Permitting or contact your regional Department office.

The Department requests any data or comments on the species' ecology, genetics, life history, distribution, abundance, habitat, the degree and immediacy of threats to its reproduction or survival, the adequacy of existing management, and recommendations for management of the species. Please provide such data or comments to the Department contact via email: Anne.Hilborn@wildlife.ca.gov, and include "Mojave desert tortoise" in the subject line. Comments may also be submitted by mail addressed to "Attn: Anne Hilborn" at the address in the letterhead.

The Department has 12 months to review the petition, evaluate the available information, and report back to the Commission whether the petitioned action is warranted (Fish & G. Code, § 2074.6). The written report will indicate, based on the best scientific information available, whether the Department concludes the petitioned action is warranted or not warranted. The Commission will place receipt of the report on the agenda for the next available Commission meeting after delivery. The report will be made available to the public at that meeting. Following receipt of the Department's report, the Commission will allow a 30-day public comment period prior to taking any action on the Department's recommendation.

The Department respectfully requests your responses and information before **June 25th, 2022,** to allow sufficient time to evaluate the information for possible incorporation in the Department's final status review report to the Commission.

If you have any questions regarding this notice, please contact the Department via email at: Anne.Hilborn@wildlife.ca.gov.

CDFW Seeks Public Comment Related to Mojave Desert Tortoise

The California Department of Fish and Wildlife (CDFW) is seeking public comment on a proposal to uplist the Mojave Desert Tortoise from threatened to endangered under the California Endangered Species Act (CESA).

The Mojave Desert Tortoise (*Gopherus agassizii*) is found in the Mojave Desert, the western Sonoran Desert and the southern Great Basin Desert. They spend much of the year underground in burrows to shelter from extreme temperatures. When they do emerge, they feed on native grasses. Their densities have declined drastically in many places in California in the past 20 years. Threats include habitat fragmentation, development in the desert including sustainable energy projects, increasing drought due to climate change, invasive grasses out-competing food items preferred by tortoise, disease, predation by coyotes and ravens, and human-caused mortality.

In March 2020, Defenders of Wildlife submitted a petition to the California Fish and Game Commission to formally uplist the Mojave Desert Tortoise as an endangered species under CESA. The Commission published findings of its decision to advance the species to candidacy on Oct. 14, 2020, triggering a period during which CDFW will conduct a status review to inform the Commission's decision on whether to uplist the species.

As part of the status review process, CDFW is soliciting public comment regarding the species' ecology, biology, life history, distribution, abundance, threats, and habitat that may be essential for the species, and any recommendations for management. Comments, data, and other information can be submitted by email to: wildlifemgt@wildlife.ca.gov. If submitting comments by email, please include "Mojave Desert Tortoise" in the subject heading.

Comments may also be submitted by surface mail to:

California Department of Fish and Wildlife
Wildlife Diversity Program
Attn: Anne Hilborn
P.O. Box 944209
Sacramento, CA 94244-2090

All comments received by June 10, 2022 will be evaluated prior to submission of the CDFW report to the Commission. Receipt of the report will be placed on the agenda for the next available meeting of the Commission after delivery and the report will be made available to the public at that time. Following the receipt of the CDFW report, the Commission will allow a 30-day public comment period prior to taking any action on the petition.

CDFW's Mohave Desert Tortoise petition evaluation report can be found on the CDFW website.

Public Response

The Department received 54 letters or emails from the public and 3 from NGOs/government agencies. Fifty four letters expressed or implied support for the listing of the Mojave Desert Tortoise under CESA. Three letters had no obvious stated stance.

The Department received 2 substantive comments. Information in the comments included previously published data on threats and population trends which has been addressed in the status review. One of the comments included unpublished location data that was not of a quality that could be included in the status review.

All communications are on file with the Department and can be provided on request by emailing wildlifemgt@wildlife.ca.gov.

APPENDIX C. TRIBAL NOTIFICATION

In June of 2022 the Department mailed and emailed the following notifications (see below) to 85 members of Tribal governments whose ancestral lands overlap with the historic range of the Mojave Desert Tortoise.

The Xolon Salinan Tribe and the Yuhaaviatam of San Manuel Nation asked some clarifying questions which staff were able to answer.

The Fernandeño Tataviam Band of Mission Indians reviewed the project and did not wish to engage in consultation.

The Rincon Band of Luiseño Indians acknowledged the receipt of the notification and asked to be kept informed of findings and determinations following the review.

Notification for Federally Listed Tribes

June 1, 2022

NOTIFICATION OF STATUS REVIEW FOR MOJAVE DESERT TORTOISE UNDER THE CALIFORNIA ENDANGERED SPECIES ACT

Dear Honorable Member:

NOTICE IS HEREBY GIVEN that the California Department of Fish and Wildlife (Department) has initiated a status review for Mojave desert tortoise (Gopherus agassizii) pursuant to Fish and Game Code section 2074.6. The Department is providing this notice pursuant to Fish and Game Code section 2074.4, and the Department's Tribal Communication and Consultation Policy, to solicit data and comments on the petitioned action from interested and affected parties and to notify California Tribes of this process and to offer government-to-government consultation if desired by a Tribe.

The Department has initiated this status review following related action by the Fish and Game Commission. Having provided public notice (Cal. Reg. Notice Reg. 2020, No. 44-Z, p. 1445; Fish & Game Code, § 2074.2), the Mojave desert tortoise is a candidate species under the California Endangered Species Act (CESA) and as such, retains the same legal protection afforded to an endangered or threatened species (Fish & Game Code §§ 2074.2 and 2085). The listing petition and the Department's petition evaluation report are available at: https://fgc.ca.gov/CESA#adt

The Department welcomes direct communication and consultation to discuss the status review for Mojave desert tortoise and to identify any impacts to Tribal interests or cultural resources. The Department is committed to open communication with your Tribe under its Tribal Communication and Consultation Policy, which is available through the Department's Tribal Affairs webpage at: https://www.wildlife.ca.gov/General-Counsel/Tribal-Affairs.

To request formal government-to-government consultation pursuant to the Department's Tribal Communication and Consultation Policy, please contact the Department's Tribal Liaison by email at tribal.liaison@wildlife.ca.gov. Please designate and provide contact information for the appropriate Tribal lead person.

In addition to notifying the Department of any impacts to tribal interests or cultural resources, the Department welcomes any data or comments on the species' ecology, genetics, life history, distribution, abundance, habitat, the degree and immediacy of threats to its reproduction or survival, the adequacy of existing management, and recommendations for management of the species. Please provide such data or comments to the Department contact via email wildlifemgt@wildlife.ca.gov and include "Desert Tortoise" in the subject line. Comments may also be submitted by mail addressed to "Attn: Anne Hilborn at the address in the letterhead.

The Department has 12 months to review the petition, evaluate the available information, and report back to the Commission whether the petitioned action is warranted (Fish & Game Code, § 2074.6). The written report will indicate, based on the best scientific information available, whether the Department concludes the petitioned action is warranted or not warranted. The Commission will place receipt of the report on the agenda for the next available Commission meeting after delivery. The report will be made available to the public at that meeting. Following receipt of the Department's report, the Commission will allow a 30-day public comment period prior to taking any action on the Department's recommendation.

The Department respectfully requests your responses and information before June 30th, 2022, to allow sufficient time to evaluate the information for possible incorporation in the Department's final status review report to the Commission. If you would like more information on the status review, please contact Anne Hilborn, Senior Environmental Scientist (Specialist) at anne.hilborn@wildlife.ca.gov or at the address in the letterhead.

We look forward to your response and input on this status review.

Sincerely,

Scott Gardner, Wildlife Branch Chief

ec: California Department of Fish and Wildlife

Chad Dibble, Deputy Director, Wildlife and Fisheries Division,

Tribal Liaison

Christine Found-Jackson, Acting Environmental Program Manager, Wildlife Diversity Program

Tribal Liaison

Christine Found-Jackson, Acting Environmental Program Manager, Wildlife Diversity Program

Anne Hilborn, Senior Environmental Scientist (Specialist), Wildlife Diversity Program

APPENDIX D. COMMENTS FROM PEER REVIEWERS ON THE MOJAVE DESERT TORTOISE STATUS REVIEW

Pursuant to Fish and Game Code section 2074.6, the review process included independent and competent peer review of the draft status review by persons in the scientific/academic community acknowledged to be experts on Mojave Desert Tortoise and related topics, and possessing the knowledge and expertise to critique the scientific validity of the status review contents. Appendix D contains the specific comments provided to the Department by the individual peer reviewers, the Department's written response to the comments, and any amendments made to the status review (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)(2)). Independent experts that reviewed the status review are listed in Table D1, below.

Table D1. Status Review Peer Reviewers

Name	Affiliation
Jeffery Lovich	USGS
Kristina Drake, Kerry Holcomb, Corey Mitchell	USFWS Desert Tortoise Recovery Office
Kenneth Nussear	University of Nevada, Reno

Comments by external reviewers and response from the Department. Line numbers refer to lines in the version of the status review sent to external reviewers (available at end of this appendix)

GENERAL COMMENT (Lovich): This is a very thorough and well-written review but there is a lot more literature available and I will point some out. The desert tortoise is one of the most-studied turtle in the United States (Lovich, J.E., and J.R. Ennen. 2013. A quantitative analysis of the state of knowledge of turtles of the United States and Canada. Amphibia-Reptilia 34:11-23.). Particularly surprising was finding no citation for Ernst and Lovich. 2009. Turtles of the United States and Canada. Johns Hopkins University Press. 827 pp. That book summarizes more data and publications on desert tortoises that are not included in this report. Based on the available scientific information presented, the CDFW makes a compelling case for listing the tortoise as endangered in California. The weight of scientific evidence presented supports the contention that populations continue to decline since their listing as threatened decades ago. However, extinction would probably take a long time to occur given the number of tortoises that still exist, their longevity, and the availability of topographic refugia to respond to global warming as pointed out by Cam Barrows' publications.
RESPONSE: Have added citations for Ernst and Lovich 1994 version of the book, especially in section 2 on Biology. Note: As stated in section 1.2, the status review "is not intended to be an

exhaustive review of all published scientific literature on Mojave Desert Tortoise; rather it is intended to summarize key points relevant to the status of the species and address regulatory report requirements. "

GENERAL COMMENT (DTRT): Throughout the report, the referenced findings related to translocation/augmentation outcomes and associated literature for *G. agassizii* do not reflect the full body of available literature. Please review the document and include appropriate references and findings translocation outcomes. For example, publications such as Brand et al. 2016, Dickson et al. 2019, Drake et al. 2012, Esque et al. 2010, Farnsworth et al. 2015, Field et al. 2007, Harju et al. 2019, Hinderle et al. 2015, Nafus et al. 2017, Nussear et al. 2012, Mack and Berry 2023 should all be considered cumulatively. Additionally, all most no information is available on the long-term effects of translocation. Only one published paper reports outcomes for translocated tortoises for 10 years (Mack and Berry 2023), and this study did not include resident and control tortoise comparisons, excluding the ability to evaluate the efficiacy of translocation. We need long-term studies (i.e., 15-25 yrs) with balanced designs (translocated, resident, and control tortoises) to evaluate translocation outcomes and its effectiveness as a conservation tool.
RESPONSE: Due to this and other feedback, the section on translocation was extensively altered. References were added (Brand et al. 2016, Dickson et al. 2019, Drake et al. 2012, Esque et al. 2010, Farnsworth et al. 2015, Field et al. 2007, Harju et al. 2019, Hinderle et al. 2015, Nafus et al. 2017, Nussear et al. 2012, Mack and Berry 2023), and specific statements about the efficacy of translocation were reworked.

GENERAL COMMENT (Nussear): Overall I agree with the assessment. Given that after more than 30 years of protection under both state and federal ESAs. While recovery planning efforts have been found to provide sound recommendations, difficulties in implementation and enforcement of implementations (e.g. maintaining closed roads and routes) have contributed toward continued habitat loss and degradation. With continued growth of urban areas and infrastructure, expansion of military training areas, expansive recreation, challenges of invasive species with respect to wildfire and nutrition, subsidization of key predators, and a changing climate the tortoise faces a challenging road to recovery, and indeed continues to decline in much of its range.
While the right decision for the species, this decision will no doubt draw scrutiny and contestation. Toward improving the factual evidence brought to bear, there are several areas were the literature cited could be improved as the attribution is either incorrect, or incomplete.

LINE 140 (DTRT)

Suggested edit: "his Status Review of the Mojave desert tortoise (*Gopherus agassizii*, tortoise; also known as Agassiz's desert tortoise)." Edit throughout document.
RESPONSE: The USFWS doesn't capitalize the full name, however the Department made the decision to fully capitalize Mojave Desert Tortoise.

LINE 144-158 (DTRT)

Suggested edit: The tortoise was designated a threatened species under CESA in 1989. On March 23, 2020, the Commission received a petition from Defenders of Wildlife, Desert Tortoise Council, and Desert Tortoise Preserve Committee to change the status of the tortoise

from threatened to endangered. On April 13, 2020, the Commission referred the Petition to the Department for evaluation pursuant to Fish and Game Code section 2073 and published a formal notice of receipt of the petition (Cal. Reg. Notice Register 2020, No. 18-Z, p. 693). At its meeting on August 20, 2020, the Commission received the Department's petition evaluation report. which was based on available information and recommended to the Commission that the petition be accepted. At its October 14, 2020, meeting, the Commission accepted the petition to change the status of the tortoise from threatened to endangered (Cal. Reg. Notice Register 2020, No. 44-Z, p. 1445). As a result, the Department was directed to complete this Status Review, which is a detailed evaluation of the current status of the tortoise and includes its recommendation regarding whether the tortoise's status should be changed from threatened to endangered.
RESPONSE: This section has been extensively reworked to get closer to statutory requirements

LINE 169-177 (DTRT)

Suggested edit: In 2011, studies of tortoise genetics, morphometrics, and ecology led experts to conclude that the species complex formerly known as the "desert tortoise" in fact consists of two separate species—Mojave desert tortoise ~~,~~and Sonoran desert tortoise (*G. morafkai*), (Murphy et al. 2011). Five years later, in 2016, the Sonoran desert tortoise was further split into two species – Sonoran desert tortoise and thornscrub tortoise (*G. evgoodei*) (Edwards et al. 2016). The Mojave Desert Tortoise~~,~~ retains the binomial *G. agassizii*, and ranges contemporarily across the Mojave and Sonoran deserts of southeastern California, southern Nevada, and small areas of Arizona north of the Colorado River as well as southwestern Utah.

LINE 172 (DTRT)

Citation for recommendation above: Murphy, R.W., Berry, K.H., Edwards, T., Leviton, A.E., Lathrop, A. and Riedle, J.D., 2011. The dazed and confused identity of Agassiz's land tortoise, Gopherus agassizii (Testudines, Testudinidae) with the description of a new species, and its consequences for conservation. *ZooKeys*, (113), p.39.
RESPONSE: The executive summary acts as an abstract without references. The Murphy et al. 2011 reference is cited in section 2.1 on Taxonomy

LINE 172 (DTRT)

Citation for recommendation above: Edwards, T., Karl, A.E., Vaughn, M., Rosen, P.C., Torres, C.M. and Murphy, R.W., 2016. The desert tortoise trichotomy: Mexico hosts a third, new sister-species of tortoise in the Gopherus morafkai–G. agassizii group. *ZooKeys*, (562), p.131.
RESPONSE: The executive summary acts as an abstract without references. The Edwards et al. 2016 reference is cited in section 2.1 on Taxonomy.
RESPONSE: This paragraph has been deleted but in the taxonomy section (2.1) the text now reads "In 2011, studies of tortoise genetics, morphometrics, and ecology led experts to conclude that the species complex formerly known as "Desert Tortoise" in fact consists of two separate species—Mojave Desert Tortoise and Sonoran Desert Tortoise (G. morafkai). The Mojave Desert Tortoise, also known as Agassiz's Desert Tortoise, retains the binomial G. agassizii, and ranges currently across the Mojave and Sonoran deserts of southeastern California, southern Nevada, and small areas of Arizona and Utah north of the Colorado River as well as southwestern Utah....... More recent work by Edwards et al. (2016) separates Desert tortoises living in the thorn scrub and tropical deciduous forests of southern Mexico into another species Gopherus evgoodei."

LINE 180 (Lovich)

I was surprised that no papers by David Germano were cited. This line should cite GERMANO, D. J. 1994. Growth and age at maturity of North American tortoises in relation to regional climates. Can. J. Zool. 72:918-931. AND GERMANO, D. J. 1994. Comparative life histories of North American tortoises. National Biological Survey, Fish and Wildlife Research 13.
RESPONSE: The executive summary acts as an abstract without references.

LINE 180 (DTRT)

Recommended citation for line 180: Peterson, C.C., 1996. Anhomeostasis: seasonal water and solute relations in two populations of the desert tortoise (Gopherus agassizii) during chronic drought. Physiological Zoology, 69(6), pp.1324-1358.
RESPONSE: The executive summary acts as an abstract without references. Pederson et al. 1996 is cited in section 2.2 on Life History

LINE 180 (DTRT)

Recommended citation for line 180: Medica, P.A., Nussear, K.E., Esque, T.C. and Saethre, M.B., 2012. Long-term growth of desert tortoises (Gopherus agassizii) in a southern Nevada population. *Journal of Herpetology*, pp.213-220.
RESPONSE: The executive summary acts as an abstract without references. Medica et al. 2012 has been added to the relevant text in section 2.2 on Life History

LINE 180 (Lovich)

30 eggs per year is impossible. This claim is later associated with a citation by Berry and Murphy but they say that nowhere in the publication. Instead, someone assumed that if tortoises can have up to 10 eggs in a clutch and up to three clutches/year they can produce 30. The literature says annual egg production can be 16-18 eggs, about half the number given.
RESPONSE: Altered text to read "typically lay one or two clutches of eggs (about 6 eggs per clutch)"

LINE 181 (DTRT)

Recommended citation for line 181: Mitchell, C.I., Friend, D.A., Phillips, L.T., Hunter, E.A., Lovich, J.E., Agha, M., Puffer, S.R., Cummings, K.L., Medica, P.A., Esque, T.C. and Nussear, K.E., 2021. 'Unscrambling' the drivers of egg production in Agassiz's desert tortoise: climate and individual attributes predict reproductive output. Endangered Species Research, 44, pp.217-230.
RESPONSE: The executive summary acts as an abstract without references. Mitchell et al. 2021 is cited IN relevant text in section 2.2 on Life History.

LINE 182 (DTRT)

Recommended citation for line 182: Spotila, J.R., Zimmerman, L.C., Binckley, C.A., Grumbles, J.S., Rostal, D.C., List Jr, A., Beyer, E.C., Phillips, K.M. and Kemp, S.J., 1994. Effects of incubation conditions on sex determination, hatching success, and growth of hatchling desert tortoises, Gopherus agassizii. *Herpetological Monographs*, pp.103-116.
RESPONSE: The executive summary acts as an abstract without references. Rostal et al. 2002 is a reference for incubation temperatures in section 2.2

LINE 182 (DTRT)

Recommended citation for line 182: Bjurlin, C.D. and Bissonette, J.A., 2004. Survival during early life stages of the desert tortoise (Gopherus agassizii) in the south-central Mojave Desert. Journal of Herpetology, pp.527-535.

RESPONSE: The executive summary acts as an abstract without references. Bjurlin and Bissonette 2004 is cited on relevant text in section 2.2 on Life History

LINE 175 - 179 (DTRT)

Suggested edit: The Mojave Desert Tortoise is a long-lived, desert-dwelling reptile. Consequently, tortoises must use behavioral and physiological adaptations to avoid extreme body temperatures <15 to >35°C (<59 to >95°F Zimmermann et al. 1994) and dehydration (Peterson 1996), as well as budget stored energy (Henen 1997, Peterson 1996) They primarily regulate their temperature by using underground burrows where the air is cooler and higher in humidity than ~~the~~ outside air in summer and warmer in winter, which results in tortoises spending more than 90% of their lives underground (Zimmermann et al. 1994).

RESPONSE: Text has been altered to "The Mojave Desert Tortoise is a long-lived, desert-dwelling reptile that uses behavioral and physiological adaptations to avoid extreme temperatures and dehydration, and to budget stored energy. Mojave Desert Tortoises primarily regulate their temperature by using underground burrows where the air is cooler and higher in humidity in summer, and warmer in winter. They can spend more than 90% of their lives underground." The executive summary does not contain references.

LINE 180-184 (DTRT)

Suggested edit: Females become sexually mature at 12–20 (mean 18.8, Medica et al. 2012) years old and typically lay one or two clutches of eggs (~ 6 eggs per clutch) per year; however, some females have been document to oviposit more than two clutches (Mitchell et al. 2021). Tortoise nests are typically placed near the mouth or entrance to the burrow or within suitable soil (Ennen et al 2012). Nest predation is common, with 12-26% of nests generally destroyed by predators (Ennen et al. 2012, Bjurlin & Bissonette 2004). Reported incubation time in the wild varies from 67–104 days (Berry and Murphy 2019) and incubation temperatures determine the sex of the hatchlings, with hotter temperatures (>32.8°C) producing female-skewed clutches (Spotila et al. 1994).

RESPONSE: The executive summary acts as an abstract without references. Text has been altered to read "Females become sexually mature at 12–20 years old, typically lay one or two clutches of eggs (about 6 eggs per clutch) per year. Nest predation is common, with 12–47% of nests lost to predators annually. Reported incubation time in the wild varies from 67–104 days and incubation temperatures determine the sex of the hatchlings, with hotter temperatures producing female-skewed clutches." 47% is the depredation rate on nests in 1998 in Bjurlin & Bissonette 2004. Suggested references (Medica et al 2012, Mitchell et al. 2021, Ennen et al. 2012, Bjurlin & Bissonette 2004) have been added to the relevant text in section 2.2 on life history.

Line 185-190 (Nussear)

Your summation of dietary preferences given in lines 185 to 190 is inaccurate - we have published information indicating that they neither avoid plants with high potassium, nor exotics - although these can be detrimental to health. With respect to annual forage they are really more of a generalist"

RESPONSE: The information referred to has been deleted.

LINE 185-186 (DTRT)

Suggested edit: Tortoises selectively feed on annual forbs, annual and perennial grasses, and herbaceous perennial plants and will consume some cacti.

RESPONSE: Done

LINE 191-198 (DTRT)

Suggested edit: Tortoise habitat typically occurs on alluvial fans and plains and colluvial/bedrock slopes that facilitate the digging of burrows. Tortoises need sufficient forage as well as large shrubs and bushes for shade and protection of burrows. They are associated with saltbush, creosote bush, white bur-sage, and cheesebush. At higher elevations, tortoises are more likely to be found near Joshua tree, Mojave yucca, and blackbrush. Tortoises occur in very low densities or are absent where shrub cover is sparse, and annual food plants are available only intermittently (e.g., the lower elevations in Death Valley). They also occur at low densities in moderately to severely disturbed areas, regardless of desert or region.
RESPONSE: The executive summary has been shortened and much of this paragraph has been cut.

LINE 191 (Lovich)

G. agassizii can also occupy boulder piles as they often do in Joshua Tree National Park. See Cummings, K.C., J.E. Lovich, S.R. Puffer, T.R. Arundel, and K.D. Brundige. 2020. Micro-geographic variation in burrow use of Agassiz's desert tortoises in the Sonoran Desert of California. Herpetological Journal 30:177-188.
RESPONSE: The executive summary is not that detailed but have added "by using underground burrows or rock shelters (Cummings et al., 2020)" in the relevant place in section 2.2.

LINE 197-198 (DTRT)

A terrestrial development index of approximately 7 (or 7% developed) resulted in mean maximum encounter rates of live tortoise that approached zero -- see Carter et al. 2020. Recommended citation - Carter, S.K., Nussear, K.E., Esque, T.C., Leinwand, I.I., Masters, E., Inman, R.D., Carr, N.B. and Allison, L.J., 2020. Quantifying development to inform management of Mojave and Sonoran desert tortoise habitat in the American southwest. Endangered Species Research, 42, pp.167-184.
RESPONSE: The results from Carter et al 2020 are discussed in section 4.1 on habitat modification and destruction.

LINE 199-201 (DTRT)

Suggested edit: Ravens are a major predator of juvenile tortoises while coyotes target both juvenile and adult tortoises. Raven populations have expanded dramatically in the desert due to resource subsidies from humans (Holcomb et al. 2021).
RESPONSE: The executive summary acts as an abstract without references. Holcomb et al. 2021 is cited in section 4.4 on Predation.

LINE 201 (DTRT)

Recommended citation for Line 201: Holcomb, K.L., Coates, P.S., Prochazka, B.G., Shields, T. and Boarman, W.I., 2021. A desert tortoise–common raven viable conflict threshold. *Human–Wildlife Interactions*, *15*(3), p.14.
RESPONSE: The executive summary acts as an abstract without references. Holcomb et al. 2021 is cited in section 4.4 on Predation.

LINE 203-207 (DTRT)

Suggested edit: In California, the range of the tortoise includes the Mojave Desert and Colorado Subunit of the Sonoran Desert and even a sliver of the Great Basin desert~~s~~, from the southern end of the Owens Valley south of the town of Lone Pine in Inyo County to the Mexican border

near the southeastern corner of the state, and from the Colorado River in the east to the lower slopes of the Peninsular , Sierra Nevada, and Transverse mountains in the west.
RESPONSE: The executive summary has been shortened and much of this text has been cut. Text now reads "In California, the range of the Mojave Desert Tortoise includes the Mojave Desert and portions of the Sonoran and Great Basin deserts. "

LINE 208 (DTRT)

Surveys began in 2001. Edit accordingly.
RESPONSE: Done

LINE 210-221 (DTRT)

Suggest updating tortoise trends based on Zylstra et al. 2023:
Zylstra, E.R., Allison, L.J., Averill-Murray, R.C., Landau, V., Pope, N.S. and Steidl, R.J., 2023. A spatially explicit model for density that accounts for availability: a case study with Mojave desert tortoises. Ecosphere, 14(3), p.e4448.
RESPONSE: Have updated this using the results from Zylstra et al. 2023.

LINE 233 (DTRT)

Comment to line 233 "critical habitat units" - Critical habitat was designated based on the best available data available prior to 1994. The Service considers Critical habitat to be areas considered essential for the conservation of a listed species.
RESPONSE: The relevant sentence has been removed in the editing of the executive summary

LINE 255 (DTRT)

This statement is incorrect. "large scale translocations do not tend to have high survival rates". Most unpublished and published data related to small scale and large scale translocations indicate that survival is similar between resident, control, and translocated tortoises. Mortality rates do vary by rate based on climate (drought), habitat condition, and predator-prey dynamics in the area.
RESPONSE: Have deleted this sentence following a re write of the translocation section.

LINE 255 (Nussear)

Your statement on translocations on line 255 is potentially misleading: *"Large scale tortoise translocations do not tend to have high survival rates."* What have you defined as a high survival rate? Is this relative to 100%? Relative to resident and control populations inhabiting the same areas and conditions? The potential losses if tortoises are otherwise removed, or worse yet left in place where development or increased military training will occur? Without explicit decisions about what your criteria are this sounds arbitrary
RESPONSE: Have deleted this sentence following a rewrite of the translocation section.

LINE 223-225 (DTRT)

Suggested edit: The population data available indicate that there were sharp drops in density before listing as threatened, and those losses have continued to the point where most tortoise habitats no longer supports viable tortoise densities and adult densities are rapidly declining.
This sentence has been deleted following a rewrite of the population status due to using Zylstra et al. 2023.

LINE 226-236 (DTRT)

Suggested edit: The slow maturation and low reproductive rates of tortoises mean~~s~~ that if past and current management is successful at addressing threats and stemming the decline of tortoise populations, it would still take at more than 25 years of positive population growth to

reach the USFWS Recovery Criteria (U.S. Fish and Wildlife Service 2022*a*). For example, the USFWS 1994 Recovery Plan estimates that when adult survivorship is 98%, population growth would be less than 0.5% per year, and would take 140 years to double in size. Contemporary annual survival rates for both adults and juveniles are much lower than 98% in all areas, making population stability, let alone growth, unlikely. Collectively, the available data show that in the critical habitat units, tortoise densities are low to very low, and despite 30 years of state and federal protection as a threatened species, tortoise populations continue to decline and do not show consistent signs of recovery.
RESPONSE: This paragraph has been reworked to shorten the executive summary. It now reads in part "For example, the USFWS 1994 Recovery Plan estimates that when adult survivorship is 98%, population growth would be less than 0.5% per year, and would take 140 years to double in size. Annual survival rates for both adults and juveniles are much lower than 98% in most areas, and since the late 1970s, the number of juveniles detected on surveys has also fallen sharply, to the point that in some recent surveys in the western Mojave Desert almost no juveniles were found. "

LINE 238-241 (DTRT)

Suggested edit: The dramatic declines of tortoise populations are likely due to the extensive number and interconnected nature of the threats they face. The important threats fall into two categories, those that directly kill adults and juveniles, and those that cause longer-term changes to habitat availability and quality.
RESPONSE: Done

LINE 242-249. (DTRT)

Suggested edit: In long-lived species that are slow to reproduce, decreased survival has long lasting impacts on the population viability and can alter demographic rates for decades. Increased numbers of predators including ravens and coyotes reduce the survival of juvenile and adult tortoises, respectively. Development within the tortoise range often creates roads that can lead to road-killed tortoises, and extensive networks of trails for off highway vehicles on public land increase the chance that tortoises will be run over in areas without paved roads. Moreover, road infrastructure provides subsidies in the form of roadkill and garbage to ravens and coyotes. Well-designed fences and culverts can help prevent tortoises and other wildlife from being killed by vehicles along major roads, but little fencing has been built since 2011.
RESPONSE: Done

LINE 250-255 (DTRT)

Suggested edit: Habitat modification, fragmentation, and destruction reduces the amount of habitat that can support tortoises in the long-term and reduce the size of remaining habitat patches. Although a large proportion of the tortoise’s range is under federal control, renewable energy, housing, illegal cannabis, and other types of development reduce the amount of habitat available. Most concerningly, subsidized predators like the raven and coyote leverage habitat fragmentation and disturbances to expand their densities throughout “undisturbed” habitats. The Department of Defense is a large landowner in the tortoise’s range and frequently expands the areas that it uses for training, requiring the translocation of hundreds of tortoises. Large scale tortoise translocations do not tend to have high survival rates.
RESPONSE: Done

LINE 256 (Nussear)

Line 256: the effects of climate change are likely under stated you state "Additional factors have direct and indirect impacts on tortoises and their habitat. Climate change, which is likely to cause hotter and periodically drier conditions in the desert tortoise range, will increase their physiological stress and change activity patterns." it will likely make areas of habitat unsuitable, potentially alter reproduction, hibernation, and many other facets of tortoise ecology. I think this is well beyond the changing of activity patterns and increased physiological stress. I think that Barrows did a paper on this with tortoises in Joshua tree, and there is certainly more that could be referenced here.
RESPONSE: Have added "In combination, the impacts of climate change will likely result in less available suitable habitat." But this is a brief summary, and section 4.6 on Climate change and drought goes into more detail.

LINE 259 (DTRT)

Suggested edit: The nutritious native vegetation tortoises feed on is being outcompeted
RESPONSE: Done

LINE 270-274 (DTRT)

Consider updating with Zylstra et al. 2023 density information. "However, there is still a large amount of available habitat and even at low densities, in 2014 there were estimated to be more than 61,000 adult tortoises within the TCAs. This is a decrease from an estimated 310,000 adults in 2004, and as densities have continued to fall since 2014, current abundance is likely lower than 60,000 adult tortoises".
RESPONSE: Have updated with information from Zylstra et al. 2023

LINE 356 (Lovich)

What about G. evgoodi? See EDWARDS, T., A. KARL, M. VAUGHN, P. ROSEN, C. MELÉNDEZ TORRES, AND R. W. MURPHY. 2016. The desert tortoise trichotomy: Mexico hosts a third, new sister-species of tortoise in the Gopherus morafkai–G. agassizii group. ZooKeys. 562:131-158.
RESPONSE: Have added "More recent work by Edwards et al. (2016) separates Desert tortoises living in the thorn scrub and tropical deciduous forests of southern Mexico into another species Gopherus evgoodei. "

LINE 366 (Lovich)

There are G. agassizii and hybrids "east of the Colorado River in the Kingman area of AZ. See EDWARDS, T., K. H. BERRY, R. D. INMAN, T. C. ESQUE, K. E. NUSSEAR, C. A. JONES, AND M. CULVER. 2015. Testing taxon tenacity of tortoises: evidence for a geographical selection gradient at a secondary contact zone. Ecology and Evolution. 5:2095-2114.
RESPONSE: Have added "However, there is “anomalous" population of G. agassizii east of the Colorado River in the Black Mountains of Arizona (Edwards et al. 2015)."

LINE 357-362 (DTRT)

Suggested edit: Desert tortoises are members of the order Testudines, family Testudinidae, genus *Gopherus*. When the Commission listed Desert Tortoise as threatened in 1989, *Gopherus agassizii* was understood to range from southeastern California, across southern Nevada, through western Arizona, and south into Sonora and Sinaloa, Mexico. In 2011, studies of tortoise genetics, morphometrics, and ecology led experts to conclude that the complex formerly known as “desert tortoise” in fact consists of two separate species, Mojave desert tortoise and Sonoran desert tortoise (Murphy et al. 2011, Iverson et al. 2017). Five years later,

in 2016, the Sonoran desert tortoise was further split into two species – Sonoran desert tortoise and thornscrub tortoise (G. evgoodei) (Edwards et al. 2016).
RESPONSE: Text now reads "More recent work by Edwards et al. (2016) separates Desert tortoises living in the thorn scrub and tropical deciduous forests of southern Mexico into another species Gopherus evgoodei."

LINE 363-365 (DTRT)

Suggested edit: "Desert tortoises east of the Colorado River in Arizona and northern Mexico are now classified as Sonoran desert tortoise, also known as Morafka's desert tortoise (*Gopherus morafkai*)." See the 2022 USFWS 5-year review for more details regarding tortoise populations found east of the Colorado River that are genetically G. agassizii.
RESPONSE: See above comments for additions to text regarding this population of tortoises. This document is California specific and doesn't focus on this population.

LINE 379 (Lovich)

what about the largest female they reported? It was bigger
RESPONSE: Have amended sentence to "Generally males are larger than females (Ernst and Lovich 1994) but the largest measured wild individual was a female in 1986 whose carapace length was 374 mm (Berry and Murphy 2019)"

LINE 396 (Lovich)

See comment in line 4 of the spreadsheet
RESPONSE: This references the comment about line 191 and the text in section 2.2 now reads "by using underground burrows or rock shelters (Cummings et al., 2020)"

LINE 397 (DTRT)

Medica et al. 2012 reported a mean of 18.8, please include.
RESPONSE: Done

LINE 402 (DTRT)

Citation referenced above. Include in literature. Mitchell, C.I., Friend, D.A., Phillips, L.T., Hunter, E.A., Lovich, J.E., Agha, M., Puffer, S.R., Cummings, K.L., Medica, P.A., Esque, T.C. and Nussear, K.E., 2021. 'Unscrambling' the drivers of egg production in Agassiz's desert tortoise: climate and individual attributes predict reproductive output. *Endangered Species Research*, *44*, pp.217-230.
RESPONSE: Done

LINE 403 (Nussear)

Line 403: "There are anecdotal reports of females nest guarding against humans and Gila Monsters, but there is no parental care once eggs have hatched (Berry and Murphy 2019)"
This is the wrong reference to cite here - you should probably cite Gienger and Tracy 2008
In general throughout this assessment it appears that you put entirely too much emphasis on Berry and Murphy 2019 - rather than more direct references.
RESPONSE: Changed to "Tortoise nests are typically placed near the mouth or entrance to the burrow or within suitable soil (Ennen et al. 2012), and there is no parental care once eggs have hatched (Berry and Murphy 2019)." Made the changes since Gila Monsters not being widespread in California and human attacks on nests not necessarily being a major issue.

LINE 404 (DTRT)

"Gila Monsters": Gila monsters occur at low densities in only a few locations in California and likely do not pose a threat to tortoise nest success for this reason.

RESPONSE: Changed to "Tortoise nests are typically placed near the mouth or entrance to the burrow or within suitable soil (Ennen et al. 2012), and there is no parental care once eggs have hatched (Berry and Murphy 2019). "due to Gila Monsters not being widespread in California and human attacks on nests not necessarily being a major issue

LINE 392-394 (DTRT)

Suggested edit: They also found that the overlap in the area in an individual's home range from one year to the next was ~35% and did not vary significantly by sex. Individuals tend to have fidelity to home ranges and activity centers, even after a fire (Drake et al. 2015, Lovich et al. 2018).

RESPONSE: Done

LINE 401-402 (DTRT)

Suggested edit: Females lay 0–3 clutches in the spring and the number of eggs laid per clutch ranges from 1–10. Females typically lay one or two clutches of eggs (~ 6 eggs per clutch) per year; however, some females have been document to oviposit more than two clutches (Mitchell et al. 2021). Tortoise nests are typically placed near the mouth or entrance to the burrow or within suitable soil (Ennen et al 2012).

RESPONSE: Done

LINE 403-404 (Lovich)

Not true. See Agha, M., J.E. Lovich, J.R. Ennen, and E. Wilcox. 2013. Nest-guarding by female Agassiz's desert tortoise (Gopherus agassizii) at a wind-energy facility near Palm Springs, California. The Southwestern Naturalist 58:254-257.

RESPONSE: Changed to "Tortoise nests are typically placed near the mouth or entrance to the burrow or within suitable soil (Ennen et al. 2012), and there is no parental care once eggs have hatched (Berry and Murphy 2019). " due to Gila Monsters not being widespread in California and human attacks on nests not necessarily being a major issue

LINE 409 (DTRT)

Replace 52% with 26%. Nest predation is common, with 12–26% . Comment - I cant seem to find 55% nest predation stat in Berry and Murry 2019. Please revise accordingly.

RESPONSE: Percentages changed to 26-47% based on yearly numbers in Bjurlin and Bissonette 2004

LINE 410 (Nussear)

Line 410: "When nests are not predated, hatchling success is about 80% " - The verb here should be depredated, predated is to come before something - e.g. [pree-deyt] verb (used with object), pre·dat·ed, pre·dat·ing. to date before the actual time; antedate: He predated the check by three days. to precede in date: a house that predates the Civil War.

RESPONSE: Done

LINE 412 (DTRT)

Delete "At that age they become less vulnerable to predators.

RESPONSE: Done

LINE 418 (DTRT)

Add scientific names to "red brome, cheat grass, red stem filaree, and African mustard".

RESPONSE: Done

LINE 419 (Nussear)

Line 419–420: "but tortoises avoid eating exotic grasses when possible as they are low in nitrogen and require relatively large amounts of water to process."
no, they don't. See Esque 1984, and Tracy et al. 2006
RESPONSE: Deleted. Text now reads "Much of the range of the desert tortoise is highly invaded by nonnative plants including grasses like red brome (Bromus rubens) and cheatgrass (Bromus tectorum). Experimental studies found that grass diets that included no forbs were detrimental to tortoises, leading to weight loss, poor body condition, or even death (Hazard et al. 2009, Drake et al. 2016). This was the case even when the diet included native grasses (Drake et al. 2016). "

LINE 433 (Nussear)

Line 433: Berry and Murphy (2019) report that desert tortoises spend >90% of their lives underground. - this has been reported by numerous other studies, and entirely too much accredited to this reference - see also lines 438 - 441. kines 444 - 445, and I can't even list how many places. Repeatedly gives the appearance of a really shallow review of the primary literature.
RESPONSE: Noted, and the thoroughness of the citations provide throughout is appreciated. However, as stated in section 1.2, the status review " is not intended to be an exhaustive review of all published scientific literature on Mojave Desert Tortoise; rather it is intended to summarize key points relevant to the status of the species and address regulatory report requirements."

LINE 435 (Lovich)

You may want to cite HUTCHISON, V. H., A. VINEGAR, AND R. J. KOSH. 1966. Critical thermal maxima in turtles. Herpetologica. 22:32-41. and ZIMMERMAN, L. C., M. P. O'CONNOR, S. J. BULOVA, J. R. SPOTILA, S. J. KEMP, AND C. J. SALICE. 1994. Thermal ecology of desert tortoises in the eastern Mojave Desert: seasonal patterns of operative and body temperatures, and microhabitat selection. Herpetological Monographs. 8:45-59.
RESPONSE: Have expanded the range of temperatures when tortoises go to shade based on info in Zimmerman et al 1994

LINE 447 (Lovich)

See Ennen, J.R., K.P. Meyer, and J.E. Lovich. 2012. Female Agassiz's desert tortoise activity at a wind energy facility in southern California: the influence of an El Niño event. Natural Science 4:30-37. doi:10.4236/ns.2012.41006.
RESPONSE: Changed/ added so text now reads "Tortoises moved less, used fewer burrows, and had smaller home ranges during drought years as compared to wet years in the mid-1990s (Duda et al. 1999). However, at a different site in the late 1990s, the relationships between precipitation and activity area, rate of movement, and burrows used were less clear (Ennen et al. 2012), suggesting that there are many interacting forces that determine tortoise activity and movement levels**."**

LINE 409-412 (DTRT)

Suggested edit: Nest predation is common, with 12–26% of nests generally destroyed by predators (Berry and Murphy 2019, Ennen et al. 2012, Bjurlin & Bissonette 2004). When nests are not predated, hatchling success is about 80% (Bjurlin and Bissonette 2004). Newly hatched tortoises are about 4–5 cm in length (Bjurlin and Bissonette 2004) and their shells do not fully ossify until they are 5–7 years old. For more information about predation, see section 4.4.

RESPONSE: Percentages changed to 26-47% based on yearly numbers in Bjurlin and Bissonette 2004

LINE 434-436 (DTRT)

"Tortoises are active when their body temperatures are between 19.0°C and 37.8°C (66.2–100°F), they retreat to shade when body temperatures are 37–38°C (98.6–100.4°F), and body temperatures of 43°C (109.4°F) are deadly (Brattstrom 1965)". Review and add Zimmerman, L.C., O'Connor, M.P., Bulova, S.J., Spotila, J.R., Kemp, S.J. and Salice, C.J., 1994. Thermal ecology of desert tortoises in the eastern Mojave Desert: seasonal patterns of operative and body temperatures, and microhabitat utilization. Herpetological Monographs, pp.45-59.
RESPONSE: Have expanded the range of temperatures when tortoises go to shade based on info in Zimmerman et al 1994

LINE 460-461 (Nussear)

Lines 460–461: "Therefore, desert tortoise habitat typically consists of alluvial fans and plains and colluvial/bedrock slopes (Nussear et al.
2012)". This isn't the best reference for this, how about Germano 1994, or Nussear and Tuberville 2014? See also 465 and 466
RESPONSE: Have changed citation to Germano et al. 1994

LINE 515-417 (DTRT)

Delete these sentences "Tortoises favor native plants and plant parts that are high in water and low in potassium (Oftedal et al. 2002). Potassium is potentially toxic and requires a large amount of water and nitrogen to excrete.".
RESPONSE: Deleted

LINE 451 (Lovich)

Citation?
RESPONSE: Have added Ernst and Lovich 1994 as a reference to this cluster of sentences

LINE 461 (Lovich)

How about burrows under caliche layers?
RESPONSE: Although not mentioned specifically, this sentence is sufficiently broad enough to cover caliche layers. “Due to their dependence on burrows, they require soils, topography, geological features, and vegetation that facilitate the creation of burrows or dens (Andersen et al. 2000).”

LINE 482 (Lovich)

Berry 1984 not in lit cit
RESPONSE: Citations within a quote are not included in the bibliography

LINE 485 (Lovich)

Lower elevation areas free of tortoises include the Salton Trough. See Lovich, J.E., T. Edwards, K.H. Berry, S. Puffer, K. Cummings, J. Ennen, M. Agha, R. Woodard, K. Brundige, and R.W. Murphy. 2020. Refining genetic boundaries in the western Sonoran Desert for Agassiz’s desert tortoise (Gopherus agassizii): the influence of the Coachella Valley on gene flow among populations in southern California. Frontiers of Biogeography 12:1-14. https://escholarship.org/uc/item/54r0m1cq.
RESPONSE: Have added some text to the section on range and distribution "While caution should be used in using these types of data, there appear to be fewer occurrences in the

northern part of the range and in the Death Valley/Mojave Central Trough (see grey area on Figure 3), and few occur in low areas near the Salton Sea (Lovich et al. 2020)**."**

LINE 494 (DTRT)

Suggested edit: In California, the range of the Mojave Desert Tortoise includes the Mojave Desert and portions of the Colorado subunit of the Sonoran and Great Basin Deserts
RESPONSE: Done

LINE 507 (DTRT)

Suggested edit: In 2016, park staff began surveying for tortoises and formally collecting incidental observation data, and subsequent genetic analysis of tortoise blood and scat suggested “evidence of a naturally reproducing Mojave desert tortoise population in Anza Borrego Desert State Park” (Manning 2018).
RESPONSE: Done

LINE 516-520 (DTRT)

Suggested edit: The distribution of desert tortoises within California is uneven, and portions of the range no longer provide suitable tortoise habitat due to agriculture, development, and military activity. Data on tortoise occurrences from the California Natural Diversity Database (CNDDB) and the Global Biodiversity Information Facility (GBIF) were used to plot the distribution
RESPONSE: Done

LINE 548 (DTRT)

"Outbreeding depression has not been studied in G. agassizii." Also see Averill-Murray and Hagerty 2014 for discussion/calculations related to outbreeding depression. Translocation Relative to Spatial Genetic Structure of the Mojave Desert Tortoise,
Gopherus agassizii. Chelonian Conservation and Biology 13:35-41.
RESPONSE: Altered text to read "Outbreeding depression has not been well studied in G. agassizii; however, the potential negative impacts of outbreeding are expected to occur at long time scales (~600 years; Averill-Murray and Hagerty 2014). This suggests that habitat quality and predator numbers are more important than outbreeding depression when evaluating suitable recipient sites for translocation. Despite this, Sánchez-Ramírez et al. (2018) advise caution when moving tortoises long distances for translocation or population augmentation. For more details about translocations see section 5.2"

LINE 538-551 (DTRT)

Please also consider Scott, P.A., Allison, L.J., Field, K.J., Averill-Murray, R.C. and Shaffer, H.B., 2020. Individual heterozygosity predicts translocation success in threatened desert tortoises. Science, 370(6520), pp.1086-1089. and the Translocation of Mojave Desert Tortoises from Project Sites: Plan Development Guidance:
https://www.fws.gov/sites/default/files/documents/Revised%20USFWS%20DT%20Translocation%20Guidance.20200603final.pdf
RESPONSE: This paper is focused on tortoises from captive origins, and is not a great fit for this section of the status review.

LINE 638 (DTRT)

The use of square transects with 3 km sides was initiated in 2004, prior to this different transect lengths/shapes were used for line distance surveys

RESPONSE: Added text "In 2001–2003, two person teams surveyed TCAs using line transect surveys. Transects were searched out to 8–10 m from the centerline. The shape and length of the transect changed year to year (USFWS 2006). Starting in 2004, square transects with 3 km sides were set up to provide good coverage of each TCA, and a random selection of these transects are surveyed each year."

LINE 649 (DTRT)

As currently presented, the estimates in Table 2 for 2014 do not represent a survey in IV, CK, CM, FE, PT, or JT, but rather an extrapolated estimate based on trends outlined in USFWS 2022a. Recommend updating the table to reflect either only years surveyed or adding notation to differentiate.

RESPONSE: Following the inclusion of Zylstra et al. 2023, this table has been moved to the Appendix. Have listed the density estimates from line sampling from Allison and McLuckie, and bolded the densities estimated from trends as presented in USFWS 2022a. Added following text to legend "In 2014, the density estimates for the Western Mojave TCAs and Chocolate Mountain are estimated from line distance sampling and are found in Allison and Mcluckie (2018). The bolded estimates from Ivanpah and the Colorado Desert TCAs (excluding Chocolate Mountain) come not from that years' line distance sampling but are mean densities calculated from trends using data from previous years (USFWS 2022a)"

LINE 639-640 (DTRT)

Suggested edit: Two surveyors walk line transects along the boundary of the square or as close to it as is feasible, where the lead surveyor walks in a straight line on a specified compass bearing, trailing 25m of cord, and the second crew member follows at the end of the line.

RESPONSE: Done

LINE 640-642 (DTRT)

Suggested edit: They record the distance and bearing from the survey line to all tortoises seen and live tortoises are measured and sexed. In addition, data from tortoises carrying radio transmitters are used to estimate what portion of tortoises are above ground. These data are then used to calculate the proportion of tortoises that are detectable during the entire period transects are walked in an area.

RESPONSE: Text modified to "In addition, data from tortoises carrying radio transmitters are used to estimate what portion of tortoises are above ground and detectable during the transects."

LINE 684 (DTRT)

Spatially explicit estimates based on line distance data presented in Zylstra et al. 2023 demonstrate that in 2020 all TCA's are below the 3.9 threshold.

Have updated this section to use results from Zylstra et al 2023

LINE 682-685 (DTRT)

"The most recent surveys (2019–2021) show that in the Eastern and Western Mojave Recovery Units, all of the TCAs surveyed were below the 3.9 adult tortoises/km2 threshold. In the Colorado Desert Recovery Unit, two were at the threshold, two were below it, and only one TCA (Fenner) was above (U.S. Fish and Wildlife Service 2022a)". Comment - Spatially explicit estimates based on line distance data presented in Zylstra et al. 2023 demonstrate that in 2020 all TCA's are below the 3.9 threshold.

RESPONSE: Have updated this section to use results from Zylstra et al 2023

LINE 688 (DTRT)

Recommend updating figures 8 and 9 based on updated values in Table 2

RESPONSE: Done

LINE 698 (DTRT)

Table 2. 2014, density estimate values listed for this year come from two different sources, estimates calculated from annual line distance sampling in TCAs (Chocolate Mtn and SC; Allison and McLuckie 2018) and extrapolated estimates based on trends (all other TCAs) from USFWS 2022a. However, FK and OR were also surveyed in 2014. Recommend consistency in citing estimates, either 1) list density estimates for all areas surveyed in 2014 (AG, SC, FK, OR) from Allison and McLuckie 2018, include extrapolated estimates for other TCAs not surveyed and **add notation to differentiate** OR 2) list extrapolated estimates for all **including notation to differentiate extrapolated estimates** from actual years surveyed.

RESPONSE: Following the inclusion of Zylstra et al. 2023, this table has been moved to the Appendix. Have listed the density estimates from line sampling from Allison and McLuckie, and bolded the densities estimated from trends as presented in USFWS 2022a. Added following text to legend "In 2014, the density estimates for the Western Mojave TCAs and Chocolate Mountain are estimated from line distance sampling and are found in Allison and McLuckie (2018). The bolded estimates from Ivanpah and the Colorado Desert TCAs (excluding Chocolate Mountain) come not from that years' line distance sampling but are mean densities calculated from trends using data from previous years (USFWS 2022a)"

Table 2, 2018, please correct the coefficient of variation for the Ord-Rodman estimate from 20.79 to 30.79 (USFWS 2019b)

RESPONSE: Done

LINE 698 (DTRT)

Table 2, 2019, missing values for Chocolate Mountain, please update (USFWS 2020a)

RESPONSE: Done

LINE 700 (DTRT)

Table 2, need to add USFWS 2022a citation

RESPONSE: Done

LINE 718 (Lovich)

Estimating live tortoises from sign is not a reliable method.

RESPONSE: Added text "These early monitoring programs sometimes relied on tortoise sign (tracks, scats, burrows, or carcasses) as well as observations of live tortoises, or employed mark-recapture methods to obtain estimates of abundance or density. It should be noted that survey methods that rely on sign to estimate numbers of live tortoises are not reliable. In addition, mark recapture methods contain several assumptions that are violated in surveys of tortoises (Corn 1994), and the lack of spatial information in conventional mark recapture analysis leads to inflated estimates of density (Mitchell et al. 2021b). Therefore, estimates of density before 2001 must be approached with caution and direct comparisons between density estimates from mark recapture and line transect density methods are not advised. However, we can use these studies to give a rough picture of the state of tortoise populations in the late 20th century." Deleted "From 1979–1980 to 2020–2021, densities of adults in the corresponding TCAs fell 93% in Fenner, 96% in Chuckwalla, 89% in Chemehuevi, and 93% in Ivanpah" as this is a flawed direct comparison.

LINE 738 (DTRT)

"In addition, the BLM density estimates are only for the single plot per TCA". Comment - In addition, these results are likely biased high due to violations of statistical assumptions (Mitchell et al. 2021). Mitchell, C. I., K. T. Shoemaker, T. C. Esque, A. G. Vandergast, S. J. Hromada, K. E. Dutcher, J. S. Heaton, and K. E. Nussear. 2021. “Integrating Telemetry Data at Several Scales with Spatial Capture-Recapture to Improve Density Estimates.” Ecosphere 12: e03689.

RESPONSE: Added text "In addition, mark recapture methods contain several assumptions that are violated in surveys of tortoises (Corn 1994), and the lack of spatial information in conventional mark recapture analysis leads to inflated estimates of density (Mitchell et al. 2021b)." Added text "Comparing the density estimates in Berry and Medica (1995) to the USFWS estimates in 2001–2021 is not appropriate due to the differences in methodology described above. However, comparing the mark recapture density estimates between 1979 and 1992 can give us a sense of the general scale of decline even if the estimates themselves are biased high (Berry and Medica 1995, Mitchell et al. 2021b). "

LINE 711 and forward (Lovich)

These plot-based surveys cannot reliably be compared to data from line distance sampling data as that is like comparing apples to oranges. In the omitted Ernst and Lovich 2009 citation (page 564) mentioned above we compared and contrasted the techniques, their strengths and weaknesses. Plot-based surveys cannot be reliably extrapolated to surrounding areas and have been heavily criticized in the literature for their limitations. See CORN, P. S. 1994. Recent trends of desert tortoise populations in the Mojave Desert, p. 85-93. In: Biology of North American Tortoises. R. B. Bury and D. J. Germano (eds.). United States Department of the Interior, National Biological Survey. Fish and Wildlife Research 13. AND BURY, R. B., AND P. S. CORN. 1995. Have desert tortoises undergone a long-term decline in abundance? Wildlife Society Bulletin. 23:41-47. While I believe the plot-based data are valuable when those limitations are considered, you need to clarify that they are very different techniques and may not be useful for integration of data on declines.

RESPONSE: Bury and Corn 1995 question the assertions in Berry 1984 that there has been large scale declines in the desert tortoise densities up until that point and to claims of a 60-90% decline from 1900-1970s. The status review does not touch on population status or density prior to Berry 1984's strip transects which have rough density classes. Corn 1994 has a similar data set to Berry and Medina 1995, however because the violations of assumption in mark recapture in 60 days surveys, they present the data as relative abundance. The overall trends are similar over 1979-1990 as reported in Berry and Medina. Have reworded the section on Berry and Medica 1995's results to make it more clear about their limitations. See above

LINE 768 (Lovich)

Freilich worked on a one square mile plot (the Barrow Plot) in JTREE. That's "well-defined"
RESPONSE: Removed "and since they did not have a well-defined effective trapping area, their density estimates are rough. "

LINE 816 (Lovich)

Desert tortoises have the following life history traits: long-lived, late maturing, variable nest success due to predation, high adult survival, bet-hedging reproductive strategy (see ENNEN, J. R., J. E. LOVICH, R. C. AVERILL-MURRAY, C. B. YACKULIC, M. AGHA, C. LOUGHRAN, L. TENNANT, AND B. SINERVO. 2017. The evolution of different maternal investment strategies in two closely related desert vertebrates. Ecology and Evolution:1-13.), and relatively high juvenile survival to compensate for variable nest success. Classic studies of turtles with similar traits are: CONGDON, J. D., A. E. DUNHAM, AND R. C. LOBEN SELS. 1993. Delayed sexual maturity and demographics of Blanding's turtles (Emydoidea blandingii): Implications for conservation management of long-lived organisms. Conserv Biol. 7. AND CONGDON, J. D., A. E. DUNHAM, AND R. C. VAN LOBEN SELS. 1994. Demographics of common snapping turtles (Chelydra serpentina): implications for conservation and management of long-lived organisms. Amer. Zool. 34:397-408. You even show fairly high rates of juvenile survivorship on page 37. Without compensation for high nest mortality if hatchlings (you say this is high on page 37 line 903 and with the Daly et al. citation on page 37) populations could not survive.
RESPONSE: Have added text "In long-lived species like the tortoise, if adult survivorship drops, reproductive rates or juvenile survival would have to increase dramatically to keep populations stable. Analysis by the USFWS (1994) estimated that “a 10% increase in adult mortality can require a 300% increase in juvenile survivorship” to maintain a stable population. Many of the threats to adult survival also affect juveniles, making it unlikely that juvenile survivorship can naturally increase to the levels needed to compensate for the decreasing adult survival documented above"

Page 34 Figure (Lovich)

All of the presumed confidence intervals overlap each other so they aren't really different
RESPONSE: Assume this refers to figure 12. Have added/altered relevant text to read "In the yearly transect surveys done in the TCAs, the median midline carapace length did not change significantly between 2001 and 2015 (Figure 10). However, fewer juveniles small enough to be classified as outliers (the small circles below the lower ‘whisker’ in the box and whisker plot of Figure 10) were found in 2007–2015 compared to 2001–2005. In 2011, only one juvenile (midline carapace length <180 mm) was found, and in 2012 none were found. In some areas, the youngest tortoises found in recent years were at least 30 years old (Holcomb 2022a). Despite a steady median carapace length across 2001–2015, the range of carapace lengths decreased, with most of that change due to fewer smaller individuals found. Even with thousands of adults in a population, if sufficient juvenile tortoises are not surviving to breeding age, the population will decline without interventions like head-starting, although that decline may take decades to manifest (Lovich et al. 2018)."

LINE 856-857 (Lovich)

Prey switching was the mechanism proposed

RESPONSE: Text amended to read "It should be noted that other factors that impact survival, such as predation, roadkill, and disease were not tested independently" prey switching is discussed more in section 4.5 on predation.

LINE 870-881 (DTRT)

Comment - Esque et al. 2010 highlighted that we have too many subsidized predators (e.g., coyotes) throughout the Mojave Desert and that prolonged drought conditions likely created a shift in predator-prey dynamics. Increased mortality for G. agassizii was observed range-wide in 2008-2009. Please rephrase to include the importance of this finding.

RESPONSE: Prey switching and Esque et al 2010 is talked about at the end of the section 4.4 on predation. The addition of Cypher et al. 2018 adds some counterpoints to the discussion. Text read "During periods of suppressed rodent and prey populations following dry years, it has been suggested that coyotes will switch to preying on tortoises (Esque et al. 2010). This may help explain the widespread high mortality rates due to predation in 2008 (Esque et al. 2010). However, work by Cypher et al. (2018) did not necessarily support that hypothesis. In a study following the 2008 translocation of tortoises to an area south of Fort Irwin, they collected data on the relative abundance of rodents and rabbits, as well as the contents of coyote scats in 2009–2014. The years 2011–2014 were very dry compared to the wetter years of 2009–2010. While the frequency of occurrence of rodents in scat was lower in dry years (24.3%–46.3%) than in the wet years (53%–65%), the frequency of tortoises in scat was also lower in dry years (2.4%–2.6%) compared to wet years (5.6%–5.8%). These results suggest that it is unlikely coyotes switched to tortoise prey because of lack of rodents. Instead, as coyotes ate fewer rodents in the dry years, their amount of anthropogenic food sources increased (Cypher et al. 2018). While 2008 may have been an anomalous widespread pulse in predation pressure (Esque et al. 2010), there is a lack of rigorous evidence that coyotes regularly prey switch to tortoises when rodent or lagomorph populations are low because of drought. "

LINE 897 (Lovich)

is 300% the right number?

RESPONSE: Full quote is "Indeed, somewhere in the order of only 1% of all eggs need survive to reproductive age. On the other hand, a 10% increase in adult mortality can require a 300% increase in juvenile survivorship. Furthermore, any reduction in the fecundity of adults exacerbates this further."

LINE 901 (DTRT)

"Several factors limit the number of hatchlings that are produced in the wild each year." Comment See Mitchell et al. 2021 for more information related to the drivers of egg production. The authors modeled reproductive output as a factor of climate and individual attributes and detected a declining trend in egg production across all recovery units over time.

RESPONSE: Citation was previously added. Altered text to read "Several factors limit the number of hatchlings that are produced in the wild each year. Temperature, precipitation and body size influence the number eggs females lay (Mitchell et al. 2021a), with the maximum being 12-18 eggs a year (J. Lovich Pers comm 2023). "

LINE 902 (Lovich)

See earlier comment about 30 eggs/year being wrong

RESPONSE: Altered text to read "Several factors limit the number of hatchlings that are produced in the wild each year. Temperature, precipitation and body size influence the number eggs females lay (Mitchell et al. 2021a), with the maximum being 12-18 eggs a year (J. Lovich Pers comm 2023). "

LINE 918 (Lovich)

This addresses a proximate (not enough turtles) not an ultimate (impacts continue to kill turtles in the wild) cause. See FRAZER, N. B. 1992. Sea turtle conservation and halfway technology. Conservation Biology. 6:179-184. for a critique of headstarting.

RESPONSE: True, but this distinction may not be necessary here.

LINE 901-917 (Lovich)

juvenile survival rates aren't that low. See comments line 23 of spreadsheet

RESPONSE: Have deleted that sentence.

LINE 953 (DTRT)

Again, you say survival rates of juveniles are low but you say 100% on page 37 line 928

RESPONSE: That is a modelled survival rate that hasn't been ground truthed and focused mostly on predation risk from ravens. Other factors make it unlikely annual survival would be 100%

LINE 986-987 (Lovich)

The west Mojave is highly built up and growing. See HUNTER, L. M., M. D. J. GONZALEZ G, M. STEVENSON, K. S. KARISH, R. TOTH, T. C. EDWARDS, R. J. LILIEHOLM, AND M. CABLK. 2003. Population and land use change in the California Mojave: Natural habitat implications of alternative futures. Population Research and Policy Review. 22:373-397.

RESPONSE: Added some text at the end of the paragraph to add context about how the results of the Carter et al. 2020 paper may not hold into the future "However, these categories of development used above do not take into account unpaved roads and tracks for off-highway vehicles (OHVs) which are allowed on BLM land (see section 4.2), and given the pace of a variety of development in the desert, the conclusions may be less applicable in the future."

LINE 997 (Lovich)

Cite Hunter et al. above?

RESPONSE: This paper is interesting, but it is from 2003 and offers 2 potential development possibilities by 2020 with amounts of DT tortoise habitat in conflict with development. With the information easily available it would be hard to judge which scenario most closely matches reality and it is unclear it would add much to what information is already presented.

LINE 1034 (Lovich)

Cite Lovich and Bainbridge for recovery

RESPONSE: Done "Recovery from disturbance can take a long time in desert ecosystems (Lovich and Bainbridge 1999). "

LINE 1043 (Lovich)

How about fire as an impact esp. on bases like China Lake where lots of ordinance is fired

RESPONSE: Unable to find specific information about fires on DoD land.

LINE 1055 (Lovich)

Citation is Lovich and Ennen, not et al.

RESPONSE: Changed. "

LINE 1057 (Lovich)

after "infrastructure" add "for wind"

RESPONSE: The relevant sentence has been removed due to further editing

LINE 1112 (Nussear)

line 1112 Cannabis operations - this seems like a trivial inclusion. 12 km^2? This seems to be about the equivalent of party balloon effects, surprised to see this here.

RESPONSE: As noted, the visited acres of illegal cannabis grows are likely an underestimate of the true number of acres and it is probable that active and abandoned acres will continue to grow. The Department felt it is worthy to mention as something to keep an eye on in the future.

LINE 1117 (Lovich)

Guard dogs or any dogs?

RESPONSE: In the context of cannabis operations the dogs are mostly guard dogs. Pet/ feral dogs can be an issue generally near homes.

LINE 1208 (Lovich)

West where? Mojave?

RESPONSE: Have modified to clarify "According to the BLM, in 2008 there were four times the number of off-highway vehicles in western states than in 1998 (Bisson 2008)."

LINE 1258 (DTRT)

Suggested edit: Grasses are high in fiber, contain less digestible energy, and little protein (Hazard et al. 2009; Drake et al. 2016),

RESPONSE: That text is within a quote, alterations would not be appropriate

LINE 1242-1243 (DTRT)

"Fueled in part by nitrogen pollution carried by wind from the Los Angeles Basin which enriches desert soils (Fenn et al. 2010), invasive Mediterranean grasses have spread through much of the Mojave Desert." Comment- nitrogen pollution is not a significant contributor to the spread and establishment of invasive Mediterranean grasses. Habitat disturbance, recreation activities, and loss of native plants plays the biggest roles.

RESPONSE: Have deleted the relevant part of the sentence.

LINE 1297 (DTRT)

Suggested edit: The best studied predators of tortoises are ravens , coyotes, and badgers. " Include scientific name the first time predators are referenced in document.

RESPONSE: Have added scientific names to the document.

LINE 1341-1343 (DTRT)

Suggested edit: Ten years later, 104 were dead, an estimated 60% of which were killed by coyotes (Esque et al. 2010; Mack and Berry 2023). Increased tortoise mortality due to coyote depredation was observed throughout the tortoise’s range (Esque et al. 2010).

RESPONSE: Sentence has been altered to read "Coyotes are thought to be a major predator of adult tortoises. In a study of translocated tortoises in the Superior-Cronese CHU, between 2008 and 2018 an estimated 60% were killed by predators, likely coyotes based on nearby tracks and scat (Esque et al. 2010, Mack and Berry 2023). " Esque et al. 2010 range wide results are discussed in the paragraph that follows this text.

LINE 1357 (DTRT)

Add Emblidge et al. 2014 citation after badger. Suggest adding this citation from Endangered Species Research 28:109-116 and maybe a statement that evidence is mounting that badgers may play an important role in heavy localized mortality event.

RESPONSE: Have added the text "Badgers are thought to be partially responsible for high levels of mortality of tortoises in 2012-2013 on and near Ft. Irwin and may be important predators in certain locales (Emblidge et al. 2015). "

LINE 1360 (Lovich)

The following two citations also discuss prey switching: Lovich, J.E., S.R. Puffer, K. Cummings, T.R. Arundel, M.S. Vamstad, and K.D. Brundige. 2023. High female desert tortoise mortality in the western Sonoran Desert during California's epic 2012–2016 drought. Endangered Species Research 50:1-16. https://doi.org/10.3354/esr01215 and Lovich et al. 2014 already in lit cit.
RESPONSE: The coyote predation/scavenging discussion in Lovich et al. 2014 is included the section on predation. The 2023 reference was useful for the section on impacts of drought.

LINE 1505 (Nussear)

line 1505 - 1506 " foraging for annuals in the burned areas, while using the cover of perennial shrubs only found in unburned areas (Drake et al. 2015). "
This really isn't true, and not what Drake et al says if you read beyond just the abstract. Tortoises also used cover in burned areas, and that consisted of both burned and unburned perennials in the scar of the burn. - see also Snyder et al. 2019
RESPONSE: Altered text to "Tortoises tend to remain in same areas after fire (Lovich et al. 2018), and one study found that tortoises used burned and unburned areas nearly equally, starting the first year after the fire (Drake et al. 2015). Tortoises moved into the burned areas seasonally to forage for preferred annuals and herbaceous perennials (Drake et al. 2015). The use of burned habitats did not appear to affect their health or reproduction in the short term. However, the expansion of red brome grass in burned areas and the injuries that fire can cause tortoises remained concerns (Drake et al. 2015)."

LINE 1531 (Lovich)

You might cite SCHUMACHER, I. M., D. C. ROSTAL, R. A. YATES, D. R. BROWN, E. R. JACOBSON, AND P. KLEIN, A. 1999. Persistence of maternal antibodies against Mycoplasma agassizii in desert tortoise hatchlings. American Journal of Veterinary Research. 60:826-831. as there is no evidence of transmission of URTD from females to their embryos
RESPONSE: Was unable get a copy of this paper and mother to offspring transmission is not mentioned in the document.

LINE 1534 (Lovich)

add "potentially" I'm not aware of evidence that tortoises have to smell to find food
RESPONSE: Have added the word potentially "The disease both directly kills tortoises and can potentially interfere with their sense of smell and therefore their ability to forage for food and can potentially negatively affect their reproductive fitness (Germano et al. 2014, Jacobson et al. 2014)"

LINE 1527-1528 (DTRT)

Suggested edit: The disease presents as lesions in the nasal cavity and inflammation of mucosa of the upper respiratory tract, muchoid discharge from the nares, damaged nasal scales due to chronic muchoid discharge
RESPONSE: Done

LINE 1569 (DTRT)

Delete this sentence. There is no evidence of this. Being captured by humans for research and/or translocation can stress tortoises and make them more susceptible to URTD.

RESPONSE: Unclear what this comment refers to as the original sentence says "Being captured by humans for research and/or translocation can stress tortoises and make them more susceptible to URTD. " However, that sentence has been deleted in the general editing process.

LINE 1580 (Lovich)

Change associated to correlated
RESPONSE: Done. "Shell lesions were correlated with high mortality rates of desert tortoises in Chuckwalla Bench in 1982–1988 "

LINE 1569-1570 (DTRT)

Edit this sentence to the following: Official handling protocols have strict guidelines in place to minimize human-mediated transfer of pathogens stress as much as possible (U.S. Fish and Wildlife Service 2020b, a).
RESPONSE: text altered to "Official handling protocols include strict guidelines to minimize human mediated transfer of pathogens and stress (USFWS 2020b). "

LINE 1636 (Lovich)

morafkai misspelled
RESPONSE: Fixed

LINE 1643 (Lovich)

15.4 tortoises/km squared at my Palm Springs tortoise site as cited in Lovich et al. 2011 already in lit cit
RESPONSE: This whole section has been deleted.

LINE 1647 (DTRT)

"the most recent estimates of abundance…" Predicted abundances at the recovery unit level are available for 2020 from Zylstra et al 2023
RESPONSE: Have deleted this section and deleted the table with abundances from 2014

LINE 1648 (DTRT)

Predicted abundances at the recovery unit level are available for 2020 from Zylstra et al 2023
RESPONSE: Have deleted this section and deleted the table with abundances from 2014

1658 (DTRT)

Recommend incorporating trends and predicted densities from Zylstra et al. 2023 into this section
RESPONSE: Have deleted this section

LINE 1678 (Lovich)

While adult sex ratios in desert tortoises tend to be equal the issue is much more complicated. See these citations: LOVICH, J. E., AND J. W. GIBBONS. 1990. Age at maturity influences adult sex ratio in the turtle Malaclemys terrapin. Oikos. 59:126-134. AND Lovich, J. E. 1996. Possible demographic and ecologic consequences of sex ratio manipulation in turtles. Chelonian Conservation and Biology 2:114-117. AND Lovich, J.E., J.W. Gibbons, and M. Agha. 2014. Does the timing of attainment of maturity influence sexual size dimorphism and adult sex ratio in turtles? Biological Journal of the Linnean Society 112:142-149. AND Lovich, J.E., S.R. Puffer, K. Cummings, T.R. Arundel, M.S. Vamstad, and K.D. Brundige. 2023. High female desert tortoise mortality in the western Sonoran Desert during California's epic 2012–2016 drought. Endangered Species Research 50:1-16. https://doi.org/10.3354/esr01215
RESPONSE: Have added Lovich 2023 as a citation, see below.

LINE 1680 (Lovich)

Not true. See Lovich, J.E., S.R. Puffer, K. Cummings, T.R. Arundel, M.S. Vamstad, and K.D. Brundige. 2023. High female desert tortoise mortality in the western Sonoran Desert during California's epic 2012–2016 drought. Endangered Species Research 50:1-16. https://doi.org/10.3354/esr01215

RESPONSE: This comment refers to sex ratios. The sex ratio text has been moved to section 4.6 Climate Change and Drought and now reads "There is some evidence that drought is affecting sex ratios of adult tortoises. Unequal sex ratios are thought to lower effective population size, which in small populations with limited connectivity could exacerbate inbreeding (Frankham 1995). In 2015–2016, Lovich et al. (2023) surveyed two sites in Shaver's Valley about 70 km southeast of Palm Springs along the boundary of the Joshua Tree and Chuckwalla TCAs. At both sites there was a male bias in live tortoises. At the cooler, wetter site there was an even sex ratio in tortoises found dead, but in the hotter and drier Chuckwalla site, more females were found dead. It is possible that the energetic requirements required for reproduction make females less likely to survive long-term drought conditions (Lovich et al. 2023)."

LINE 1680 (Nussear)

Line 1680 you state "Unfortunately, there are no published data on sex ratios in the 17 TCAs (Berry and Murphy 2019)," - this isn't really the case, Allison and Mcluckie, Esque et al, and many other studies and datasets exist.

RESPONSE: Deleted

LINE 1658-1659 (Lovich)

Are these "small populations"?

RESPONSE: Have deleted section on small populations.

LINE 1671-1676 (Lovich)

This is discussed in more detail in Lovich, J.E., J.R. Ennen, M. Agha, and J.W. Gibbons. 2018. Where have all the turtles gone, and why does it matter? BioScience 68:771–781. The long lives of tortoises can give the perception of population persistence even with no juvenile recruitment.

RESPONSE: Moved text to section 3.2 Trends in Density and Abundance has been added "Even with thousands of adults in a population, if sufficient juvenile tortoises are not surviving to breeding age, the population will decline without interventions like head-starting, although that decline may take decades to manifest (Lovich et al. 2018)."

LINE 1694 (Lovich)

cite Lovich, J.E., S.R. Puffer, K. Cummings, T.R. Arundel, M.S. Vamstad, and K.D. Brundige. 2023. High female desert tortoise mortality in the western Sonoran Desert during California's epic 2012–2016 drought. Endangered Species Research 50:1-16. https://doi.org/10.3354/esr01215

RESPONSE: Resolved, see above

LINE 1815 (Lovich)

"The" Mojave Desert Tortoise

RESPONSE: Fixed

LINE 1847 (Lovich)

How about Utah?

RESPONSE: Added Utah. "The Desert Tortoise Management Oversight Group (MOG), formed in 1994, is comprised of senior managers from USFWS, BLM, state transportation agencies, state wildlife agencies, county governments, and non-governmental organizations (NGOs) that work in the tortoise range in Arizona, Nevada, Utah, and California. "

LINE 1871 (DTRT)

"In 2008 and 2011….". 2008 was a draft for review. Please only use 2011.
RESPONSE: Deleted 2008

LINE 1871 (DTRT)

Suggested edit: "the USFWS published revisions to the a Revised Recovery Plan…"
RESPONSE: Done

LINE 1880 (DTRT)

delete 2008
RESPONSE: Done

LINE 1886 (DTRT)

Edit to "As part of the revised 2011 Revised Recovery Plan".
RESPONSE: Done

LINE 1957 (Lovich)

You included the Yermo logistics base earlier but not here (and they have tortoises)
RESPONSE: Amended "DoD facilities within the Mojave Desert Tortoise range include Naval Air Weapons Station China Lake, Edwards Air Force Base, Fort Irwin, Marine Air Ground Task Force Training Command and Marine Corps Air Ground Combat Center Twenty-Nine Palms, Marine Corps Logistics Base Barstow, and the Chocolate Mountain Aerial Gunnery Range. "

LINE 2079 (Nussear)

Line 2079 - competition, you should probably address that there is active grazing of sheep and cattle in California, and whether that overlaps with desert tortoises (it does), and where and to what extent that occurs.
RESPONSE: This section has been reworked and a new section 4.4 Competition has been added to better align the document with statutory requirements. The text now reads "Grazing by livestock is a major part of the recent history of the desert. While grazing on BLM lands was historically permitted in tortoise range (Berry et al. 2014) after federal listing in 1990 it was halted in the CHUs. However, grazing is allowed on private inholdings within the CHUs, which are often unfenced. The documented impacts of livestock on tortoises include competition for food, trampling to death, and causing the collapse of burrows (see Berry and Murphy (2019)). Livestock also degrade habitat by creating or expanding trails which reduces annual plant cover and can (but does not always) promote wind erosion and compaction (Webb and Stielstra 1979, Lovich and Bainbridge 1999). "

LINE 2097 (Nussear)

Line 2097: Climate change - there are local and regional modeling efforts that demonstrate a predicted loss of habitat. The potential for this to impact tortoise populations lies far beyond the potential for the military to train more.
RESPONSE: True, have added this sentence "Modelling by Barrows (2011) predicts that under 2°C (3.6°F) of warming with 50 mm decrease in precipitation, habitat area will decrease by about 88% in the Sonoran Desert portion and by about 66% in the Mojave Desert portion."

LINE 2172 (Lovich)

You should cite Lovich, J.E., J.R. Ennen, S.V. Madrak, and B. Grover. 2011. Turtles, culverts and alternative energy development: an unreported but potentially significant mortality threat to

the desert tortoise (Gopherus agassizii). Chelonian Conservation and Biology 10:124-129. Culverts can be death traps for tortoises.
RESPONSE: This section has been deleted, but have added this sentence section 4.2 on road fencing "However, proper design is key, culverts can become death traps for tortoises if not properly designed and implemented (Lovich et al. 2011)."

LINE 2176 (Lovich)

Cite Hunter et al. above?
RESPONSE: This section has been deleted to bring the document in line with regulatory requirements

LINE 2230-2237 (DTRT)

General Comment. Given the declining status Mojave desert tortoises in California and continued habitat loss and degradation due to increased human activity and infrastructure, we agree that the Department's recommendation to change the status of Mojave desert tortoises from threatened to endangered is warranted in California.

LINE 2330 (Lovich)

There is no discussion of the negative effects of fencing on tortoises and other wildlife and there is a huge literature on that needs to be mentioned
RESPONSE: Have emphasized that the fencing has to be well designed "Erecting well designed tortoise exclusion fencing along major roadways and funneling them into appropriate crossings is a key recovery action. "

LINE 2374 (Lovich)

Has anyone ever quantified the effectiveness of these efforts? It may use funds that could be more meaningful in other recovery efforts
RESPONSE: There may not be specific quantification of the impact of outreach in this particular case, but there is a large body of research about effective ways to communicate with the public and how it can impact behavior change.

LINE 2397-2401 (DTRT)

Suggested edit: Population augmentation is currently accomplished through two types of projects, mitigation-driven translocation and release of head-started juveniles. Mitigation-driven translocation involves moving tortoises from a site where they would be harmed and into an appropriate recipient site. Head-starting is a strategy to reduce predation mortality on juvenile tortoises by hatching and rearing juveniles in captivity until they are large enough to avoid most predators. In the future, conservation-based translocations of adults may also be possible.
RESPONSE: Much of this section has been moved to section 5.2 Management Efforts. The first suggested text changes were made but the Department will leave any discussion of conservation-based translocation to a future Recovery Plan

LINE 2406-2411 (DTRT)

Suggested edit. There are a number of considerations that need to be taken into account when tortoises are translocated as laid out in the USFWS’s guidance on translocating tortoises from project sites Plan Development Guidelines (U.S. Fish and Wildlife Service 2020b).
Considerations Major concerns include the habitat suitability of potential translocation sites

and the disease prevalence of both tortoises being moved and at the recipient site possibility of disease transfer from transplants to resident tortoises.
RESPONSE: Much of this section has been moved to section 5.2 Management Efforts, but the suggested text edits were made.

LINE 2408 (DTRT)

Suggested edit: Considerations recipient site of potential translocation sites and the disease prevalence of both tortoises being moved into and at the recipient site.
RESPONSE: The section on translocation was heavily modified and moved. This sentence has been deleted.

LINE 2409 (DTRT)

In reference to resident tortoises - This is only part of it. The residents can also transfer pathogens to the translocated and increased contacts rates could change the background disease dynamics at the site.
RESPONSE: Have clarified with the suggested edits above.

LINE 2410 (DTRT)

In reference to "ITP holders monitor" - Please consider the monitoring guidance in USFWS 2020b vs requiring the monitoring of small numbers of translocated tortoises.
RESPONSE: Have re arranged the paragraphs and add the text "The Department" to clarify that these are monitoring actions via CDFW ITPs and not guidance issued by USFWS

LINE 2412 (DTRT)

In reference to "sufficient burrows of appropriate size...": Existing burrows should not be a requirement. The focus should be on shelter sites in general. They must be able to seek shade and protection immediately, but that doesn't need to be within a burrow. The abundance of other types of shelter is likely more important, as tortoises released into a new environment would need to find the existing burrow vs taking immediate shelter under shrubs, boulders, etc.
RESPONSE: This paragraph discusses actions related to ITPs issued by CDFW which can differ from the USFWS guidance on burrows vs shelter sites. Have rearranged the paragraphs and added some text to make that more clear "The Department requires that ITP holders monitor any tortoises translocated, and has teams carefully examine recipient sites for soil and vegetation communities that are suitable for all life stages of the tortoise, evaluate the presence and abundance of predators, and make sure there are sufficient burrows of appropriate size so that translocated tortoises can quickly find shelter"

LINE 2419 (DTRT)

Start this paragraph as... "There is evidence from more than a dozen sites that translocation, including large-scale translocation, can be an important conservation tool (Brand et al. 2016, Dickson et al. 2019, Drake et al. 2012, Esque et al. 2010, Farnsworth et al. 2015, Field et al. 2007, Harju et al. 2019, Hinderle et al. 2015, Nafus et al. 2017, Nussear et al. 2012). Finding recipient sites for for large numbers of tortoises is challenging. If donor sites are chosen because resident populations are depleted ..."
RESPONSE: Have included these references in this paragraph "Beyond the survival of tortoises involved in large scale translocations, there have been many studies looking at how body conditions and temperature (Brand et al. 2016), environmental feature and conditions (Nafus et al. 2017, Dickson et al. 2019), physiological stress (Drake et al. 2012), proximity of anthropogenic resources (Esque et al. 2010), movement and space use (Nussear et al. 2012,

Farnsworth et al. 2015, Hinderle et al. 2015), and water availability (Field et al. 2007) affect the outcomes of translocations. These results should be used to keep improving and refining decision making around translocations." This text is now in section 5.2 Management Efforts

LINE 2429 (Nussear)

you misrepresent the findings in Esque 2010 - animals that were in control groups also suffered similar mortality rates, as did animals throughout the range of the tortoise. Another oversight is that you don't factor in the number of animals lost from habitat if they are removed and not translocated. This is an important consideration - The better option is to find alternative siting for things like solar facilities etc that result in the loss and degradation of tortoise habitat, but the continued lack of the ability to say no to these large scale disturbances leaves you with little choice.

RESPONSE: The translocation section was extensively rewritten to incorporate this and other feedback

LINE 2402 onward (Lovich)

This section doesn't do much to change my perception of the lack of effectiveness of translocation based on the literature. You should cite: SULLIVAN, B. K., E. M. NOWAK, AND M. A. KWIATKOWSKI. 2015. Problems with mitigation translocation of herpetofauna. Conservation Biology. 29:12-18. AND GERMANO, J. M., K. J. FIELD, R. A. GRIFFITHS, S. CLULOW, J. FOSTER, G. HARDING, AND R. R. SWAISGOOD. 2015. Mitigation-driven translocations: are we moving wildlife in the right direction? Frontiers in Ecology and the Environment. 13:100-105. AND GERMANO, J. M., AND P. J. BISHOP. 2008. Suitability of amphibians and reptiles for translocation. Conservation Biology. 23:7-15.

RESPONSE: The translocation section was extensively rewritten to incorporate this and other feedback

LINE 2413-2414 (DTRT)

In reference to "most of the tortoises translocated under IPTs…." - Does the Department try to keep them within 4 miles or is this a result of moving from harm's way into adjacent habitat? Putting such restraints on the distance tortoises can be moved will limit the ability to get tortoises into good quality, high priority augmentation sites that are consistent with greater conservation objectives.

RESPONSE: Have added the text "(although distance is only one of many considerations when choosing a recipient site)" This sentence is now in section 5.2 Management Efforts

LINE 2456- (DTRT)

Edit translation to translocation

RESPONSE: Done

LINE 2489 (DTRT)

In reference to "high death rates". Unlikely. Studies showed former captives did very well when in good health upon release. More likely factors were the lack of stringent translocation suitability evaluations and rigorous health assessments as are now requirements.

RESPONSE: The translocation section was extensively rewritten to incorporate this and other feedback

LINE 2486-2499 (DTRT)

Suggest editing this paragraph to the following. "The failure of these large and long-term translocations to either keep translocated tortoises alive or the resident population stable

suggests translocation may often not be an effective management strategy without figuring out and addressing the drivers of declines within the subject populations. Augmentation of populations through translocations may buy time and keep tortoises present on the landscape while the threats causing declines are addressed. The majority of the tortoises translocated into LSTS came from captivity and were likely not well adapted to surviving in the wild, which is likely a factor in their high death rates. Most official translocations in California involve moving wild tortoises from a project site to a nearby area, and so may not face the same difficulties in survival that releasing captive tortoises appear to create. However, the evidence from Ord-Rodman suggests that even an addition of large numbers of new adults to a nearby area can slow but does not prevent population declines. The low survival rates of translocated adults and the lack of genetic integration of males suggest that large scale translocation may not provide much recorded benefit to recipient populations and does not necessarily remove the translocated tortoises from harm's way. Thus, identification of the reasons for the depleted population in the recipient site is important to ensure translocation is conducted in a manner appropriate to facilitate survival, and to prevent its failure as a minimization measure."
RESPONSE: The translocation section has been modified extensively, but this particular text is now "However, given the continuing decline of tortoise populations in general, translocations may often not be an effective conservation strategy without addressing the drivers of declines within the subject populations. At best, augmentation of populations through translocations can buy time and keep tortoises present on the landscape while the threats causing declines are addressed. "

LINE 2487-2488 (Lovich)

If it isn't an effective strategy, why pursue it?
RESPONSE: The translocation section was extensively rewritten to incorporate this and other feedback

LINE 2520 (Lovich)

The Frazer citation above should be incorporated in this section
RESPONSE: Have added text " Daly et al. (2019) points out that by itself, head-starting is unlikely to lead to population recovery if larger issues that depress survival such as raven density and habitat degradation are not addressed. Another consideration is that unless factors that depress adult survival are also reduced, focusing on putting more juveniles in a "degraded environment in which their parents have already demonstrated that they cannot flourish" is not an effective long-term solution (Frazer 1992). "

LINE 2541 (DTRT)

Delete "yearly"
RESPONSE: Done

LINE 2545 (Lovich)

How would making sex ratio data public help stakeholders given the complexities of interpreting sex ratios listed above in this spreadsheet?
RESPONSE: Have deleted this paragraph

LINE 2545 (Nussear)

Line 2545 - Regarding sex ratio data - these are easily obtained. Just ask the FWS for it, I have done so repeatedly and they have always been happy to provide it. This seems like a straw man argument that is a result of poor communication.

RESPONSE: Have deleted this paragraph

LINE 2568 (Lovich)

Adaptive management is thrown around by people that don't fully understand what it means. In its simplest form it is using policy as a testable hypothesis, monitoring its effectiveness, adjusting the policy to increase effectiveness and repeating the cycle. Is that what you mean? It requires a substantial investment of time and people as shown in the Glen Canyon Dam Adaptive Management Program https://www.usbr.gov/uc/progact/amp/index.html.

RESPONSE: Have altered to "Implement a formal Recovery Plan"

LINE 2615 (Lovich)

Why only 5 years for a species with a cohort generation time of about 25 years that lives to be 50 or so? Isn't recruitment an important component of success?

RESPONSE: Ideally the monitoring period would be longer for such a long lived animal, but until the Department effectively organizes and analyzes the data they have, asking permit holders to do more monitoring seems like an unnecessary burden.

LINE See section 2.2. (DTRT)

Comment. Too much of 2.2 Species Description and Life History is extrapolated from Berry and Murphy 2019. Please review broader literature for appropriate citations and information.

RESPONSE: Some primary references have been added to this section thanks to the suggestions of multiple reviewers, but as stated in section 1.2, the status review is not intended to be an exhaustive review of all published scientific literature on Mojave Desert Tortoise; rather it is intended to summarize key points relevant to the status of the species and address regulatory report requirements.

EXECUTIVE SUMMARY

This Status Review of Mojave Desert Tortoise (*Gopherus agassizii*; also known as Agassiz's Desert Tortoise) has been prepared by the California Department of Fish and Wildlife (Department) for the California Fish and Game Commission (Commission) pursuant to the requirements of the California Endangered Species Act (CESA; Fish & G. Code, § 2050 et seq.).

The Mojave Desert Tortoise was designated a threatened species under CESA in 1989. On March 23, 2020, the Commission received a petition from the Defenders of Wildlife, the Desert Tortoise Council, and the Desert Tortoise Preserve Committee to change the status of the Mojave Desert Tortoise from threatened to endangered. On April 13, 2020, the Commission referred the Petition to the Department for evaluation pursuant to Fish and Game Code section 2073 and published a formal notice of receipt of the petition (Cal. Reg. Notice Register 2020, No. 18-Z, p. 693). At its meeting on August 20, 2020, the Commission received the Department's petition evaluation report. The Department based its evaluation on available information and recommended to the Commission that the petition be accepted. At its October 14, 2020 meeting, the Commission accepted the petition to change the status of the Mojave Desert Tortoise from threatened to endangered (Cal. Reg. Notice Register 2020, No. 44-Z, p. 1445). As a result, the Department was directed to complete this Status Review, which is a detailed evaluation of the current status of the tortoise and includes its recommendation regarding whether the tortoise's status should be changed from threatened to endangered.

This Status Review is based on the best scientific information currently available to the Department regarding each of the components listed under section 2072.3 of the Fish and Game Code, and section 670.1 of Title 14 of the California Code of Regulations. In addition, this Status Review includes a preliminary identification of habitat that may be essential to the continued existence of the species, and the Department's recommendations for management activities and other recommendations for recovery of the species. (Fish & G. Code, § 2074.6.). This Status Review has been independently reviewed by scientific peers pursuant to Fish and Game Code section 2074.6.

Species Description, Biology, and Ecology

In 2011, studies of tortoise genetics, morphometrics, and ecology led experts to conclude that the complex formerly known as "Desert Tortoise" in fact consists of two separate species—Mojave Desert Tortoise and Sonoran Desert Tortoise. Mojave Desert Tortoise, also known as Agassiz's Desert Tortoise, retains the binomial *G. agassizii*, and ranges across the deserts of southeastern California, southern Nevada, and small areas of Arizona and Utah north of the Colorado River.

The Mojave Desert Tortoise is a long-lived, desert-dwelling reptile. Tortoise body temperature is closely linked to the temperature in the environment, and Mojave Desert Tortoises live in places that can fluctuate up to 40°C (104°F) seasonally. They primarily regulate their temperature by using underground burrows where the air is cooler and moister than the outside air in summer and warmer in winter and can spend more than 90% of their lives underground.

Females become sexually mature at 12–20 years old and lay a maximum of 30 eggs per year and nest in a den or burrow or under trees. Nest predation is common, with 12–55% of nests generally destroyed by predators. Reported incubation time in the wild varies from 67–104 days and incubation temperatures determine the sex of the hatchlings, with hotter temperatures producing female-skewed clutches.

Tortoises selectively feed on forbs, grasses, and herbaceous perennial plants and will consume cacti during droughts. They favor native plants and plant parts that are high in water and low in potassium. Much of the range of the desert tortoise is highly invaded by nonnative plants like red brome, cheat grass, red stem filaree, and African mustard, but tortoises avoid eating exotic grasses when possible as they are low in nitrogen and require relatively large amounts of water to process.

Desert tortoise habitat typically consists of alluvial fans and plains and colluvial/bedrock slopes that facilitate the digging of burrows. Tortoises need sufficient food plants as well as larger shrubs and bushes for shade and protection of burrows. They are associated with saltbush, creosote bush, white bur-sage, and cheesebush. At higher elevations, tortoises are more likely to be found near Joshua tree, Mojave yucca, and blackbrush. Tortoises occur in very low densities or are absent where shrub cover is sparse, precipitation is low, and annual food plants are available only intermittently (e.g., the lower elevations in Death Valley). They also occur at low densities in moderately to severely disturbed areas, regardless of desert or region.

Ravens are a major predator of juvenile tortoises while coyotes target both juvenile and adult tortoises. Raven populations have expanded dramatically in the desert due to resource subsidies from humans.

Status and Trends

In California, the range of the Mojave Desert Tortoise includes the Mojave Desert and portions of the Sonoran and Great Basin deserts from the southern end of the Owens Valley south of the town of Lone Pine in Inyo County to the Mexican border near the southeastern corner of the state, and from the Colorado River in the east to the lower slopes of the Sierra Nevada, Transverse, and Peninsular mountains in the west.

The most robust estimates of densities come from annual systematic surveys done in the Tortoise Conservation Areas (TCAs). These surveys began in 2004 and cover large areas of the best habitat for tortoises, including federally designated critical habitat. Most of the surveys provide consistent evidence that populations are declining at rapid rates. In 2004–2014, densities in the TCAs declined between 3.3% and 10.8% per year. These rates are unsustainable for most species, but especially for a long-lived and slow-reproducing species such as the desert tortoise. Sixty percent of the TCAs currently have densities below that which is necessary for population viability (3.9 adult tortoises/km^2), while another 30% are at the threshold. Only one

TCA currently has a tortoise density above what is needed for population viability. While we do not have estimates of density in all the TCAs prior to the desert tortoise being listed as threatened in 1989, densities in select TCAs varied between 35 and 90 adults/km^2 in the early 1980s, and between 35 and 70 adults/km^2 when they were listed. It is estimated that densities of adults in certain TCAs fell between 89% and 97% from the early 1980s to 2020–2021. Since the late 1970s, the number of juveniles detected on surveys has also fallen sharply, to the point that in recent surveys in the western Mojave Desert almost no juveniles were found. The population data available indicate that there were sharp drops in density before listing as threatened, and those losses have continued to the point where much of the best tortoise habitat no longer supports viable tortoise densities.

The slow maturation and low reproductive rates of tortoises means that if past and current management is successful at addressing threats and stemming the decline of tortoise populations, it would still take at least 25 years of positive population growth to reach the USFWS Recovery Criteria (U.S. Fish and Wildlife Service 2022*a*). For example, the USFWS 1994 Recovery Plan estimates that when adult survivorship is 98%, population growth would be less than 0.5% per year, and would take 140 years to double in size. Annual survival rates for both adults and juveniles are much lower than 98% in most areas, making population stability, let alone growth, unlikely. Collectively, the available data show that in the critical habitat units (which are assumed to be the best tortoise habitat), tortoise densities are low to very low, and despite 30 years of state and federal protection, tortoise populations continue to decline and do not show consistent signs of recovery.

Threats

The dramatic declines in Mojave Desert Tortoise populations are likely due to the extensive number and interconnected nature of the threats they face. The important threats fall in two categories, those that directly kill adults and juveniles, and those that cause longer-term changes to habitat availability and quality.

In long-lived species that are slow to reproduce, decreased survival has long lasting impacts on the population and can alter demographic patterns for decades. Increased numbers of predators including ravens and coyotes reduce the survival of juvenile and adult tortoises, respectively. Development within the tortoise range often creates roads that can lead to road-killed tortoises, and extensive networks of trails for off highway vehicles on public land increase the chance that tortoises will be run over in areas without paved roads. Well-designed fences and culverts can help prevent tortoises and other wildlife being killed by vehicles along major roads, but little fencing has been built since 2011.

Habitat modification and destruction reduces the amount of habitat that can support tortoises in the long-term. Although a large proportion of desert tortoise range is under federal control, renewable energy, housing, illegal cannabis, and other types of development reduce the amount of habitat available. The Department of Defense is a large landowner in desert tortoise range and frequently expands the areas that it uses for training, requiring translocation of hundreds of tortoises. Large scale tortoise translocations do not tend to have high survival rates.

Additional factors have direct and indirect impacts on tortoises and their habitat. Climate change, which is likely to cause hotter and periodically drier conditions in the desert tortoise range, will increase their physiological stress and change activity patterns. The nutritious native vegetation tortoises feed on are being outcompeted by nutritionally poor invasive grasses, which can lower tortoise survival rates. Fires fueled by invasive grasses decrease the amount of native vegetation available for tortoises to feed on and remove other important vegetation components of tortoise habitat.

Some threats appear to be declining since the species was listed. Upper respiratory tract diseases were a major concern when tortoises were listed as threatened. Encouragingly, the prevalence of diseased tortoises is lower than in previous decades, and it does not appear to be an acute threat to wild populations. The prevalence of gunshot deaths has also decreased in the past several decades, but it is unclear if this is due to change in human behavior or simply reflects a lower tortoise encounter rate due to declining tortoise density.

Historical and current conservation efforts have not proven sufficient to halt the population declines of desert tortoise. However, there is still a large amount of available habitat and even at low densities, in 2014 there were estimated to be more than 61,000 adult tortoises within the TCAs. This is a decrease from an estimated 310,000 adults in 2004, and as densities have continued to fall since 2014, current abundance is likely lower than 60,000 adult tortoises. Given that there are multiple interacting threats that are reducing the amount and quality of viable habitat and lowering survival rates of adults and juveniles, the available information suggests that tortoises populations will continue to decline for the foreseeable future. However, several of the major threats like raven predation on juveniles and the lack of tortoise exclusion fencing on highways are issues that can be addressed with the appropriate resources and policy changes. Implementing these actions where appropriate to improve survival in the short term is critical to give desert tortoises populations the resilience to weather longer term habitat and climactic effects.

Several recommended management actions are described in this report. Improved coordination and communication between the Department and other state and federal agencies would help the implementation of these actions. We also point to several needs for increasing capacity at the Department to better track the impact of threats and conservation actions on tortoise populations.

Recommendation—The Department provides this status review report, including its recommendation, to the Commission in an advisory capacity based on the best scientific information available. In consideration of the scientific information contained herein, the Department has determined that listing the Mojave Desert Tortoise as endangered under CESA is warranted at this time.

1. REGULATORY SETTING

1.1 Petition Evaluation Process

On March 23, 2020, the Commission received a Petition from Defenders of Wildlife, The Desert Tortoise Council, and The Desert Tortoise Preserve Committee to change the status of Mojave Desert Tortoise from threatened to endangered. On April 13, 2020, the Commission referred the Petition to the Department for evaluation pursuant to Fish and Game Code section 2073 and published a formal notice of receipt of the petition (Cal. Reg. Notice Register 2020, No. 18-Z, p. 693). At its meeting on April 16, 2020, the Commission officially received the Petition.

A petition to list, delist, or change the status of a species under CESA must include "information regarding the population trend, range, distribution, abundance, and life history of a species, the factors affecting the ability of the population to survive and reproduce, the degree and immediacy of the threat, the impact of existing management efforts, suggestions for future management, and the availability and sources of information. The petition shall also include information regarding the kind of habitat necessary for species survival, a detailed distribution map, and any other factors that the petitioner deems relevant" (Fish & G. Code, § 2072.3).

The Department's charge and focus in its advisory capacity to the Commission is scientific, and it evaluates petitions based on the best scientific information available regarding potential listing factors including those listed above. At its meeting on August 20, 2020, the Commission received the Department's petition evaluation report, which is intended to assist the Commission in making a determination as to whether the petitioned action may be warranted based on the sufficiency of scientific information (Fish & G. Code, §§ 2073.5 & 2074.2; Cal. Code Regs., tit. 14, § 670.1, subds. (d) & I). Focusing on the information available to the Department relating to each of the required information categories listed above, the Department recommended to the Commission that the petition be accepted.

At its public meeting on October 14, 2020, the Commission considered the petition, the Department's petition evaluation and recommendation, and comments received. The Commission found that sufficient information existed to indicate the petitioned action may be warranted and accepted the petition for consideration. Upon publication of the Commission's notice of its findings, the Mojave Desert Tortoise was designated a candidate species on October 19, 2020 (Cal. Reg. Notice Register 2020, No. 44-Z, p. 1445).

1.2 Status Review Overview

The Commission's decision to designate the Mojave Desert Tortoise as a candidate species triggered the Department's process for conducting a 12-month status review to inform the Commission's decision on whether the change in status is warranted (Fish & G. Code, § 2074.6 and Cal. Code of Regs., title 14, § 670.1). At its meeting on October 14, 2021, the Commission granted the Department a six-month extension to complete the status review and facilitate external peer review.

This status review report is not intended to be an exhaustive review of all published scientific literature relevant to the Mojave Desert Tortoise. Rather, it is intended to summarize the best scientific information available relevant to the status of the species, provide that information to the Commission, and to serve as the basis for the Department's recommendation to the Commission on whether the petitioned action is warranted. This final report is informed by independent peer review of an earlier draft by scientists with expertise relevant to the Mojave Desert Tortoise. Specifically, this status review represents the Department's evaluation of whether the status of the tortoise should be changed from threatened to endangered. Species that are "threatened" are not presently threatened with extinction but are likely to become endangered in the foreseeable future without special protection and management. An "endangered" species is one that is in serious danger of becoming extinct throughout all or a significant portion of its range due to one or more of the following factors: present or threatened modification or destruction of its habitat; overexploitation; predation; competition; disease; or other natural occurrences or human-related activities. (Fish & G. Code, § 2062; § 2067; Cal. Code Regs., tit. 14, § 670.1, subd. (i)(1)(A).)). The status review report also identifies habitat that may be essential to the continued existence of the species and provides management recommendations for recovery of the species (Fish & G. Code, § 2074.6).

Receipt of this report is to be placed on the agenda for the next available meeting of the Commission after delivery. At that time, the report will be made available to the public for a 30-day public comment period prior to the Commission taking any action on the petition.

2. BIOLOGY

2.1 Taxonomy

Desert tortoises are members of the order Testudines, family Testudinidae, genus *Gopherus*. When the Commission listed Desert Tortoise as threatened in 1989, *Gopherus agassizii* was understood to range from southeastern California, across southern Nevada, through western Arizona, and south into Sonora and Sinaloa, Mexico. In 2011, studies of tortoise genetics, morphometrics, and ecology led experts to conclude that the complex formerly known as "Desert Tortoise" in fact consists of two separate species, Mojave Desert Tortoise and Sonoran Desert Tortoise (Murphy et al. 2011, Iverson et al. 2017). Mojave Desert Tortoise, also known as Agassiz's Desert Tortoise or Mohave Desert Tortoise, retains the binomial *G. agassizii*, and ranges across the deserts of southeastern California, southern Nevada, and small areas of Arizona and Utah north of the Colorado River. Desert tortoises east of the Colorado River in Arizona and northern Mexico are now classified as Sonoran Desert Tortoise, also known as Morafka's Desert Tortoise (*Gopherus morafkai*). Only the Mojave Desert Tortoise occurs in California. This status review uses the common name Mojave Desert Tortoise when referring to *G. agassizii* as the species is currently understood. Any reference to Agassiz's or Mohave Desert Tortoise in this document should be considered synonymous with Mojave Desert Tortoise.

2.2 Species Description and Life History

Much of the information in this section is summarized from a Berry and Murphy (2019) monograph on *Gopherus agassizii*. The Mojave Desert Tortoise is a long-lived, desert-dwelling reptile. The upper shell or carapace of adults ranges in size from 178mm to over 370mm in length. Shell color varies from light yellow to dark charcoal in hatchling tortoises and from light to dark brown in adults (Berry and Murphy 2019). The largest measured wild individual was a female in 1986 whose carapace length was 374 mm. The largest male measured in the wild was 330 mm carapace length (Berry and Murphy 2019).

Figure 1. Mojave Desert Tortoise. Pictures by Dana Wilson BLM (left) and Roy Averill-Murray USFWS (right).

Desert tortoises make extensive use of underground burrows to regulate body temperature and as protection from predators. Temperatures in burrows can be up to 20°C (36°F) cooler than summer air temperatures, especially very deep in the burrows (Berry and Murphy 2019). Home range size depends on sex, age, and environmental conditions. Over a 2-year study in the western Mojave Desert, male home range size was 39–47 ha and female home range size was 14–17 ha (Harless et al. 2009). Home ranges of juveniles tend to be smaller, and home ranges are larger during wet years than in dry years. Home ranges of individuals can overlap (O'Connor et al. 1994) and in the western Mojave Desert Harless et al. (2009) found that males overlap more with other tortoises than do females. They also found that the overlap in area in an individual's home range from one year to the next was ~35% and did not vary significantly by sex. Individuals tend to have fidelity to home ranges and activity centers, even after fire (Drake et al. 2015, Lovich et al. 2018).

Tortoises are long-lived and females are thought to become sexually mature at 12–20 years old, depending on locality (Woodbury and Hardy 1948, Turner et al. 1986, Curtin et al. 2009). Generation time is estimated to be around 25 years (U.S. Fish and Wildlife Service 1994). Mating occurs in late summer and fall, and females can mate with multiple males (Davy et al. 2011). Female tortoises can store sperm/delay implantation so that nesting and egg laying occurs in April–July depending on the region (Berry and Murphy 2019). Females lay 0–3 clutches in the spring and the number of eggs laid per clutch ranges from 1–10. Females nest in a den or burrow under large shrubs. There are anecdotal reports of females nest guarding against humans and Gila Monsters, but there is no parental care once eggs have hatched (Berry and Murphy 2019). Reported incubation time in the wild varies from 67–104 days (McLuckie and Fridell 2002) and incubation temperatures determine the sex of the hatchlings. Sex ratios were 1:1 at an incubation temperature of 31.3°C (88.3°F), while eggs incubated at under 30°C (86°F) produced only male hatchlings and only females hatched from eggs incubated over 32.5° (90.5°F) (Rostal et al. 2002). Nest predation is common, with 12–55% of nests generally destroyed by predators (Berry and Murphy 2019). When nests are not predated, hatchling success is about 80% (Bjurlin and Bissonette 2004). Newly hatched tortoises are about 4–5 cm in length (Bjurlin and Bissonette 2004) and their shells do not fully ossify until they are 5–7 years old. At that age they become less vulnerable to predators. For more information about predation, see section 4.4.

Tortoises selectively feed on annual and perennial forbs, grasses, and will consume cacti during droughts (Berry and Murphy 2019). Tortoises favor native plants and plant parts that are high in water and low in potassium (Oftedal et al. 2002). Potassium is potentially toxic and requires a large amount of water and nitrogen to excrete. Much of the range of the desert tortoise is highly invaded by nonnative plants like red brome, cheat grass, red stem filaree, and African mustard, but tortoises avoid eating exotic grasses when possible as they are low in nitrogen and require relatively large amounts of water to process. Experimental studies found that grass diets that included no forbs were detrimental to tortoises, leading to weight loss, poor body condition, or even death (Hazard et al. 2009, Drake et al. 2016). This was the case even when the diet included native grasses (Drake et al. 2016). According to Berry & Murphy (2019), tortoises "favored species of forbs or herbaceous perennials from several plant families: Asteraceae, Boraginaceae, Cactaceae, Fabaceae, Malvaceae, Nyctaginaceae, Onagraceae, and Plantaginaceae (Burge and Bradley 1976; Avery and Neibergs 1997; Jennings and Berry 2015)."

Tortoises are ectotherms whose body temperature is closely linked to the temperature in the environment around them. Mojave Desert Tortoises live in places that can fluctuate up to 40°C (104°F) seasonally and they primarily regulate their temperature by using underground burrows where the air is cooler and moister than the outside air in summer and warmer in winter. Depending on the type, length, and depth of burrow, average temperatures inside vary from 33.7–36.6°C (92.6–97.8°F) in the summer and 8.9–13.5°C (48–56.3°F) in the winter (Mack et al. 2015). Berry and Murphy (2019) report that desert tortoises spend >90% of their lives underground. Tortoises are active when their body temperatures are between 19.0°C and 37.8°C (66.2–100°F), they retreat to shade when body temperatures are 37–38°C (98.6–100.4°F), and body temperatures of 43°C (109.4°F) are deadly (Brattstrom 1965). However, tortoises can be active above ground at any time of year, especially if it has rained and they can drink, or if they need to move between shelters. They generally are underground or in rock shelters in late fall and winter, and in late spring through the hot summer. In early spring and fall they are more active above ground, feeding, travelling, and interacting with other tortoises (Berry and Murphy 2019). On a given day, air temperature determines when the tortoises are active above ground. In the cooler late winter and spring, they are active late morning to mid-afternoon. In the hotter summer and fall, if activity occurs, it tends to be in the cool of the morning and late evening. Smaller juvenile tortoises can be active at cooler temperatures than larger tortoises so tend to be active more days per year (Berry and Murphy 2019). Available water and forage have a strong impact on activity and movement. Tortoises had lower metabolic rates, moved less, used fewer burrows, and had smaller home ranges during drought years.

Tortoises also have additional behavioral and physiological strategies to deal with extremes of temperature and resource availability. During droughts, tortoises can lose up to 40% of their body mass. They can resorb water from their bladders and store sodium, chloride, and urea in their blood and in the bladder. When it rains, they drink, void their bladders, and rapidly increase their body weight (Peterson 1996, Berry and Murphy 2019).

2.3 Habitat Associations

Figure 2. Mojave Desert Tortoise in the Mojave Desert. Photo by Rachel London via USFWS

Mojave Desert Tortoises in California can be found in part of the southern Great Basin, Mojave, and western Sonoran deserts in southeastern California (Berry and Murphy 2019). Due to their dependence on burrows, they require soils, topography, geological features, and vegetation that facilitate the creation of burrows or dens (Andersen et al. 2000). Therefore, desert tortoise habitat typically consists of alluvial fans and plains and colluvial/bedrock slopes (Nussear et al. 2012). Tortoises also need appropriate vegetation communities for forage and shelter. Most burrows are found beneath shrubs, though they can also be dug into the sides of ephemeral streams.

The vegetation types that tortoises use varies across their range and by altitude. As Berry and Murphy (2019) put it:

> “Within the Mojave Desert ecosystem, tortoises occur in several vegetation associations. At lower elevations or adjacent to dry lake beds, saltbush associations (*Atriplex* spp.) and other members of the Chenopodiaceae provide habitat. The most common associations contain creosote bush (*Larrea tridentata*), usually with white bur-sage (*Ambrosia dumosa*) or cheesebush (*A. salsola*) and several other species of shrubs, cacti, and perennial grasses. With increasing elevation, multiple species of woody shrubs and tree yuccas (Joshua tree, *Yucca brevifolia,* and Mojave yucca, *Y. schidigera*) become more common, with blackbrush (*Coleogyne ramosissima*) associations present in higher elevations.
>
> The western Sonoran Desert is a warmer, hotter desert with a higher proportion of precipitation occurring in summer. This desert is also characterized by creosote bushes, but a major difference is the presence of microphyll woodlands of blue palo verde (*Parkinsonia florida*), smoke tree (*Psorothamnus spinosus*), and ironwood (*Olneya tesota*) in ephemeral stream channels separated by desert pavements or open desert with ocotillo (*Fouqueria splendens*) mixed with creosote bush, other shrubs, and cacti (Berry 1984).
>
> Tortoises occur in very low densities or are absent where shrub cover is sparse, precipitation is low and timing erratic, and annual food plants are available only intermittently (e.g., the lower elevations in Death Valley). They are also in low densities in moderately to severely disturbed areas, regardless of desert or region (e.g., Bury and Luckenbach 2002; Keith et al. 2008; Berry et al. 2013).”

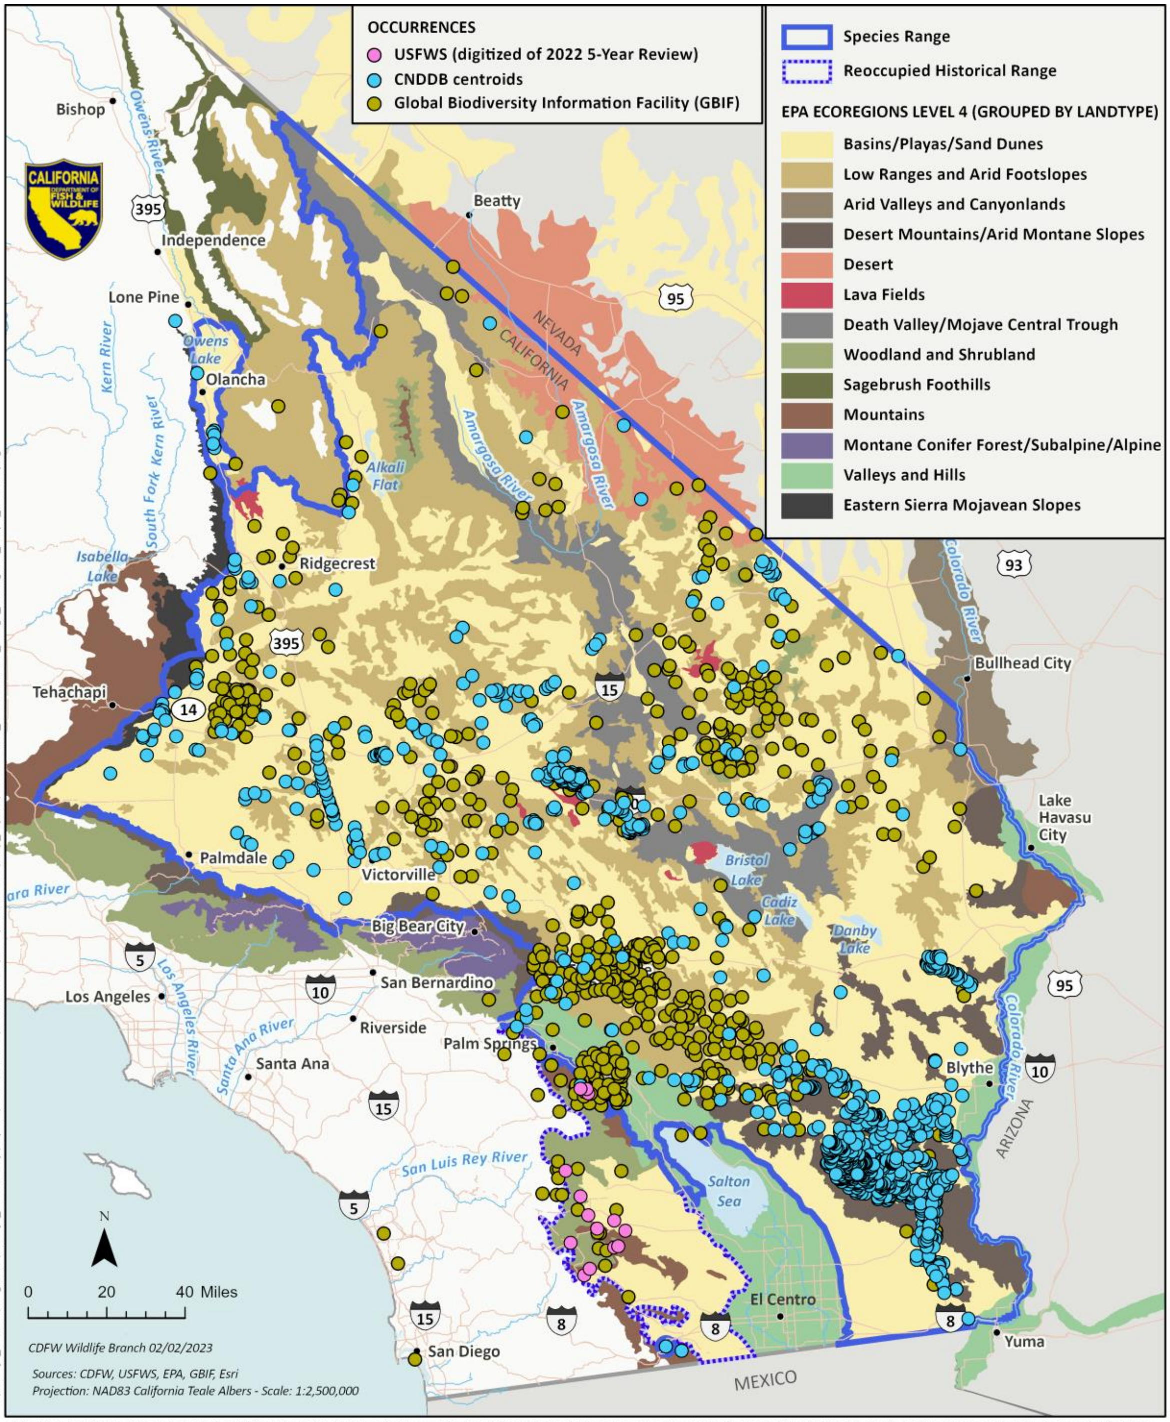
2.4 Range and Distribution

Range is the general geographical area in which a species occurs. For purposes of CESA and this status review, we are describing and evaluating the tortoise’s range in California. Distribution describes the sites where individuals and populations of the species occur, and the spatial arrangement of individuals within the species’ range.

In California, the range of the Mojave Desert Tortoise includes the Mojave Desert and portions of the Sonoran and Great Basin Deserts from the southern end of the Owens Valley south of the town of Lone Pine in Inyo County to the Mexican border near the southeastern corner of the state, and from the Colorado River in the east to the lower slopes of the Sierra Nevada, Transverse, and Peninsular mountains in the west (Berry and Murphy 2019).

The range of tortoises has also been dynamic due to the release of captive tortoises and potential immigration into areas from which they were previously extirpated. For example, tortoises were largely extirpated from the area of Anza Borrego Desert State Park by the 1940s (Manning 2018). In the early 1970s taking tortoises from the wild became illegal, and people began turning in their captive tortoises to the Department. Between 1970 and 1972 the Department released about 65 previously captive tortoises into the park. There were occasional sightings in the decades since, with more sightings since 2010. The tortoises there today could be descendants of released tortoises, however natural immigration to the park is possible as there is a tenuous corridor of suitable habitat that connects the park to habitat occupied by tortoises to the north. In 2016, park staff began surveying for tortoise and formally collecting incidental observation data, and subsequent genetic analysis of tortoise blood and scat suggested “evidence of a naturally reproducing Mojave Desert Tortoise population in Anza Borrego Desert State Park” (Manning 2018). These tortoises extend “the distribution of reproducing Mojave Desert Tortoises greater than 60 km south of Palm Springs and beyond the southern edge of the Colorado Desert Recovery Unit boundary depicted in the recovery plan (Service 2011a)” (U.S. Fish and Wildlife Service 2022*a*). We show this reoccupation of historical range in Figure 3, delineated using suitable ecoregion boundaries.

The distribution of desert tortoises within the California range is uneven, and portions of the range no longer provide suitable tortoise habitat due to agriculture, development, and military activity. Data on tortoise occurrences from the California Natural Diversity Database (CNDDB) and the Global Biodiversity Information Facility (GBIF) were used to plot distribution of observations in California (Figure 3). These datasets do not represent exhaustive and comprehensive inventories of desert tortoises in California and are largely presence-only datasets. While caution should be used in using these types of data, there appear to be fewer occurrences in the northern part of the range and in the Death Valley Mojave Central Trough (see grey area on Figure 3).



Disclaimer: Information presented on this map is for visual reference only. Consult primary data sources to ascertain the usability of this information for any use other than visual reference.

Figure 3. Map of the California range of the Mojave Desert Tortoise, occurrence locations, and Ecoregions. CNDDB data are sightings from 1935 to 2011. The GBIF occurrences are sightings that are confirmed by a picture from 1978 to 2022. The pink dots are the locations of tortoises in the reoccupied historical range as reported in U.S. Fish and Wildlife Service (2022a). Range boundary is from the California Wildlife Habitat Relationship System (California Department of Fish and Wildlife 2014).

2.5 Population Genetic Structure

For imperiled species, understanding the populations' genetic structuring is important for effective management. Head-starting and translocation are two actions used in desert tortoise conservation (see section 9.1 for more details), and the efficacy of both depends on knowledge of genetic boundaries to avoid the potentially negative impacts of artificially mixing individuals from different genetic populations (Sánchez-Ramírez et al. 2018).

The 1994 U.S. Fish and Wildlife Service (USFWS) Recovery Plan outlined recovery units consisting of "evolutionarily distinct" populations, with three recovery units occurring in California: Western Mojave, Eastern Mojave, and Colorado Desert Recovery Units (see section 3.1 for details). However, a recent study found that the best supported number of genetic clusters in California was five, with the Western Mojave Recovery Unit which encompasses much of the northern and western part of tortoise range in California, consisting of three genetic groups (Sánchez-Ramírez et al. 2018) (Figure 4). This differs from the earlier work of Hagerty and Tracy (2010) which found the Western Mojave Recovery Unit to be one genetic group. This means that populations within 200–300 km of each other which were previously considered genetically correlated and a single genetic unit for management purposes may actually be several genetically identifiable populations. Outbreeding depression has not been studied in *G. agassizii*, and the impacts of moving tortoises between genetic units are unknown, but Sánchez-Ramírez et al. (2018) advise caution when moving tortoises long distances for translocation or population augmentation. For more detail about translocations see section 9.1.

3. STATUS AND POPULATION TRENDS IN CALIFORNIA

3.1 Administrative Status

The Mojave Desert Tortoise has been protected as a threatened species under the California Endangered Species Act (CESA) (Title 14, §670.5) since 1989 and under the federal Endangered Species Act (ESA) since 1990. Unauthorized "take" of threatened and endangered species is prohibited. "Take" is defined under CESA as hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill (*Id.*, § 86).

The 1994 USFWS Desert Tortoise Recovery Plan designated six federal recovery units that cover desert tortoise range in California, Arizona, Nevada, and Utah. The recovery units were based on genetics, morphology, behavior, ecology, and habitat use, and each was considered an "evolutionarily distinct" population. These recovery units were revised in the 2011 Recovery Plan with better information and mapping tools. Of the six, all the Western Mojave, the majority of the Colorado Desert, and the western portion of the Eastern Mojave (formerly the Northeastern Mojave) Recovery Units are within California (Figure 4).

The Western Mojave Recovery Unit is differentiated from the other recovery units by rainfall and vegetation (U.S. Fish and Wildlife Service 2011). Summers are warm and winters are cold, with most rainfall occurring in fall and winter. Tortoises in the Western Mojave Recovery Unit dig deep burrows (usually located under shrubs on bajadas) for winter hibernation and summer

Figure 4. Map of genetic groups of the Mojave Desert Tortoise. Superimposition of the boundaries of the Recovery Units over Figure 3 panel F in Sánchez-Ramírez et al. (2018). The base map is the "spatial interpolation of ancestry coefficients of Agassiz's desert tortoises using Krig modeling…combines areas of maximal ancestry proportion for each of the five genetic groups"

estivation. Above-ground activity occurs primarily in spring when winter annuals provide food (U.S. Fish and Wildlife Service 2011).

The Colorado Desert Recovery Unit receives about 1/3 of its annual rainfall in summer and supports distinct summer and winter annual plants that tortoises feed on. The climate is somewhat warmer than in other recovery units, with very few freezing days per year. Tortoises are found in the valleys, on bajadas, desert pavements, rocky slopes, and in the broad, well-developed washes (U.S. Fish and Wildlife Service 2011).

The Eastern Mojave Recovery Unit is separated from the Western Mojave Recovery Unit by an inhospitable barrier created by the Saline Valley, Death Valley, and Silurian Valley. Desert tortoises in the Eastern Mojave Recovery Unit are generally found in creosote bush scrub communities of flats, valley bottoms, alluvial fans, and bajadas. They are often active in spring, late summer, and early fall, as this region receives up to about 40% of its annual rainfall in summer and there are two distinct annual floras on which tortoises can feed (U.S. Fish and Wildlife Service 2011).

Each recovery unit contains one or more Critical Habitat Units (CHUs). Under section 3 of the ESA, the Department of the Interior is directed to designate the specific areas supporting those physical and biological features that are essential for the conservation of the species. The Department of Interior designated critical habitat areas for the Mojave Desert Tortoise in early 1994 (59 FR 5820) that encompass over 24,281 km^2 in the Mojave and Colorado deserts (U.S. Fish and Wildlife Service 2011). The critical habitat units are administrative areas managed to give reserve-level protection to desert tortoise populations while maintaining and protecting other sensitive species and ecosystem functions (U. S. Fish and Wildlife Service 1994). According to USFWS (2019a):

> "The specific physical and biological features of desert tortoise critical habitat are (1) sufficient space to support viable populations within each of the six recovery units and to provide for movement, dispersal, and gene flow; sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species; (2) suitable substrates for burrowing, nesting, and overwintering; (3) burrows, caliche caves, and other shelter sites; (4) sufficient vegetation for shelter from temperature extremes and predators; and (5) habitat protected from disturbance and human-caused mortality."

In California, federal critical habitat designation totals 19,239 km^2. Of this, 13,465 km^2 are Bureau of Land Management (BLM) land, 980 km^2 are military land, 538 km^2 are state land, and 4,255 km^2 are private land (U. S. Fish and Wildlife Service 1994) (Figure 5).

Figure 5. Landownership, RUs, and CHUs in the Mojave Desert Tortoise range in California.

Tortoise Conservation Areas (TCAs) are areas that mostly align with CHUs that the USFWS has designated for surveys to evaluate tortoise population status and recovery (see Figures 5, 6 and Table 1). They include "designated critical habitat as well as contiguous areas with potential tortoise habitat and compatible management" (U.S. Fish and Wildlife Service 2019*b*). The TCAs have the same name as the CHU they encompass, with a few exceptions where there are multiple TCAs within a CHU (Allison 2015), and Joshua Tree TCA which is not within a CHU. See Figure 6 for boundaries of CHUs and TCAs, and Table 1 for overall size and amount of habitat within the CHUs, and size of TCAs.

Table 1. Area of modeled desert tortoise habitat within California CHUs, and size of associated TCAs (U.S. Fish and Wildlife Service 2019a). Modeled habitat is suitable desert tortoise habitat per Nussear et al. (2009).

Recovery Unit	Critical Habitat Unit	Area (km^2)	Modeled Habitat (km^2)	Tortoise Conservation Area	Area (km^2)
Western Mojave	Fremont-Kramer	2,096	2,028	Fremont-Kramer	2,417
	Ord-Rodman	1,025	745	Ord-Rodman	1,124
	Superior-Cronese	3,104	2,934	Superior-Cronese	3,332
Eastern Mojave	Ivanpah	2,559	2,067	Ivanpah	2,567
Colorado Desert	Chuckwalla	4,130	3,275	Chuckwalla	3,509
	Chuckwalla			Chocolate Mountain Gunnery Range	755
	Chemehuevi	3,794	3,701	Chemehuevi	4,038

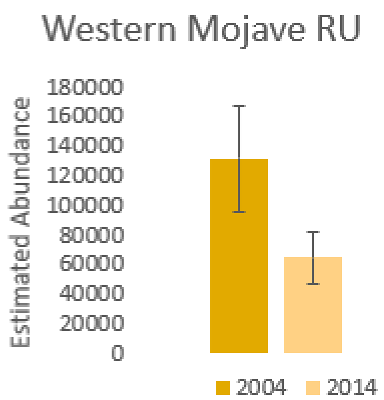
Figure 6. Mojave Desert Tortoise range, RUs, CHUs, and TCAs.

3.2 Trends in Density and Abundance

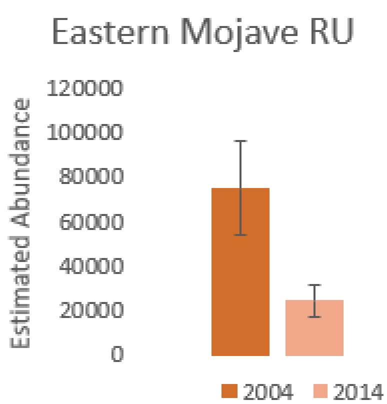
Tortoises are long lived, reach sexual maturity late, and have decades of reproductive life. These life history characteristics make it difficult to assess trends in tortoise populations. For such species, short- and medium-term studies (1–10 years) may not be long enough to adequately understand population trends (Tracy et al. 2004). Also, studies that cover only very small, localized portions of the tortoise's range have limited value in assessing the overall population status. This makes long-term studies with consistent methodology that cover large portions of the range in California key to understanding the extent to which tortoise populations are declining or recovering over time.

Since the species was listed as threatened under CESA in 1989, the most robust estimates of density over time come from long-term surveys of TCAs within each CHU using line distance sampling. Square transects with 3 km sides were set up to provide good coverage of each TCA, and a random selection of these transects are surveyed each year. Two surveyors walk line transects along the boundary of the square or as close to it as is feasible. They record the distance and bearing from the survey line to all tortoises seen and live tortoises are measured and sexed. In addition, data from tortoises carrying radio transmitters are used to estimate what portion of tortoises are above ground during the transects. Transects are scheduled in mid-March to May to maximize the chance tortoises will be active and above ground. Standard models are used to calculate density for the TCA from the line transect data in each sampling stratum. Funding for these efforts has varied, but in most years from 2001 to 2021 the USFWS has coordinated the distance sampling monitoring program for desert tortoises in the three recovery units that cover tortoise range in California (U.S. Fish and Wildlife Service 2015, 2019*b*, 2020*a*, 2022*b*, *c*). The years that each specific TCA was surveyed are presented in Table 2.

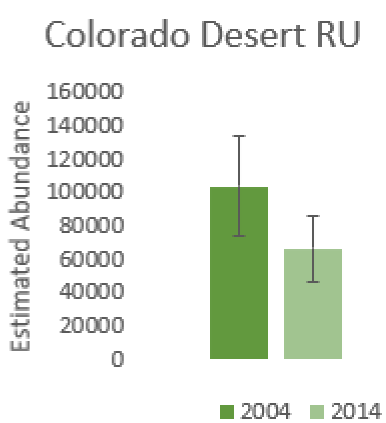
Despite the protections afforded though the federal ESA and CESA, tortoise populations have declined in recent decades. The 1994 USFWS Recovery Plan for desert tortoise identified 3.9 adult tortoises/km^2 as the minimum density necessary for population viability (U. S. Fish and Wildlife Service 1994, U.S. Fish and Wildlife Service 2011). Only one of the TCAs was below this threshold in 2004, but by 2014, 8 out of 10 were at or below it. Between 2004 and 2014, annual declines per year ranged from 3.3% in the Chocolate Mountain Gunnery Range to 10.8% in Chemehuevi (Allison and McLuckie 2018) (Figure 7). Joshua Tree was the only TCA in California where the population increased (6.2% annual rate of increase). However, Joshua Tree started with a very low estimated density of 1.9 tortoise/km^2 in 2004, most likely due to extended drought (Lovich et al. 2014, Allison and McLuckie 2018). These annual rates of decline are very high, and a species that reproduces as slowly as the desert tortoise will likely require a long time to recover from such losses.



Area	Annual Trend in Density 2004–2014
Fremont-Kramer TCA	-6.80%
Ord-Rodman TCA	-8.20%
Superior-Cronese TCA	-9.30%
Western Mojave RU	-7.10%



Ivanpah TCA	-7.40%
Eastern Mojave RU	-11.20%



Chocolate Mountain TCA	-3.30%
Chuckwalla TCA	-4.10%
Chemehuevi TCA	-10.80%
Fenner TCA	-7.30%
Joshua Tree TCA	6.20%
Pinto Mountains TCA	-8.30%
Colorado Desert RU	-4.50%

Figure 7. Estimated abundances (with standard errors) of adult Mojave Desert Tortoises (*Gopherus agassizii*) in 2004 and 2014 in the recovery units relevant to California (left). Estimated annual rates of change in density for recovery units and associated Tortoise Conservation Areas (right). Abundance estimates for recovery units are based on densities calculated from the model in Table 4 of Allison and McLuckie (2018) and applied to all areas of the associated recovery unit that meet criteria as modeled habitat. TCA annual trends in population are from U.S. Fish and Wildlife Service (2022a).

Allison and McLuckie (2018) estimated the abundance of desert tortoises in the three recovery units that fall within California in 2004 and 2014 from the density estimates in the TCAs (Figure 7). Abundance declined precipitously between 2004 and 2014 in the Western Mojave, Colorado Desert, and Eastern Mojave Recovery Units, with each of them losing between 35,000 and 65,000 adults. It should be noted that the Eastern Mojave and Colorado Desert Recovery Units each have one TCA outside of California so the abundance estimates are an over-estimate for California. Allison and McLuckie (2018) estimated that the Western Mojave Recovery Unit experienced a 51% decline in adults from 2004 to 2014.

Since 2014, densities have not declined as steeply as in the previous decade. Although no populations have reached pre-2014 highs, between 2015 and 2021, densities increased somewhat in Chemehuevi, Fenner, and Ivanpah. The declines continued in Chocolate Mountains, Ord-Rodman, Fremont-Kramer, and Superior-Cronese (U.S. Fish and Wildlife Service 2022*a*, *c*) (Figures 8 and 9, Table 2). The most recent surveys (2019–2021) show that in the Eastern and Western Mojave Recovery Units, all of the TCAs surveyed were below the 3.9 adult tortoises/km^2 threshold. In the Colorado Desert Recovery Unit, two were at the threshold, two were below it, and only one TCA (Fenner) was above (U.S. Fish and Wildlife Service 2022*a*) (Figures 8 and 9, Table 2). The declines in the TCAs occurred despite most of the land falling under federal land management agency ownership (Figure 5).

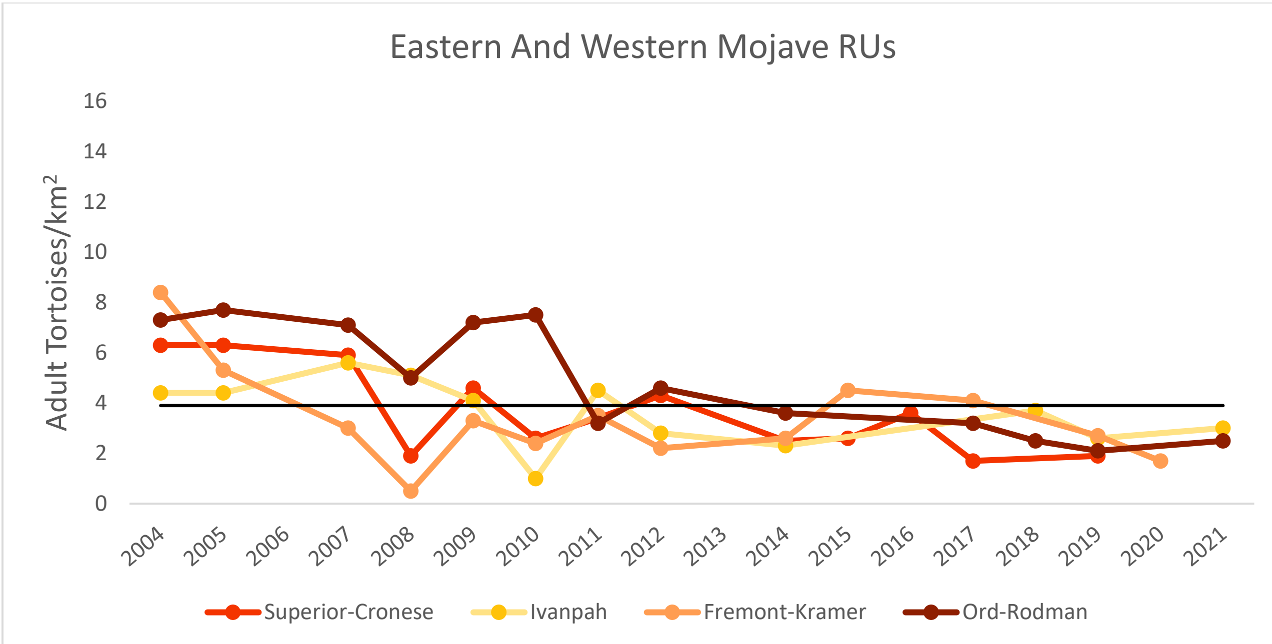


Figure 8. Estimated densities of adult tortoises (≥ 180 mm carapace length) in TCAs in the Eastern and Western Mojave RUs in California 2004–2021. Black horizontal line represents 3.9 adults/km^2, the estimated minimum density needed for population viability. For time series figures of individual TCAs including error bars, see Appendix A.

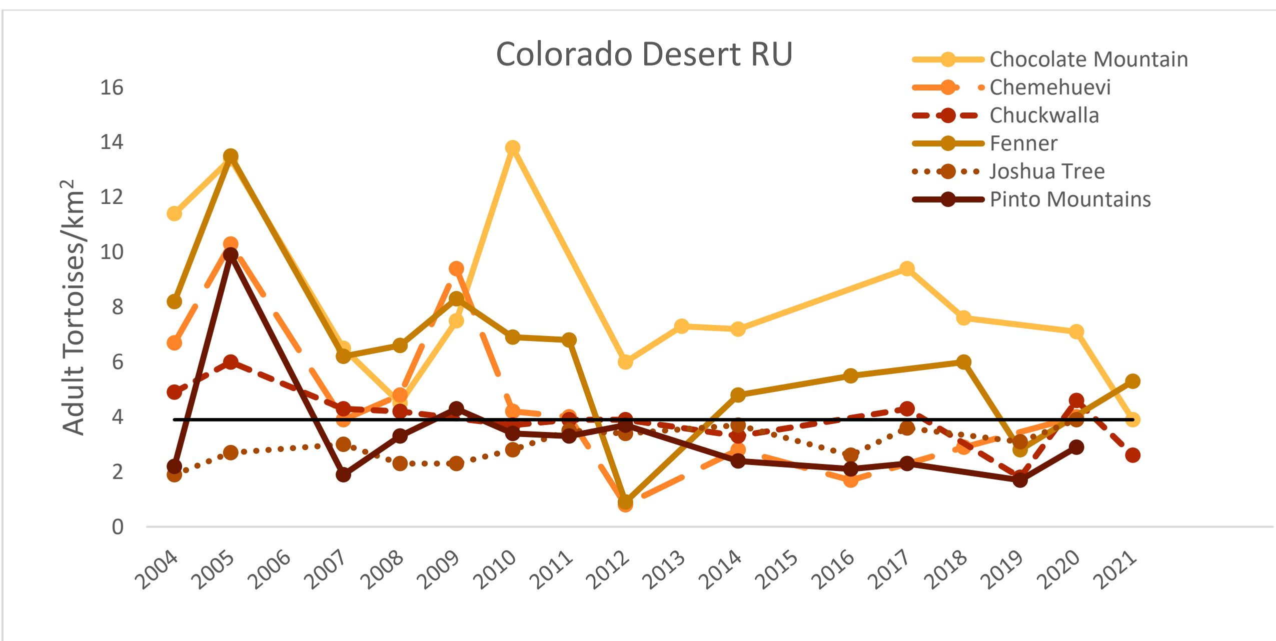

Figure 9. Estimated densities of adult tortoises (≥ 180 mm carapace length) in TCAs in Colorado Desert RU in California 2004–2021. Black horizontal line represents 3.9 adults/km^2, the estimated minimum density needed for population viability. For time series figures of individual TCAs including error bars, see Appendix A.

Table 2. Estimated densities of adult tortoises (≥ 180 mm carapace length) in Tortoise Conservation Areas in California. Estimates for 2004–2014 have standard errors (SE); estimates for 2015–2021 have coefficients of variation expressed as percentages. Data from (U.S. Fish and Wildlife Service 2015, 2016, 2018, 2019*b*, 2020*a*, 2022*c*, *b*, Allison and McLuckie 2018), and presented in Figures 8 and 9.

		Estimated Density (number/km^2)

	Chemehuevi	6.7 (1.27)	10.3 (3.10)	3.9 (1.71)	4.8 (3.07)	9.4 (5.98)	4.2 (1.40)	4.0 (1.51)	0.8 (0.90)		2.8 (0.3)		1.7 (30.6)		2.9 (24.21)		4.0 (15.2)	
	Fenner	8.2 (1.94)	13.5 (2.80)	6.2 (2.37)	6.6 (3.05)	8.3 (4.01)	6.9 (2.49)	6.8 (2.78)	0.9 (0.95)		4.8 (0.5)		5.5 (30.0)		6.0 (26.25)	2.8 (29.8)		5.3 (19.8)
	Pinto Mountains	2.2 (2.12)	9.9 (3.58)	1.9 (0.98)	3.3 (3.53)	4.3 (2.38)	3.4 (1.85)	3.3 (1.39)	3.7 (1.57)		2.4 (0.3)		2.1 (31.6)	2.3 (32.7)		1.7 (31.8)	2.9 (20.6)	
	Joshua Tree	1.9 (0.53)	2.7 (0.79)	3.0 (1.94)	2.3 (1.75)	2.3 (1.56)	2.8 (1.56)	3.5 (1.33)	3.4 (1.63)		3.7 (0.4)		2.6 (34.7)	3.6 (22.5)		3.1 (20.2)	3.9 (23.3)	

*724 adults were translocated into the Ord-Rodman TCA in 2017–2019 due to expansion at 29 Palms Marine Corps Air Gunnery Command Center. These are included in these density estimates.

The long-term surveys in the TCAs provide robust data on declines in density since 2004. However, tortoise populations had been in decline for decades previously, and estimates of densities from before the species was listed under CESA in 1989 are important for understanding the scale of long-term decline. While there were no large scale or frequent systematic population monitoring programs in the 20th century, multiple regional or short-term surveys give snapshots of density in certain areas pre and post listing. Collectively, these studies give a broad picture of the state of tortoise populations in the past several decades.

Estimates of tortoise densities in California before the species was listed under CESA can be found in Berry (1986*a*):

> "Berry and Nicholson (1984a) developed a more detailed map of relative tortoise abundance throughout an area of over 100,000 km^2 using data from 1,808 strip transects. Transects, which were 2.4 km by 9.1 m, provided counts of tortoise signs (live individuals, carcasses, scats, cover sites, tracks, drinking sites, and courtship rings). Counts of signs were calibrated against counts along transects in areas where tortoise densities had been estimated by repeated censuses. The map prepared by this method showed five relative density classes: 0–8, 9–19, 20–39, 40–97, and >97 tortoises/km^2. Four major tortoise population centers or crucial habitats with densities of >77 tortoises/km^2 were identified: (1) Fremont-Stoddard in the western Mojave Desert (4864 km^2), (2) Ivanpah in the eastern Mojave Desert (918 km^2), (3) Fenner-Chemehuevi in the eastern Mojave and northeastern Colorado deserts (3881 km^2), and (4) Chuckwalla (1333 km^2) in the southern Colorado Desert."

In addition, in the 1970s the BLM established 27 2.6 km^2 (1 $mile^2$) survey sites in California (Berry and Turner 1986). Using mark recapture methods, researchers surveyed the plots over 60-day periods in the spring every 2–10 years (Berry and Medica 1995). Berry (1986*a*) reports that of those 27 sites, "eight had estimated densities of $\leq$8 tortoises/km^2, six had 8–39 tortoises/km^2, and 13 sites supported 42–184 tortoises/km^2", though the years those estimates come from are not reported. Multiple of these sites are located within the current Tortoise Conservation Areas, with sites in the Ivanpah, Chuckwalla, Fenner, and Chemehuevi TCAs. Using data reported in Berry and Medica (1995), rough comparisons can be made between the estimated densities in 1979–1992 and the 2004–2014 surveys. The earlier surveys covered the whole of the plot and did mark recapture methods to estimate density, while the later USFWS surveys used line transects. In addition, the BLM density estimates are only for the single plot per TCA, while the more recent line transects use multiple line transects per TCA to estimate density across the whole TCA. However, the combined density estimates provide a benchmark of declines over the past 50 years. The Desert Tortoise Natural Area overlaps with the northern border of the Fremont-Kramer TCA. Estimates of densities in 1979–1980 vary from 36 adults/km^2 in Chemehuevi to a high of 73 adults/km^2 in Fenner and Chuckwalla (Figure 10). By the early 1990s, density of adults had not fallen particularly dramatically except in Chuckwalla which had a 57% decline from about 73 adults/km^2 to about 31 adults/km^2, and the Desert Tortoise Natural Area which saw a 93% decline to 3.7 adults/km^2 which is below the density needed for population viability (Figure 10). However, on the scale of multiple decades, all the surveyed areas experienced very steep declines. From 1979–1980 to 2020–2021, densities of adults in the corresponding TCAs fell 93% in Fenner, 96% in Chuckwalla, 89% in Chemehuevi, and 93% in Ivanpah (Table 2 and Figures 8, 9,10).

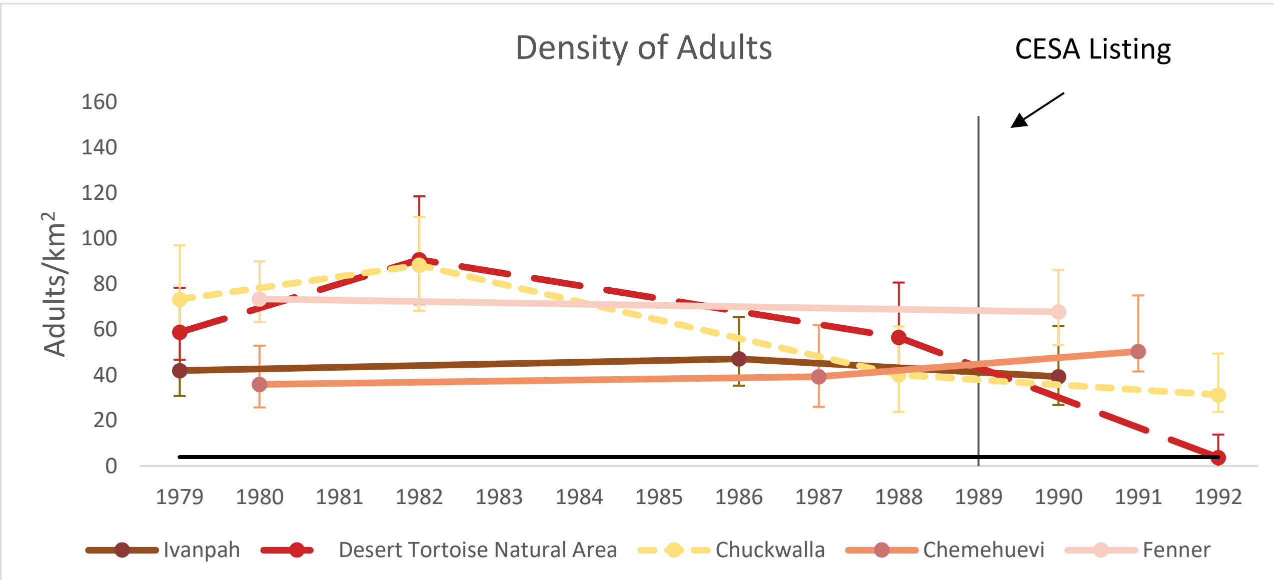

Figure 10. Estimated densities of adults/km^2 in plots surveyed 1979–1992 using mark recapture methods. The dot represents the midpoint of the density estimates, bars are 95% confidence intervals. Black horizontal line represents 3.9 adults/km^2, the estimated minimum density needed for population viability. Redrawn from figures in Berry and Medica (1995).

Berry et al. (2020b) continued the work of surveying tortoises at Desert Tortoise Research Natural Area in the western Mojave Desert for decades. Part of the site was fenced to keep out sheep, vehicles and humans but allow movement of tortoises, and surveys were done both inside and outside the fence. In 1979 when they started the surveys, estimated densities of all tortoises inside the fence were 103/km^2, and 79/km^2 outside the fence. In 2002 it had declined to 10.2/km^2 inside the fence and 4.17/ km^2 outside the fence. By 2012 densities had increased to 15.6/ km^2 inside the fence, and to 4.9/km^2 outside the fence. Counts of tortoises (from which densities were estimated) followed an estimated linear decline of 9.1% per year over the 30+ years of the study.

Other studies give rough estimates of historical density in other parts of the range. In the Pinto Basin of Joshua Tree National Park in 1991–1996, Freilich et al. (2000) used mark recapture methods to resurvey an area that had been surveyed in the 1970s. Their methods were designed to estimate abundance rather than density, and since they did not have a well-defined effective trapping area, their density estimates are rough. However, they report that in the 1970s the density estimates were 29–31 adults and juveniles/km^2, while their estimate for the early 1990s was 42 adults/km^2. Lovich et al. (2014) reports that surveys in the Pinto Basin in 1987–1988 estimated densities as high as 77 tortoises/km^2.

Medium-term tracking of densities did occur in four study sites in California at various times between 1977 and 1985 (Berry et al. 1986). At one site in the western Mojave Desert, Fremont Peak, sampling occurred three times (1977, 1980, and 1985) over a 9-year period and the population density declined from 27/km^2 in 1980 to 15/km^2 in 1985 (Berry et al. 1986). However, at three other sites there were no significant changes in density during those years. At the Kramer Hills site in the Western Mojave Desert there were an estimated 42 adults/km^2 in 1980 and 44 adults/km^2 in 1982. The Chemehuevi Wash site in the Colorado Desert was surveyed in 1979 and 1982 and saw a nonsignificant increase from 18 adults/km^2 to 22 adults/km^2. The Chuckwalla Bench study site also in the Colorado Desert had a non-significant increase in density from 75 adults/km^2 in 1979 to 87 adults/km^2 in 1982 (Berry et al. 1986), see Figure 10.

Although the density surveys in the 1970s and 1980s do not use the same methodology as later surveys and only cover small areas, they do give an idea of the range of tortoise densities in the decades before the start of the surveys in the TCAs, providing context for more recent density estimates.

Juveniles

Juvenile tortoises are easier to overlook during surveys than adults, and the U.S. Fish and Wildlife surveys in the TCAs do not report densities of juveniles (but see below). However, Berry and Medica (1995) report on the density of adults and all tortoises using mark recapture surveys in BLM plots from 1979 to 1992. From those we can roughly calculate historic density of juveniles (density of all tortoises minus density of adult tortoises) (Figure 11).

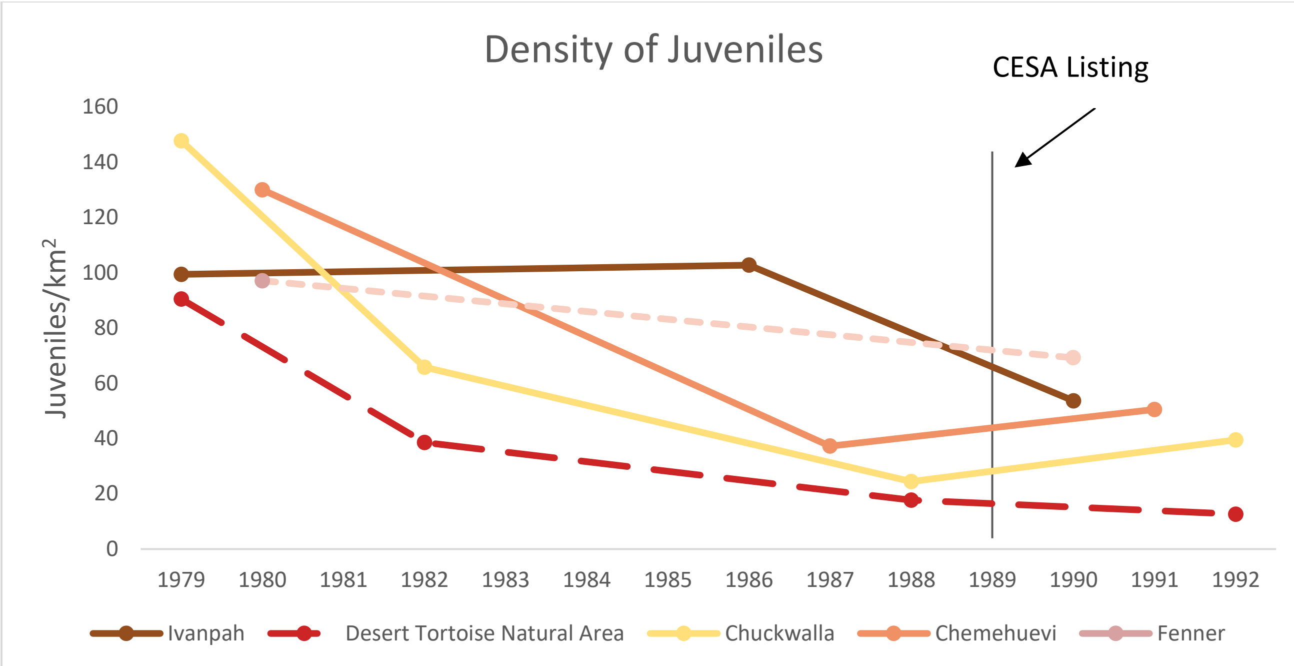

Figure 11. Density of juvenile tortoises in plots in California from 1979 to 1992. Juvenile density was calculated by subtracting density of adults from density of all tortoises presented in Berry and Medica (1995).

Between the late 1970s and early 1990s, the density of juveniles declined roughly 46% in Ivanpah, 86% in the Desert Tortoise Natural Area, 73% in Chuckwalla, 62% in Chemehuevi, and 29% in Fenner (Figure 11). While juvenile tortoises are expected to have low survival rates, this long-term loss of juveniles from the landscape is concerning, and there is evidence that it is continuing into recent years. In 2014 in the Western Mojave Recovery Unit, the density of adult tortoises was 49% of what it had been in 2004, and the proportion of juveniles in the population declined by 9% (Allison and McLuckie 2018). In the yearly transect surveys done in the TCAs, many fewer tortoises with midline carapace length <180 mm were found in 2007–2015 compared to 2001–2005 (Figure 12). In some areas, the youngest tortoises found in recent years were at least 30 years old (Holcomb 2022*a*). Even if conditions quickly improve for juveniles, such a long period with little recruitment of juveniles into the population will hinder population recovery significantly.

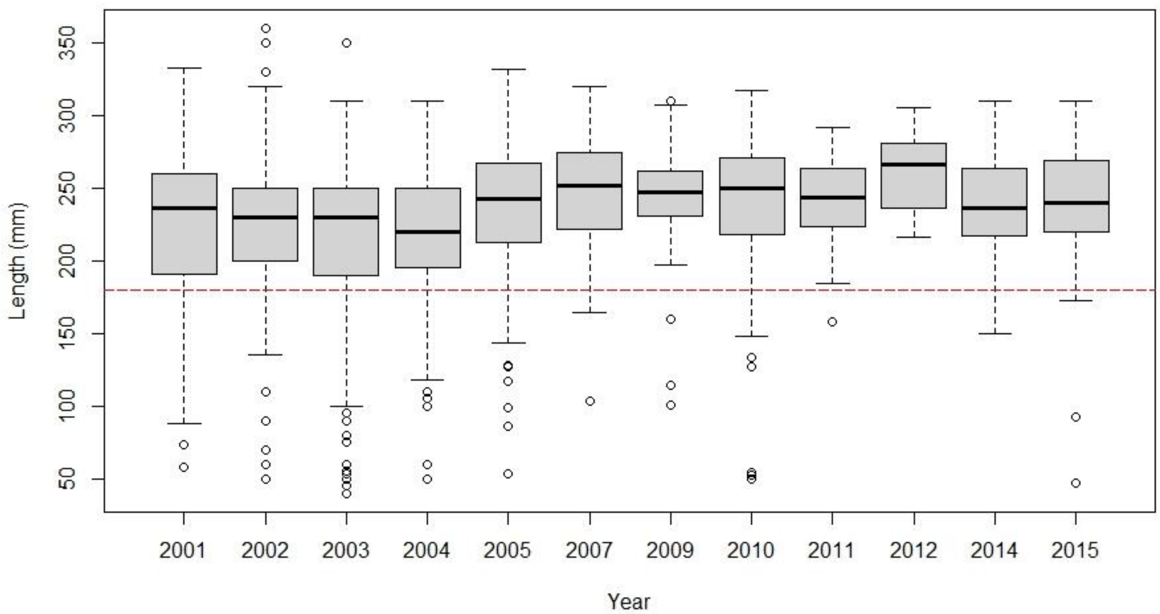

Figure 12. Midline carapace length of tortoises surveyed within the Western Mojave Recovery Unit Tortoise Conservation Areas, showing a reduction in observations of tortoises smaller than 180mm after about 2005. Described in Alison and McLuckie (2018), and figure made with USFWS unpublished data provided by K. Holcomb and used with permission. The horizontal dashed line at 180 mm represents the size over which tortoises are considered to be adults.

3.3 Mortality and Survival Rates

Adult and juvenile survival rates are important demographic factors that can affect whether a population is increasing, stable, or declining. Desert tortoises generally have low survival rates (i.e., high mortality rates) as hatchlings and juveniles, and relatively high adult survival rates (Berry and Murphy 2019). The adult survival rate needed for population stability depends on a number of factors, including population reproduction and/or recruitment rates, but the USFWS 1994 Recovery Plan estimated that an adult survival rate of 98% per year is needed for population growth of 0.5% per year. A more recent estimate that incorporated current adult densities and juvenile survival rates found that an adult survival rate of 93% per year was necessary for desert tortoise population stability (no growth or decline) (Holcomb 2022*a*). Estimates of survival/mortality rates come from a variety of studies within California, most of which were quite limited in geographic scale. When comparing survival rates to mortality/death rates, a broad rule of thumb is that mortality or death rate ≈ 1-(survival rate).

Adult tortoises are much easier to survey than juveniles, consequently most of the information about survival and mortality in the wild relates to adults. In the late 1970s and early 1980s, a study from four sites provided some limited information on annual mortality rates in stable and declining populations (Berry et al. 1986). At Fremont Peak in an area that became the Fremont-Kramer TCA, densities of adults and subadults declined significantly between 1977 and 1985, and the estimated annual mortality rate was 4.5% per year. In contrast, three other sites surveyed during that period that did not see significant declines in density had annual mortality rates of 2.2–2.9% (Berry et al. 1986). Berry et al. (2020b) estimated survival rates (1979–2012) of adults and juvenile tortoises inside and outside of the fenced portion of the Desert Tortoise Research Natural Area in the Western Mojave. As mentioned previously, in 1979 estimated densities of all tortoises was 103/km^2 inside the fence, and 79/km^2 outside the fence. By 2012 densities had decreased to 15.6/km^2 inside the fence, and to 4.9/km^2 outside the fence. During those years the population suffered an estimated 87.6% decline. Median annual survival probability (converted into percentages for ease of comparison) for adults inside and outside of the fenced area ranged from 79%–83% in 1979–1989, 71%–78% in 1989–2002, and 94%–96% in 2002–2012. These estimates are all well below the necessary survival rate identified in the USFWS 1994 Recovery Plan to achieve modest population growth. Juveniles had lower survival, their estimated median annual survival probability was 66%–73% in 1979–1989, 57%–65% in 1989–2002, and 90%-93% in 2002–2012.

In Eastern Joshua Tree National Park, tortoises were surveyed intermittently from 1978 to 2012 (Lovich et al. 2014). The authors tested the impact of rainfall on survival, and the best model of survival was based on the average estimated winter precipitation over the preceding three winters. They estimated a mean annual (apparent) survival rate of 0.87 (87%). Values below the mean occurred in 1991, 1997–2004 and 2008, which were years of lower rainfall (Lovich et al. 2014). Estimated survival was above the mean in 2010–2011. It should be noted that other factors that impact survival, such as predation and disease, were not tested independently. Instead, it was assumed that these factors would be mediated by rainfall (i.e., tortoises would be in poorer conditions in drier years and therefore they would be more susceptible to predation or disease).

Between 2002 and 2004, Berry and Keith (2008) evaluated the status of desert tortoise populations in Red Rock Canyon State Park in Kern County. Previous surveys had occurred in the 1970s, and density was estimated to be <8 tortoises/km^2. The death rate over four years was estimated at 67% for adults and subadults, and densities were between 2.7 and 3.6 tortoises/km^2.

In 2007–2008, Berry et al. (2020c) evaluated the status of a population of tortoises in the El Paso Mountains close to the Fremont-Kramer Critical Habitat Unit. Estimated density of adults was 4.8/km^2 and the annual death rate of adults in 2003–2008 was 6.9% (Berry et al. 2020*c*). The top causes of known death were mammalian and avian predators, gunshots, and vehicles. The authors concluded that “the high death rate of adults, low population density, high human visitor use, and ongoing decline in the adjacent critical habitat unit indicate that a viable population is unlikely to persist in the study area” (Berry et al. 2020*c*).

Esque et al. (2010) tracked several hundred adult tortoises before and after translocations from Fort Irwin National Training Center to neighboring public land in the Superior-Cronese Critical Habitat Unit. They monitored translocated tortoises, tortoises resident at the release sites, and control tortoises in nearby areas that were not affected by the translocations. In the first year (2008), 19% of control tortoises, 20% of resident tortoises, and 25% of translocated tortoises died. Most of the mortalities were thought to be due to coyote predation. As a comparison, at a different reference site in the Superior-Cronese Critical Habitat Unit, 8.3% of tracked tortoises died in 2008. At reference sites in other critical habitat units in California, percent mortality in 2008 ranged from 0% in Ivanpah and Ord-Rodman to 28–30% in Chemehuevi and Chuckwalla. Esque et al. (2010) also showed that mortality can vary greatly year to year in the same site. For example, at Soda Mountain outside of the Superior-Cronese Critical Habitat Unit, in 2006 at there was no mortality, in 2007 mortality was 17%, and in 2010 it was 43% (Esque et al. 2010).

In 2009, Berry et al. (2020a) surveyed about 93 km^2 of BLM land within the eastern Chemehuevi Valley, adjacent to the Chemehuevi Critical Habitat Unit. Based on the number of live and dead tortoises found, they concluded that the density of adults was 2.0/km^2 (+/- 1.0), and that the annual death rate in the four years prior to the survey was 13.1%/year. These data led them to conclude that the population was probably nonviable (Berry et al. 2020*a*).

Collectively, these data suggest that adult survival rates in most recently surveyed areas are too low to support stable populations and have been below the thresholds established by the USFWS 1994 Recovery Plan and by Holcomb (2022a) for some time (Table 3). Although survival rates have not been estimated systematically across the tortoise's range in California, rates appear to be particularly low outside of CHUs.

Table 3. Survival and mortality rates of adult and subadult tortoises in various studies.

Life stage	Survival vs Mortality	Rate	Location	Time scale	Reference
Adults	Median annual survival probability	79%-83%	Desert Tortoise Research Natural Area	1979-1989	Berry et al. 2020b
Adults	Median annual survival probability	71%-78%	Desert Tortoise Research Natural Area	1989-2002	Berry et al. 2020b
Adults	Median annual survival probability	94%-96%	Desert Tortoise Research Natural Area	2002-2012	Berry et al. 2020b
All	Mean annual survival	87%	Eastern Joshua Tree National Park	1978-2012	Lovich et al. 2014
Adults & subadults	Annual mortality	4.5%	Fremont -Kramer TCA	1977-1985	Berry et al. 1986
Adults & subadults	Annual mortality	2.2%-2.9%	Kramer Hills, Chemehuevi, Chuckwalla	1977-1985	Berry et al. 1986
Adults & subadults	Death rate over 4 years	67%	Red Rock Canyon State Park	2002-2004	Berry and Keith 2008
Adults	Annual death rate	6.9%	El Paso Mountains near Fremont-Kramer CHU	2003-2008	Berry et al. 2020c
Adults	Annual mortality	13%	Chemehuevi Valley	2005-2009	Berry et al. 2020a
Adults	Annual mortality	0%	Ivanpah	2006-2008	Esque et al. 2010
Adults	Annual mortality	0%	Ord-Rodman	2006-2008	Esque et al. 2010
Adults	Annual mortality	0%-31%	Chemehuevi	2006-2008	Esque et al. 2010
Adults	Annual mortality	9%-29%	Chuckwalla	2006-2008	Esque et al. 2010
Adults	Annual mortality	0%-44%	Soda Mountain	2006-2008	Esque et al. 2010

Adults	Annual mortality	6.3%-8%	Superior-Cronese	2007-2008	Esque et al. 2010

Juvenile Survival

In long-lived species like the tortoise, if adult survivorship drops, reproductive rates or juvenile survival would have to increase dramatically to keep populations stable. Analysis by the USFWS (1994) estimated that “a 10% increase in adult mortality can require a 300% increase in juvenile survivorship” to maintain a stable population. Many of the threats to adult survival affect juveniles, making it unlikely that juvenile survivorship can naturally increase to the levels needed to compensate for the decreasing adult survival documented above.

Several factors limit the number of hatchlings that are produced in the wild each year. Females lay a maximum of about 30 eggs per year, incubation success depends on temperature, and nest predation is common (Berry and Murphy 2019). After emerging from the egg, survival rates of wild hatchlings can be low. In the Ivanpah Valley between 2011 and 2014, Tuberville et al. (2019) compared survival and growth of free ranging hatchlings to those reared in pens under different rainfall scenarios. Both groups were hatched from eggs laid by wild females and brought into captivity for the study. Free ranging hatchlings were released into the wild between 0 and 18 months old. Estimated annual survival rates for the free ranging hatchlings was 48%–49% compared to 94% of those reared in pens.

We do not have much information on historical juvenile survival rates, but the impact of recent low survival rates can be seen in demographic information. As mentioned previously, in the yearly surveys performed in the Western Mojave TCAs, many fewer tortoises with midline carapace length <180 mm were found in 2007–2015 compared to 2001–2005 (Figure 12). One likely cause of juvenile mortality is raven predation. Holcomb et al. (2021) estimated that annual survival rates for 1–10-year-old tortoises in 5 CHUs averaged 63% when within 500m of a raven’s nest, and ~76% when the median distance to a nest was 1.72 km. See section 4.4 for more detail on predation.

One strategy to improve juvenile survival is to raise tortoises in captivity and then release them once they reach a certain size (referred to as head-starting; for more details see section 9.1). A study at the Fort Irwin National Training Center on head-started juvenile tortoises (Nagy et al. 2015*b*) found that in the two years after release, survivorship was 76–79%, but in the third year survivorship dropped to 53%, resulting in an overall three year survival rate of 32%. Survival was generally higher amongst tortoises with a carapace length of at least 100 mm (9 years old). Another study on head-starting found that found no significant difference in the survival rate of hatchlings released vs those reared indoors for 7 months vs those reared in outdoor pens for 7 months (Daly et al. 2019). Although the head-started tortoises grew quickly, the three groups combined annual survival after release was 44%, with the odds of survival increasing 51% for every 100m away from a raven’s nest. They predicted that survival would be near 100% if the nearest nest was more than 1.6 km away (Daly et al. 2019)

Even with head-starting, juvenile survival rates are often lower than the 59% average annual juvenile survival rate estimated by Holcomb (2022a) to be necessary for population stability if adult annual survival rates are 93% (Table 4). The available information suggests that low juvenile survival is one of the major reasons why there have been widespread declines in density.

Table 4. Survival and mortality rates of juvenile tortoises in various studies.

Life stage	Survival vs Mortality	Rate	Location	Time scale	Reference
Juveniles	Median annual survival probability	66%-73%	Desert Tortoise Research Natural Area	1979-1989	Berry et al. 2020b
Juveniles	Median annual survival probability	57%-65%	Desert Tortoise Research Natural Area	1989-2002	Berry et al. 2020b
Juveniles	Median annual survival probability	90%-93%	Desert Tortoise Research Natural Area	2002-2012	Berry et al. 2020b
Head started juveniles	Survivorship after 2 years	76-79%	Fort Irwin	2005-2007	Nagy et al. 2015
Head started juveniles	Survivorship after 3 years	53%	Fort Irwin	2005-2008	Nagy et al. 2015
Wild Hatchlings	Survival rate	48%-49%	Ivanpah Valley	2011-2014	Tuberville et al 2019
Head started juveniles	Annual survival after release	44%	Mojave National Preserve	2015	Daly et al. 2019
Juveniles	Annual survival close to ravens' nest	63%	Mojave Desert	2020	Holcomb et al. 2021
Juveniles	Annual survival far from raven's nest	76%	Mojave Desert	2020	Holcomb et al. 2021

For species like tortoise with slow growth, delayed maturation, and low reproduction rates (Shine 2005), factors that lower adult survival rates can have long-term negative impacts on abundance/density. Snapping turtles have similar life history traits as desert tortoises, and in a population in Ontario Canada, river otters killed about 50% of the adults over three years in the late 1980s (Keevil et al. 2018). Female annual survival rates fell from 94% to 76–86% during those years, and the population was reduced by about 40% (Keevil et al. 2018). Twenty-three years later, survival rates had returned to early 1980s level, but abundance did not rebound. This suggests that even if threats are removed, and survival rates increase, for a long-lived species like the desert tortoise, populations may not recover for several decades. The problem is magnified if juvenile survival is very low as is seen in multiple survey areas in California. Having breeding adults on the landscape is vital for population viability, and low rates of juvenile recruitment create an unstable demographic structure that will make it less likely for populations to recover and makes them vulnerable to any additional sources of mortality (Holcomb 2022*b*).

4 FACTORS AFFECTING THE ABILITY TO SURVIVE AND REPRODUCE

Desert tortoise life history traits, including delayed reproductive maturity, relatively low annual fecundity, and low survival rates of juvenile tortoises cause populations to be vulnerable to a multitude of threats (Berry et al. 2020*b*). Their vulnerability is increased because many of the threats are interactive and amplify each other. For clarity, this document focuses on individual threats, but also recognizes that many of them are fundamentally intertwined. Many of the threats described in the initial desert tortoise status review and the USFWS Recovery Plans (U.S. Fish and Wildlife Service 1994, U.S. Fish and Wildlife Service 2011) continue to affect the species.

4.1 Habitat Modification and Destruction

Mojave Desert Tortoise range in California occurs on a variety of public and private land jurisdictions, the top three being BLM (39,251 km^2), National Park Service (NPS) (17,035 km^2), and Department of Defense (DoD) (13,018 km^2). The type of habitat modification and destruction permitted on each of these land types varies. BLM land is managed for a wide range of uses and stakeholders, and permitted activities that may impact tortoises include off-highway driving, mining, and renewable energy projects. Activities on NPS land are much more restricted; off-highway driving, mining, and renewable energy projects are not allowed. DoD land is not generally open to the public and uses range from extremely low impact to high impact live artillery use. See Figure 5 for more details on land ownership.

In the large majority of tortoise habitat, at least some alteration is allowed which can impact tortoises. Across all states, an estimated 66% of Mojave Desert Tortoise habitat has some development within 1 km, where development is defined as “urban development, cultivated agriculture, energy development (e.g., oil and gas well pads, solar energy facilities), surface mines and quarries, pipelines and transmission lines, and transportation (e.g., roads and railroads” (Carter et al. 2020). The direct impacts of development include removal of soil and vegetation, destruction of burrows, and creation of roads and other infrastructure that can kill tortoises or hinder their movements (Boarman and Sazaki 1996, 2006). An important indirect impact of development is subsidization of predators (see section 4.4) (Boarman et al. 2006).

Tortoises are less likely to occur in areas that have even a low level of development. Carter et al. (2020) found that “encounter rates of both live and dead Mojave Desert Tortoises combined decreased significantly with development levels” and that when “10% of the area within 1 km of that location has been altered by development” (10% development), it was rare to find live or dead tortoises at a location. The authors estimated that encounter rates for both live and dead Mojave Desert Tortoises decreased an average of 4% for every 1% increase in the development index (Carter et al. 2020).

In the Western Mojave Recovery Unit (which is wholly within California) 47% of tortoise habitat has almost no development (<1% within 1 km), and 5% of habitat has >10% development (U.S. Fish and Wildlife Service 2022*a*). For the Eastern Mojave Recovery Unit, the proportion of habitat with <1% development within 1 km is 58%, and 5% is at 10% development. In the Colorado Desert Recovery Unit, it is 65% and 4% respectively (U.S. Fish and Wildlife Service 2022*a*). However, those two units extend outside of California (see Figure 6), and it is unclear whether those percentages are representative of the range in California. In their 2022 5-year review, the USFWS concluded that "space does not appear to be a limiting factor to tortoise recovery". However, these categories of development used above do not take into account unpaved roads and tracks for off-highway vehicles (OHVs) which are allowed on BLM land (see section 4.2).

Driven by a number of forces, the human population in the inland deserts of California has increased significantly in the past 30 years. Between 1990 and 2022, the number of housing units increased 58% in Imperial County, 79% in Riverside County, and 37% in San Bernadino County (numbers calculated from State of California Department of Finance 2023). Urban or suburban development typically expands along the edges of previously impacted habitats which generally contain few tortoises. Therefore, we focus discussion on other types of projects that are more likely to have large-scale impacts on areas with desert tortoise populations.

Department of Defense

The Department of Defense is a major landholder in desert tortoise range. Military bases in California deserts include Fort Irwin, Naval Air Weapons Station China Lake, Edwards Air Force Base, George Air Force Base, Chocolate Mountain Aerial Gunnery Range, Marine Corps Air Ground Combat Center Twentynine Palms, and Marine Corps Logistics Base Barstow. In total, these bases encompass over 3 million acres (14.78% of the total tortoise range in California, see Figure 4). A wide variety of land uses occur on DoD property, and some of those uses are very compatible with desert tortoises while others are not. Training areas are generally high impact and tortoises in training designated areas are translocated to other sites. For example, according to the USFWS (2022c), the "Department of the Army (Army) expanded training onto 18,197 acres (73.6 km^2) of designated critical habitat on the southern area of Fort Irwin that had previously been off-limits to training, thus requiring the translocation of approximately 650 adult desert tortoises. In addition, the Army plans to expand activities onto and displace tortoises from up to 62,045 acres (~250 km^2) of its western training area in the near future, which is designated critical habitat and currently off limits to training. The Department of the Navy (Navy) expanded training for the Marine Corps Air Ground Combat Center (MCAGCC) at Twentynine Palms into approximately 167,982 acres (680 km^2) of public and private land, which required translocating approximately 1,000 adult tortoises." Around 700 of those tortoises were translocated into the Ord-Rodman TCA (see section 9.1 on Translocation).

Along with translocation of tortoises, other strategies used by the DoD to offset the impact of converting large areas of habitat into training grounds include acquiring land (making it federal) within a CHU, buying out grazing allotments, increased law enforcement in tortoise habitat, predator monitoring and targeted control within translocation sites, rehabilitation of closed routes, installation of off-highway vehicle barriers and desert tortoise exclusion fencing, and constructing perimeter fences to prevent public trespass into tortoise habitat (U.S. Fish and Wildlife Service 2022*a*). For more discussion of efforts to conserve tortoises, see section 5.2 Current Management Actions.

Given the relatively large amount of DoD land with land use practices that require translocation of tortoises, it is of interest whether and how quickly that habitat might become suitable again for tortoises if and when the areas are no longer used for training. Recovery from disturbance can take a long time in desert ecosystems. This has been documented in soils and vegetation of the Desert Training Center which spans parts of southern California, southern Nevada, and western Arizona. This area was used for military training exercises in the 1940s and 1960s, and 40–60 years later the soil in tank tracks remained compacted and rain infiltration rates were low (Prose and Wilshire 2000). These soil differences led to increased plant density in the tracks, but those plants had restricted growth. In addition, grass species with shallow fibrous root systems increased in density in the tracks while species with long tap roots had reduced density and cover (Prose and Wilshire 2000). USFWS (1994) estimated that areas where camps, roads, and parking lots were built would take "decades or centuries to recover." Other documented direct negative impacts to tortoises on military property include "vandalism, predation, mycoplasmosis and shell diseases" with "significantly more tortoises with shell disease…found on plots with current and recent military use than on plots with no history of military use" (Berry et al. 2006). For more detail on shell disease see section 4.7.

Renewable Energy Projects

Renewable energy projects, namely solar farms and wind energy facilities are a major source of development in desert tortoise habitat. These facilities are regarded as key to reducing CO_2 emissions, and their development has been prioritized on public land (e.g., American Reinvestment and Recovery Act 2008; National Energy Policy Act 2005, Infrastructure Investment and Jobs Act 2021, Inflation Reduction Act 2022). Unlike urban or suburban development, energy projects tend to be sited in mostly undeveloped public land, thus leading to the potential degradation and fragmentation of relatively high-quality tortoise habitat (Lovich et al. 2011).

The impacts of wind and solar energy facilities generally differ from more typical forms of development, primarily due to the diffuse nature of the infrastructure. Data specifically evaluating the impacts of renewable energy facilities on desert tortoises remains limited, however two studies suggest that tortoise survival rates are relatively high. A study near Palm Springs in Riverside County estimated tortoise survival rate within a wind energy facility (WEF) and a nearby wilderness area (NWA) using data from 1997–2000 and 2009–2014 (Agha et al. 2015). They found "long-term tortoise survivorship within the WEF (96.7 %) was significantly higher than in the nearby NWA (92.1 %)" (Agha et al. 2015). This counter intuitive result may have been due to tortoises at the WEF benefiting from "edge enhancement of vegetation (food resources), turbine pads (artificial rain catchments), reduced subsidized predators and low traffic." (Agha et al. 2015).

Lovich et al. (2011) tracked tortoises at a wind energy facility near Palm Springs for six field seasons (1997–2000 and 2009–2010). The facility contained turbines, electrical transformers, and an extensive network of roads (Lovich et al 2011). Their estimated annual survivorship rate of 91.6% (confidence interval 90.5–93.5%) was based only on adult females, which is a much higher survival rate than has been reported in many areas across the range in California (see section 3.3). The authors suggested a few characteristics of the site that might have led to high survival rates including very restricted public access and fewer ravens. However, they cautioned that without before-and-after studies of the impact of energy facilities, of which there are very few, it is hard to draw conclusions about the long-term impacts of energy facilities on desert tortoise.

Development of a wind power project results in a variety of disturbances that are classified as temporary or permanent. Permanent impacts include land occupied by wind turbine pads, access roads, substations, and transmission lines. Temporary direct impacts include temporary roads, staging areas, and substation/transmission construction (Denholm et al. 2009). However, in desert ecosystems, 'temporary' disturbances may have decades-long impacts if sites are not actively rehabilitated. Denholm et al. (2009) collated data on the size of several wind projects in California including total size (land associated with the complete wind plant project) and area of direct (permanent and temporary) impact. Of the four projects with complete data, direct impacts accounted for 1.5–7% of the total area of the project.

Solar power plants have a different design and land use than windfarms. However, similar types of impact classifications occur. Direct impacts occur where land is occupied by solar arrays, access roads, substations, service buildings, and other infrastructure (Ong et al. 2013). Three types of solar power plants were evaluated in one study, and the percentage of total land that was directly impacted was between 38% and 100% of the project site (N=12 projects) (Ong et al. 2013). The impact of infrastructure to wildlife extends beyond the habitat that is directly modified, including fragmentation and barriers to gene flow, effects due to noise, vibration, and shadow flicker, electromagnetic field generation, macro- and micro-climate change, predator attraction, dust and dust suppressants, and increased fire risk (Lovich and Ennen 2011, 2013). A study in southern California compared wind farms with nearby areas and found that species richness, evenness, and diversity was lower on the farm sites for reptiles, birds, mammals, arachnids, and plants (Keehn and Feldman 2018). Renewable energy facilities are not sited within tortoise CHUs, however they can be close enough that the impacts listed above spill over into critical habitat (K. Berry USGS, pers. comm 2022).

Renewable energy projects that could potentially cause 'take' of desert tortoises must apply for incidental take permits (ITPs) from the Department or from the USFWS depending on jurisdiction (see section 5.1 for more detail). Between 2010 and 2021, the Department issued ITPs for desert tortoise for 49 renewable energy projects. In 2022, the Department completed ITP permitting for six renewable energy projects within San Bernadino and Riverside counties that would have a total footprint of about 10,600 acres (43 km^2). As of October 2022, the Department was in the process of reviewing or issuing ITPs for 14 more renewable energy projects in Riverside and San Bernadino counties that could potentially have footprints of up to 20,750 acres (84 km^2). Not all of these projects are necessarily sited within the recovery units or will end up receiving permits from the Department. However, it does show that there is increasing demand to use land within the Mojave Desert for renewable energy projects (for more information about ITPs, see Section 5.2).

Cannabis Operations

Illegal cannabis farms are an emerging threat to tortoises and their habitat in the Mojave Desert. Habitat is destroyed to put up greenhouses, and there are potential associated spillover effects like chemical leakage into stream beds, trash dumps, and other land disturbances beyond the footprint of the greenhouses. In addition, water and trash may attract and increase densities of predators like coyotes and ravens, and guard dogs are thought to kill tortoises (CDFW unpublished data, Holcomb 2022a, U.S. Fish and Wildlife Service 2022a). In the Department's Region 6, which includes the majority of desert tortoise range, as of 2022 there had been 3,065 acres (~12 km^2) of illegal cannabis cultivation visited by law enforcement. However, the Department acknowledges that there are vastly more illegal sites within tortoise range for which a law enforcement response has not been possible, therefore these numbers likely underestimate the true impacts. The presence of illegal cannabis farms can have additional indirect impacts on tortoise conservation. For example, according to USFWS (2022a), "illegal cannabis farms have already led to the cessation of raven monitoring and management efforts in the Fremont-Kramer Critical Habitat Unit in 2021, with the likelihood that tortoise monitoring in the same unit scheduled for 2022 will be cancelled due to safety concerns for field workers."

Legal cannabis cultivation also occurs within the desert tortoise range. Currently in Region 6 there are 2,394 acres (~9.5 km^2) of legal cannabis cultivation that have Streambed Alteration Agreements. The Department evaluates each development project individually for the purposes of the California Environmental Quality Act, and there has not been a robust analysis of the cumulative impacts to the species resulting from cannabis development in the area. Due to the newness of the threat, the overall impact on tortoises from illegal and legal cultivation has not been quantified. However, it a matter of increasing concern, and the current tools of permitting and law enforcement resources may not be sufficient to lessen the negative impacts on tortoises.

While the long-term impact of habitat modification and destruction resulting from all the land use types described above, along with any associated mitigation measures, is not fully known, the USFWS (2019a) states the impacts are "unlikely to be positive, despite the numerous conservation measures that have been (or will be) implemented as part of the actions." Although there are multiple science-based measures enacted to manage and mitigate threats, U.S. Fish and Wildlife Service (2019a) warns that they "have been unable, to date, to determine whether the expected benefits of the measures have yet been realized, at least in part because of the low reproductive capacity of the desert tortoise. Therefore, the conversion of habitat into areas that are unsuitable for this species continues the trend of constricting the desert tortoise into a smaller portion of its range".

Across the entire species range, it has been estimated that 7.4% of modelled tortoise habitat is now completely unsuitable for tortoise survival due to development and recent fire (Holcomb 2022*a*). Additionally, habitat is degraded in many additional areas as a result of factors such as off-highway vehicle use, wildfire, invasive plan species, and increased temperature due to climate change Therefore, focusing solely on the proportion of direct habitat loss in the desert tortoise range may be misleading and create an overly optimistic picture. With more than 90% of historical habitat still accessible, tortoise populations have declined severely in the past two decades.

4.2 Vehicle Strikes, Roads, and Fencing

Development of all types creates roads and other transport corridors that impact tortoises directly through vehicle strikes and as barriers to movement. Indirect impacts of transport corridors include habitat degradation including the spread of invasive species (Boarman et al. 1997, Brooks et al. 2005).

Desert tortoises are particularly susceptible to being killed on roads due to their slow rate of travel. Human behavior also plays a role. Boarman et al. (1997) anecdotally reported drivers intentionally swerving to hit turtles and tortoises. Even if drivers are not intentionally hitting tortoises, speeding on all types of roads can lead to unintentional but deadly strikes on tortoises (A. Ellsworth pers. comm. Nov 2022). Boarman and Sazaki (1996) estimated a kill rate of 1 tortoise per 2.4 km of road per year on Highway 58 in the western Mojave Desert, but warned their estimate was likely low because carcasses disappear quickly in the desert (likely due to scavenging). Anecdotal evidence from the Mojave Desert Preserve indicates an average of 5.3 tortoises are killed per year on the 216 km of paved road in the Preserve. Using 2008-2010 data from the Preserve, Hughson and Darby (2013) estimated that 31 female tortoises per year killed (on top of natural mortality) would be unsustainable, concluding that road mortalities may account for about ~9% of the excess mortality per year (assuming equal sex ratios). Juvenile dispersing tortoises are more likely to be killed on roads compared to adults (Boarman and Sazaki 1996).

Tortoises are often attracted to roads within their home ranges as places where appropriate forage plants grow and rain runoff collects (Boarman et al. 1997). However, impacts from direct mortality and increased access for predators near roads can result in the creation of reduced occupancy zones along roads, whose width can vary (Boarman et al. 1997). Two-lane paved roads in Mojave National Preserve had reduced occupancy up to 400 m away from the road (Hughson and Darby 2013). Boarman and Sazaki (1996) studied Highway 58 in California and found reduced occupancy up to 800m away. If the roads occur at a sufficient density, these zones could impact enough habitat to affect tortoise density across large scales. Although these results are only correlative, the TCAs that have road densities above 0.75 km/km^2 all had declines in tortoise densities between 2004 and 2014, while TCAs with less dense roads had both increases and declines in tortoise density (U.S. Fish and Wildlife Service 2022*a*).

Keeping tortoises off roads is a conservation priority (U.S. Fish and Wildlife Service 2022*a*). Well-constructed fencing designed to stop tortoises from accessing roads can lead to 93% fewer tortoise carcasses along highways as well as reducing road kills of other small vertebrates (Boarman and Sazaki 1996). Properly designed culverts under roads facilitate tortoise movements and help prevent fences from fragmenting tortoise populations (Boarman and Sazaki 1996). According to the USFWS (2022c):

> "Through 2011 approximately 1,660 km of highway roadside (including both sides of roads for those fenced on each side) had tortoise exclusion fencing installed to prevent road mortalities. Unfortunately, only approximately 43 km of roadside have been fenced in the decade since 2011. Almost 500 km of roadside have been identified as priorities for fencing based on our current understanding of road-effect zone area, relative habitat potential, and locations of extant populations (Holcomb 2019)."

Considerations that can slow or prevent fence building include cost, maintenance, visual disruption of the landscape, and loss of habitat during construction. At the October 2022 Desert Tortoise Management Oversight Group Meeting, the BLM reported that 3.5 miles of I-40 in the Ord-Rodman CHU will be fenced soon, and 5 miles of fence will be built soon in Mojave National Preserve. Other strategies to reduce tortoise mortalities on roads such as lowering speed limits, installing warning signs, and driver education have not been shown to be particularly effective (Hughson and Darby 2013).

Off-highway vehicles

Off-roading is a popular pastime in the California's deserts. According to the BLM, in 2008 there were four times the number of off-highway vehicles in the West than in 1998 (Bisson 2008). In Desert Wildlife Management Areas and CHUs, OHVs are legally required to stay on established roads and trails, while on the remainder of BLM land they can travel cross-country, although local BLM offices can enact further restrictions. OHVs and their associated unpaved trails lead to habitat degradation, but the impacts are thought to be generally less severe than paved roads.

OHV trails are typically <4m wide with a dirt surface, and are unimproved (i.e., they have never been bladed or filled) (Brooks et al. 2005). When the trails are created, it alters soils, vegetation, and some types of wildlife may potentially be killed. Tortoises can be run over on and off these trails and vehicles can crush burrows, depriving tortoises of refuge from extreme temperatures and drought. In areas of very frequent OHV use, multiple routes may merge into broad areas devoid of perennial vegetation 10–100 m or more across. These extremely high impact areas are rare, however there are large networks of OHV trails across the Mojave Desert which collectively can create significant changes to habitat and soils (Brooks et al. 2005). OHV trails change water runoff patterns especially on slopes and lead to greater erosion (Brooks et al. 2005). In addition, roads of all kinds can serve as pathways for invasive species. Inholding of private parcels within BLM land often are set aside for conservation, and OHV trails formally stop and restart at the boundaries. However, drivers often trespass across those private parcels, creating negative impacts for the tortoises even in areas that are designated as protected (A. Ellsworth, CDFW pers. comm. Oct 2022). The ecosystem or landscape-wide impact of OHV use can be hard to tease out in areas like the Mojave Desert that have multiple land uses, and Brooks et al. (2005) warned that “dispersed landscape effects … should be generalized very cautiously”.

The extent of OHV trails in desert tortoise habitat is hard to quantify, however the recent expansion of the Spangler, El Mirage, and Johnson Valley off-highway vehicle recreation areas under the 2019 John D. Dingell, Jr. Conservation, Management, and Recreation Act opened up an additional 60,000 acres (~242 km^2) of public land to cross country OHV use (U.S. Fish andWildlife Service 2022a). At the October 2022 Desert Tortoise Management Oversight Group Meeting, the BLM reported that there is a multi-year restoration project in Fremont-Kramer CHU to monitor and restore OHV routes.

4.3 Impacts from Invasive and Non-Native Species

Invasive Grasses and Forbs

Like many of the processes threatening desert tortoise, the impacts of invasive species are often tied to and synergistic with other factors such as livestock grazing, drought, and wildfire. Fueled in part by nitrogen pollution carried by wind from the Los Angeles Basin which enriches desert soils (Fenn et al. 2010), invasive Mediterranean grasses have spread through much of the Mojave Desert. These grasses create fuel for wildfires (Drake et al. 2015) and outcompete native annual plants (DeFalco et al. 2003). In 1995, 34 plots in the Mojave Desert near Barstow had frequencies of occurrence of 17% for *Bromus* and 38% for *Schismus* (both invasive grasses) (Brooks 1999). A more recent study sampled 718 plots across the Mojave Desert in 2009–2013 to investigate invasive grasses (*Bromus* spp. and *Schismus* spp.) and an invasive forb *(Erodium cictarium*). At least one of the invasive taxa occurred in 91% of the plots with herbaceous cover, and two or more of the species co-occurred in 77% (Underwood et al. 2019). Although these two methodologies are different, the general trend of increasing cover of invasive grass and forb species has occurred broadly across the Mojave Desert.

Berry et al. (2020b) summarized the impacts of invasive grasses on desert tortoise:

> “Tortoises avoid plants high in potassium and do not thrive on diets of native or non-native grasses. Both juveniles and adults lose mass and are out of nitrogen balance when consuming grasses (Barboza 1995a, b; Hazard et al. 2009, 2010; Drake et al. 2016). Grasses are high in fiber, contain less digestible energy, and little protein (Hazard et al. 2009), causing juveniles to lose phosphorus and potentially shell volume (Hazard et al. 2010). Because of numerous human activities, invasive, non-native, and fire-prone grasses became established in tortoise habitat and now contribute substantially to the biomass of annual plants in late winter and spring, the principal feeding time for the tortoise (Brooks and Berry 2006, Brooks and Matchett 2006, Brooks et al. 2006, Minnich 2008). These grasses compete with native forbs for nutrients (Brooks 2000a). A diet of grasses is insufficient in nutrients and leads to water loss during digestion (Hazard et al. 2009, 2010). In experimental studies, 32–37% of neonates and yearlings did not survive on a diet of grasses, whereas individuals in these size groups fed native

> forbs or a mix of native forbs and grasses had better body condition, immune functions, growth, and survival rates exceeding 95% (Drake et al. 2016)."

In contrast to grasses, the alien forb *Erodium* provided sufficient nitrogen and is of similar nutritional quality as a native forb (Nagy et al. 1998), allowing juvenile tortoises fed on forbs to gain weight (Hazard et al. 2009).

Livestock and other grazers

Grazing by livestock is a major part of the recent history of the desert. Until the 1990 listing of the desert tortoise as threatened under the ESA, grazing by livestock was allowed on BLM land in tortoise range (Berry et al. 2014). After listing, BLM banned livestock grazing in the CHUs. However, grazing is allowed on private inholdings within the CHUs, which are often unfenced. The documented impacts of livestock on tortoises include competition for food, trampling to death, and causing the collapse of burrows (see Berry and Murphy (2019)). Livestock also degrade habitat by creating or expanding trails via trampling which reduces annual cover and disrupts the soil surface, thus promoting wind erosion, and compacts the soil which slows future growth of annual plants (Webb and Stielstra 1979, Lovich and Bainbridge 1999). Livestock increase browsing pressure on the trees and shrubs tortoises require for shade and for establishing burrows (Berry et al. 2020a). Artificial watering sites set up for livestock concentrate activity of wild and domesticated large herbivores, potentially changing aspects of soil nutrients, compaction, seedbanks, and density of invasive species nearby. In a grazing allotment on BLM land in the west central Mojave Desert, cover of native plants decreased with increasing proximity to water site, while cover of alien (but not necessarily invasive) species increased (Brooks et al. 2006). This change in plant composition was observed up to 800m away from the watering site. Ninety-six percent of the alien plant cover was made up of three species, including the forb *Erodium cicutarium* and the alien grass *Schismus* spp. (Brooks et al. 2006).

4.4 Predation

Predation affects tortoises across age classes, with different species predating various age classes. While there have always been predators that target tortoises, the number of predators and their distribution on the landscape has increased in tandem with human development.

The best studied predators of tortoises are ravens and coyotes. These species are generalist predators which utilize a variety of habitats including human modified ones. Human presence in tortoise habitat provides food resources such as unsecured trash, water, and road-killed carcasses, and buildings and other structures that provide shelter (Boarman et al. 2006, Kristan and Boarman 2007). These 'resources bonanzas' (Kristan and Boarman 2007) allow raven and coyote populations to flourish, increasing predation pressure on native prey.

Raven populations have drastically increased in the Mojave Desert since the 20th century and have become a major predator of juvenile tortoises. This contrasts with population trends for many other bird species. Between the early 20th century and 2013–16, survey sites in the

Mojave Desert lost 43% of their bird species on average (Iknayan and Beissinger 2018). Ravens were the only species to substantially increase across survey sites. The probability that ravens would be detected at a survey site was on average 35% in the first half of the 20th century and 76% in 2013–2016 (Iknayan and Beissinger 2018). In 2020, surveys in Fenner, Ivanpah, Fremont-Kramer, Ord-Rodman, and Superior-Cronese CHUs found average densities of 0.63 ravens/km^2 in Fenner in the east to 2.44 ravens/km^2 in Fremont-Kramer in the west (Holcomb et al. 2021). This expansion of raven presence in extent and abundance is due at least in part to increased anthropogenic subsidies (Boarman and Berry 1995). Ravens spend their time near these subsidies (Boarman and Berry 1995, Boarman et al. 1995, 2006), which is one of the factors that leads to higher mortality for tortoises near human infrastructure than in open desert (Berry et al. 2006, Esque et al. 2010). As human infrastructure has increased in the Mojave Desert, the impact of raven predation on desert tortoise populations has likely increased. Nagy et al. (2015b) released 53 tortoises on Fort Irwin National Training Center in 2005, and 78% of the mortality of smaller tortoises (carapace 45–80 mm) was due to ravens, while coyotes were a major source of mortality for larger (111–175 mm) tortoises (Nagy et al. 2015*b*). High levels of raven predation on juveniles are thought to have led to far fewer juveniles being observed in the annual TCA surveys. In an area with a raven density of 2.4/km^2, the USFWS estimated survival of 0–12-year-old tortoises at 51%, which is much lower than in areas without ravens (Holcomb 2022*b*). Distance to the nearest raven nest impacts the survival rates of 0-10 year old tortoises. Using decoy tortoises, Holcomb et al. (2021) found that juvenile tortoises on average had an annual survival rate of 63% 500m from a raven's nest, while tortoises 1.72 km away had ~76% annual survival rates. They estimated that in areas where there were more than 0.89 ravens/km^2, and tortoises were less than 1.72 km from a nest, juvenile mortality would be great enough to cause population decline. If these criteria were applied to the Fremont-Kramer CHU, raven predation alone would likely have caused "inadequate" recruitment of juvenile tortoises across the majority of the CHUs over the past 20 years (Holcomb et al. 2021). Ivanpah and Fenner CHUs have fewer anthropogenic subsidies for ravens and therefore lower raven densities. However, the densities in those CHUs are high enough that predation pressure combined with drought, road mortality and invasive species together permit sustained recruitment of juvenile tortoises only in a few places. (Holcomb et al. 2021)

Predation pressure by ravens is not even across the tortoise range. In a study in the El Paso Mountains east of Bakersfield between 2008 and 2009, avian predators (mostly ravens) accounted for only 2.5% (on plot) and 3.7% (off plot) of observed mortalities (Berry et al. 2020*c*).

Coyotes are a major predator of adult tortoises. In a translocation study in the Superior-Cronese CHU, 158 tortoises were translocated from Ft. Irwin in 2008. Ten years later, 104 were dead, an estimated 60% of which were killed by coyotes (Mack and Berry 2023). Kelly et al. (2021) found that coyotes in the Mojave Desert predated more adult than juvenile tortoises while desert kit foxes focused on juveniles. In an examination of the dead tortoises found in the El Paso Mountains east of Bakersfield between 2008 and 2009, 20% of the carcasses found on the survey plots and about 52% of those found off plots were killed by mammalian predators including coyote, kit fox, and badger (Berry et al. 2020*c*).

There is also some evidence that canid predators focus more on females than males. In the Superior-Cronese CHU in 2008, Esque et al. (2010) found that tortoises suffered high levels of mortality (8.3–25% of tracked tortoises died in the year covered by the study), with the majority of tortoises found dead having been killed by predators (likely coyotes) and that females were more likely to be killed because they were smaller. They also looked at reference sites across the Mojave Desert and found that coyote predation on tortoises was strongly associated with the size of nearby human populations (Esque et al. 2010).

Other predators of tortoises include fire ants, white-tailed antelope squirrels, bobcats (Nagy et al. 2015*a,b*), red-tailed Hawks (Anderson and Berry 2019), rattlesnakes (Berry et al. 2016), domestic dogs (Berry and Murphy 2019), and badgers (Smith et al. 2016).

Like many threats facing desert tortoises, predation may be influenced by other factors including drought (Esque et al. 2010). The periods of extended drought may exacerbate coyote predation pressure due to low rodent and lagomorph numbers and coyotes switching to relying more on tortoises for food, however data on small mammal abundances that would provide direct evidence of this is lacking (Esque et al. 2010).

4.5 Climate Change and Drought

Anthropogenic climate change has led to higher annual average air temperatures in general as well as increased volatility of California's climate. Extreme events like drought and heat waves are more frequent, rainfall is increasingly variable, and flow regimes of rivers are changing (Bedsworth et al. 2018). These changes have led to observable shifts in species distributions and timing of life history events (Office of Environmental Health Hazard Assessment 2018). In California, Mojave Desert Tortoises inhabit the relatively cooler high Mojave Desert, and the hotter low Sonoran Desert. The western part of the tortoise range in the Mojave Desert gets most of its precipitation in the winter with only about 15% from summer monsoons, whereas the monsoons account for about 30% of yearly precipitation in the eastern deserts (Hopkins 2018).

Impacts of Increased heat

In the inland deserts of California, daily maximum temperatures warmed by 0.4–0.7°F (0.2–0.38°C) when 1976–2005 was compared to a historical base line of 1961–1990 (Hopkins 2018). Annual average maximum daily temperatures are projected to rise 5.6–8.8°F (3.1–4.9°C) by 2100 across the state generally as compared to a historical average from 1976–2005. In the already hot inland deserts, maximum daily temperatures are projected to see increases of up to 8–14°F (4.4–7.7°C) by 2070–2100, depending on the future emission levels of greenhouse gases (Hopkins 2018). It is projected that there will up to 141 days a year in the Mojave Desert when the temperature exceeds 95°F (35°C), with minimum daily temperatures projected to rise 4–7°F (2.2–3.8°C) by 2070–2100 (Hopkins 2018).

Under warming scenarios described above, desert tortoises will have fewer areas where they can stay within their physiological limits. As habitat area shrinks, tortoises are already heading upslope in some areas to escape the heat of the valley bottoms, a distribution known as the ‘toilet bowl effect’ (W. Campbell pers. comm. May 2022). This type of movement may become more difficult as temperatures increase and suitable upslope areas shrink. Sadoti et al. (2017) found that tortoises restrict their movements when it is hotter. While this is not necessarily surprising, if there are more days when it is too hot for tortoises to move, they might find it harder to move to avoid those hot temperatures and will have limited opportunities to disperse or find mates. However, the degree to which increased heat in the summer will shift mating season or impact reproductive success is unknown. Increased temperatures will make burrows as refugia from the heat more critical. Since only certain types of soils and substrates allow for creation of adequately long tunnels, available tunnel sites may become a critical habitat concern in the future and should be taken into consideration in conservation efforts (Mack et al. 2015).

Impacts of drought

Desert tortoises are adapted to drought and heat. However, increasing levels of both are likely to cause physiological stress, alter the availability of edible vegetation, and increase the impact of predation. Barrows (2011) lists some of the physiological and behavioral impacts of drought:

> “Drought conditions result in reduced tortoise activity (Duda et al., 1999) and lower metabolic and reproductive rates (Peterson, 1996a; Henen, 1997; Henen et al., 1998) although some breeding activity occurs even during periods of water stress (Henen, 1997). Despite these behavioral and physiological adaptations, during droughts tortoises experience as much as 40% loss of body mass and a 60% loss of water volume relative to body mass as well as large variations in blood osmolarity (Peterson, 1996b) and can have higher levels of mortality (Turner et al., 1984).”

California has undergone extreme drought recently with the 2000–2021 span being the driest in the southwestern US in the past 1,200 years (Williams et al. 2022). Although there is significant uncertainty regarding projected precipitation changes, current models show that winter precipitation is likely to increase in the inland deserts, but the summer monsoon precipitation could decrease up to 40% (Hopkins 2018). Precipitation events are likely to be more intense and at the same time soils are predicted to be drier, leading to more flash flooding (Hopkins 2018). The projected warmer and periodically drier conditions during the 21st century may increase the risk for more severe drought (Hopkins 2018).

Long-term drought has caused die offs of perennial plants in desert tortoise habitat, likely driven by lack of winter rain (McAuliffe and Hamerlynck 2010). Die offs were extensive but not homogenous, and soil conditions likely played a role (McAuliffe and Hamerlynck 2010). Tortoises are selective herbivores that will feed from a wide variety of available plants if necessary but primarily focus their observed foraging effort on a small set of species, many of which are so rare on the landscape they were not detected during plant surveys (Jennings and Berry 2015). Given predictions that winters may become wetter but summers drier (Hopkins

2018), the impacts of future droughts on the vegetation that tortoises rely on is unclear. Some invasive species of *Bromus* grasses are successful in disturbed habitats, and their presence in desert habitat has helped alter the fire cycle (Brooks 1999, Bradley et al. 2016). However, germination, growth, and reproduction are limited by temperature and rainfall which makes it difficult to predict the relative success of invasive grasses vs. native forbs under predicted climate changes (Bradley et al. 2016). It is possible that tortoises will also face increased nutritional stress if preferred plants die off and more nutrient poor grasses like *Bromus* remain available.

Lovich et al. (2014) used surveys in Joshua Tree NP from 1979 to 2012 to estimate the impact of persistent and recurrent drought on tortoise survival. Estimated population size decreased dramatically from 1996 to 2012, with high survival in 1978–1996, and lower survival in 1997–2002. The lower survival rates were concurrent to persistent drought, and estimated survival rates were best explained by winter precipitation. Being in a national park, tortoises in Joshua Tree should be sheltered from many anthropogenic impacts including large scale habitat modification and degradation and direct killing by humans. In addition, in 2012, many of the dead tortoises showed signs consistent with death by dehydration and starvation. Therefore, the authors concluded the decline was likely the result of reduced survival rates due to drought (Lovich et al. 2014). Other populations of desert tortoises have also shown a negative impact of drought on survival and abundance. Populations in Arizona of *G. agassizii* and *G. morafkai* were surveyed multiple times between 1990 and 2017 and experienced very low survival (30% in the Black Mountains and 34% in the Hualapai Mountains) during a drought, which led to a drop in adult abundances of about 50% (U.S. Fish and Wildlife Service 2022*a*).

Another potential source of indirect stress from increasing drought comes from predators. Under drought conditions, the rodents and lagomorphs that coyotes regularly prey on tend to be depleted, and it is likely that this leads to increased predation pressure on tortoises (Esque et al. 2010, Nagy et al. 2015*b*). Ravens particularly target juvenile tortoises, but since they are heavily subsidized by human activities, drought may have less of an impact on their predation behavior.

A major question is how much desert tortoise habitat will become unsuitable in the future due to heat and drought. Species have shifted altitude and/or latitude as climate has changed (Vanderwal et al. 2013, Wolf et al. 2016), but species that are not nimble dispersers may have trouble accessing new areas, and those areas may not contain the full suite of conditions necessary for survival. However, within current habitats, local refugia may persist in future climatic conditions and allow species to persist. Barrows et al. (2016) evaluated potential habitat refugia on US Marine Corps Air Ground Combat Center (MCAGCC) at Twentynine Palms and found that 33% of the study area (283,900 ha) supported desert tortoise habitat at the time. With a simulated 1°C (1.8°F) of warming, the amount of habitat shrunk by 25%, with remaining habitat occurring at higher elevation. Under a simulated 3°C warming, habitat area shrunk by 56% (to 127,650 ha). Of the remaining available habitat, 91% overlapped with current tortoise habitat, suggesting that climate refugia would be relatively easy for tortoises to access. However, it should be noted that while Barrows et al. (2016) considered 3°C (5.4°F) to be an end of century level of warming, California's 4th Climate Change Assessment from 2018 predicts that level of warming to occur in the inland deserts by 2039 (Bedsworth et al. 2018). In Joshua Tree National Park, desert tortoises are found in both the Mojave and Sonoran desert portions. Modelling by Barrows (2011) predicts that under 2°C (3.6°F) of warming with 50 mm decrease in precipitation, habitat area will decrease by about 88% in the Sonoran Desert portion and by about 66% in the Mojave Desert portion.

4.6 Fire

Desert tortoise habitat historically experienced few fires due to low plant productivity and sparse fuel loads, and those that did occur tended to burn in a patchy mosaic pattern (Esque et al. 2003). Consequently, desert tortoise are not well adapted to fire, although use of burrows can prevent mass casualties in fires (Esque et al. 2003). The expansion of invasive plants (primarily grasses like *Bromus*) has increased fuel loads in the Mojave Desert (Brooks 1999), and fire frequency in the California portion of the Mojave Desert increased between 1980 and 1995 (Brooks and Esque 2002). However, longer term studies looking at fires in 1980–2004 (Brooks and Matchett 2006) and 1992–2011 (Hegeman et al. 2014) in the Mojave Desert show no clear increase in numbers of fires or acres burned per year, though 2005 stood out since "the amount of area burned in the Mojave Desert was 385,357 ha (952,238 acres) (M. Brooks unpublished data), representing 132% of the total area that burned during the previous 25 years (Brooks and Matchett 2006). However, those time series do not include the 2020 Dome Fire in Mojave National Preserve which burned 43,273 acres (175 km^2) of higher elevation tortoise habitat (U.S. Fish and Wildlife Service 2022*a*). Fire-caused tortoise death is summarized in Berry and Murphy (2019)):

> "Woodbury and Hardy (1948) reported deaths of about 14 tortoises from a fire covering ca. 5.2 km^2 on part of the Beaver Dam Slope south of Bunkerville in 1942. In a post-fire study, Lovich et al. (2011c) described a fire in the western Sonoran Desert that killed an adult female tortoise and injured five other adult tortoises. Nussear et al. (2012) reported that three of 30 tortoises died from fire during a comparative study of translocated and resident tortoises. In the Red Cliffs Desert Reserve and critical habitat in Utah, 687 tortoises died in 2005 in a fire that burned ca. 23% of the approximately 251 km^2 habitat (A. McLuckie, pers. comm.). Drake et al. (2012) described a tortoise recovering from burns three years post-fire."

The effects of wildfire on vegetation can negatively impact tortoises. A study in the low elevation Mojave Desert shrubland found that invasive *Bromus* cover increased after one fire but did not continue increasing after additional fires (Brooks 2012). However, native vegetation cover decreased with multiple fires, with percentage cover dropping from about 25% to about 1% when fire frequency increased from one every ten years to three every ten years. Given the poor nutritional content of *Bromus*, increasing fire frequency threatens tortoises' ability to find sufficient and adequate food. Tortoises tend to remain in same areas after fire (Lovich et al.

2018), foraging for annuals in the burned areas, while using the cover of perennial shrubs only found in unburned areas (Drake et al. 2015).

The effects of a changing climate on wildfire size and frequency in desert tortoise habitat are uncertain. Increased winter rain could promote biomass growth that dries out in the hotter summers and increases fuel load (Tagestad et al. 2016). Alternately, the predicted increase in drought like conditions may keep fuel loads low. Another variable is the cause of ignitions. In the past 40 years, human caused fires were more prevalent in areas with high visitation levels such as low to mid elevation and desert montane zones, while lightning caused fires were more common in the central and eastern areas that get summer monsoons (Brooks and Matchett 2006). There are widespread campaigns and regulations aimed at reducing the chances that visitors will cause fires in the desert, and the efficacy of these campaigns may influence fire frequency and spatial distribution in the future. Overall, Hopkins (2018) suggests that strong temporal and spatial variability in precipitation and fuel load across the desert makes long-term and widespread trends in fire regime hard to predict.

4.7 Disease and Parasites

Desert tortoises are susceptible to a variety of diseases, some of which are likely to have caused or contributed to population declines. Upper respiratory tract disease (URTD) has been cited as a cause of population declines in desert tortoise and was a reason for listing under the ESA in 1990 (U.S. Fish and Wildlife Service 1990).

The disease can be caused by the bacteria *Mycoplasma agassizii* and *Mycoplasma testudineum*, while herpesviruses can cause similar symptoms (Johnson et al. 2005, Jacobson et al. 2014). The disease presents as lesions in the nasal cavity and inflammation of mucosa of the upper respiratory tract, mucal discharge from the nares, damaged nasal scales due to chronic mucal discharge, wheezing breath, swollen and watery eyes, and extreme lethargy (Jacobson et al. 1995, 2014, Johnson et al. 2005, Sandmeier et al. 2013). Tortoises that do not show clinical signs of infection can still serve as a reservoir for the disease and likely can transmit it to healthy tortoises (Jacobson et al. 1995). Transmission is most likely through direct contact that happens during courtship, mating, and fighting, and aerosol transmission is not likely (U.S. Fish and Wildlife Service 1990, Jacobson et al. 2014). The disease both directly kills tortoises and can interfere with their sense of smell and therefore their ability to forage for food and can potentially negatively affect their reproductive fitness (Germano et al. 2014, Jacobson et al. 2014). Sandmeier et al. (2013) found evidence that longer and colder winters correlated positively with the proportion of tortoises exhibiting URTD, possibly because time spent underground depresses the tortoise immune system or allows the bacteria to flourish.

Outbreaks of the disease occurred in the Desert Tortoise Natural Area in Kern County in 1989 when 627 dead tortoises were recovered during a survey, and 43% of 468 live tortoises had signs of the disease (Jacobson et al. 1991). The population declined by 90% between 1979 and 1992 (Berry and Medica 1995). In 1990–1995, Christopher et al. (2003) sampled tortoises in three sites in the Mojave Desert:

> "Of 108 tortoises, 68.5% had clinical signs of upper respiratory tract disease consistent with mycoplasmosis at least once during the study period. In addition, 48.1% developed moderate to severe shell lesions consistent with cutaneous dyskeratosis. Ulcerated or plaque-like oral lesions were noted on single occasions in 23% of tortoises at Goffs and 6% of tortoises at Ivanpah. Tortoises with oral lesions were significantly more likely than tortoises without lesions to have positive nasal cultures *for Mycoplasma agassizii* (P=0.001) and to be dehydrated (P=0.0007)"(Christopher et al. 2003).

More recent studies have found much lower prevalence of URTD. In the central Mojave Desert in 2005–2008, Berry et al. (2015) found only 1.49% of sampled tortoises were antibody positive, and a study in a similar area in 1997–2003 found 2.2% antibody positivity rate.

It is thought that the high prevalence of the disease in wild populations in the 1970s–1990s was due in part from infected captive tortoises being released into the wild. A number of factors are correlated with outbreaks of the disease, mainly factors that increase physiological stress in tortoises such as drought, heavy metal pollution, and human disturbance (Jacobson et al. 2014). Berry et al. (2015) pointed out that many of the stressors that increase tortoise vulnerability to disease, especially drought and proximity to human populations, are increasing in desert tortoise range. However, there have not been any large outbreaks documented in California recently, and in the Desert Tortoise Natural Area the disease has "evolved from an acute, epizootic disease with high mortality to a chronic endemic disease with variable morbidity, low mortality"(Jacobson et al. 2014). Reflecting the decreased level of threat currently posed by the disease, in their 2022 5-year review the USFWS stated that "direct disease management of wild tortoise populations is less important (other than in translocations of tortoises between populations) than managing factors that affect their habitat and its capacity to support healthy tortoises" (U.S. Fish and Wildlife Service 2022*a*).

Being captured by humans for research and/or translocation can stress tortoises and make them more susceptible to URTD. Therefore, official handling protocols have strict guidelines in place to minimize stress as much as possible (U.S. Fish and Wildlife Service 2020*b*, *a*). In addition, translocating sick individuals runs the risk of spreading URTD, so translocation protocols involve health assessments and quarantine to minimize disease transfer between populations (U.S. Fish and Wildlife Service 2020*b*). However, disease can be transferred by tortoises naturally dispersing, and reservoirs of the disease in populations outside of California should be considered in discussions of connectivity (Burgess et al. 2021).

Shell diseases like cutaneous dyskeratosis also affect tortoises and present as "abnormal conformation and loss of normal integrity of the horny layer (scute) of the shell and cutaneous scales. Deep shell defects may expose dermal bone" (Homer et al. 2001). Shell lesions were associated with high mortality rates of desert tortoises in Chuckwalla Bench in 1982–1988 (Figures 10 and 11, Jacobson et al. 1994). In 1979, 56% of the tortoises surveyed had shell lesions. The proportion of effected tortoises increased to 65% in 1982, to 90% in 1988, and remained high in 1990 at 87%. During those years the density of all tortoises (adults and juveniles) fell from 221/km^2 to 71/km^2, a 68% decline (Berry and Medica 1995). While the declines in population cannot be definitively tied to shell lesions, they could be a sign of a deficiency disease or toxicosis (Jacobson et al. 1994). There has been very little reported on shell disease in wild tortoises in California since the mid-1990s.

4.8 Overexploitation

Under the California Fish and Game Code, desert tortoises have had some legal protection from take or collection since 1961 (Fish & G. Code, § 5000). However, vandalism (gunshots) and collecting for pets were listed as reasons for population declines in the USFWS's 1990 decision to list the desert tortoise as threatened (U.S. Fish and Wildlife Service 1990). Before tortoises were listed, Berry (1986*b*) found that percentage of tortoise deaths from gunshots in California deserts (1972–1982) ranged from a low of 1.8% at Chuckwalla Bench to a high of 28.9% in the Fremont Valley. Overall, 14.3% of carcasses found had evidence of gunshots, with the areas with the highest percentage in the Western Mojave. In a 2008–2009 study in the El Paso Mountains in Kern County, 6 of 67 carcasses had evidence of gunshots (Berry et al. 2020*c*). Direct take of tortoises has been illegal since the species was listed under the ESA and CESA, however shooting of tortoises still occurs. Berry and Murphy (2019) reported gunshot deaths subsequent to listing in Fort Irwin National Training Center (1997-2003), Red Rock State Park (2002-2004), and the Desert Research Natural Area (2011).

Despite legal protection, Berry et al. (1996) (reported in Berry and Murphy (2019)) estimated that more than 2,000 tortoises were removed from four study areas over a 10-year period from the mid-1980s to the mid-1990s. It is likely some tortoises are still being taken from the wild, with those near roads most vulnerable. A study in the Sonoran Desert of Arizona in 2008–2009 placed decoy tortoises on roads and found 1.4% of drivers stopped and tried to collect the decoy by placing it in their vehicle. Drivers were more likely to notice the tortoises on maintained gravel roads compared to paved roads or unmaintained gravel roads. However, road type did not influence the probability a driver would try to collect the tortoise (Grandmaison and Frary 2012).

4.9 Other Human-related Activities

Mining and pollution

Although Spanish colonizers panned for gold in the Chocolate Mountains in the late 1700s, commercial mining in California deserts began in the 1800s. Prospectors and miners dug shafts to extract gold, tungsten, silver, copper, and other valuable materials (Shumway et al. 1980). Some of these shafts remain open and unfenced, and tortoises can fall in and become trapped (Berry and Murphy 2019). Mining also leaves behind pollutants of various types including mercury, arsenic, and lead that impact soil and plants (including those favored by tortoises) up to 15 km from mining sites (Chaffee and Berry 2006). These pollutants can enter tortoises via breathing, ingestion of impacted plants, or absorption through skin, and there is some concern that exposure to these toxins may make tortoises more susceptible to disease (Berry et al. 2015, Berry and Murphy 2019). Tortoises collected from the Kelly Rand Ming District northeast of California City and from Edwards Airforce Base had bioaccumulated arsenic in their shell plates compared to tortoises from areas with minimal land disturbance (Foster et al. 2009). However, Cohn et al. (2021) analyzed the blood of tortoises in the Ivanpah Valley and found that heavy metal levels in the blood were generally low (0%–7%), heavy metal levels in the soil did not exceed soil health guidelines, and there was no relationship between metal concentrations and body health or disease prevalence suggesting that tortoises were not negatively impacted by mining pollution in that area.

Deliberate Releases

Based on public comments received by the Department, well-meaning individuals may release captive tortoises, believing it will help wild populations. People may also release animals they no longer wish to keep as pets. The deliberate release of captive tortoises presents several issues. Captive tortoises can have high prevalence of respiratory diseases which could be passed on to wild tortoises if they are released (Berry et al. 2015). Releasing animals of unknown genetic origin, or even different species like *G. morfaka* or the Texas tortoise (*G. berlandieri*), could result in hybridization with wild *G. agassizii* (U. S. Fish and Wildlife Service 1994). The release of diseased captive tortoises was a large enough concern to be mentioned as reason for population declines in the 1994 Recovery Plan (U. S. Fish and Wildlife Service 1994), but we lack robust recent data on the current prevalence of releases and their effects. A public education campaign highlighting the downsides to freeing captive tortoises may help address this threat. Translocations of captive tortoises into the wild are also discussed in section 9.1.

4.10 Vulnerability of Small Populations

Desert tortoises occupy a large range in California, and even at very low densities, populations in conservation areas can still number in the thousands. However, the various factors described above have nonetheless led to dramatic declines in density and abundance across the surveyed critical habitat units (Figure 7, Tables 2 and 5. The most recent estimates of abundance in the Tortoise Conservation Areas are from 2014. In 2014, tortoise density in all the TCAs except Chocolate Mountain and Fenner was below the estimated 3.9 tortoises per km^2 needed for population viability (Table 2). Estimated abundances ranged from 1,241 in the Pinto Mountains TCA to 10,469 individuals in Chemehuevi TCA (Table 5). Although these estimates remain in the thousands, most of these areas encompass hundreds to thousands of square kilometers (see Table 1).

Table 5. Estimated abundance in the Tortoise Conservation Areas within California in 2014. Reported in U.S. Fish and Wildlife Service (2022a) using data from Allison and McLuckie (2018).

Recovery Unit	Tortoise Conservation Area	Estimated Abundance in 2014
Western Mojave	Fremont-Kramer	6,196
	Ord-Rodman	3,064
	Superior-Cronese	7,398
Eastern Mojave	Ivanpah	5,578
Colorado Desert	Chocolate Mountain	5,146
	Chuckwalla	9,304
	Chemehuevi	10,469
	Fenner	8,517
	Pinto Mountains	1,241
	Joshua Tree	4,319

Since 2014, estimated densities have declined in all the TCAs in the Western Mojave, Chuckwalla, and dramatically in the Chocolate Mountains. Ivanpah and Pinto Mountains TCAs have increased in density since 2014 but are still below the 3.9 adults/km^2 threshold. Chemehuevi and Fenner have both increased in density since 2014 and are above the viability threshold, while Joshua Tree has increased slightly in density and was at the 3.9 adults/km^2 threshold in 2020. We do not have estimated abundances that are based on these most recent density estimates, and the 2014 abundance estimates are based on amount of potential habitat in Nussear et al. (2009). Given all of the factors mentioned in the previous sections, it is likely that some suitable habitat has been lost since then due to destruction and degradation, meaning that in the TCAs where densities have gone up, abundances may not have increased concordantly. Systematic surveys of populations are not conducted outside of the TCAs, but Berry et al. (2020a, c) concluded densities and survival rates in the El Paso Mountains and the Chemehuevi Valley were so low that the populations were unviable.

Desert tortoise populations are currently vulnerable to demographic pressures that are likely to exacerbate declining trends if not addressed. Foremost is the lack of recruitment. Low reproductive output and high predation pressure on juveniles has led to a worrying lack of young tortoises (Figure 12). Even with thousands of adults in a population, if sufficient juvenile tortoises are not surviving to breeding age, the population will decline without interventions like head-starting.

The threshold density for population viability of 3.9 adults/km^2 assumes equal sex ratios in the population (U.S. Fish and Wildlife Service 2011). Unequal sex ratios are thought to lower effective population size which in small populations with limited connectivity could exacerbate inbreeding (Frankham 1995). Unfortunately, there are no published data on sex ratios in the 17 TCAs (Berry and Murphy 2019), and the recent data we have are from very limited short term sampling efforts elsewhere. Berry and Keith (2008) surveyed a ~4 km^2 plot in Red Rock Canyon

State Park, and in 2004 they found three males and one adult female. Five subadult or adult females and four subadult or adult males had died 2–4 years previously, and the authors point out that if those animals had survived, the sex ratio of the population would have been much more balanced. In a 1 mi^2 study plot in Joshua Tree NP, “Sex ratios, defined as the number of live males divided by the number of females, ranged from unity, to male biased (5:1), to female biased (0.22:1) across years with no trend in any one direction” (Lovich et al. 2014). As mentioned in the section on life history, the sex of the hatchling is heavily influenced by incubation temperature. As temperatures rise and heat extremes become more common due to anthropogenic climate change, it is likely that sex ratios at hatching will skew to be more female dominated, however the degree to which this will impact adult sex ratios is unknown. Increased reporting of the sex ratios during surveys in the TCAs would illuminate the severity of this issue and allow detection the predicted skew toward females if it were to occur.

5 EXISTING MANAGEMENT

5.1 Regulatory Status and Legal Protections

Federal

Federal Endangered Species Act
In August 1989, the USFWS listed the Mojave population of desert tortoise as endangered on an interim basis. Eight months later in April 1990, it issued a final rule to list it as threatened (U.S. Fish and Wildlife Service 1990). In July 2002, the USFWS received a petition to reclassify the species from threatened to endangered. In 2017, the USFWS announced a 90-day finding that the petition did not present substantial scientific or commercial information indicating that reclassifying the Mojave population of the desert tortoise may be warranted, and no status review was initiated in response to the petition. The USFWS has published status reviews in 2010 and 2022, both recommending that the threatened status be retained (U.S. Fish and Wildlife Service 2010, U.S. Fish and Wildlife Service 2022a). The 2022 status review uses much of the same data presented here and acknowledges that “the status of the Mojave Desert Tortoise had not improved by 2014 and most threats to the species persist at or above 2010–2011 levels. These conditions portend further status deterioration in the absence of concerted efforts by land managers to meaningfully reduce predator subsidies, vehicle-caused tortoise mortalities, and invasive annual plants in important tortoise habitats” (U.S. Fish and Wildlife Service 2022*a*). The recommendation to retain the threatened status was based on finding about a dozen *G. agassizii* in Arizona, east of the Colorado River and outside the boundaries of the recovery units, recognition that the range-wide population of tortoises is in the hundreds of thousands, and optimism that conservation actions will eventually result in population improvements (U.S. Fish and Wildlife Service 2022*a*).

National Environmental Policy Act
The National Environmental Policy Act (NEPA) requires federal agencies to assess the environmental effects of their proposed actions prior to making certain decisions. Using the NEPA process, agencies evaluate the environmental and related social and economic effects of

their proposed actions. Agencies also provide opportunities for public review and comment on those evaluations. Title I of NEPA contains a Declaration of National Environmental Policy. This policy requires the federal government to use all practicable means to create and maintain conditions under which man and nature can exist in productive harmony. Section 102 in Title I of the Act requires federal agencies to incorporate environmental considerations in their planning and decision-making through a systematic interdisciplinary approach. Specifically, all federal agencies are to prepare detailed statements assessing the environmental impact of and alternatives to major federal actions significantly affecting the environment. These statements are commonly referred to as Environmental Impact Statements and Environmental Assessments.

5.1.2 State

California Law/Fish and Game Code

California law has long included protections for Mojave Desert Tortoise. In 1939, California state law prohibited purchase or sale of the species. In 1961, and additional law was passed to prohibit shooting, harming, or possessing the species (Fish & G. Code, § 5000). In 1972, the Fish and Game Code was amended to allow possession of tortoises as long as the tortoise was legally acquired (Fish & G. Code, § 5001).

California Endangered Species Act

On August 3, 1989, the Commission listed the desert tortoise as a threatened species under CESA. CESA prohibits the import, export, take, possession, purchase, or sale of Mojave Desert Tortoise, or any part or product of Mojave Desert Tortoise, except as otherwise provided by the Fish and Game Code, such as through a permit or agreement issued by the Department under the authority of the Fish and Game Code (Fish & G. Code, § 2080 *et seq.*). For example, the Department may issue permits that authorize the incidental take of listed and candidate species if the take is incidental to an otherwise lawful activity, the impacts of the authorized take are minimized and fully mitigated, the activity will not jeopardize the continued existence of the species, and other conditions are met (Fish & G. Code, §§ 2081, subd. (b).). The Department may also authorize incidental take through voluntary local programs and safe harbor agreements (Fish & G. Code, §§ 2086 and 2089.2 et. *seq.*) and for scientific, educational, or management purposes (Fish & G. Code, § 2081, subd. (a).). If the species is listed under both the federal ESA and CESA, a project that has received a federal incidental take statement or incidental take permit that is consistent with CESA can receive a consistency determination (CD) from the Department (Fish & G. Code, § 2080.1.).

Given the predominance of federal land in desert tortoise range, it should be noted that federal agencies undertaking federal projects on federal land are usually not subject to CESA and instead must typically consult with the USFWS to “ensure that actions they fund, authorize, permit, or otherwise carry out will not jeopardize the continued existence of any listed species or adversely modify designated critical habitats” (U.S. Fish and Wildlife Service 2022). However, non-federal entities working on federal lands are subject to CESA. For example, timber companies with permission to harvest timber on U.S. Forest Service lands must comply with both federal and state wildlife laws.

In 2000 and 2005, the Department prepared summary status reports describing the status of desert tortoise as declining (California Department of Fish and Wildlife 2000, California Department of Fish and Wildlife 2005). These reports summarize the status of all species listed as endangered, threatened, or candidate under CESA (Fish and G. Code § 2079), and are made available to the public on the Department's website. The 2005 report described the desert tortoise as severely threatened by population losses and further stated that tortoise populations were extremely low in some areas and may not have been viable (California Department of Fish and Wildlife 2005).

<u>California Environmental Quality Act</u>

State and local agencies must conduct environmental review under the California Environmental Quality Act (CEQA) for discretionary projects proposed to be carried out or approved by the public agency unless the agency properly determines the project is exempt from CEQA (Pub. Resources Code, § 21080). If a project has the potential to substantially reduce the habitat, decrease the number, or restrict the range of any rare, threatened, or endangered species, the lead agency must make a finding that the project will have a significant effect on the environment and prepare an environmental impact report (EIR) or mitigated negative declaration as appropriate before proceeding with or approving the project (Cal. Code Regs., tit. 14, §§ 15065(a)(1), 15070, and 15380.). An agency cannot approve or carry out any project for which the EIR identifies one or more significant effects on the environment unless it makes one or more of the following findings: (1) changes have been required in or incorporated into the project that avoid the significant environmental effects or mitigate them to a less than significant level; (2) those changes are in the responsibility and jurisdiction of another agency and have been, or can and should be, adopted by that other agency; or (3) specific economic, legal, social, technological, or other considerations make infeasible the mitigation measures or alternatives identified in the environmental impact report (Pub. Resources Code, § 21081; Cal. Code Regs., tit. 14, §§ 15091 and 15093.). For (3), the agency must adopt a statement of overriding considerations finding that the overriding benefits of the project outweigh the significant effects on the environment. CEQA establishes a duty for public agencies to avoid or minimize such significant negative effects where feasible (Cal. Code regs., tit. 14, § 15021.). Impacts to Mojave Desert Tortoise, as a CESA-threatened species, must be identified, evaluated, disclosed, and mitigated or justified under the Biological Resources section of an environmental document prepared pursuant to CEQA.

Nonregulatory Status

<u>Natural Heritage Program Ranking and IUCN Red List</u>

Natural heritage ranking does not provide any regulatory protections but is often considered during the CEQA process (Hammerson, G.A. et al. 2008). All Natural Heritage Programs, such as the CNDDB, use the same ranking methodology originally developed by The Nature Conservancy and now maintained by NatureServe. This ranking methodology consists of a global rank describing the rank for a given taxon over its entire distribution, and a state rank describing the rank for the taxon over its state distribution. Both global and state ranks reflect a combination of rarity, threat, and trend factors. The ranking methodology uses a standardized calculator that uses available information to assign a numeric score or range of scores to the taxon, with lower scores indicating that a taxon is more vulnerable to extinction, and higher scores indicating that a taxon is more stable (Faber-Langendoen et al. 2012). The rank calculation process begins with an initial rank score based on rarity and threats, with rarity (multiplied by 0.7) factored more heavily into the calculator than threats (multiplied by 0.3). The combined rarity and threat rank is then either raised or lowered based on trends. When there is a negative trend, the rank score is lowered, and when there is a positive trend the rank score is raised. Short-term trends are factored more heavily into the calculator than long-term trends. International Union for Conservation of Nature (IUCN) and NatureServe assess extinction risk for species using a time period of 10 years or 3 generations, whichever is longer, up to a maximum of 100 years (Faber-Langendoen et al. 2012).

Mojave Desert Tortoise has been assigned a global rank of G3 indicating the species is “vulnerable and at moderate risk of extinction or collapse due to a fairly restricted range, relatively few populations or occurrences, recent and widespread declines, threats, or other factors”. This species has been assigned a state rank of S2 indicating the species is locally imperiled and “at high risk of extirpation in the jurisdiction due to restricted range, few populations or occurrences, steep declines, severe threats, or other factors”. The factors cited for this rank include widespread habitat loss, degradation, and fragmentation, and human-associated factors that cause mortality (NatureServe 2022).

The IUCN Red List provided a global scope assessment of Mojave Desert Tortoise in October 2021 (Berry et al. 2021) resulting in a designation of critically endangered. This Red List category represents the highest risk of extinction and is assigned when a taxon has been evaluated against the ranking criteria and is not yet designated Extinct in the Wild, but qualifies above endangered, vulnerable, and near threatened. The species was originally assessed as vulnerable in 1996 and its designation has steadily increased in severity (Berry and Murphy 2019).

5.2 Management Efforts

Due to its large range and the decades since it was formally protected under the ESA and CESA, a diverse suite of government and other entities are involved in land ownership and management within the range of Mojave Desert Tortoise (Table 6). The majority of land is managed by federal agencies, but the range also includes a substantial portion of private lands. The BLM is responsible for managing nearly 11,000 km^2 of Mojave Desert Tortoise critical habitat and is the largest landowner within the species range. The NPS is responsible for the next largest section of the range, most of which is congressionally designated Wilderness Areas where motorized vehicles are prohibited. Private lands and DoD lands comprise most of the remaining land ownership within the species range.

Table 6. Land ownership within the entire range of Mojave Desert Tortoise and within designated critical habitat.

Land Management Entity	Landownership in Species Range (Km^2)	Percent of Landownership in Species Range (%)	Landownership in Critical Habitat (Km^2)	Percent of Landownership in Critical Habitat (%)
United States Bureau of Land Management	37,960	42.5	10,917	56.6
United States National Park Service	18,418	20.6	3,702	19.2
Private Lands	15,147	17	1,730	9.0
United States Department of Defense	13,018	14.6	2,270	11.8
State of California	2,018	2.3	485	2.5
Cities, Counties, Non-Profits, Special Districts	995	1.1	114	0.6
Other Public or Private Lands	391	0.4	30	0.2
Other Federal	79	0.1	19	0.1
United States Bureau of Indian Affairs	689	0.8	NA	NA
United States Forest Service	242	0.3	NA	NA
United States Bureau of Reclamation	181	0.2	NA	NA
United States Fish and Wildlife Service	89	0.1	NA	NA

Partnerships and Working Groups

The Desert Tortoise Management Oversight Group (MOG), formed in 1994, is comprised of senior managers from USFWS, BLM, state transportation agencies, state wildlife agencies, county governments, and non-governmental organizations (NGOs) that work in the tortoise range in Arizona, Nevada, and California. This group identifies regional recovery priorities, addresses issues common to multiple agencies, and shares information and updates about tortoise status and their recovery activities.

The Recovery and Sustainment Partnership (RASP) is comprised of DoD and Department of Interior agencies and is intended to provide increased flexibility for the use of land for military operations (i.e., make it easier to conduct training in areas with tortoise populations) in return for developing recovery initiatives. Under this partnership, agencies contribute to a pooled funding source to implement recovery actions such as raven management in California. Pooled funding and the Memorandum of Understanding between RASP partners allows for increased flexibility and reduced regulatory hurdles for implementation of broad, regional scale recovery actions.

The California Desert Conservation Act (Fish & G. Code, § 1450 et seq.) became effective on January 1, 2022, and establishes a California Desert Conservation Program within the California Wildlife Conservation Board with the goals of protecting habitat in California's Mojave and Colorado deserts by planning and implementing land acquisition and restoration projects. The California Desert Conservation Program could result in increased conservation or restoration of Mojave Desert Tortoise habitat in California.

United States Fish and Wildlife Service

The USFWS has developed and revised range-wide Recovery Plans for Mojave Desert Tortoise that encourage collaboration, identify research priorities, and encourage management actions for the benefit of the species. In 1994, the USFWS published the first Recovery Plan and designated more than 25,000 km^2 of critical habitat, most of which is in California (U.S. Fish and Wildlife Service 1994). The plan identified Desert Wildlife Management Areas and included management recommendations such as landscape-level management and monitoring, public education, and habitat protection (U.S. Fish and Wildlife Service 1994). In 2008 and 2011, the USFWS published revisions to the Recovery Plan which identified research priorities and recovery actions, including facilitation of recovery partnerships, protection of existing populations and habitat, supplementing populations, and implementing adaptive management (U.S. Fish and Wildlife Service 2011). In 2010, the USFWS published its first 5-year review for Mojave Desert Tortoise across its multi-state range, in which they assigned a recovery priority number indicating that the species faces a moderate degree of threat, has a low potential for recovery, and faces conflict with construction or other development projects or other forms of economic activity. The USFWS recommended no change in status from threatened to endangered, in part because implementation of the 2008 Revised Recovery Plan was expected to resolve key uncertainties and improve recovery potential. In 2022, the USFWS published another 5-year review reporting the continuing declines in density in all of the California Tortoise Conservation Areas except Joshua Tree in 2004–2014 (see Table 2), but also recommended no change in the listing status of the Mojave Desert Tortoise (U.S. Fish and Wildlife Service 2022*a*). For more detail see section 5.1.

As part of the revised 2011 Recovery Plan, Recovery Implementation Teams were developed, which are "composed of representatives from government agencies and non-profit organizations. Participants in these teams prepare proposals for recovery actions, seek funding to support the proposals, and assist with implementation when funding becomes available" (Berry and Murphy 2019). Recovery Implementation Teams have focused on restoration of habitat burned and/or denuded by livestock, trash management to subsidize predators, invasive plant control, roadway fencing, and other conservation and management actions (Berry and Murphy 2019).

Bureau of Land Management

The 2016 Desert Renewable Energy and Conversation Plan (DRECP) Land Use Plan Amendment to the California Desert Conservation Act Plan of 1980 guides management of 10 million acres (~40,469 km^2) of BLM lands, some of which is Mojave Desert Tortoise habitat. The entire DRECP Plan Area covers approximately 22.5 million acres (~91,054 km^2) of federal and non-federal land. Phase I of the DRECP focused on the BLM lands and was released as a Land Use Plan Amendment (LUPA). Phase II will focus on county-level planning designed to work in conjunction with the LUPA. Along with many other agencies and stakeholders, the Department was involved in the development of the DRECP but is not a signatory to the 2016 LUPA.

Under the DRECP, 11,290 acres (~46 km^2) of modeled desert tortoise habitat would eventually be developed for renewable energy, with a streamlined permit review process (Bureau of Land Management 2016). The LUPA contains numerous conservation and management actions, including establishment of a cumulative limit (no more than 1%) on ground-disturbing activities within BLM-owned portions of TCAs and mapped linkages. The plan amendment further prohibits long-term habitat removal in high density tortoise areas (more than five tortoises at least 160 mm carapace length per square mile, or more than 35 individuals in total), but gives an exception for transmission projects. Outside of the development focus areas intended for renewable energy, the plan amendment includes actions that are more protective of desert tortoises than direction contained in the previous land use plan (U.S. Fish and Wildlife Service 2022*a*).

National Park Service

Management of the Mojave Desert Tortoise on NPS lands is guided by the NPS Organic Act of 1916, the ESA of 1973, the Wilderness Act of 1964, the 2006 NPS Management Policies, and each unit's General Management Plan (GMP), Superintendent's compendiums, and Resource Stewardship Strategies. Broad conservation actions are outlined in GMPs and specific closures and updates to prohibited actions are contained in the Superintendent's compendium. Examples include prohibitions on use of Unmanned Aircraft Systems (drones), limits on use of artificial lights to view wildlife, requirements for food storage and trash management, and commitments for restoration of disturbed areas and/or mitigation of direct vegetation impacts.

In desert tortoise range, the NPS administers Joshua Tree National Park, Death Valley National Park, and Mojave National Preserve. The majority of lands across these three units are congressionally designated Wilderness, including nearly 50% of lands in Mojave National Preserve, approximately 85% of lands in Joshua Tree National Park, and roughly 93% of lands in Death Valley National Park. The Wilderness Act of 1964 is intended to preserve places "where the earth and its community of life are untrammeled by man, where man himself is a visitor who does not remain" (Wilderness Act section 2, subd. I). Most notably, use of offroad vehicles and motorized equipment is prohibited in Wilderness areas.

The NPS Organic Act of 1916 (39 Stat. 535, 16 U.S.C. 1, as amended), states that the NPS "shall promote and regulate the use of the Federal areas known as national parks, monuments, and reservations…to conserve the scenery and the national and historic objects and the wildlife therein and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations." The NPS Management Policies indicate that Parks will "meet its obligations under the National Park Service Organic Act and the Act to both pro-actively conserve listed species and prevent detrimental effects on these species." This includes working with other agencies and partners to implement management programs which inventory, monitor, restore, and maintain listed species habitats. The Mojave Desert Inventory & Monitoring Network of the NPS regularly implements monitoring programs at all three NPS units focused on desert spring riparian vegetation and water quality as well as upland vegetation and soil characteristics that might influence the survival of Mojave Desert Tortoise.

United States Department of Defense

The Sikes Act was established in 1960 to ensure conservation and protection of natural resources used by the DoD. The U.S. Congress amended the Sikes Act in 1997 requiring the DoD to develop and implement Integrated Natural Resources Management Plans (INRMPs). These plans outline how each military installation will manage its significant natural resources holistically while maintaining military readiness. Since these lands are often protected from access and use by the general public, they may contain some of the more significant remaining large tracts of habitat and play important roles for species conservation and habitat connectivity.

Under the ESA, the DoD is responsible for managing and protecting the threatened and endangered species found on its installations. DoD is required to consult with the USFWS and National Oceanic and Atmospheric Association (NOAA) Fisheries to manage their threatened and endangered species efforts (Dalsimer 2016).

DoD facilities within the Mojave Desert Tortoise range include Naval Air Weapons Station China Lake, Edwards Air Force Base, Fort Irwin, the Marine Corps Air Ground Combat Center, and the Chocolate Mountain Aerial Gunnery Range. DoD is an active collaborator in the MOG and RASP partnerships and contributes funding to many recovery actions. Unlike most other federal land, tortoise habitat under DoD jurisdiction is “subject to more dramatic changes in management or use than other Federal lands depending on the changing national security situation” (U.S. Fish and Wildlife Service 2011). This means that large tracts of desert tortoise habitat can relatively quickly be converted to uses that are incompatible with desert tortoise, requiring translocation of large number of tortoises (see section 4.1 for more details). To offset these losses of tortoise habitat, the DoD undertakes a variety of actions such as purchasing land in critical habitat units, increasing law enforcement, predator control and monitoring, rehabilitation of closed roads, and installation of fencing.

California Department of Fish and Wildlife

CESA prohibits the unauthorized take of desert tortoise, but the Department may permit take that is incidental to otherwise lawful activities if the impacts of the take are minimized and fully mitigated. These permits are commonly called incidental take permits.

The Department is required to determine what qualifies as "full mitigation" for each permit on a case-by-case basis. As a practical matter, perpetual protection and management of habitat mitigation lands has often been the type of mitigation required. In addition, projects may have to implement a variety of measures to minimize take of tortoises including but not limited to surveying and monitoring for their presence, fencing to keep tortoises out of the project site, relocating of nests to safe offsite locations, translocating tortoises on the project site, and managing ravens on the site.

Since 1989, CDFW has issued 192 ITPs and 49 CDs covering incidental take of Mojave Desert Tortoise; the most common project types include renewable energy, transportation, and utility infrastructure (for locations of permitted projects see Figure 13). The Department's records are not complete; however, at minimum these permits authorize 62,131 acres (~250 km^2) of permanent impacts and 14,672 acres (~59 km^2) of temporary impacts (based on data available about temporary acres from 36% of ITPs and 79% of ITPs for permanent impacts). The ratio at which projects have to protect and manage mitigation habitat varies on a project-by-project basis, however projects sited in federally designated Critical Habitat are generally mitigated at a 5:1 ratio and other habitats at around a 3:1 ratio depending on quality. Permit holders have multiple options when choosing mitigation lands but must typically provide for permanent protection and perpetual management of habitat for the listed species either on the project site or at another location approved by the Department. This requires transfer of fee-title and/or recordation of a conservation easement, to which the Department must be at least a third-party beneficiary, funding of short-term management practices and a long-term management endowment, and monitoring to ensure compliance with the conservation easement. Alternatively, permittees may purchase credits at conservation and mitigation banks.

The desert tortoise is addressed in several Natural Community Conservation Plans (NCCPs) and Habitat Conservation Plans (HCPs) in California, including the West Mojave Plan, the Coachella Valley Multi Species Habitat Conservation Plan (MSHCP), and the California Energy Commission's Habitat and Species Protection Research Project. The Coachella Valley MSHCP area supports a small, but significant population of desert tortoise in Riverside County (CDFW 2005). This MSHCP includes all federally designated critical habitat within the plan area as part of the Desert Tortoise and Linkage Conservation Area.

Figure 13. Map of Incidental Take Permits (ITPs) and Consistency Determinations (CD) in the general area of Mojave Desert Tortoise range in California. The linear permit areas are for energy transmission lines, pipelines, fiber optic lines, and other linear features. Other types of projects are represented as polygons.

6 SUMMARY OF LISTING FACTORS

The preceding sections of this status review describe the best scientific information available to the Department, with respect to the key factors identified in the regulations. This section considers the significance of any threat to the continued existence of Mojave Desert Tortoise for each of the factors.

6.1 Present or Threatened Modification or Destruction of Habitat

Like many species, habitat loss and degradation are major concerns for desert tortoise. Tortoises are sensitive to habitat alteration by development and an estimated 66% of Mojave Desert Tortoise habitat has some development within 1 km (Carter et al. 2020). The direct impacts of development include removal of soil and vegetation, destruction of burrows, and creation of roads and other infrastructure that can kill tortoises or hinder their movements (Boarman and Sazaki 1996, 2006). Large amounts of desert tortoise habitat are open to renewable energy development, off road driving, or is under DoD jurisdiction and could be used for training or associated infrastructure development. For example, in the past 10 years, a net of ~150,000 acres of the ~3,000,000 acres (~607 km^2 of ~12,140 km^2) of viable desert tortoise habitat under DoD jurisdiction have been eliminated (U.S. Fish and Wildlife Service 2022*a*).

Tortoises are less likely to utilize areas that have even a low level of development. Carter et al. (2020) found that "encounter rates for both live and dead Mojave desert tortoises combined decreased significantly with increased development levels" and that when "10% of the area within 1 km of that location has been altered by development", it was rare to find live or dead tortoises at that location. To date, models show that only 5% of Mojave Desert Tortoise habitat falls into that category (Carter et al. 2020). However, as the demands for housing and renewable energy facilities increase in the desert, it is likely that the amount of development within or near tortoise habitat will continue to increase.

Currently there are about 62,000 acres (about 250 km^2) permitted to be permanently impacted by renewable energy projects within desert tortoise range in California. Wind and solar farms alter the habitat in permanent and temporary ways (though some alterations considered to be temporary can have impacts lasting decades in the desert. Studies of the impacts of wind farms on tortoises indicate that tortoises can survive on some farm sites, and that in some cases their survivorship may be higher on farms than in surrounding areas. However, such studies are few and the impacts of wind and solar farms on tortoises remain uncertain. Roads and OHV routes are a direct threat to tortoises through roadkill, as well as habitat degradation and fragmentation. The proliferation of such features in desert tortoise habitat adversely impacts tortoises, especially since the installation of exclusion fencing has been limited over the past decade. Other factors that degrade habitat include increasing temperatures and potential drought frequency, which are expected to reduce the ability of current habitat areas to support tortoise populations in the future.

Invasive grasses have caused widespread impacts to desert tortoise habitat. These grasses, mostly *Bromus* and *Schismus* species, are outcompeting native grasses and forbs that tortoises preferentially eat. The invasive grasses lack sufficient levels of the nutrients that tortoises need to survive and consuming them leads to increased water loss. The impact seems especially acute on juvenile tortoises and is likely being a factor in the low survival rates for juveniles seen in some areas. The grasses also intensify the fire cycle which in turn decreases the amount of native vegetation that is an important food source for tortoises.

Loss of habitat is traditionally considered to be one of the major drivers of species declines worldwide. However, direct loss of habitat may be less of an issue for desert tortoises than habitat degradation. Although current estimates indicate more than 90% of historical habitat still available (only 7.4% of modelled habitat is currently considered completely unsuitable (Holcomb 2022*a*)), tortoise populations have declined severely in the past two decades. Habitat degradation through road construction and off-vehicle vehicle use, fire, invasive species outcompeting native plants, and increasing temperatures due to climate change have likely reduced the quality of much of the remaining habitat. Therefore, focusing solely on the proportion of habitat loss in the desert tortoise range as a means of measuring population impacts may be misleading and create an overly optimistic picture.

6.2 Overexploitation

People still shoot and collect desert tortoises but seemingly not at the frequencies seen in the late 20th century. This may have to do with changing human behavior patterns or because there are simply fewer tortoises on the landscape for humans to encounter. Overexploitation is not currently considered a major threat to Mojave Desert Tortoise.

6.3 Predation

Predation, especially by ravens and coyotes, is a significant factor in desert tortoise population decline. Ravens (and to lesser extent coyotes) are subsidized by the infrastructure, water, and food around human development, and their populations have dramatically increased in recent decades. Ravens preferentially target juvenile tortoises, and since clutch sizes are low and tortoises can take 12–20 years to become sexually mature, decreased juvenile survival is likely an important factor in many areas with declining tortoise densities. Given the slow life history traits of tortoises, lower juvenile survival will be a long-term issue for the population, impacting populations for decades. Coyotes can kill older tortoises, and in some areas are a significant cause of death meaning that even in the unlikely scenario where the threat from ravens is eliminated quickly, predation could remain an issue and recovery is unlikely to be swift.

6.4 Competition

There is some direct competition with livestock for food however there is not much recent data on the severity of the impacts specifically in California. In a recent paper on anthropogenic stressors to desert tortoises, livestock grazing is listed as a threat in Nevada but not California (Tuma et al. 2016).

6.5 Disease

Upper respiratory tract disease has been cited as a cause of population declines in desert tortoise and was a reason for listing under the ESA in 1990. It is thought that its high prevalence in wild populations in the 1970s through 1990s was due in part to infected captive tortoises being released into the wild. Drought, heavy metal pollution, and human disturbance increase physiological stress in tortoises and are correlated with outbreaks of the disease (Jacobson et al. 2014). Berry et al. (2015) points out that many of the stressors that increase tortoise vulnerability to disease, especially drought and proximity to human populations, are increasing in desert tortoise range. However, there have not been any large outbreaks causing mortality documented in California since the 1990s. There is not currently significant concern about the disease in wild populations, although great care still needs to be taken during translocations to prevent any accidental spread.

6.6 Other Natural Occurrences or Human-related Activities

Climate Change

Climate change is a major threat which will also intensify other threats. The predicted increase in heat and periodically drier conditions increase the chances drought in California through the end of the century will increase the amount of time tortoises experience physiological stress, decrease the amount of suitable habitat, and likely negatively alter the vegetation they rely on. Climate change in general is causing governments to invest in the expansion of wind and solar farms, and the number of proposed renewable energy projects in desert tortoise habitat are increasing. The DoD considers climate change a major threat to global stability (U.S. Department of Defense 2021) and predicts that global climate change will intensify political unrest worldwide. This makes it possible that training activity in the many military bases in desert tortoise habitat will increase in the future, converting more land from suitable tortoise habitat to training areas, and requiring large scale translocations of resident tortoise as mitigation.

Fire

Desert tortoise habitat historically experienced few fires due to low plant productivity and sparse fuel loads, and those that did ignite generally burned at low severity in a patchy mosaic pattern. Consequently, desert tortoise and the vegetation they rely on are not well adapted to fire. Tortoises have some direct protection from fire as they spend much of their time underground. The expansion of invasive plants (primarily invasive *Bromus* species) has increased fuel loads, though over the long-term fires have not become more common in the desert. Fire directly causes some tortoise death and further changes the vegetative community making it more difficult for tortoises to find nutritious foods.

Mining

Mining has a long legacy in desert tortoise habitat. Some mining shafts remain open and unfenced, and tortoises can fall in and get trapped inside. Mining leaves behind pollutants of various types including mercury, arsenic, and lead that impact soil and plants (including those favored by tortoises) up to 15 km from mining sites. Tortoises can absorb the pollutants via breathing, eating impacted plants, or absorption through skin, and exposure to these toxins may make tortoises more susceptible to disease. Though there is evidence pollution from mining has negative impacts on tortoise health, it does not appear to be a major threat to tortoise populations.

6.7 Summary of Key Findings

Historical and current conservation efforts have not proven sufficient to halt the population declines of desert tortoise. The most robust estimates of densities come from annual systematic surveys done in the Tortoise Conservation Areas, which include the Critical Habitat Units and contiguous areas with potential tortoise habitat and compatible management. These surveys began in 2004 and cover large areas of the best tortoise habitat. Taken as a whole, these surveys provide strong evidence that most tortoise populations in California have declined rapidly over the past two decades. Estimated rates of annual decline in density in the TCAs for 2004–2014 were between 3.3% and 10.8% per year, which is unsustainable for most species, but especially for such a long-lived and slow-reproducing species as the desert tortoise. Sixty percent of the TCAs currently have densities below 3.9 adult tortoises/km^2 which is the density considered necessary for population viability, while another 30% are at the threshold. Only one TCA currently has density above the 3.9/km^2 population viability threshold. While we do not have estimates of density in all the TCAs prior to the desert tortoise being listed as threatened, densities in the early 1980s in select TCAs varied between 35 and 90 adults/km^2, and between 35 and 70 adults/km^2 when they were listed as threatened under CESA in 1989. It is estimated that densities of adults in certain TCAs fell between 89% and 97% from the early 1980s to 2020–2021. Since the late 1970s, the number of juveniles detected on surveys has also fallen sharply, to the point that in recent surveys in the Western Mojave almost no juveniles were found. Overall, the population data available from the last 20 years continue to document tortoise declines in most sampled areas populations in in many TCAs, which represent much of the best habitat, are no longer considered viable.

Due to the slow components of tortoise life history, if past and current management is successful at mitigating threats and adverse impacts to tortoises, it would still take at least 25 years of positive population growth to reach the USFWS Recovery Criteria (U.S. Fish and Wildlife Service 2022*a*). For example, in the USFWS 1994 Recovery Plan they estimate that when adult survivorship is 98%, population growth would be less than 0.5% per year, and would take 140 years to double in size. Annual survival rates for both adults and juveniles in many areas are much lower than 98%, making population stability, let alone growth, unlikely. Collectively, the available data show that despite 30 years of state and federal protection, in the critical habitat units (which are considered to be the best tortoise habitat), most tortoise populations have continued to decline and do not show consistent signs of recovery. In most regularly surveyed areas, tortoise densities are below the thresholds considered to represent population viability.

The dramatic declines in Mojave Desert Tortoise populations have likely resulted from the extensive number and interconnected nature of the threats facing tortoises in California. The important threats fall in two categories, those that directly kill adults and juveniles, and changes in habitat suitability that make it less likely to support healthy populations.

Particularly in long-lived species that are slow to reproduce, decreased survival has long lasting impacts on the population and can alter demographic patterns for decades. Predation pressure from ravens and coyotes reduce the survival of juvenile and adult tortoises respectively. Increasing development removes or reduces habitat suitability and creates roads and increased traffic that can endanger tortoises. Extensive networks of trails for off-highway vehicles on public lands increase the chance that tortoises will be run over even in areas without paved roads. Well-designed fences and culverts can help prevent tortoises and other wildlife being killed by vehicles along major roads, but many primary roads remain unfenced and little fencing has been built since 2011.

Habitat modification and destruction reduces the amount of habitat that can support tortoises in the long-term. Development in the desert will likely continue and possibly speed up given California’s need for housing and renewable energy (Office of Governor Gavin Newsom 2021). The Department of Defense is a large landowner in desert tortoise range and frequently expands the areas that it uses for training, requiring translocation of hundreds of tortoises. Large scale tortoise translocations do not tend to have high survival rates. It is hard to predict the amount of land the DoD will convert into training areas in the future, but given the increases of the federal defense budget over the past 20 years (Wikipedia 2023), military training needs are not likely to decrease.

Additional factors have direct and indirect impacts on tortoises and their habitat. Climate change, which is likely to make desert tortoise range hotter and drier, will increase tortoise physiological stress and change activity patterns. The nutritious native plants tortoises preferably feed on are being outcompeted by nutritionally poor invasive grasses, which can lower tortoise survival rates. Fires fueled by invasive grasses are becoming more common, which decreases the amount of native vegetation available for tortoises to feed on.

Some threats appear to be declining. Upper respiratory tract diseases were a major concern when tortoises were listed as threatened. Encouragingly, the prevalence of diseased tortoises is lower than in previous decades, and it does not currently appear to be an acute threat to wild populations. The prevalence of gunshot deaths also decreased in the past several decades, but it is unclear if this is due to change in human behavior or simply reflects a lower tortoise encounter rate due to declining tortoise density.

There is still a large amount of available habitat and even at low densities, in 2014 there were estimated to be more than 61,000 adult tortoises within the TCAs. However, that is a decrease from an estimated ~310,000 adults in 2004, and as densities have continued to fall since 2014, current abundance is likely lower than 60,000 adult tortoises, and in 60% of the TCAs the populations are below the densities needed for viability. Given that there are multiple interacting threats that are reducing the amount and quality of viable habitat and lowering survival rates of adults and juveniles, the available information suggests that tortoise populations will continue to decline for the foreseeable future. However, several of the major threats like raven predation on juveniles and the lack of fencing on highways can be minimized with the appropriate resources and policy changes. Implementing these actions where appropriate to improve survival in the short term is critical to give desert tortoises the resilience to be able to weather longer term habitat and climactic effects.

7 PROTECTION AFFORDED BY LISTING

It is the policy of the state to conserve, protect, restore and enhance any endangered or any threatened species and its habitat (Fish & G. Code, § 2052). If listed as an endangered rather than a threatened species pursuant to CESA, unauthorized “take” of Mojave Desert Tortoise will remain prohibited and its conservation, protection, and enhancement will remain a statewide priority. As the Mojave Desert Tortoise is already listed as threatened, public agency environmental review is required under the California Environmental Quality Act (CEQA) and its federal counterpart, the National Environmental Policy Act (NEPA). There are no changes in legal protections under CESA for species changed from threatened to endangered.

However, if the status of the Mojave Desert Tortoise is changed to endangered under CESA, it may increase the likelihood that state and federal land and resource management agencies will prioritize and allocate more funds towards protection and recovery actions. The federal and state listings of the desert tortoise as threatened stimulated a great deal of interest and funding in addressing basic questions about the species, with expanded research into status and distribution of populations, ecology, genetics, and diseases, as well as collaborations to minimize conflict among the many users of desert tortoise habitats. It also triggered the creation of a federal Recovery Plan and the numerous conservation and management measures outlined in the Existing Management Section. However, funding for species recovery and management is limited, and there is a growing list of threatened and endangered species. Therefore, while a status change pursuant to CESA will highlight the urgency of tortoise conservation needs, the management effects of such a change are uncertain.

8 RECOMMENDATION FOR THE COMMISSION

CESA requires the Department to prepare this report regarding the status of Mojave Desert Tortoise in California based upon the best scientific information available to the Department (Fish & G. Code, § 2074.6). CESA also requires the Department to indicate in this status review whether the petitioned action is warranted (Fish & G. Code, § 2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f)). Based on the criteria described above, the best scientific information available to the Department indicates that Mojave Desert Tortoise is in serious danger of becoming extinct in California due to one or more causes including present or threatened degradation and loss of habitat, predation, and other natural occurrences and human-related activities.

The Department recommends that the Commission find the petitioned action to change the status of Mojave Desert Tortoise from threatened to endangered to be warranted.

9 MANAGEMENT RECOMMENDATIONS

CESA directs the Department to include in its status review recommended management activities and other recommendations for recovery of Mojave Desert Tortoise (Fish & G. Code, §

2074.6; Cal. Code Regs., tit. 14, § 670.1, subd. (f).). The USFWS created a Recovery Plan for desert tortoise in 1994 which was revised in 2011. This is currently the most comprehensive framework of actions needed to recover the desert tortoise, and many of the recommendations are still very relevant. For our recommendations we borrow heavily from the framework in the 2011 revised Recovery Plan, include examples of recent progress, and point out specific areas where the Department could engage more. We also focus on specific actions like translocation and head-starting that have been in use for multiple years to examine what evidence there is that they have been effective.

9.1 Actions

This document is not a Recovery Plan; however, it is useful to identify the conservation goals that the management recommendations are meant to achieve.

In brief, the USFWS Recovery Plan includes the following objectives:

1. Maintain self-sustaining populations of desert tortoises within each Recovery Unit into the future.
   – Criteria: Rates of population change (λ) for desert tortoises are increasing (i.e., $\lambda > 1$) over at least 25 years (a single tortoise generation)
2. Maintain well-distributed populations of desert tortoises throughout each recovery unit.
   – Criteria: Distribution of desert tortoises throughout each tortoise conservation area is increasing over at least 25 years (i.e., ψ [occupancy] > 0)
3. Ensure that habitat within each recovery unit is protected and managed to support long-term viability of desert tortoise populations.

The major elements of the USFWS Recovery Plan strategy to achieve these objectives are:

1. Develop, support, and build partnerships to facilitate recovery.
2. Protect existing populations and habitat, instituting habitat restoration where necessary.
3. Augment depleted populations in a strategic manner.
4. Monitor progress toward recovery.
5. Conduct applied research and modeling in support of recovery efforts within a strategic framework.
6. Implement a formal adaptive management program.

For each of the strategies in the Recovery Plan, the USFWS includes specific measures to contribute to those strategies. We do not list all of these specific measures here, but instead discuss the strategies and measures that are most relevant and important to recovery in California and highlight those which the Department may have a role in implementing.

1. Develop, support, and build partnerships to facilitate recovery.

There are multiple existing partnerships to facilitate recovery of desert tortoise (see section 5.2 Management Efforts). The Department could become more active in the MOG, participate in Recovery Implementation Teams, and strengthen maintain relationships with state and federal agencies to collaboratively address priorities such as highway fencing and translocation.

2. Protect existing populations and habitat, instituting habitat restoration where necessary.

Here we focus on the issues most relevant to California.

a. Conserve intact desert tortoise habitat
The majority of land (63.1%) in the tortoise range is under stewardship of the BLM or the NPS and receives some level of protection (see Table 6). Future habitat conservation efforts should consider how habitat suitability will change in the coming decades under predicted climate change and ways in which habitat can be restored and made more resilient and/or habitat degradation can be ameliorated.

b. Secure lands/habitat for conservation.
Projects that will potentially result in incidental take of tortoises may apply for an ITP from the Department. As a condition of the ITP, the Department must require any impacts to the desert tortoise to be fully mitigated. This requirement is most often met through the perpetual protection and management of off-site habitat. CDFW should continue to focus on securing high quality habitats through the ITP process and through other means (e.g., facilitating recovery land acquisitions through grants, facilitating conservation easement, etc.). The USFWS also issues take authorizations that ask for mitigation in the form of land protection. For more detail see section 5.2 Management Efforts.

As mentioned previously, “the Army acquired approximately 100,000 acres (~405 km^2) of nonfederal land within the Superior-Cronese Critical Habitat Unit for conservation management of desert tortoises. It also purchased the base property of three cattle allotments on which the Bureau subsequently re-allotted the forage to wildlife” (U.S. Fish and Wildlife Service 2022*a*).

c. Connect functional habitat
Low genetic differentiation among desert tortoise populations in California (Hagerty and Tracy 2010) suggests that historically there were few barriers to movements and mixing, aside from large mountain ranges and other significant climatic or vegetative barriers. However, this is effectively no longer the case, and instead there is what is more accurately described as a metapopulation (Berry and Murphy 2019, Desert Tortoise Council 2022) where habitat patches are separated by roads, housing, agriculture, industry, energy projects, and military activities.

The strategy outlined in the 1994 Recovery Plan suggests that habitat patches of at least 2590 km^2 (1,000 mi^2) are needed in each recovery unit to “contain a viable population of desert tortoises that is relatively resistant to extinction processes” (U.S. Fish and Wildlife Service 1994). Multiple TCAs are smaller than 2,590 km^2, therefore protecting corridors between TCAs so that tortoises can disperse is key for conservation of metapopulations. Tortoises within isolated patches are at higher risk of extirpation due to the usual risks to small populations—

stochastic catastrophes like drought and fire, reduction in genetic variation, and potential associated losses of fitness (Boarman et al. 1997, Berry and Murphy 2019, U.S. Fish and Wildlife Service 2022*a*). While many of the patches share the same threats, given the differences in land use and management across the desert tortoise's range, individual patches should be managed to minimize the most severe threats for that patch. The USFWS (2019a) points out that the current fragmented nature of desert tortoise habitat (e.g., urban and agricultural development, highways, freeways, military training areas) will make "recolonization of extirpated areas difficult, if not impossible."

Land is not equally protected across CHUs, creating potential barriers between areas of functional habitat. We recommend focusing the compensatory habitat purchases and other types of land acquisitions on connecting functional habitat. The BLM is acquiring several thousand acres of checkerboard inholding in Chuckwalla Critical Habitat Unit which will improve connectivity to Joshua Tree National Park.

d. *Fence, restrict, designate, close roads and routes*

In order for functional habitat to be connected, tortoises need to be able to move and not be isolated in patches. A major action to achieve this is to erect tortoise fencing and crossings along roads.

Erecting tortoise exclusion fencing along major roadways and funneling them into well designed crossings is a key recovery action. There are 500 kms (~310 mi) of road identified as priority for fencing (U.S. Fish and Wildlife Service 2022*a*). Currently, the regulations on highway fencing have made it extremely difficult and expensive to install tortoise fencing and are a major reason that there was very little tortoise exclusion fencing installed between 2011 and 2022. Under current practice, when an applicant applies for an ITP for a road project that includes tortoise exclusion fencing and culverts for crossing, the area of land inside of the fence including the median between lanes of traffic is considered to be habitat that is impacted and the impacts need to be fully mitigated through land acquisition. The costs of procuring land adds substantial costs to fencing projects, to the point that much needed fencing is not getting built. To speed up the building of fences, the Department can work with CalTrans and other agencies to reduce cost and administrative burden of building tortoise exclusion fencing. Having more flexibility in the measures that are used to fully mitigate the impacts of road projects will help speed up progress on recovery actions. At the moment there are some fencing projects in process, including the first phase of a BLM effort to build 3.5 miles of fencing along I-40 in the Rod-Ordman Critical Habitat Unit. In the Mojave National Preserve there is a road rebuilding project that includes 5 miles of tortoise fencing.

In addition to fencing paved roads, we recommend closing and restoring unauthorized OHV routes in CHUs.

e. Minimize excessive predation on tortoises

Implementing multiple actions simultaneously is necessary to slow the expansion of predator populations. The DoD and the USFWS have active programs to reduce anthropogenic subsidies to ravens and coyotes by securing trash and water sources and reducing the number of nesting and roosting sites created by infrastructure. The USFWS has a program to reduce raven populations via egg oiling with a goal of no raven nests in areas that are a priority for tortoise recruitment (K. Holcomb, USFWS Raven Management in CA. MOG April 16 2022).

f. Restore desert tortoise habitat

Restore closed OHV trails, and work to reduce non-native invasive grasses from desert tortoise habitat. Areas degraded by off road vehicles in Fremont Kramer Critical Habitat Unit are being restored by the BLM and Marine Corps Air Ground Combat Center Twentynine Palms is restoring habitat as part of implementing RASP.

g. Minimize factors contributing to disease (particularly upper respiratory tract disease)

Continue to discourage the release of pet tortoises into the wild. Monitor and quarantine translocated tortoises to make sure they are not diseased before relocation following recommendations in U.S. Fish and Wildlife Service (2020b).

h. Establish/continue environmental education programs

Environmental education is a preventative action that has been shown to effectively change learned behavior and can be used to reduce stakeholder conflict before it happens (Hungerford and Volk 1990). An educated public is more likely to be aware of the consequences they can have on desert tortoises and to be more willing to take responsibility for their actions than those with less knowledge (Vaske and Donnelly 2007). Aggressive and widespread efforts in museums, hunting clubs, and in BLM and NPS visitor centers and interpretive sites are needed to inform the public about the status of the desert tortoise and its recovery needs (U.S. Fish and Wildlife Service 2011).

Interpretive kiosks or visitor centers should be used to disseminate information about the desert tortoise and the need for regulated access and use of habitat. Education programs should include such subjects as husbandry and adoption programs for captive tortoises, the importance of discouraging unauthorized breeding of desert tortoises in captivity, and the illegality under State laws of releasing captive tortoises into wildlands. Education efforts should be focused on groups that use the desert on a regular basis, such as rock-hounds and off-highway vehicle enthusiasts. Additional educational tools include public service announcements, news releases, informational videos, brochures and newsletters, websites, and volunteer opportunities (U.S. Fish and Wildlife Service 2011).

i. Increase law enforcement.

Increase efforts to enforce rules banning off-roading by OHVs in Desert Wildlife Management Areas and CHUs.

3. Augment Depleted Populations through a Strategic Program

Population augmentation is currently accomplished through two types of projects, translocation and head-starting. Translocation involves moving tortoises from a site where they would be harmed and into an appropriate recipient site. Head-starting is a strategy to reduce predation mortality on juvenile tortoises by hatching and rearing juveniles in captivity until they are large enough to avoid most predators.

a. Translocation

Proposed projects that could result in incidental take of tortoises may apply for an ITP. As part of the minimization measures, tortoises in the project area are translocated to pre-approved recipient sites.

There are a number of considerations that need to be taken into account when tortoises are translocated as laid out in the USFWS Plan Development Guidelines (U.S. Fish and Wildlife Service 2020*b*). Major concerns include the habitat suitability of potential translocation sites and the possibility of disease transfer from transplants to resident tortoises. The Department requires that ITP holders monitor any tortoises translocated, and has teams carefully examine recipient sites for soil and vegetation communities that are suitable for all life stages of tortoise, evaluate the presence and abundance of predators, and make sure there are sufficient burrows of appropriate size so that translocated tortoises can quickly find shelter. Most of the tortoises translocated under ITPs granted by the Department are placed within 4 miles of the donor site and the number of tortoises translocated for any project is usually less than 50. Due to the consistent efforts to find suitable recipient sites, deaths from translocation via dehydration or predation are rare (CDFW unpublished data, W. Campbell pers comm Jan 2023). However longer-term success of those translocations is not known.

However, there is evidence that larger scale translocations are not very successful. This is likely because it is much more difficult to find recipient sites that are suitable for larger numbers of tortoises. If donor sites are chosen because resident populations are depleted or have low densities, they may not have the capacity to maintain higher densities of tortoises in general and might not be able to support large numbers of translocated animals (U.S. Fish and Wildlife Service 2011). For example, sites with a depleted population due to habitat modification or degradation may currently be at a low carrying capacity and not be able to support many transplants because the site lacks sufficient food or burrows to support more individuals, or it simply is too hot. In the spring of 2008, 570 tortoises (184 females, 293 males, 93 juveniles) were translocated from the southern edge of Fort Irwin National Training Center to neighboring public land in the Superior-Cronese Critical Habitat Unit. Esque et al. (2010) tracked the survival of the translocated tortoises and within a year, 25% of them died. In the same translocation event, (Mulder et al. 2017) found that the males that survived were not fathering hatchlings. Even though translocated males made up 46% of the males they genotyped in the population, all hatchlings that could be assigned fathers were sired by resident males. A different study examined drivers of survival when 158 adult tortoises were translocated from Ft. Irwin to release sites 7.36–42.54 km from their home sites (Mack and Berry 2023). The tortoises were tracked for 10 years. Thirty-nine percent died in the first year, more than 50% were dead by the end of the third year, and after 10 years about 66% were confirmed dead and another 15% missing. Most of the dead tortoises were killed by coyotes. After 10 years, survival was highest in the site closest to the site they had been taken from, and across the study males were more likely to survive. Low survival is not limited to the translocated tortoises; in the same time period the density of resident tortoises also declined. Supplementation of the resident population by translocated individuals does not appear to stabilize populations, as explained by (Mack and Berry (2023):

> "In 2004–2005, prior to translocation, the USFWS (2015) estimated densities of resident adult tortoises at 6.4 adults/km2 for the Superior-Cronese critical habitat unit where the translocation later occurred. In contrast, densities of adults on release plots at the time of release were approximately 40/plot or 15.5/km2, more than two times that of the surrounding resident population. Several decades ago, habitat may have supported ≥15 adult tortoises/km2 in the region (USFWS 1994, Berry and Murphy 2019). Declines in abundance occurred prior to, during, and after the release; the USFWS (2015) reported a 61.5% decline in adult tortoises in the Superior-Cronese critical habitat unit between 2004 and 2014 to 2.4 adults/km2, despite additions of several hundred tortoises from the NTC translocation project in 2008. By 2017, the density of adults had declined further to 1.7 adults/km2 (USFWS 2018)."

Further evidence that translation has not necessarily increased the recipient populations in California comes from Ord-Rodman Critical Habitat Unit. In 2014, the estimated density of tortoises in Ord-Rodman was 3.6 adults/km^2 with an estimated abundance of about 3000 adults (Tables 2 and 5). Between 2017 and 2019, 724 adult tortoises were translocated into the Ord-Rodman TCA due to expansion at 29 Palms Marine Corps Air Gunnery Command Center. From 2017 on, the surveys kept track of the densities of all adults and of residents adults only (Figure 14) (U.S. Fish and Wildlife Service 2018, 2019*b*, 2020*a*, 2022*c*, *b*). Although the initial influx of a large number of translocated adults pushed the population back up to 3.9 adults/km^2 in 2017, in subsequent years the density of residents and all adults fell and has stayed below the threshold for population viability since.

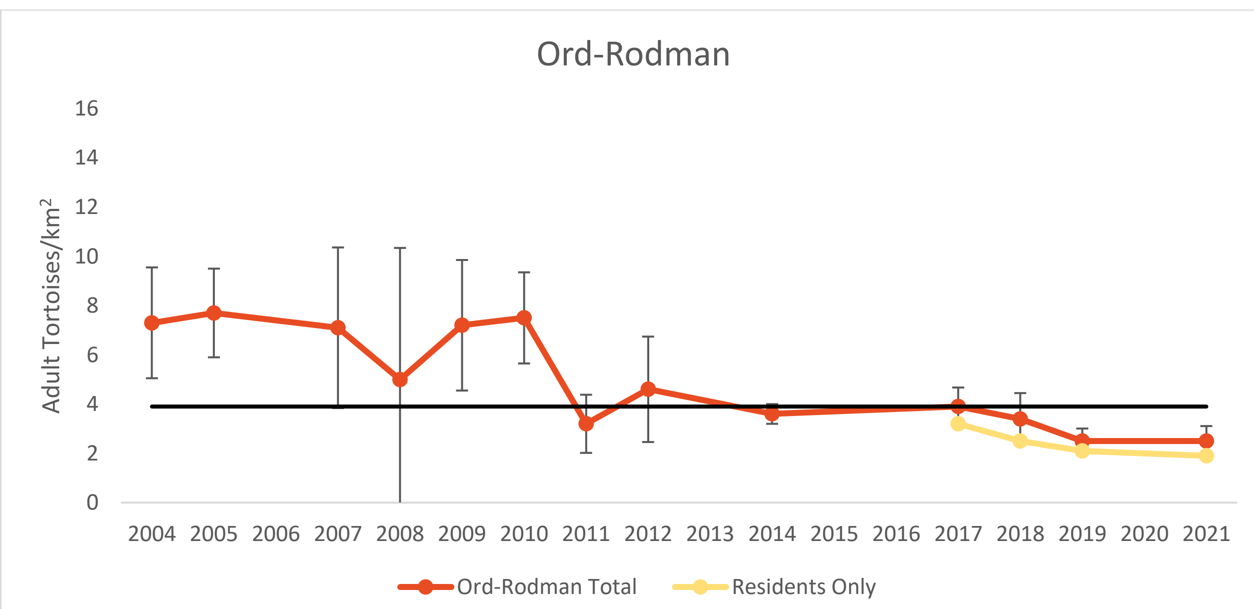

Figure 14. Estimated densities of adult tortoises (≥ 180 mm carapace length) in the Ord-Rodman TCA in the Western Mojave Recovery Unit 2004–2021. Black horizontal line represents 3.9 adults/km^2, the estimated minimum density needed for population viability. Error bars are standard errors calculated from reported coefficients of variation. The Residents Only density is for adults that were not translocated, the Ord-Rodman Total is the density of residents plus the translocated tortoises starting in 2017.

Nor has translocation been successful just across the Nevada border from the Ivanpah Critical Habitat Unit. As Scott et al. (2020) reported:

> "In 1996, the 100-km^2 Large-Scale Translocation Site (LSTS) was established. The LSTS is located in the Ivanpah Valley near Jean, Nevada, within the natural range of the tortoise, and is surrounded by either a tortoise-barrier fence or relatively inhospitable mountains….Between 1997 and 2014, ~9,105 tortoises (~50.2% of which were adults) of unknown provenance were translocated to the LSTS, where they intermingled with an estimated 1450 adult local tortoises that were natural residents at the site. Most native and translocated tortoises in the LSTS have since died, consistent with steep declines in neighboring populations and likely furthered by high post-translocation densities and less comprehensive health screening during the first decade of the translocation program. However, roughly 350 adults were estimated by line-distance surveys to be alive in 2015"

The failure of these large and long-term translocations to either keep translocated tortoises alive or the resident population stable suggests translocation may often not be an effective management strategy. The majority of the tortoises translocated into LSTS came from captivity and were likely not well adapted to surviving in the wild, which is likely a factor in their high death rates. Most official translocations in California involve moving wild tortoises from a project site to a nearby area, and so may not face the same difficulties in survival that releasing captive tortoises appear to create. However, the evidence from Ord-Rodman suggests that even an addition of large numbers of new adults to a nearby area can slow but does not prevent population declines. The low survival rates of translocated adults and the lack of genetic integration of males suggest that large scale translocation may not provide much recorded benefit to recipient populations and does not necessarily remove the translocated tortoises from harm's way. Thus, identification of the reasons for the depleted population in the recipient site is important to ensure translocation is conducted in a manner appropriate to facilitate survival, and to prevent its failure as a minimization measure.

An additional consideration is how far to translocate individuals. When tortoises must be translocated from large tracts of land such as on military bases, translocating individuals close to their home ranges is not feasible. Long distance translocation involves potential mixing of genetic subunits and possible maladaptation to the environment, and investigations into the genetic makeup of the source and recipient populations can help mangers make appropriate decisions (Weeks et al. 2011). Averill-Murray and Hagerty (2014) used microsatellite loci and concluded that "releasing tortoises at recipient sites within a straight-line distance of 200 km from the source population would most conservatively maintain historic genetic population structure.” However more recent work by Sánchez-Ramírez et al. (2018) using Single Nucleotide Polymorphisms (SNPs) suggests that there are there are three genetic subunits within the Western Mojave Recovery Unit and translocating them at distances of 200 km away could mix individuals from different genetic units.

Given the long-term decline of tortoise populations, understanding the population impacts of translocation across the state is critical. ITP holders monitor translocated tortoises for 5 years and submit reports to the Department. These data should be organized and analyzed in order to understand long-term survival rates of translocated individuals and the impacts of potential population fragmentation (see section 9.3). Increased collaboration should occur between agencies that perform translocations to understand the landscape and population impacts of short- and long-range translocations and coordinate research on disease dynamics, recruitment rates, and gene flow (U.S. Fish and Wildlife Service 2020*b*).

b. Head starting

Head-starting is a strategy to try to circumvent the high mortality of juvenile tortoises in the wild (see sections on Survival and Predation). Population modeling suggests that increased juvenile survival can improve population growth rates and is a factor managers can manipulate relatively easily (Berry and Murphy 2019). Eggs are hatched in captivity and juveniles are reared until they reach a certain size and then released. There is some evidence that this strategy appears to be effective at least in the short term (Nagy et al. 2015*a,b*, Tuberville et al. 2019), however, mortality is high for juveniles smaller than 100 mm in length. When Daly et al. (2019) monitored head started tortoises after release in the Mojave National preserve, annual survival was 44% and short-term survival was better if tortoises were more than 1.6 km from a raven’s nest. Daly et al. (2019) points out that by itself, head-starting is unlikely to lead to population recovery if larger issues such as raven density and habitat degradation are not addressed. Nagy et al. (2015*a*) recommends not releasing head-started tortoises until they are over 100 mm, which requires keeping them in captivity for about 9 years and is a considerable investment of time and resources. There is currently a head-starting program at the Ivanpah Desert Tortoise Head-starting Facility in Mojave National Preserve, a joint project between the University of Georgia and UC Davis. They have produced more than 675 hatchlings, released 324 which have been radio-tracked following release, with another approximately 275 for upcoming releases (Tuberville 2022). Another head-start program is on Edwards Air Force Base and involves San Diego Zoo, the U.S. Geological Survey, Cadiz Inc., and the BLM (San Diego Zoo Wildlife Alliance 2018).

7. Monitor progress toward recovery.

The USFWS does yearly surveys of the Tortoise Conservation Areas which are used to generate estimates of density, abundance, and annual rates of change. The results of this monitoring are summarized in section 3.2 Trends in Density and Abundance. Along with the data and estimates that are currently published in the report, making sex ratio data public would help stakeholders better understand demographic trends, especially as they are influenced by climate change.

The USFWS (2011) has more detailed recommendations on how to monitor populations on the scale of recovery units.

The Department collects a variety of data on tortoises from holders of ITPs and Scientific Collecting Permits. Improving the capacity of the Department to summarize and analyze these data to identify the cumulative impacts of permitted projects on tortoise populations will help expand the geographic scope of monitoring and is key to developing criteria for decisions on potential limits to take for desert tortoise. Sharing this information with other state and federal agencies through the MOG will help bring a broader and more comprehensive understanding of the state of tortoise populations in California. In addition, the Department should continue to engage with the USFWS and other partners to address high priority monitoring needs through the Cooperative Endangered Species Conservation Fund (Traditional Section 6) Grant Program See sections 9.2 and 9.3 for more detail.

5. Conduct applied research and modeling in support of recovery efforts within a strategic framework.

The 2011 USFWS Revised Recovery Plan includes many specific research and modeling actions that are needed to address recovery of desert tortoise. Funding for continued long term monitoring at sites outside of TCAs such as the Desert Tortoise Natural Area would expand our understanding long term trends in areas with different types of management. The Department should continue to engage with the USFWS and other partners to address high priority research needs through the Cooperative Endangered Species Conservation Fund (Traditional Section 6) Grant Program and other funding opportunities.

6. Implement a formal adaptive management program.

The USFWS Recovery Plan includes steps to

1. Revise and continue the development of a recovery decision support system.
2. Develop and revise recovery action plans.
3. Amend land use plans, habitat management plans, and other plans as needed to implement recovery actions.
4. Incorporate scientific advice for recovery through the Science Advisory Committee.

The Department has authority to develop and implement non-regulatory Recovery Plans and recovery criteria for CESA-listed species with the goal of improving the status of species and managing threats to the point where CESA listing may no longer be appropriate or necessary. The Department should consider whether adoption of the federal Recovery Plan, potentially with amendments, is warranted.

9.2 Regulations and Policy

Due to the number of interacting threats facing the desert tortoise, there is an opportunity to be more flexible with what is considered appropriate mitigation for ITPs. Acquiring land is an important measure, but it only addresses a few of the recovery actions for the desert tortoise. The Department should consider all available actions that meet the “fully mitigated” standard for offsetting project impacts. All measures that support and improve populations should be considered as mitigation, including installing tortoise fencing along highways, habitat enhancement, management and control of raven populations, and measures that improve connectivity. Focusing on land acquisition at the expense of other measures could result the protection of high-quality habitat but limited reductions in broader factors causing direct mortality or restricting movement between protected areas.

Another useful step would be to review the ITPs issued and the implementation of mitigation measures since CESA listing and assess their impact on tortoise populations in general. Section 2081 c) states “No permit shall be issued …if issuance of the permit would jeopardize the continued existence of the species.” Given the long-term decline of desert tortoise populations, the Department should include evaluations of the success of mitigation measures as a part of assessments of the cumulative impacts that inform the Department’s decisions about issuing permits. See section on Capacity Building below.

9.3 Capacity Building CDFW

a) Personnel

For these Management Recommendations to be most consistently implemented and successful, staffing and/or funding capacity that can be devoted to developing, supporting, and building partnerships to facilitate recovery of the Mojave Desert Tortoise is needed. Adequate staffing facilitates internal coordination, continuity of institutional knowledge, and coordination with other agencies and organizations to address the most important issues. If CDFW had staffing dedicated to tortoise recovery, there could be a primary point of contact for desert tortoise permitting and better coordinate collaborate internally and externally with those working on tortoise conservation and management.

b) Upgrading Systems

Currently, much of the CDFW review and issuing of ITPs for Mojave Desert Tortoise is done on a project-by-project basis, with some take permitted through Natural Community Conservation Plans and Habitat Conservation Plans like the Coachella Valley Multi Species Habitat Conservation Plan. Projects that apply for ITPs are required to collect data and submit compliance reports to the Department. If a project is required to translocate tortoises, they need to be monitored for five years and data reported to the Department. There is currently no central location for those types of data and reports at the Department. Much of the old data, reports, and information is in paper form and is stored in various Department offices and is functionally inaccessible. Data on project locations, recipient sites, release points, disease testing locations with test results, and mitigation lands need to be stored digitally and made available in compliance with relevant CDFW scientific data policies. Without a central repository for data and platforms where it can be accessed and used by staff it is difficult to understand the scope and extent of impacts of development on tortoises. Consequently, the Department does not have a complete view of how many acres have been impacted, or the amount and location of habitat that has been conserved as mitigation and the success of that mitigation. However, a permitting system is currently in development that is intended to centralize and streamline the issuing of ITPs and other permits that will make it easier for the Department to make informed decisions on future incidental take permits and jeopardy determinations.

STATUS REVIEW

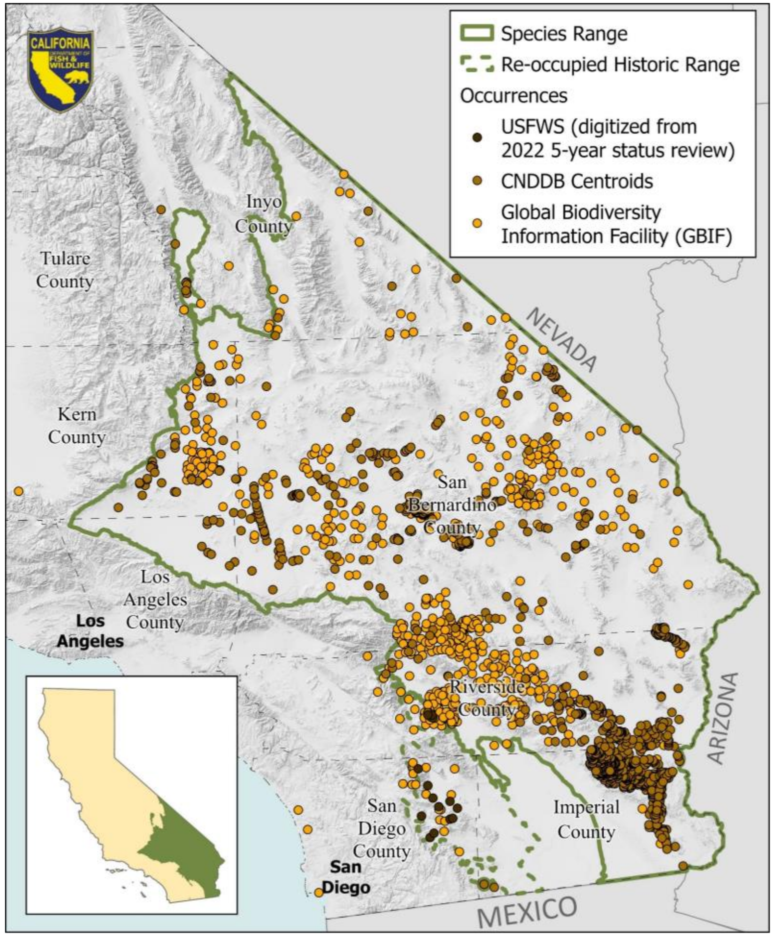
PRESENTATION TO THE CALIFORNIA FISH AND GAME COMMISSION

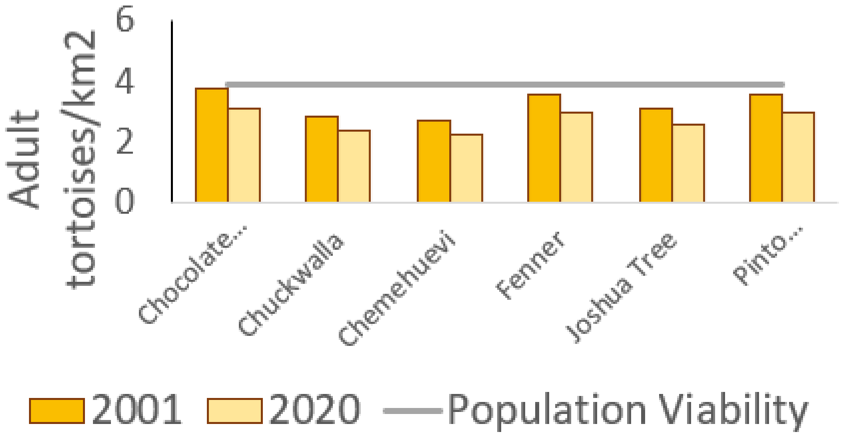
April 18, 2024 | Anne Hilborn, PhD

Wildlife Branch

Presentation Overview

- Life History/Range
- Population trends
- Threats
- Department's Recommendation





Listing History Mojave Desert Tortoise

Listed as Threatened under CESA in 1989

Listed as Threatened under the ESA in 1990

Petition sent to Commission March 2020

Designated as a candidate species October 2020

Life History

Species Biology

Long-lived desert reptile

Slow Reproduction: Sexual maturity at 12-20 years, 6-12 eggs/year

Diet: Wildflowers and herbaceous perennials

Adaptations to desert:

Use burrows to avoid desert heat and winter cold

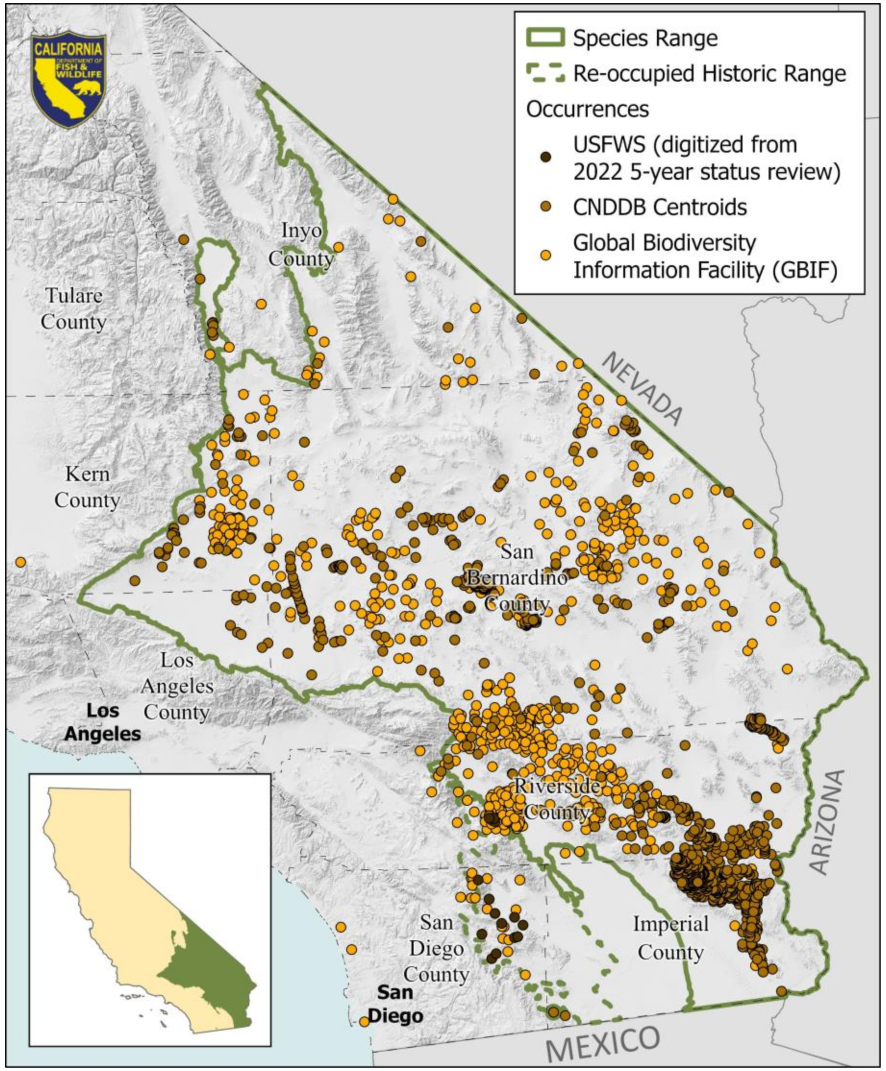
Up to 90% of the time underground

Other physiological adaptations to extreme desert conditions

Range and Distribution

- Mojave Desert
- Colorado Desert

- Distribution is uneven



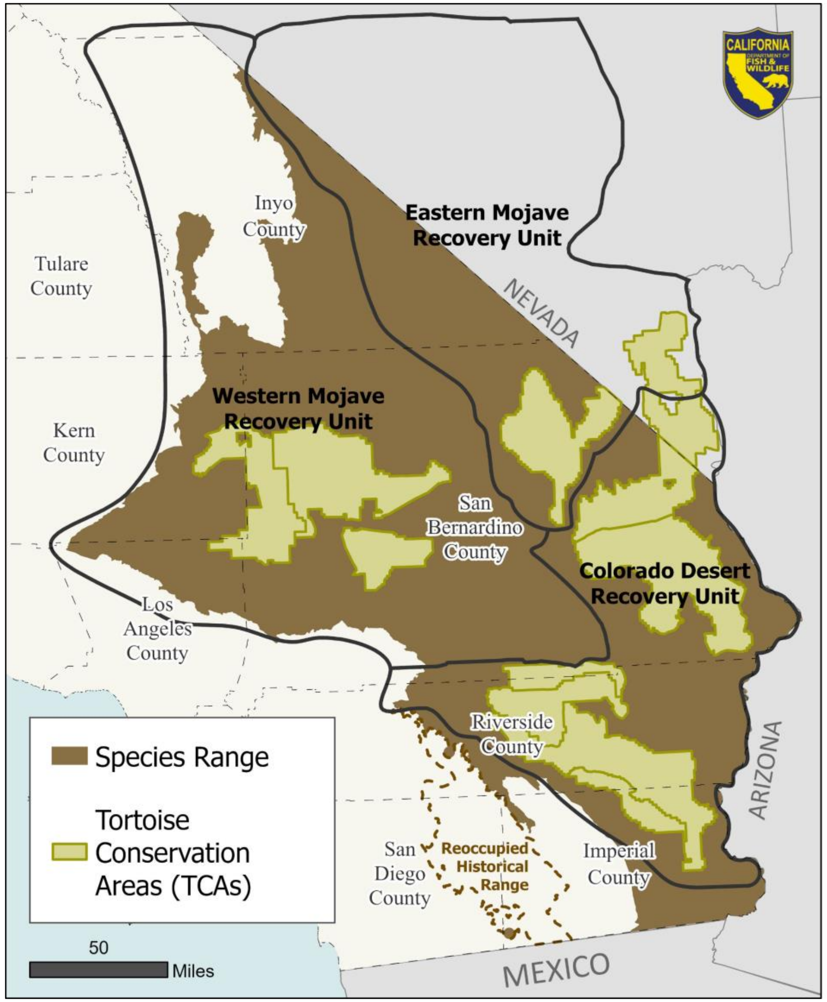
Recovery Units and Tortoise Conservation Areas

3 Recovery Units

- Western Mojave
- Eastern Mojave
- Colorado Desert

Tortoise Conservation Areas (TCAs)

- Best habitat in range
- Yearly surveys since 2001



Population Trends: Density

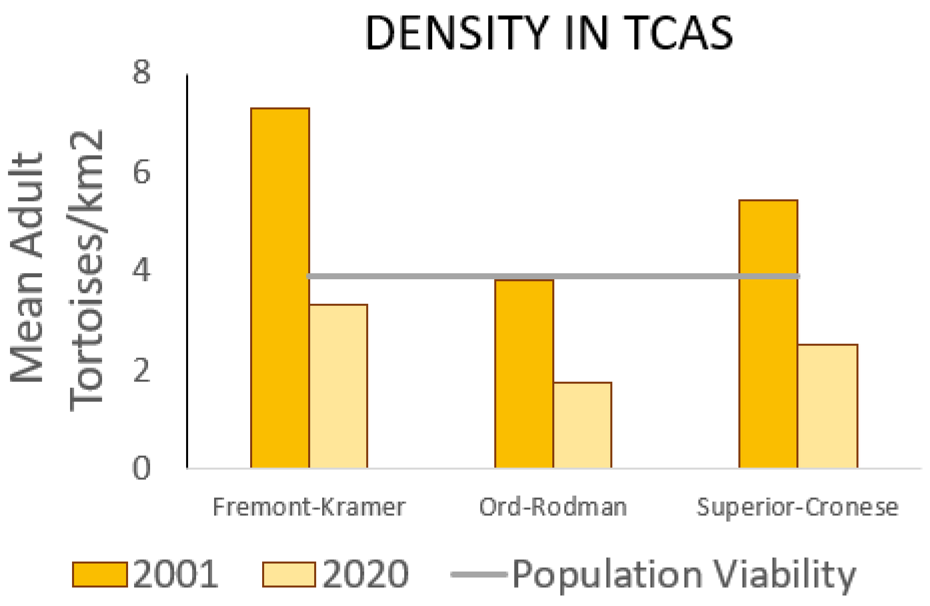
Robust estimates of density in the TCAs 2001and 2020 *

Important Benchmark:

3.9 adult tortoises/km^2 needed for population viability

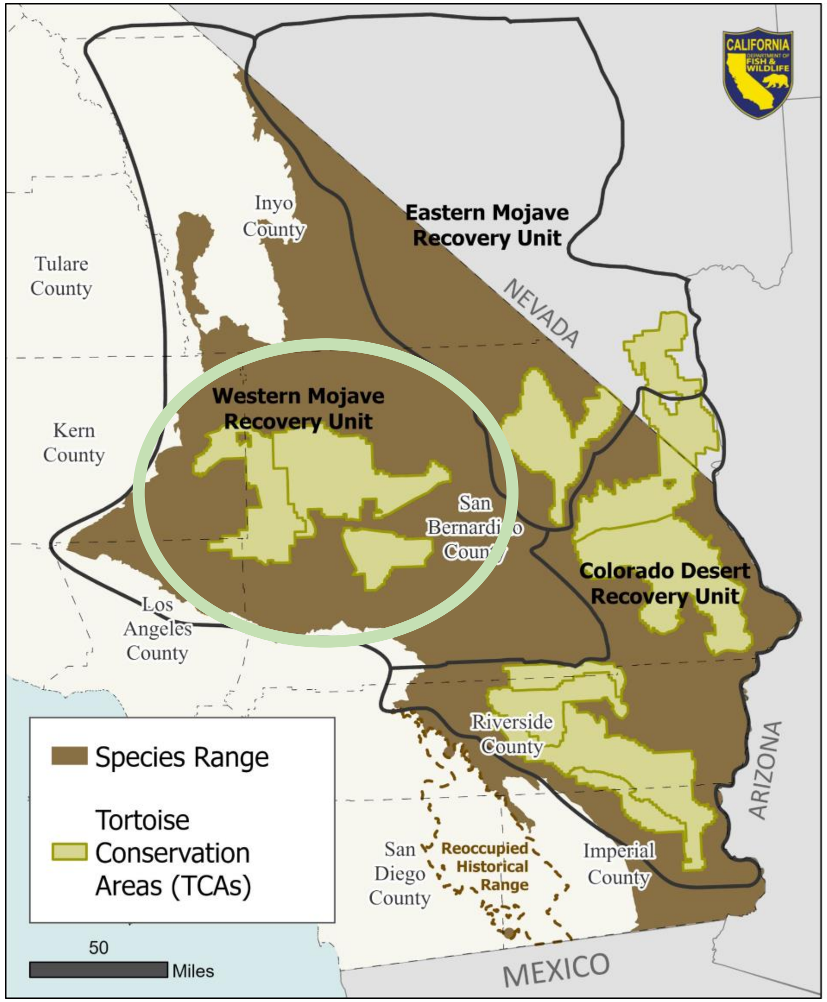
*Zylstra et al. 2023

Population Trends: Western Mojave RU

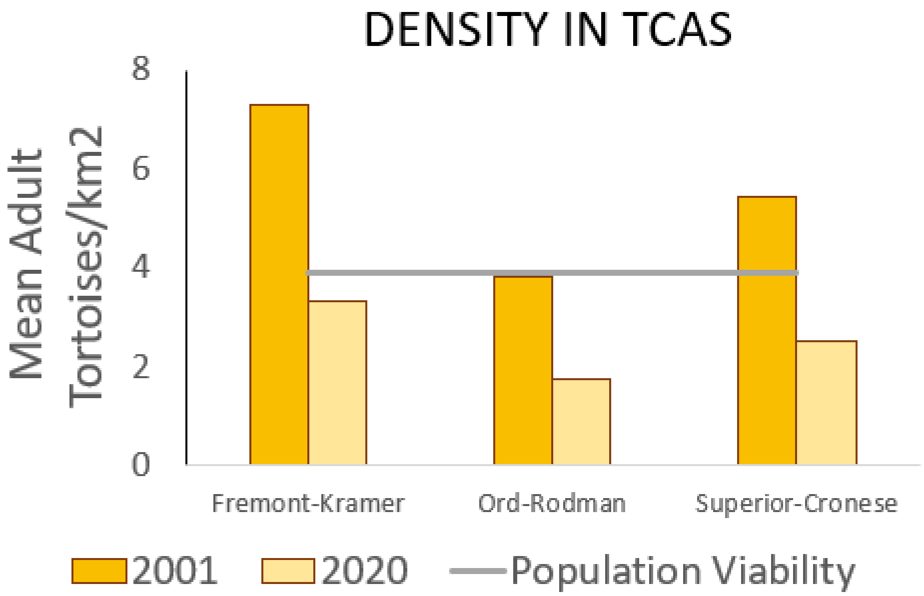


Two TCAs above population viability in 2001

All TCAs below population viability in 2020

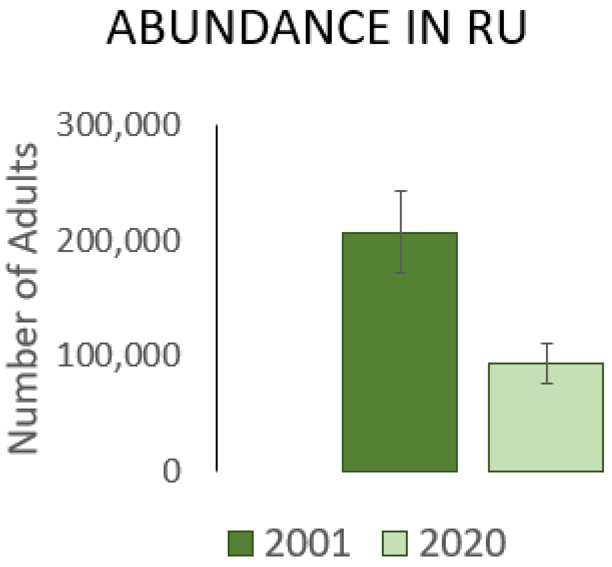


Population Trends: Western Mojave RU

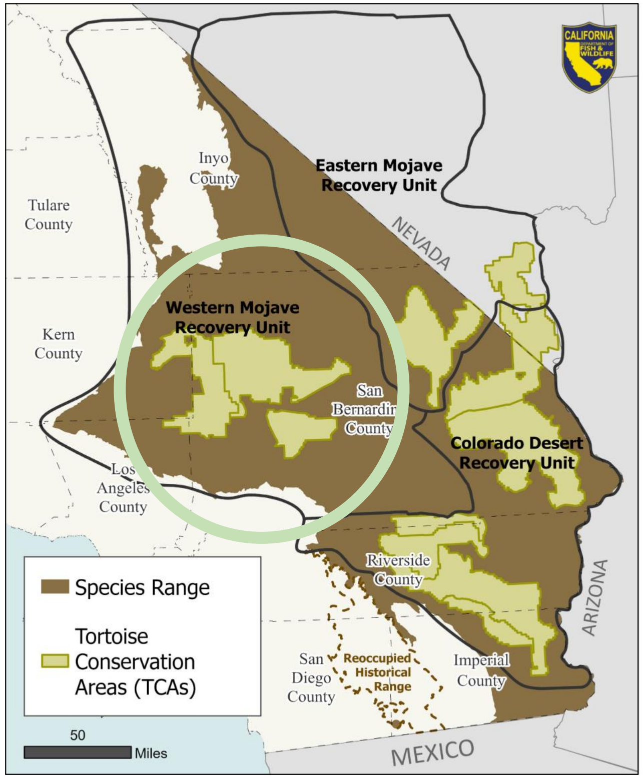


Two TCAs above population viability in 2001

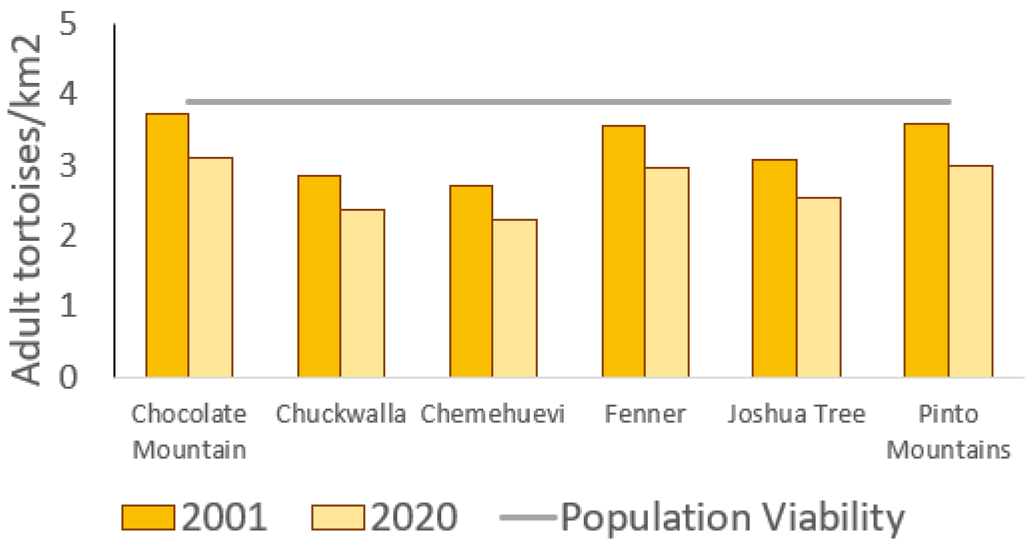
All TCAs below population viability in 2020



Loss of ~112,000 adults (54% decline)

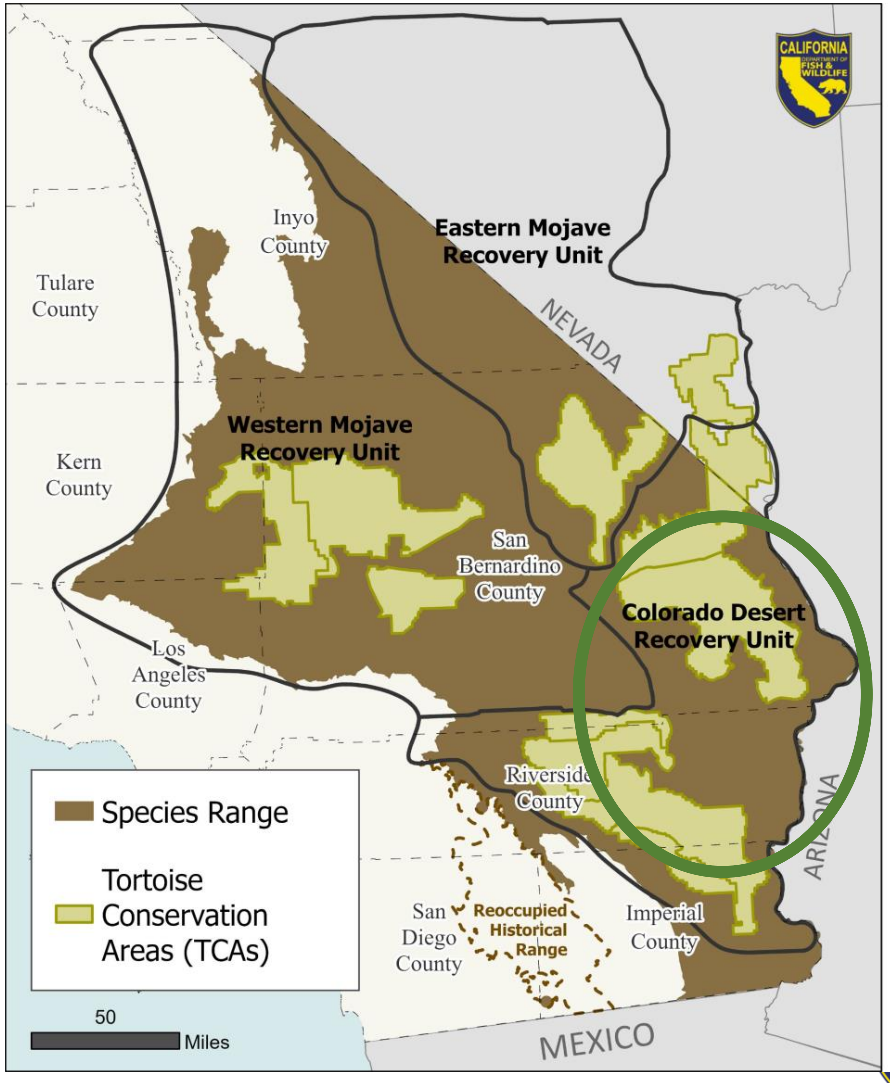


Population Trends: Colorado Desert RU

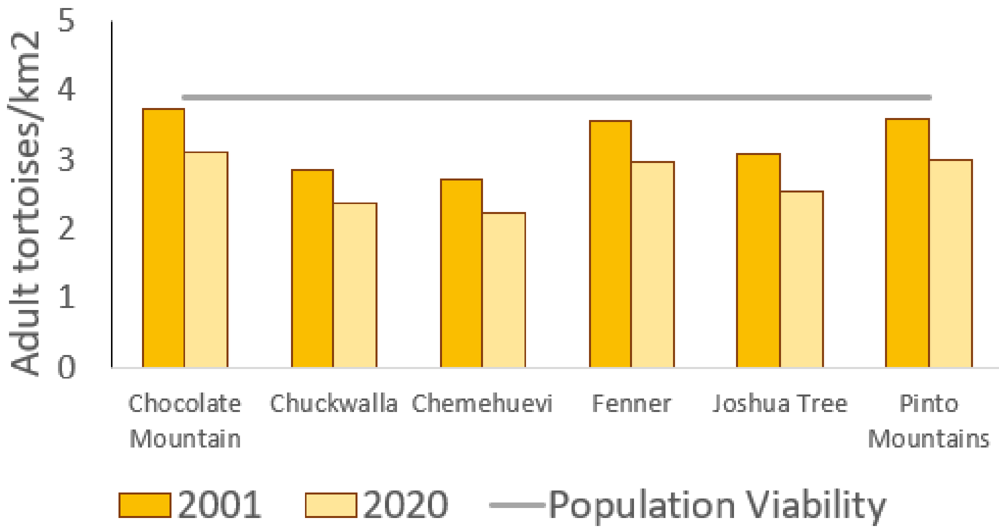


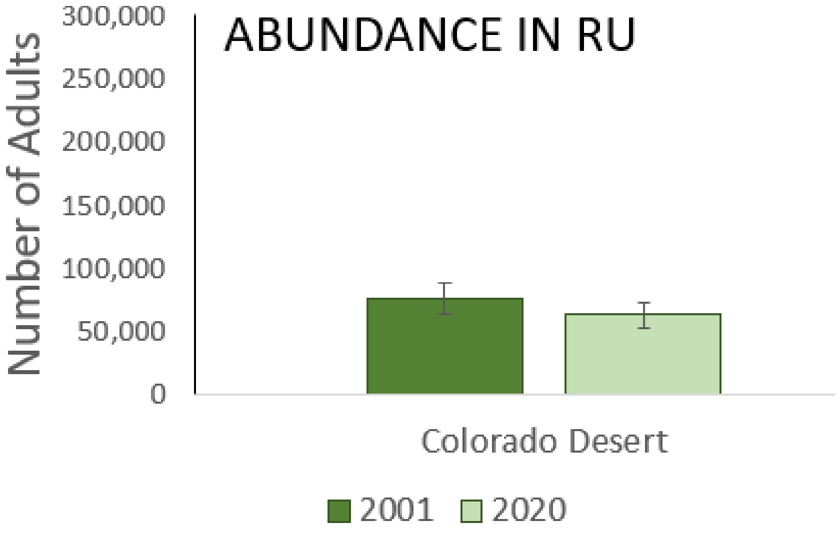
All TCAs in the Colorado Desert were below population viability in 2020

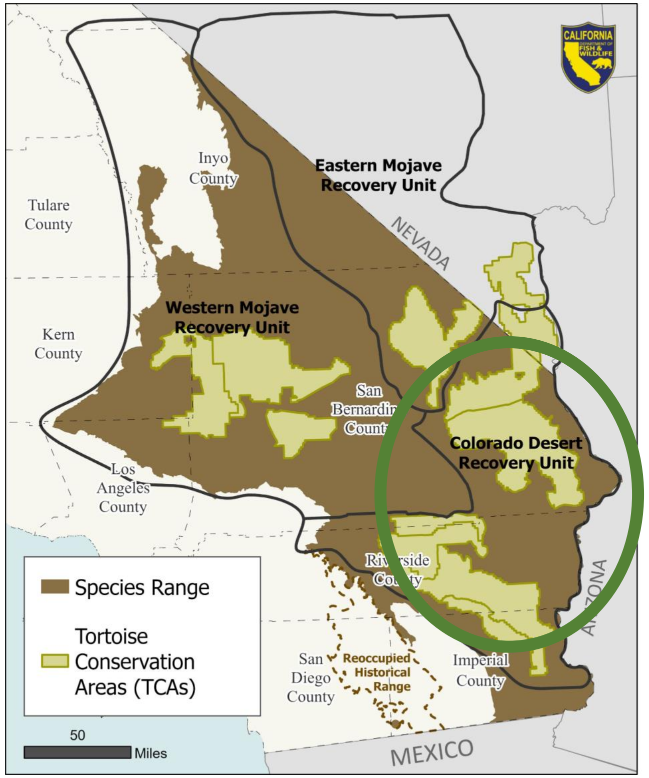
All TCAs declined between 2001 and 2020



Population Trends: Colorado Desert RU





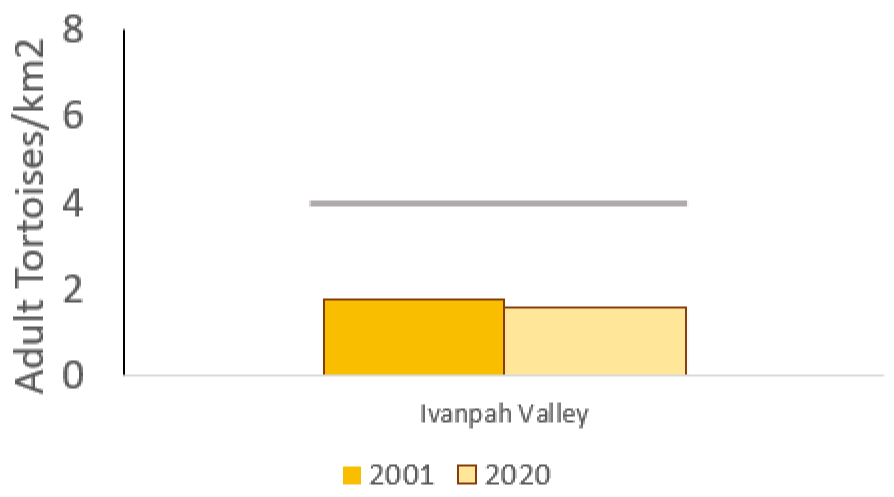


All TCAs in the Colorado Desert were below population viability in 2020

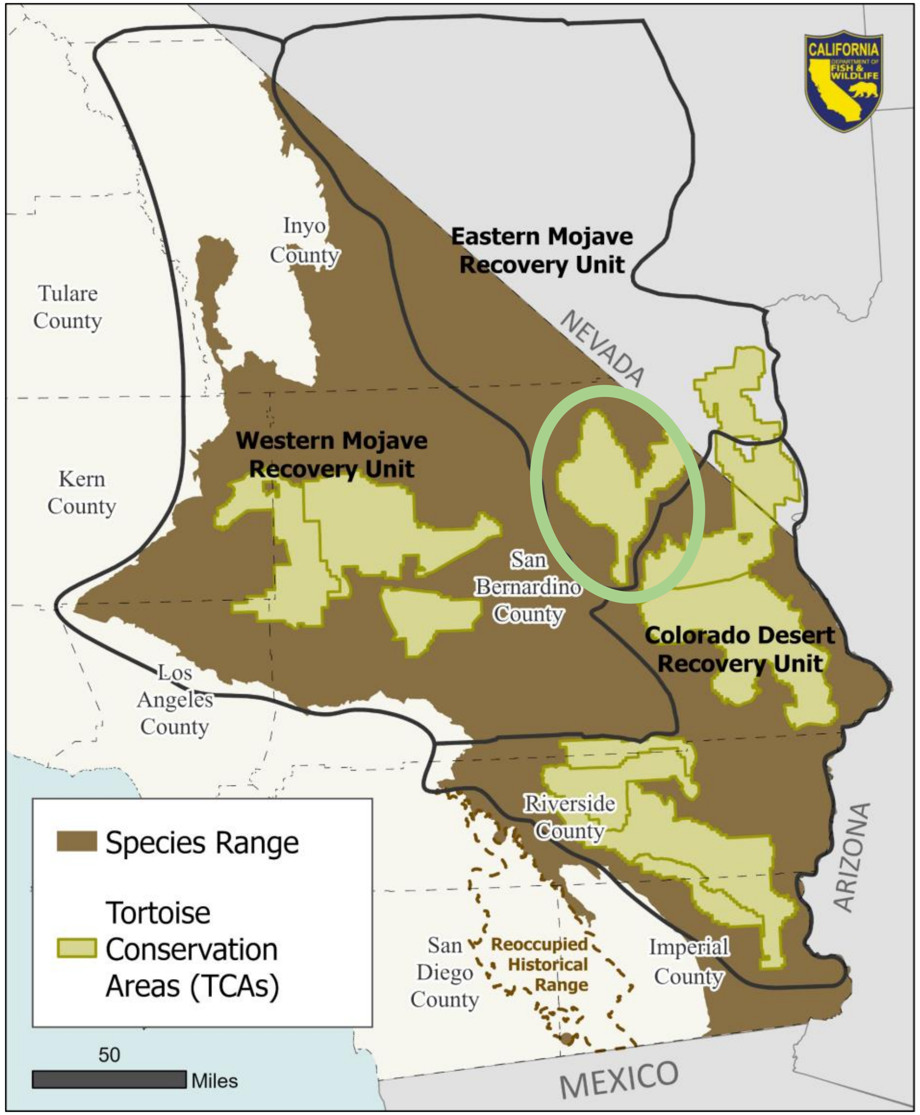
All TCAs declined between 2001 and 2020

Loss of~13,000 adults (~17% decline)

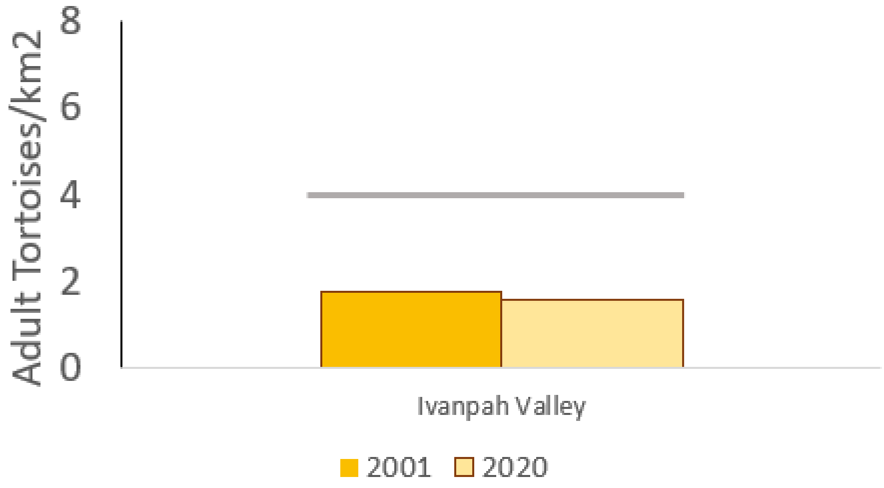
Population Trends: Eastern Mojave RU

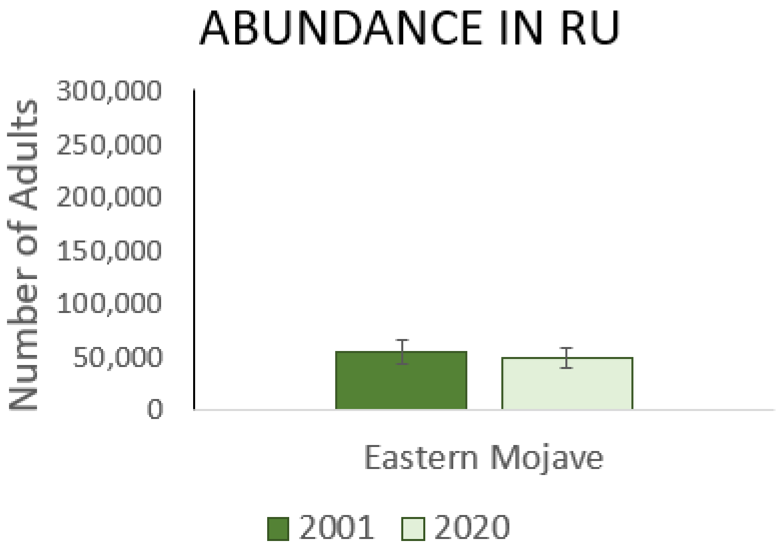


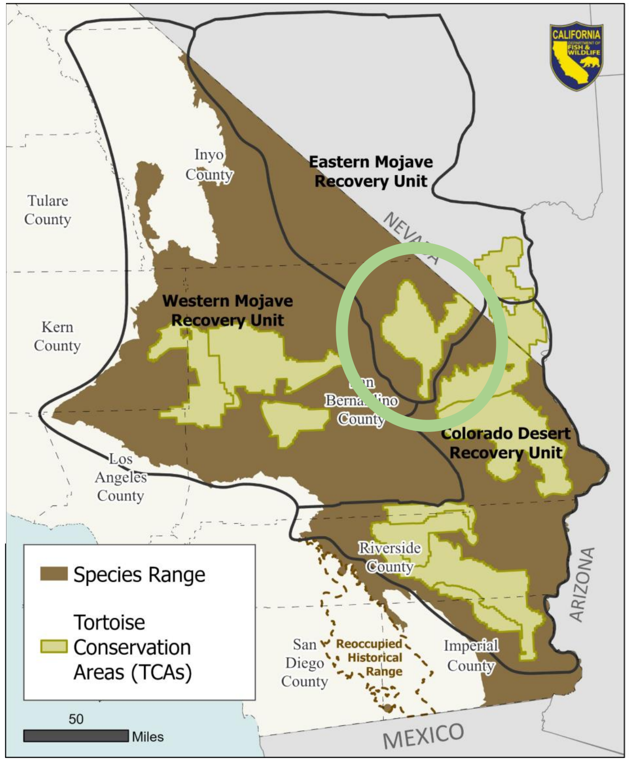
The TCA in the Eastern Mojave was below population viability in 2001 and 2020



Population Trends: Eastern Mojave RU







The TCA in the Eastern Mojave was below population viability in 2001 and 2020

Loss of ~5,000 adults (~10%)

Threats

Direct Mortality

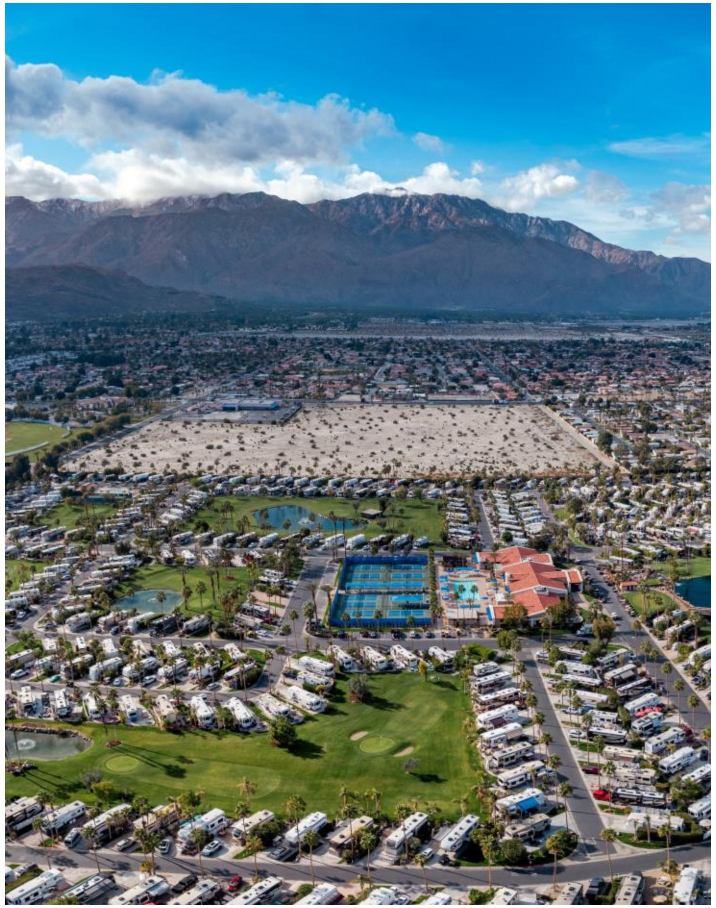
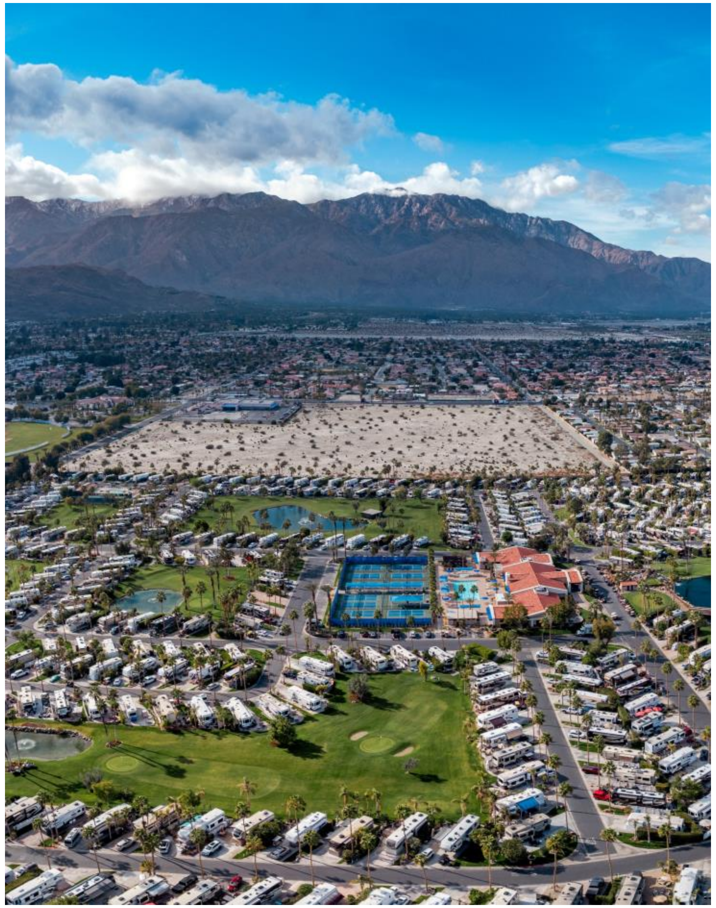
Threats: Habitat Loss and Degradation

Urban Development



Threats: Habitat Loss and Degradation

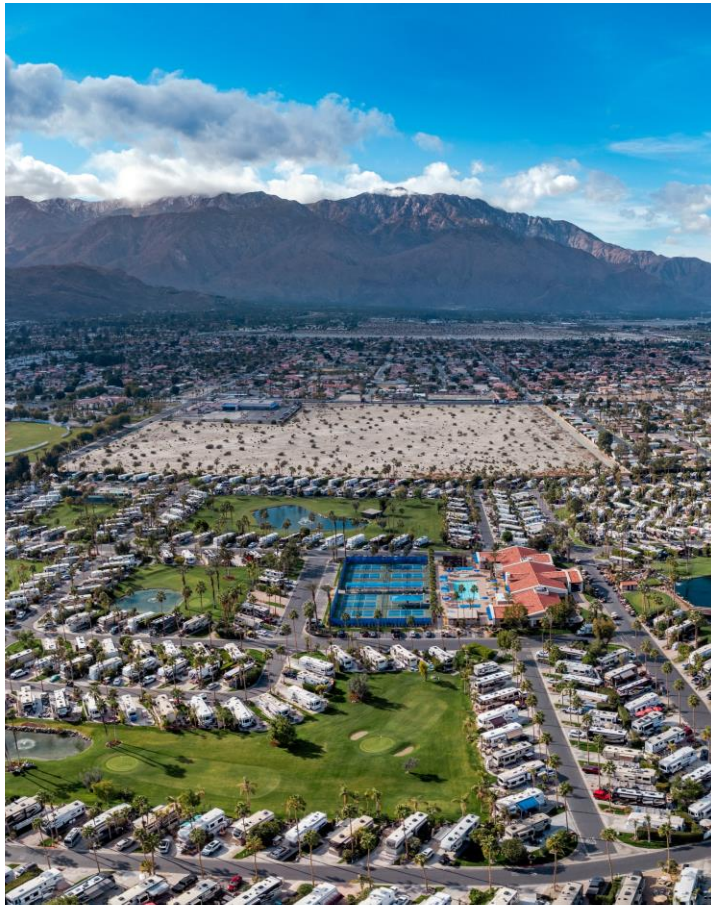
Urban Development



Renewable Energy

Threats: Habitat Loss and Degradation

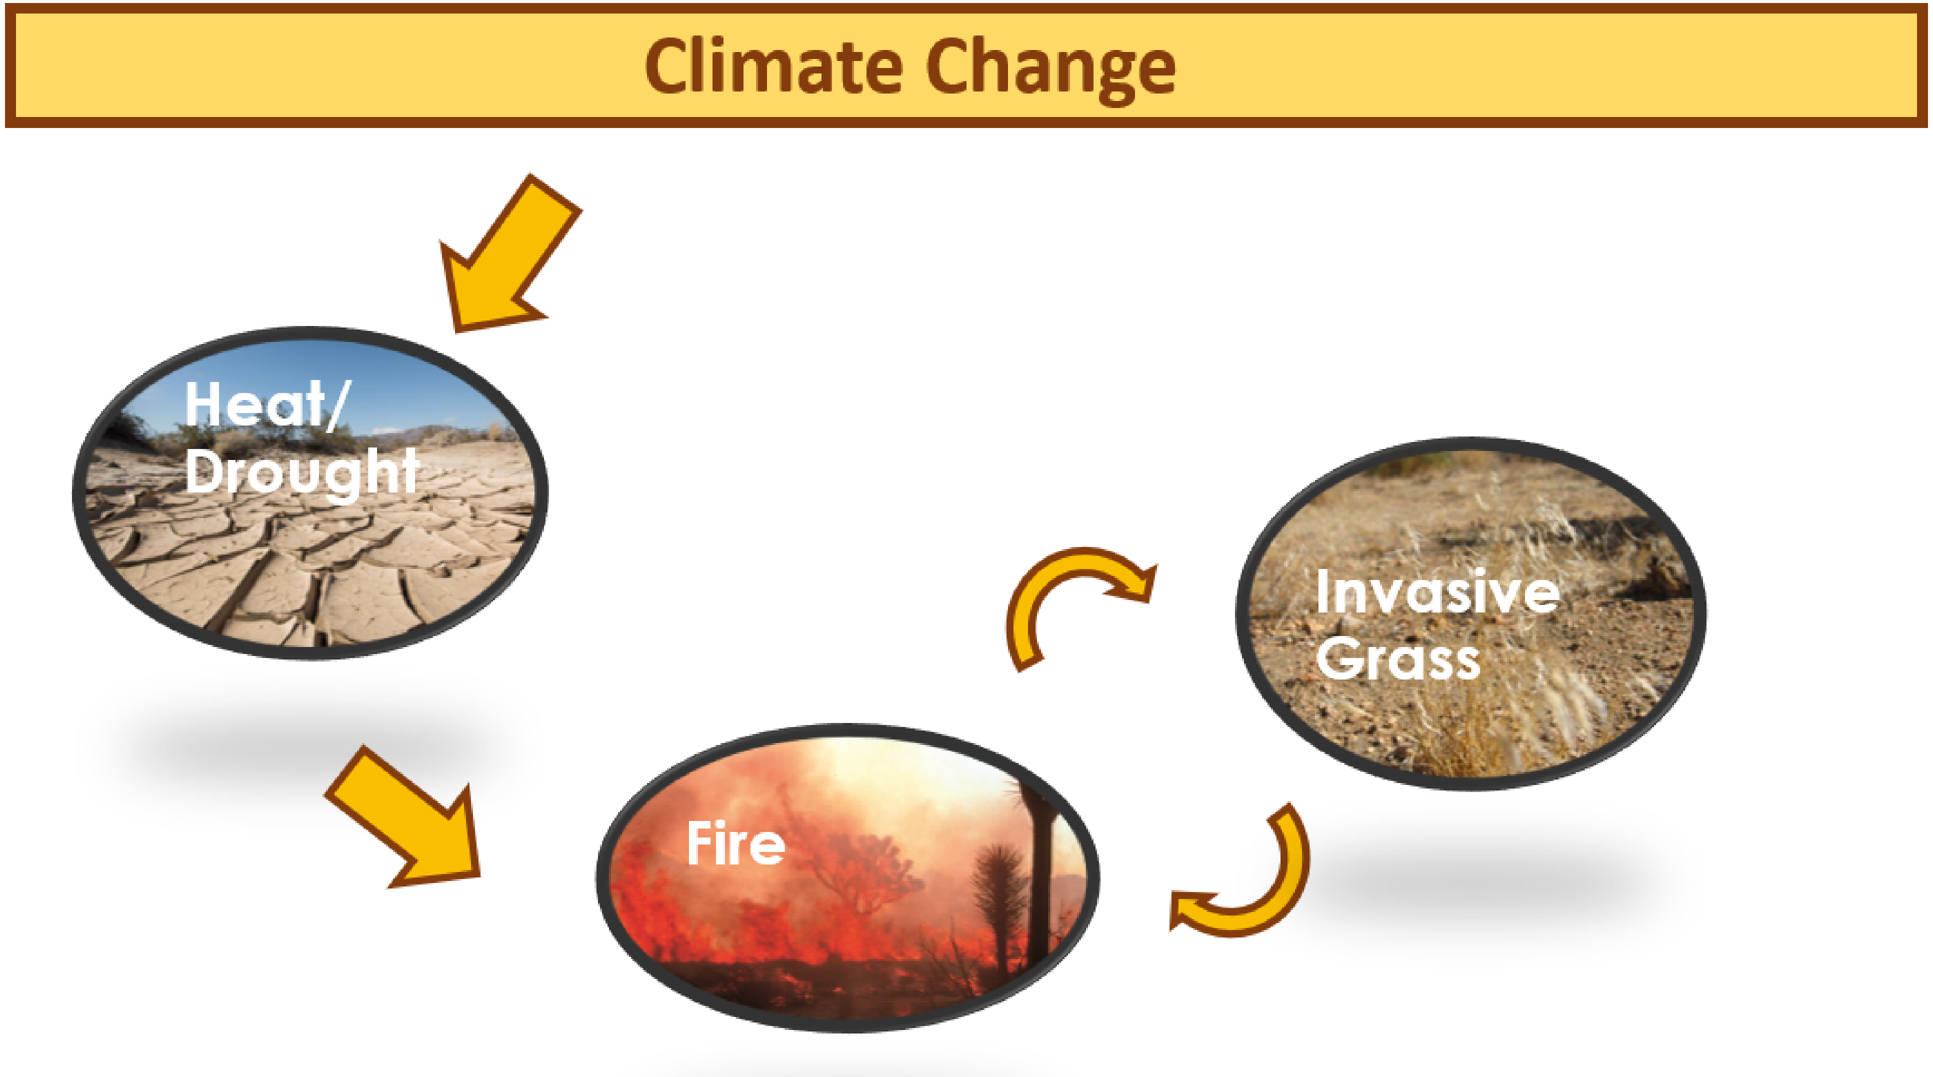
Urban Development



Renewable Energy

Department of Defense

Threats: Climate Change, Fire, Invasive Species



Threats: Climate Change

Deserts are hotter and drier

Decreases area tortoises can thrive and reproduce

Climate change has led to more severe drought

Threats: Fire

Increasing fire in the desert

Native vegetation does not recover easily

Harder to find food post fire

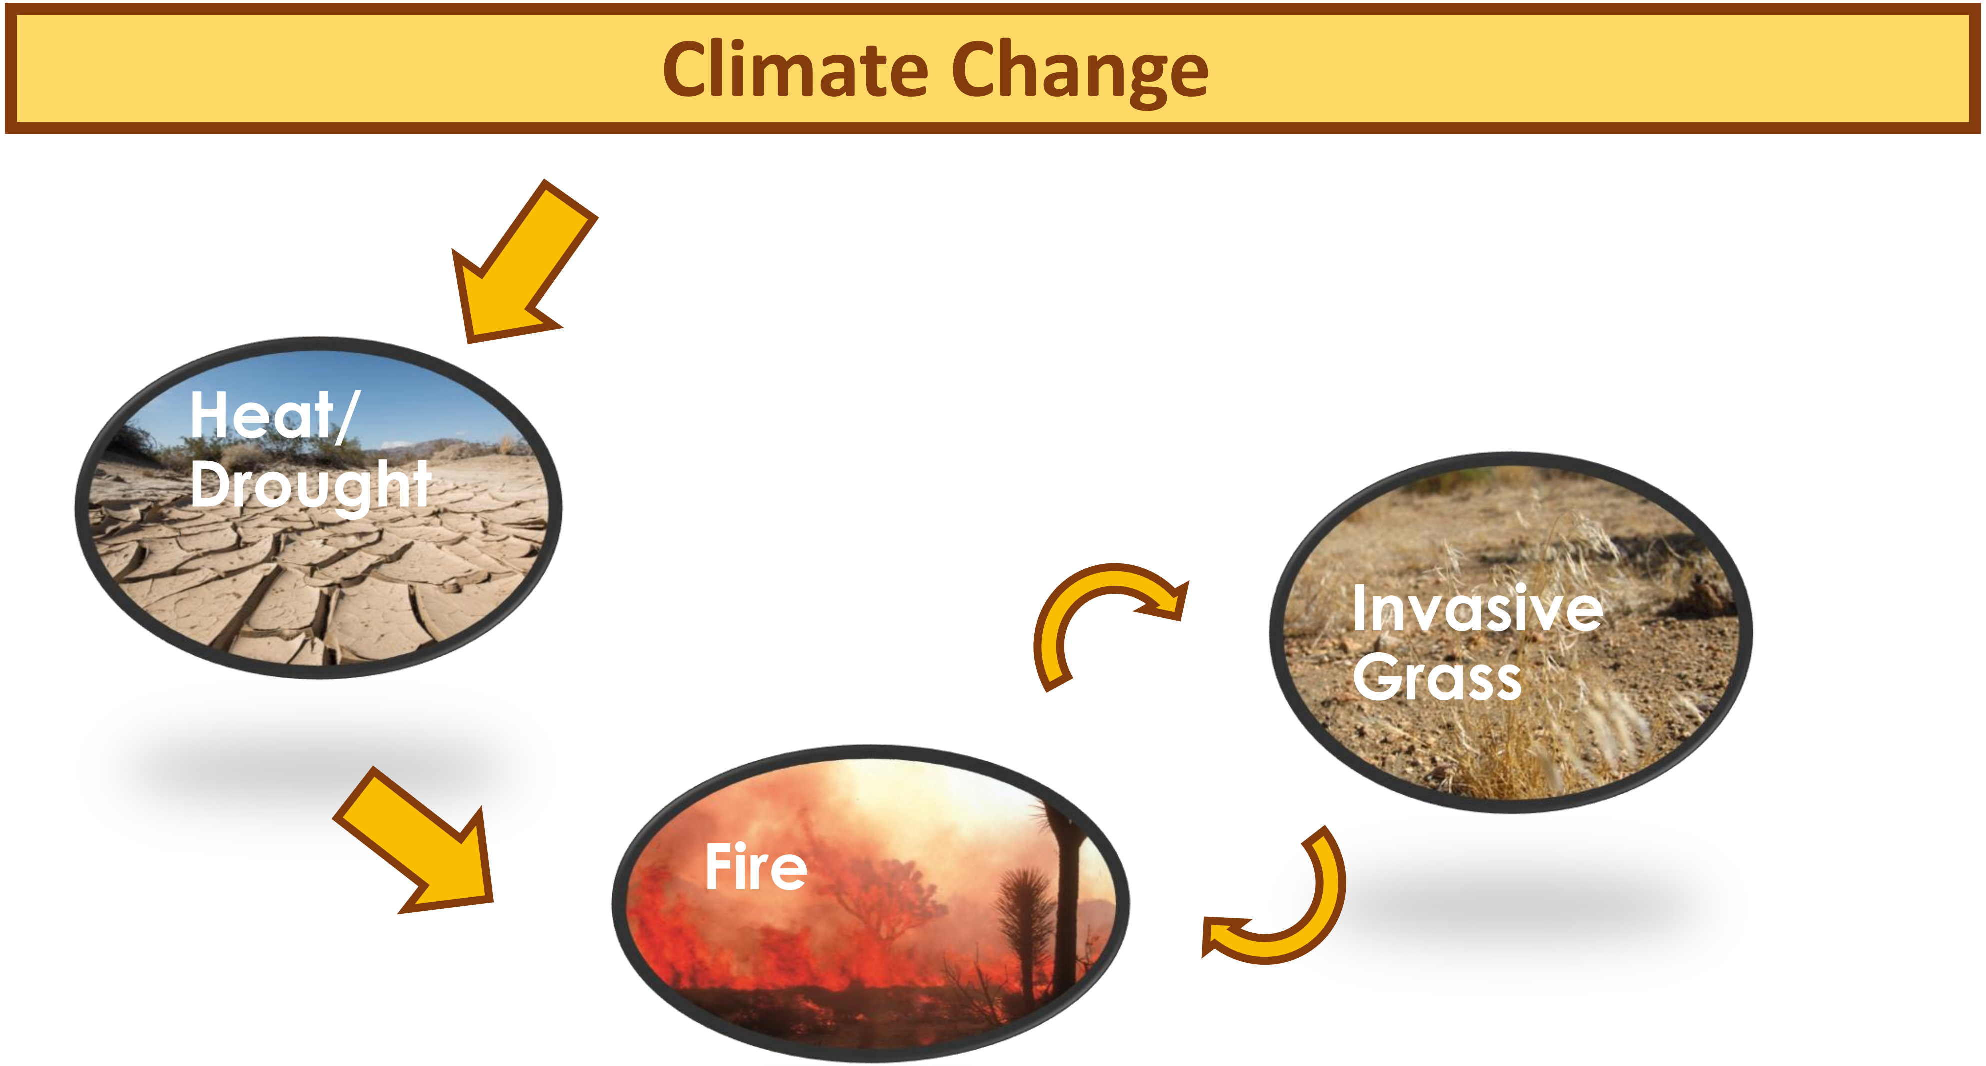
Threats: Invasive Species

Increasing invasive grasses

Create fuel for fires

Poor nutrition

Threats: Climate Change, Fire, Invasive Species



Summary

- Long term declines across the range
- Most TCAs below viability for 20 years, and continued decline
- Low recruitment of juveniles
- Continued, intersecting threats

Recommendation: Uplist to Endangered

- The Department has determined that listing the Mojave Desert Tortoise as endangered under CESA is warranted at this time

Re: Status Review for Mojave Desert Tortoise

Dear President Sklar and Executive Director Miller-Henson:

Defenders of Wildlife (Defenders), the Desert Tortoise Council (Council) and Desert Tortoise Preserve Committee (Committee) have reviewed the *Status Review for Mojave Desert Tortoise* prepared by the California Department of Fish and Wildlife (CDFW). We appreciate CDFW's approach in preparing the status review, including peer review by prominent desert tortoise research biologists.

First, and foremost, CDFW concluded that the *Mojave Desert Tortoise is in serious danger of becoming extinct in California due to one or more causes including present or threatened degradation and loss of habitat, predation, and other natural occurrences and human-related activities*, and that *The Department recommends that the Commission find the petitioned action to change the status of Mojave Desert Tortoise from threatened to endangered to be warranted*. Under the California Endangered Species Act (CESA), an endangered species is one "which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease" (Fish and Game Code Section 2062).

CDFW's conclusion confirms that the petition submitted by Defenders, the Council and Committee on March 23, 2020 was based on relevant scientific information and accurately described the threats the species continues to face, including climate change and a host of human activities.

The minimum viable density for a desert tortoise population is 3.9 adults/km^2 according to the 1994 Desert Tortoise Recovery Plan (USFWS 1994). According to the most recent (2019-2021) density estimates within Critical Habitat Units (CHUs) in California reported by the U.S. Fish and Wildlife Service (USFWS 2020, 2022a, 2022b), densities were below the minimum in six CHUs, at the minimum in two and above the minimum in three. The six CHUs with densities below the minimum threshold are proof that those populations are not viable, putting the species on a path toward extinction. After 35 years of being listed as a threatened species by the Fish and Game Commission and 34 years by the USFWS, desert tortoise populations show no sign of recovery. Furthermore, past and current regulatory actions such as the prohibition on take, development of land use plans, impact mitigation and translocation have been ineffective in halting population declines.

Severe decline of adults in CHUs is not the only indication the species is headed toward extinction. Since 2007, the number of juveniles has also declined, with the probability of encountering a juvenile lowest in the Western Mojave Recovery Unit (Allison and McLuckie 2018). Berry et al. (2014) confirmed this in a demographic study of desert tortoises in the Western Mojave, where juveniles were observed only within the 40 mi^2 Desert Tortoise Research Natural Area, which has been closed to off-highway vehicle use and domestic sheep grazing since 1976.

The Desert Tortoise Research Natural Area is also the only area in the Western Mojave where the desert tortoise population shows sign of recovery. Berry et al. (2014) reported that the number of adult desert tortoises within the Natural Area was seven times greater than those found within the adjacent Fremont-Kramer CHU in Fremont Valley.

In response to the federal listing of the desert tortoise as threatened in 1990, the BLM eliminated domestic sheep grazing throughout most of the CHUs in the Western Mojave Recovery Unit in 1994, so the primary threats to the species remaining in the area are the widespread and intense off-highway vehicle use, and predation by common ravens and coyotes. The recent expansion of the Twentynine Palms Marine Corps Base required the translocation of approximately 1,600 desert tortoises, and the impending use of the Western Training Area in Fort Irwin by the U.S. Army will require translocating an estimated 1,100 desert tortoises from approximately 60,000 acres within the Superior-Cronese CHU.

Although the legal protection of species listed under CESA as threatened or endangered are the same, listing the desert tortoise as endangered will likely increase allocation of funds for actions that are proven to be effective in conserving the species and its habitat. Listing the species as endangered may also provide a regulatory environment where greater scrutiny of the adverse impacts of proposed land uses will occur and impact avoidance and mitigation requirements will be more effective and enforced. We are also optimistic that changing the listing status to endangered may prompt CDFW to prepare a recovery plan for the species and to identify and implement conservation actions in the Western Mojave Recovery Unit where the declines have been most severe and where federal recovery actions are failing.

We fully agree with all of CDFW's recommended actions it can take as presented in Section 9 of the status review report, including preparing and implementing a recovery plan for the desert tortoise.

In conclusion, we urge the Commission to approve listing of the desert tortoise as endangered throughout its range in California. We thank CDFW staff for their thorough review of the status of the desert tortoise.

Received at California Fish and Game Commission
November 8, 2023

Electronically Received 09/28/2023 05:06 PM

SUPERIOR COURT OF THE STATE OF CALIFORNIA

FOR THE COUNTY OF LOS ANGELES

BALLONA WETLANDS LAND TRUST, Plaintiff and Petitioner, vs. CALIFORNIA FISH AND GAME COMMISSION, Defendant and Respondent.	Case No.: 20STCP03035 **[~~PROPOSED~~] WRIT OF MANDATE**

Whereas judgment was entered on 11/03/2023, ordering that a peremptory writ of mandate issue:

To CALIFORNIA FISH AND GAME COMMISSION:

YOU ARE HEREBY COMMANDED TO: make a compatibility determination pursuant to Section 630 of Title 14 of the Cal. Code of Regulations as to whether the parking lots in Area A and baseball fields in Area C of the Ballona Wetlands Ecological Reserve are compatible with the purpose of the Reserve.

YOU ARE FURTHER COMMANDED to file and serve an initial return to the writ no later than 180 days after service of the writ. The return shall specify the actions taken to comply with the terms of the peremptory writ of mandate.

The Court shall retain jurisdiction to enter injunctive relief and compel compliance with the Peremptory Writ of Mandate, including as provided in Cal. Code of Civil Procedure Section 1097.

LET THE WRIT ISSUE.

David W. Slayton, Executive Officer / Clerk of Court

DATED: 11/07/2023 K. Encinas

Clerk of the Superior Court

State of California
Department of Fish and Wildlife

Memorandum

Date: April 2, 2024

To: File

From: Region 5

Subject: Ballona Wetlands Ecological Reserve – Parking Lots and Baseball Fields

This memorandum documents the California Department of Fish and Wildlife's ("Department") determination under Title 14, California Code of Regulations, § 630(h)(3) related to parking lots in Area A of the Ballona Wetlands Ecological Reserve ("Reserve") and little league baseball fields in Area C of the Reserve. Specifically, the Department determined that restoration or other uses of the little league baseball fields or parking lots is not more appropriate at this time.

The presence of a parking lot within an ecological reserve is typical, and sharing use of the lot with another public agency is common and often benefits the Department. For example, the Los Angeles County Sheriff's Department uses one of the Area A parking lots and helps supplement the Department's law enforcement division when its resources are unavailable. However, the Department notes that little league baseball, or similar active recreational uses, are typically not allowed within an ecological reserve. In light of the nature of little league baseball occurring at the Reserve, CDFW is documenting its determination to provide context for this unique situation. Importantly, CDFW emphasizes that the circumstances and context in which these uses are allowed to continue is specific to the Reserve and in no way should be considered applicable to any other Department land or ecological reserve.

The Reserve encompasses approximately 577-acres along coastal Los Angeles County approximately five miles north of the Los Angeles International Airport, and is bordered by the communities of Westchester, Marina del Rey, and Playa Vista. The historic wetlands ecosystem in the vicinity of the Reserve once spanned more than 4,000 acres, but today the Reserve has approximately 152 acres of degraded wetlands. The Reserve is divided into three areas: A, B, and C, with areas B and C further subdivided. (See attachment 1). The little league baseball fields are in south Area C adjacent to Culver Boulevard and have operated there since 1956. The two parking lots are located at the west end of Area A adjacent to Fiji Way and were constructed between 1984 and 1985.

In 2003, the Wildlife Conservation Board ("WCB") approved the Department's acquisition of the Reserve. Then in 2005, the California Fish and Game Commission adopted regulations designating the Reserve as an ecological reserve. (Attachment 2 Final Statement of Reasons) Minutes to WCB's 2003 meeting indicate that the Reserve was acquired with the intent to restore it. (Attachment 3 WCB Meeting Minutes) A summary of the long-term restoration planning states that, "the natural resource goals for the long-term restoration planning for the Ballona Wetlands are: restore tidal circulation to the extent feasible; provide the range of freshwater, brackish and saltwater wetland habitat that is typically associated with a coastal estuary; and provide significant new habitat area for a variety of native species of plants and animals, including migratory birds. Additional long-term restoration planning goals include: providing for cost-effective flood management; protecting cultural resources; and providing appropriate public access, public recreation, educational and interpretive opportunities."

Following acquisition of the Reserve, the Department and its project partners, which included the California State Coastal Conservancy and the Bay Foundation, commenced a very deliberate restoration planning process that was informed by scientific analysis from experts in the fields of wetland and estuarine ecology and copious amount of public input. The planning process included:

- Preparing a feasibility assessment, baseline data collection, and creating and refining restoration options
- Convening a Science Advisory Committee ("SAC") composed of experts in the fields of wetland and estuarine ecology that analyzed the science being used during the planning process, assessed the appropriateness of factors being considered, and provided overall technical guidance. The SAC met seven times with all meetings open to the public. The SAC created a 2008 recommendation report for the project team in response to a feasibility study that identified potential restoration options and the rationale for their inclusion in the study. (The feasibility study is Attachment 4 and the SAC recommendation is Attachment 5) As the project team refined the proposed project, the SAC provided input and made additional recommendations.
- Twenty public stakeholder meetings held by the restoration project team
- Four public on-site open house meetings
- More than 60 presentations to groups and the public by the Bay Foundation

The Department, as lead agency under the California Environmental Quality Act ("CEQA"), built upon the prior planning and public input and prepared a draft environmental impact report ("EIR") that analyzed the environmental effects associated with implementing different alternatives for restoring the Reserve. (State Clearinghouse Number: 2012071090) The EIR's restoration alternatives were refinements of two restoration options that the project team developed during the initial planning process and were supported by the SAC for additional analysis. Likewise, the EIR's CEQA project objectives presented similar goals to those that justified the acquisition of the Reserve and included: restore, create, and enhance estuarine environments; establish natural processes and functions; strategically preserve, restore, enhance, and develop multiple habitats (including a variety of wetland habitats and upland habitats); and improve tidal circulation.

The Department released its draft EIR for public comment in 2017 and received over 7,500 pieces of correspondence consisting of nearly 3,000 discrete comments. The Department revised the draft EIR in response to comments, provided responses to the public comments, and released a final EIR in December 2019. The following year, the Department certified the EIR and approved moving forward with restoring the Reserve as analyzed in the EIR.

Four lawsuits were filed against the Department challenging the EIR and the Los Angeles County Superior Court ruled in favor of the four petitioner groups. The Court determined that CDFW is required to disclose and analyze new flood control design parameters and commit to additional environmental review if performance criteria changes, which the court believed could be easily rectified. (Attachment 6 Court Decision) In all other respects CDFW prevailed and other arguments of the lawsuits were denied. CDFW decertified the EIR on September 28, 2023, and as of the date of this document is in process of revising the EIR per the court's order.

Having acquired the property with specific goals, spent approximately two decades developing restoration plans, received scientific input from wetlands scientists, and considered significant public input on the plans, CDFW is not inclined to ignore those efforts and input to now abandon its restoration plan or goals. The current restoration plan that was developed through the above-mentioned restoration planning process continues to be the restoration project in the revised EIR. Importantly, the current plan for restoration is not affected nor in any way hindered by the presence of the baseball fields or Area A parking lots. Nor do the baseball fields or Area A parking lots negatively affect the Department's day-to-day management of the Reserve. Therefore, to ignore or modify the current plans in order to address the baseball fields or Area A parking lots would require the Department to unnecessarily shift its focus and priorities away from the purposes for which it originally acquired the Reserve, specifically a tidal restoration project that benefits native species.

Individuals of the public may prefer the baseball fields and parking lots be removed immediately and the underlying land restored with native habitat. Increasing habitat for native species at the Reserve, and anywhere else in California, is important to the Department. However, as the State's trustee for fish and wildlife resources, the Department focuses its restoration efforts on areas that result in the most benefit relative to those efforts. It will direct its efforts to what the Department determines to be the most effective for species and their habitats.

In contrast to the current restoration plans, restoring the former baseball fields or the Area A parking lots will not result in enhanced estuarine environments, improved tidal circulation, or benefit to multiple habitats including a variety of wetland habitats and upland habitats. The Area A parking lots and baseball fields are on upland areas adjacent to roads. To achieve the restoration goals one must excavate and remove some of the deepest fill material on the Reserve while at the same time avoid impacts to existing infrastructure and maintaining flood protection. As a result, improving tidal circulation in these areas is infeasible. Instead, these areas should be restored with upland vegetation, and the current restoration plans already include restoration of upland habitat in these areas.

It is important to keep in mind that the Reserve is not located in a rural area where the edge of an ecological reserve may be just as undisturbed as the interior of the land. Here, the Reserve is located within one of the most populous communities in the United States. Not only are the Area A parking lots adjacent to a street, but across the street is Fisherman's Village; a harbor front development with restaurants, shopping, and other commercial uses. Similarly, the baseball fields in south Area C are bordered and adjacent to Culver Boulevard to the north, Lincoln Boulevard to the west, State Route 90 a bit further to the east, and the Ballona Creek Bike Path to the south. Human disturbance is high for the west portion of Area A and Area C south compared to other areas of the Reserve. Additionally, Area C south is cut off from the rest of the Reserve by the aforementioned infrastructure which makes wildlife movement to and from Area C south more challenging.

When deciding if a piece of land should be restored, the ability to restore the habitat is important but not the sole factor the Department considers. The long-term maintenance of the restored habitat and ability to sustain the restored habitat values are also important factors. As a result, the Area A parking lots and baseball fields present a lower value opportunity for restoration as compared to other locations of the Reserve. Perhaps more importantly, the current restoration plan was developed with purpose over several years with extensive analysis, input from experts, and copious amount of public input. As such, the Department believes the current restoration project presents a higher value restoration opportunity as compared to focusing on the Area A parking and baseball fields.

It is worth keeping in mind that this determination does not involve constructing new infrastructure or starting new uses in an otherwise pristine ecological reserve. Rather, the existence of the baseball fields and Area A parking lots predate CDFW's acquisition of the Reserve by decades. With little league baseball ongoing in south

Area C since 1956, and the Area A parking lots in use since at least 1984, coupled with the human interference in those areas as described above, it is unsurprising that those specific areas lack beneficial habitat for native species. In particular, the baseball fields are surrounded by invasive vegetation. Still, with implementation of the restoration project that remains the focus of the EIR currently being revised, habitat around the Area A parking lots and baseball fields would be restored to upland and transitional habitat.

In light of restoration being the purpose for acquisition, and the Department's focus on restoration for the Reserve, the Department is not aware of nor has it allocated resources to identifying or developing non-restoration uses in place of the baseball fields or Area A parking lots. And because the continued presence of the Area A parking lots and baseball fields do not hinder or impede the planned restoration or the Department's day-to-day management of the Reserve, the Department is not, at this time, aware of other uses that would be more appropriate in place of the Area A parking lots or baseball fields. Accordingly, the Department is not inclined to shift its focus and limited resources towards an interim, or different, use of the areas which could be a distraction and impediment to furthering the planned for restoration.

Although the following factor did not inform the Department's determination, the Department believes it is worth mentioning in anticipation of furthering the restoration and implementing its mission within a highly urbanized environment in the 21st century. According to the Little League, it serves low-income residents, including those at the Mar Vista Housing Projects nearby the Reserve. (Attachment 7) Approximately 60%-75% of the participants in this particular little league receive some sort of assistance. Although baseball fields are not normally allowed within an ecological reserve, the little league that has operated here for decades introduces children and their guardians to an ecological reserve and to a lesser extent the Department. The Department recognizes that participants are there for baseball and softball, but once restoration is complete and the Department can expand its focus from restoration, this could be an opportunity for the Department to more actively interact with the little league's participants. It is a Department priority to increase investment in programs and resources to benefit underrepresented communities, especially to improve biodiversity and access to the outdoors. The Department needs each Californian and their diverse perspectives to be part of the conversation on how best to protect and conserve California's biodiversity as we tackle the challenges over the coming decades. Creative problem solving is needed and embracing this demographic could potentially best serve the purposes of this particular ecological reserve and the Department's mission. Until then, the Department will continue focusing on restoring the Reserve.

STATE OF CALIFORNIA
FISH AND GAME COMMISSION
FINAL STATEMENT OF REASONS FOR REGULATORY ACTION

Amend Section 630, Ecological Reserves
Title 14, California Code of Regulations
Re: Designation and Special Regulations

I. Date of Initial Statement of Reasons: March 24, 2005

II. Date of Pre-adoption Statement of Reasons: July 18, 2005

III. Date of Final Statement of Reasons: November 29, 2005

IV. Dates and Locations of Scheduled Hearings:

(a) Notice Hearing: Date: May 5, 2005
Location: Sacramento

(b) Discussion/Adoption Hearing: Date: August 19, 2005
Location: San Luis Obispo

V. Update:

No modifications were made to the originally proposed language of the Initial Statement of Reasons.

Section III. Description of Regulatory Action, Subsection (d) Identification of Reports or Documents Supporting Regulation Change is revised to read:

> See attached Management Plan Summary<u>, revised July 2005</u> for the proposed new addition<u>. Also see State Lands Commission Calendar Item C36 and Voting Record dated June 20, 2005 approving a Department of Fish and Game application to lease a 24 acre Expanded Wetlands Parcel for management and authorizing its inclusion within the proposed Ballona Wetlands Ecological Reserve.</u>

The revised Management Plan Summary is attached.

The Fish and Game Commission adopted the proposed regulatory amendments at its August 19, 2005 meeting in San Luis Obispo.

Reasons for Modification of Originally Proposed Language of Initial Statement of Reasons:

No changes have been made to the originally proposed regulatory language.

The attached revised Management Plan Summary describes the June 20, 2005 approval by the State Lands Commission (SLC) of a Department of Fish and Game (DFG) application to lease 24 acres known as the "Expanded Wetlands Parcel" for management, and authorization of its inclusion within the proposed Ballona Wetlands Ecological Reserve. SLC and DFG are in the process of finalizing this lease, and propose the inclusion of this parcel in the proposed Ballona Wetlands Ecological Reserve with this rulemaking. The management plan summary is also revised to include protection of uplands among the management objectives for the property, and includes existing gas and energy easements in the list of agreements affecting the property.

VI. Summary of Primary Considerations Raised in Support of or Opposition to the Proposed Actions and Reasons for Rejecting those considerations:

Responses to public comments received by July 18, 2005 were included in the Pre-adoption Statement of Reasons (attached).

The following is a summary of public comments received since July 18, 2005:

1. The following individuals wrote letters in support of the proposed regulatory amendments, and with the exception of Daniel S. Cooper, requested that an area known as the Freshwater Marsh not be included within the proposed Ballona Wetlands Ecological Reserve.

- Mira Tweti dated August 5, 2005
- Barbara Elliot dated August 5, 2005
- Bob and Sue Krauch dated August 7, 2005
- Jean Pickus dated August 8, 2005
- Edith Read, Ph.D. Center for Natural Lands Management dated August 9, 2005
- Ruth Lansford, Friends of Ballona Wetlands dated August 10, 2005
- Lisa Fimiani dated August 12, 2005
- Lance Williams dated August 15, 2005
- Daniel S. Cooper, Cooper Ecological Monitoring dated August 15, 2005
- Thomas and Catherine Tyrell dated August 18, 2005

The following individuals testified at the August 19, 2005 Fish and Game Commission Hearing in support of the proposed regulatory amendments and requested that the area known as the Freshwater Marsh not be included within the proposed Ballona Wetlands Ecological Reserve:

- Otella Wruck, Friends of Ballona Wetlands
- Andi Culberterson, City of Los Angeles
- Edith Read, Center for Natural Lands Management
- Lisa Fimiani, Audobon Society, Friends of Ballona Wetlands
- Kathleen Truman, Latham & Watkins representing Playa Capital

Department Response: The proposed regulatory amendments do not include the area known as the Freshwater Marsh within the proposed Ballona Wetlands Ecological Reserve

2. Stan Wisniewski, Los Angeles County Beaches and Harbors wrote a letter dated August 17, 2005 supporting the proposed regulatory amendments contingent on recognition of existing Local Coastal Permits and associated regulations and development standards. He also expressed concern regarding designation of the proposed Ballona Wetlands Ecological Reserve and any related development restrictions.

   Andi Culbertson, Los Angeles County Beaches and Harbors testified at the August 19, 2005 Fish and Game Commission hearing in support of the proposed regulatory amendments. He also expressed concerns regarding designation of the proposed Ballona Wetlands Ecological Reserve and any related development restrictions.

Department Response: The proposed regulatory action will not result in development restrictions.

3. The following individuals wrote letters requesting that the area known as the Freshwater Marsh be included within the proposed Ballona Wetlands Ecological Reserve:

- Paul Herzog, Ballona Wetlands Land Trust; Joe Geever, Surfrider Foundation; Marcia Hanscom, Sierra Club Angeles Chapter; Patricia McPherson, Grassroots Coalition; Don May, California Earth Corps; Roy Van de Hoek, Wetlands Action Network dated August 13, 2005
- Bill Rosendahl, Los Angeles City Council dated August 16, 2005
- Tracy Egoscue and Dana Palmer, Santa Monica Baykeeper dated August 16, 2005

The following individuals testified at the August 19, 2005 Fish and Game Commission Hearing requesting inclusion of the Freshwater Marsh within the proposed Ballona Wetlands Ecological Reserve:

- Marcia Hanscom, Wetlands Action Network
- Peggy Forster, Grass Roots
- Andrew Christie
- Robert VandeHoek
- Sabrina Venskus, Ballona Wetlands Land Trust

Department Response: The Freshwater Marsh is a mitigation parcel owned by the State Lands Commission and managed by the Center for Natural Lands Management under agreement with Playa Vista Development. There is no need to include the Freshwater Marsh within the proposed Ballona Wetlands Ecological Reserve, because its restoration, funding, management and uses are governed by multiple regulatory agencies and funded by Playa Vista Development.

4. Paul Weakland testified at the August 19, 2005 Fish and Game Commission hearing that Ecological Reserves should not be named after individuals.

Department Response: It is the policy of the Fish and Game Commission that no facility of the Department of Fish and Game shall be named for persons living or dead.

VII. Location and Index of Rulemaking File:

A rulemaking file with attached file index is maintained at:
California Fish and Game Commission
1416 Ninth Street
Sacramento, CA 95814

VIII. Location of Department Files:

Department of Fish and Game
1812 Ninth Street
Sacramento, CA 95814

IX. Description of Reasonable Alternatives to Regulatory Action:

(a) Alternatives to Regulatory Action:

Designation of the properties as wildlife areas in Section 550, Title 14, CCR. This alternative is inappropriate because of the purposes for which these properties were acquired. The sensitive habitats and species require additional protection not provided under Section 550.

(b) No Change Alternative:

By not adding these properties and providing special regulations, the appropriate level of protection for the properties is not provided. Also, appropriate public use activities will not be enforceable unless the amendments are made.

(c) Consideration of Alternatives:

In view of information currently possessed, no reasonable alternative considered would be more effective in carrying out the purposes for which the regulations are proposed or would be as effective, and less burdensome to the affected private persons than the proposed regulations.

X. Impact of Regulatory Action:

The potential for significant statewide adverse economic impacts that might result from the proposed regulatory action has been assessed, and the following initial determinations relative to the required statutory categories have been made:

(a) Significant Statewide Adverse Economic Impact Directly Affecting Businesses, Including the Ability of California Businesses to Compete with Businesses in Other States:

The proposed action will not have a significant statewide adverse economic impact directly affecting business, including the ability of California businesses to compete with businesses in other states.

The proposed regulatory action adds one ecological reserve to Title 14 with special regulations. The proposed regulatory action is proposed to provide maximum protection of wildlife and habitat and to manage appropriate public use. It is not expected to negatively affect businesses, because the regulations are enforced only on the specific properties named.

(b) Impact on the Creation or Elimination of Jobs Within the State, the Creation of New Businesses or the Elimination of Existing Businesses, or the Expansion of Businesses in California:

None

(c) Cost Impacts on a Representative Private Person or Business:

The agency is not aware of any cost impacts that a representative private person or business would necessarily incur in reasonable compliance with the proposed action.

(d) Costs or Savings to State Agencies or Costs/Savings in Federal Funding to the State:

None

(e) Nondiscretionary Costs/Savings to Local Agencies:

None

(f) Programs mandated on Local Agencies or School Districts:

None

(g) Costs Imposed on Any Local Agency or School District that is Required to be Reimbursed Under Part 7 (commencing with Section 17500) of Division 4:

None

(h) Effect on Housing Costs:

None

Updated Informative Digest/Policy Statement Overview

Currently, there are 132 ecological reserves designated in Section 630, Title 14, CCR, for the purpose of protecting sensitive habitats and species. The department is requesting that this section be amended to add one new ecological reserve, Ballona Wetlands, to this listing.

Ballona Wetlands consisting of 553 acres in Los Angeles County is proposed for designation as an ecological reserve for the protection and enhancement of coastal salt marsh, freshwater marsh, transitional uplands, and associated species, including the state listed endangered Belding's savannah sparrow. The area is also an important wildlife movement corridor to other public lands in the vicinity of the wetlands.

The reasons for listing this property in Title 14 are to regulate public use and provide the best available protection for the species and habitats the property was acquired to protect. Since the property contains sensitive species, including a state listed endangered species, sensitive vegetation communities and acts as a linkage for other important protected lands, it is necessary and appropriate to provide this level of regulatory protection to prevent improper use and degradation of wildlife resources. In order to do this efficiently, the department has a set of general regulations which apply to all ecological reserves.

The department may also write special regulations for individual properties, as it thinks appropriate, to give an additional level of protection, or to permit specific public uses not governed by the general regulations. The department is requesting special regulations for this reserve based on management information gathered which shows these amendments are necessary to protect the habitat or species the property supports.

Three special regulations will protect sensitive species and habitats of Ballona Wetlands by allowing pedestrian use only on designated trails; bicycle use only on a designated bike path on the north side of the Ballona Creek flood channel; and boating only within the Ballona Creek flood channel. One special regulation will allow fishing only with barbless hooks from shore in designated areas along the Ballona Creek flood channel or from a boat within the Ballona Creek flood channel for the protection of sensitive species and habitats and to minimize mortality of fish and aquatic species caught by anglers and returned to Ballona Creek. Two additional special regulations will allow licensed recreational use of a portion of an area of the proposed reserve known as Area C, and leased parking use under existing agreements, unless it is determined that other uses are more appropriate for these areas. Because these licensed recreational and parking uses are not normally allowed on ecological reserves, these two special regulations are necessary when the department has determined these activities are appropriate and will cause no impacts to protected species and habitats.

No changes have been made to the originally proposed regulatory language. The attached Management Plan Summary is revised from the version included with the

Initial Statement of reasons to include protection of uplands among the management objectives of the property, and to include existing gas and energy easements in the list of agreements affecting the property. The Management Plan Summary is also revised to reflect recent developments in the Department's efforts to include an additional 24 acre parcel, known as the "Expanded Wetlands Parcel" within the proposed Ballona Wetlands Ecological Reserve. On June 20, 2005 the State Lands Commission (SLC) approved a Department of Fish and Game (DFG) application to lease the Expanded Wetlands Parcel for management, and authorized its inclusion within the proposed Ballona Wetlands Ecological Reserve. SLC and DFG are in the process of finalizing this lease, and propose the inclusion of this parcel in the proposed Ballona Wetlands Ecological Reserve with this rulemaking.

The Fish and Game Commission adopted the proposed regulatory amendments to designate Ballona Wetlands Ecological Reserve at its August 19, 2005 meeting in San Luis Obispo.

§630. Ecological Reserves is amended to read:

The areas specified in this chapter have been declared by the Fish and Game Commission to be ecological reserves. A legal description of the boundaries of each ecological reserve is on file at the department's headquarters, 1416 Ninth Street, Sacramento. Ecological reserves are established to provide protection for rare, threatened or endangered native plants, wildlife, aquatic organism and specialized terrestrial or aquatic habitat types. Public entry and use of ecological reserves shall be compatible with the primary purposes of such reserves, and subject to the following applicable general rules and regulations, except as otherwise provided for in the special area regulations:

(a) General Rules and Regulations:

(1) Protection of Resources. No person shall mine or disturb geological formations or archeological artifacts or take or disturb any bird or nest, or eggs thereof, or any plant, mammal, fish, mollusk, crustacean, amphibian, reptile, or any other form of plant or animal life in an ecological reserve except as provided in subsections 630(a)(2) and (a)(8). The department may implement enhancement and protective measures to assure proper utilization and maintenance of ecological reserves.

(2) Fishing. Fishing shall be allowed in accordance with the general fishing regulations of the commission except that the method of taking fish shall be limited to angling from shore. No person shall take fish for commercial purposes in any ecological reserve except by permit from the commission.

(3) Collecting. No collecting shall be done in an ecological reserve except by permit issued pursuant to section 650 of these regulations. Any person applying for a permit must have a valid scientific collecting permit issued pursuant to part 3 of this title.

(4) Motor Vehicles. No person shall drive, operate, leave, or stop any motor vehicle, bicycle, tractor, or other type of vehicle in an ecological reserve except on designated access roads and parking areas.

(5) Swimming. No person shall swim, wade, dive, or use any diving equipment within an ecological reserve except as authorized under the terms of a permit issued pursuant to subsection (3).

(6) Boating. No person shall launch or operate a boat or other floating device within an ecological reserve except by permit from the commission.

(7) Trails. The department may designate areas within an ecological reserve where added protection of plant or animal life is desirable, and may establish equestrian or walking trails or paths within such designated areas. No person shall walk or ride horseback in such areas except upon the established trails or paths.

(8) Firearms. No person shall fire or discharge any firearm, bow and arrow, air or gas gun, spear gun, or any other weapon of any kind within or into an ecological reserve or possess such weapons within an ecological reserve, except law enforcement personnel and as provided for in individual area regulations that allow for hunting.

(9) Ejection. Employees of the department may eject any person from an ecological reserve for violation of any of these rules or regulations or for any reason when it appears that the general safety or welfare of the ecological reserve or persons thereon is endangered.

(10) Public Entry. Public entry may be restricted on any area at the discretion of the department to protect the wildlife, aquatic life, or habitat. No person, except state and local law enforcement officers, fire suppression agencies and employees of the department in the performance of their official duties or persons possessing written permission from the department, may enter any ecological reserve, or portion thereof, which is closed to public entry. No person may enter any Ecological Reserve between sunset and sunrise except with written permission from the Department, which may be granted for purposes including night fishing in accordance with subsection (a)(2) from designated shore areas only.

A $2.00 day use pass or a valid $10.00 annual wildlife pass is required of all users of Elkhorn Slough and Upper Newport Bay ecological reserves except for users that possess a valid California sport fishing license hunting license or trapping license, or users that are under 16 years of age or users that are part of an organized youth or school group and having free permits issued by the appropriate regional office. Refer to subsection 550(b)(16)(B), Title 14, CCR, for regulations for fee requirements for wildlife areas.

(11) Introduction of Species. Unless authorized by the commission, the release of any fish or wildlife species, including domestic or domesticated species, or the introduction of any plant species, is

prohibited. The department may reintroduce endemic species on ecological reserves for management purposes.

(12) Feeding of Wildlife. The feeding of wildlife is prohibited.

(13) Pesticides. The use of pesticides is prohibited on any ecological reserve unless authorized by the commission with the exception that the department may use pesticides for management purposes and for public safety.

(14) Litter. No person shall deposit, drop, or scatter any debris on any ecological reserve except in a receptacle or area designated for that purpose. Where no designated receptacles are provided, any refuse resulting from a person's use of an area must be removed from that area by such person.

(15) Grazing. The grazing of livestock is prohibited on any ecological reserve.

(16) Falconry. Falconry is prohibited.

(17) Aircraft. No person shall operate any aircraft or hovercraft within a reserve, except as authorized by a permit from the commission.

(18) Pets. Pets, including dogs and cats, are prohibited from entering reserves unless they are retained on a leash of less than ten feet or are inside a motor vehicle, except as provided for in individual area regulations that allow for hunting or training activities.

(19) Fires. No person shall light fireworks or other explosive or incendiary devices, or start or maintain any fire on or in any reserve, except for management purposes as provided in subsection (a)(1).

(20) Camping. No person shall camp on/in any ecological reserve.

(21) Vandalism. No person shall tamper with, damage or remove any property not his own when such property is located within an ecological reserve.

(b) Areas and Special Regulations for Use:

(1) Abalone Cove Ecological Reserve, Los Angeles County.

(A) Fishing is permitted for fin fish (those having vertebrae) only, from boats as well as from shore. Spear guns may be used for the taking of fin fish.

(B) Swimming, surfing, boating, skin and SCUBA diving are permitted.

(2) Agua Hedionda Lagoon Ecological Reserve, San Diego County.

(A) The department, and the County of San Diego, after consultation with the department, may carry out management activities for fish and wildlife, flood control and vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and use of associated equipment.

(B) All fishing is prohibited.

(3) Albany Mudflats Ecological Reserve, Alameda County.

(4) Alkali Sink Ecological Reserve, Fresno County.

(A) Grazing is permitted under a permit from the department.

(5) Allensworth Ecological Reserve, Tulare County.

(A) Grazing shall be allowed under permit from the department.

(B) Hunting shall be permitted in accordance with general hunting regulations, but only at such times and in specific areas as designated by the department.

(6) Apricum Hill Ecological Reserve, Amador County.

(A) No person, except as provided in subsection (a)(10), shall enter the reserve.

(7) Atascadero Creek Marsh Ecological Reserve, Sonoma County.

(8) Bair Island Ecological Reserve, San Mateo County.

(A) No person, except as provided in subsection (a)(10), shall enter this reserve during the period February 15 through May 20.

(B) Waterfowl shall be taken in accordance with the general waterfowl regulations.

(9) Baldwin Lake Ecological Reserve, San Bernardino County.

(A) All fishing is prohibited.

(B) Waterfowl and upland game hunting shall be allowed in accordance with the general hunting regulations. Waterfowl hunting shall be permitted from boats only, and in accordance with general waterfowl hunting regulations and pursuant to the provisions of Section 551, Title 14, CCR.

(C) Boating is permitted for the purpose of waterfowl hunting only. Boats may be launched and retrieved in designated areas only.

<u>(10) Ballona Wetlands Ecological Reserve, Los Angeles County.</u>

<u>(A) Pedestrian use is allowed on designated trails only.</u>

(B) Bicycle use is allowed only on the designated bike path on the north side of the Ballona Creek flood control channel.

(C) Fishing from shore is allowed only in designated areas along Ballona Creek flood control channel. Fishing from boats is allowed only within the Ballona Creek flood control channel. Only barbless hooks may be used.

(D) Boating shall be allowed only within the Ballona Creek flood control channel.

(E) Existing recreational uses may be allowed under license agreement with Playa Vista Little League in that portion of Area C identified in the license agreement unless it is determined by the department that restoration or other uses in this area are more appropriate.

(F) Existing parking areas under leases to the County of Los Angeles may be allowed unless it is determined by the department that restoration or other uses in those areas are more appropriate.

(~~10~~11) Batiquitos Lagoon Ecological Reserve, San Diego County.

(A) Notwithstanding the provisions of subsections (a)(1), (3), (5), (6) and (12), the department may issue permits to conduct biological research projects within the reserve. Such projects shall be compatible with the primary purpose of the reserve.

(B) San Diego County, after consultation with the department, may carry out management activities necessary for fish and wildlife management, flood control and vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and associated use of equipment.

(~~11~~12) Blue Ridge Ecological Reserve, Tulare County.

(A) Grazing shall be allowed under permit from the department.

(B) Hunting and trapping shall be permitted in accordance with the general hunting and trapping regulations, but only at such times and in specific areas as designated by the department. Trapping may only be done under permit from the department.

(~~12~~13) Blue Sky Ecological Reserve, San Diego County.

(A) Bicycles prohibited.

(~~13~~14) Bobelaine Ecological Reserve, Sutter County.

(A) No person, except as provided in subsection (a)(10), employees of the National Audubon Society or employees of the Department of Water Resources, in the performance of their official duties or those persons possessing written permission from the area manager, may enter the reserve for any purpose.

(B) All fishing is prohibited.

(C) The area manager may issue permits to conduct biological research projects and may restrict the use of boats, vehicles and other motorized equipment within the reserve. Such projects and use shall be compatible with the primary purposes of the reserve.

(D) The Audubon Society may carry out operation and management activities necessary for fish and wildlife management, flood control, vector control and public access. Authorized operation and maintenance activities shall include, but not be limited to, use of chemicals, vegetation control, water control and associated use of equipment.

(~~14~~15) Boden Canyon Ecological Reserve, San Diego County.

(A) Upland game hunting shall be permitted in accordance with the general hunting regulations, but only at such times and in specific areas as designated by the department.

(~~15~~16) Boggs Lake Ecological Reserve, Lake County.

(~~16~~17) Bolsa Chica Ecological Reserve, Orange County.

(A) No person, except as provided in subsection (a)(10), or employees of Signal Corporation and its invitees, for the purposes of carrying out oil and gas operations, shall enter this reserve and remain therein except on established trails, paths or other designated areas.

(B) Fishing shall be permitted at designated areas around outer Bolsa Bay only.

(C) Horses are prohibited from entering the reserve.

(D) Pets are prohibited from entering the reserve except when they remain inside a motor vehicle.

(E) No person shall enter this reserve between 8:00 p.m. and 6:00 a.m.

(F) Motor vehicles are prohibited between 8:00 p.m. and 6:00 a.m.

(G) Vehicle parking is for reserve visitors' use only.

(H) The County of Orange, after consultation with the department, may carry out management activities for fish and wildlife, flood control and vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and use of associated equipment.

(~~17~~18) Bonny Doon Ecological Reserve, Santa Cruz County.

(~~18~~19) Boulder Creek/Rutherford Ranch Ecological Reserve, San Diego County.

(~~19~~20) Buena Vista Lagoon Ecological Reserve, San Diego County.

(A) The County of San Diego, after consultation with the department, may carry out management activities for fish and wildlife, flood control and vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and use of associated equipment.

(B) Fishing is allowed at designated fishing areas only.

(~~20~~21) Burton Mesa Ecological Reserve, Santa Barbara County

(A) Motor vehicles use is prohibited, except by department personnel or department authorized contractors for management or research, or by law enforcement/public safety officers in response to public safety or health hazards.

(B) Upland game hunting may be permitted only at such times and in specific areas as designated by the department.

(~~21~~22) Butler Slough Ecological Reserve, Tehama County.

(A) Livestock grazing may be allowed under permit from the department.

(B) The department may carry out management activities necessary for habitat preservation and management. Authorized operations and maintenance activities shall include, but not be limited to, controlled livestock grazing, controlled burning, and chemical and mechanical treatment with the use of associated equipment.

(~~22~~23) Butte Creek Canyon Ecological Reserve, Butte County.

(A) Motor vehicle use in the Reserve is prohibited except by Department personnel, law enforcement officers or firefighters in response to public safety or health hazards.

(B) Horses are prohibited.

(C) Fishing by boat or other flotation device within the Reserve and in the main channel of Butte Creek is permitted only from February 1 through April 30. Only hand-carried boats or flotation devices may be launched and operated.

(D) The use, application or deposition in any form of toxic substances is prohibited unless authorized by the Commission.

(~~23~~24) Butte Creek House Ecological Reserve, Butte County.

(A) Motor vehicle use is prohibited except by Department personnel, law enforcement officers, or firefighters in response to public safety or health hazards.

(B) The use, application or deposition in any form of toxic substances is prohibited unless authorized by the Commission.

(~~24~~25) Buttonwillow Ecological Reserve, Kern County.

(A) Grazing may be allowed under permit from the department.

(B) Hunting may be permitted in accordance with general hunting regulations, but only at such times and in specific areas as designated by the department.

(~~25~~26) By-Day Creek Ecological Reserve, Mono County.

(A) All fishing is prohibited.

(B) Hunting shall be permitted in accordance with general hunting regulations.

(~~26~~27) Calhoun Cut Ecological Reserve, Solano County.

(A) No person, except as provided below and in subsection (a)(10), shall enter this reserve.

(B) Hunting for waterfowl is allowed only from a boat on waters of the main channel of Calhoun Cut and its tributaries, accessible only from Lindsey Slough and subject to the general hunting regulations and the provisions of subsection (a)(10), related to the protection of wildlife, aquatic life and habitat.

(C) Fishing is allowed only from a boat on waters of the main channel of Calhoun Cut and its tributaries, accessible only from Lindsey Slough and subject to the general sport fishing regulations and the provisions of subsection (a)(10), related to the protection of wildlife, aquatic life and habitat.

(D) Grazing may be allowed under permit from the Department.

(~~27~~28) Canada de los Osos Ecological Reserve, Santa Clara County.

(A) No person, may enter the reserve except with written permission from the department, or unless part of an organized group that has received written permission.

(B) Fishing may be allowed only with written permission from the department. Fishing may be permitted from boats, as well as from shore; only lightweight hand-carried boats or floatation devices may be launched and operated. No gasoline-powered boats shall be permitted.

(C) Swimming, diving and wading may be allowed in designated areas with permission from the department.

(D) Hunting may be allowed, but only in participation with department sponsored hunts at such times, areas, and species as designated by the department.

(E) Target and skeet shooting, other discharge of firearms, and use of bow and arrow may be allowed, but only at such times and in specific areas as designated by the department.

(F) Except as otherwise permitted by the department, all public access trails are open to foot access only.

(G) Notwithstanding the provisions of subsections (a)(1), (2), (3), (5), (6), (8), (12) and (17), the department may issue permits to conduct biological research within the reserve, and may allow collection of plants and animals for educational purposes. Such activities must be compatible with the primary purpose of the reserve.

(H) Camping and campfires may be allowed in specified areas with written permission from the department.

(I) The department may restrict any activities on the reserve to persons under 16 and adults supervising those persons.

(J) Dogs may be allowed in the reserve with written permission from the department.

(K) Livestock grazing may be allowed for habitat management purposes under permit from the department.

(~~28~~29) Canebrake Ecological Reserve, Kern County.

(A) Notwithstanding the provision of subsection (a)(15), grazing may be allowed under permit from the department.

(B) Firearms, archery equipment, and hunting dogs, either on leash or in a vehicle, may be possessed only by licensed hunters only at such times and in specific areas as designated by the department.

(C) Fishing may be allowed only in those specific areas designated by the department.

(D) Notwithstanding the provisions of subsections (a)(1), (3), (5), (6), and (12), the department may issue permits to conduct biological or archaeological research. Such research shall be compatible with the primary purpose of the reserve.

(E) Notwithstanding the provisions of subsection (a)(18), only those animals assisting visually impaired or disabled persons are permitted.

(F) Notwithstanding the provisions of subsection (a)(7), equestrian use may be allowed, but only in specific areas designated by the department.

(~~29~~30) Carlsbad Highlands Ecological Reserve, San Diego County.

(~~30~~31) Carmel Bay Ecological Reserve, Monterey County.

(A) Sport fishing with hook and line, spear gun or hand-held implements shall be permitted from boats as well as from shore. No invertebrates may be taken, possessed or destroyed.

(B) Swimming, boating, surfing, skin and SCUBA diving are permitted.

(C) Within Stillwater Cove kelp may be removed at any time to allow the passage and mooring of boats between Pescadero Rocks and Arrowhead Point.

(D) If, at any time, the director of the department finds that the harvesting of kelp will tend to destroy or impair any kelp bed or beds, or parts thereof, or tend to impair or destroy the supply of any food for fish or wildlife, the director shall serve on every person licensed to harvest kelp a 48-hour advance, written notice that the kelp bed, or a part thereof, will be closed to the harvesting of kelp for a period not to exceed one year. After service of such a notice the person upon whom notice is served may appeal to the commission for a hearing to reopen the kelp bed or part thereof.

(E) Not more than five percent (5%) of the total weight of kelp harvested in any one day shall consist of Nereocystis (bull kelp).

(F) Any licensed person or company intending to harvest kelp within the ecological reserve shall give the department's regional manager of the Marine Resources Region, or his designee, at least 48-hours oral notice of the intention to harvest. At the option of the department, an observer selected by the department may accompany the harvester during such a harvesting.

(G) Not more than 50 percent of the kelp within Bed 219 shall be harvested in any four-month period.

(~~31~~32) Carrizo Canyon Ecological Reserve, Riverside County.

(A) No person, except as provided in subsection (a)(10), and employees of the Bureau of Land Management in the performance of their official duties shall enter this reserve during the period June 15 to September 30.

(B) The County of Riverside may carry out management activities for fish and wildlife, flood control and vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and use of associated equipment.

(C) Pets are prohibited from entering the reserve except when they remain inside a motor vehicle.

(~~32~~33) Carrizo Plains Ecological Reserve, San Luis Obispo County, including the American, Panorama, Elkhorn Plain and Chimineas Units.

(A) Hunting shall be allowed in accordance with the general hunting regulations and only at such times and in such places as designated by the Department.

(B) Target shooting is permitted in designated areas.

(C) Notwithstanding the provisions of subsection (a)(15), grazing may be allowed under permit from the department.

(D) Notwithstanding the provisions on subsections (a)(1), (3), (5), (6), (10), (12) and (20), the department may issue permits to conduct biological research or monitoring compatible with the purposes of the reserve.

(~~33~~34) China Point Ecological Reserve, Siskiyou County.

(A) No person, except as provided in subsection (a)(10) and employees of the U.S. Forest Service in the performance of their official duties, shall enter this reserve during the period February 15 through July 31.

(B) Fishing shall be permitted from boats as well as from shore; boats may be launched and operated in the Klamath River.

(C) Hunting shall be allowed in accordance with the general hunting regulations and subject to subsection (~~33~~34)(A) above.

(~~34~~35) Chorro Creek Ecological Reserve, San Luis Obispo County.

(A) Except as otherwise designated by the department, all public access trails are open to foot access only.

(B) Notwithstanding the provisions of subsections (a)(1), (2), (3), (5), (6), (8), (12) and (17), the department may issue permits to conduct biological research within the reserve, and may allow collection of plants and animals for educational purposes. Such activities must be compatible with the primary purpose of the reserve.

(C) Livestock grazing may be allowed for habitat management purposes under permit from the department.

(~~35~~36) Clover Creek Ecological Reserve, Shasta County.

(A) Livestock grazing may be allowed under permit from the department.

(B) The department may carry out management activities necessary for habitat preservation and management. Authorized operations and maintenance activities shall include, but not be limited to, controlled livestock grazing, controlled burning, and chemical and mechanical treatment with the use of associated equipment.

(~~36~~37) Coachella Valley Ecological Reserve, Riverside County.

(A) The Bureau of Land Management, the Fish and Wildlife Service and The Nature Conservancy may carry out management activities necessary for fish and wildlife, flood control and vector control. Authorized operation and maintenance activities shall include, but not be limited to, use of chemicals, vegetation control, water control and associated use of equipment.

(~~37~~38) Coal Canyon Ecological Reserve, Orange County.

(A) Hunting shall be permitted in accordance with the general hunting regulations, but only at such times and in specific areas as designated by the department.

(B) Method of take restrictions: Shotguns and archery equipment only.

(~~38~~39) Coldwater Canyon Ecological Reserve, Ventura County.

(A) The existing travel corridor through the area is open to foot traffic only. All other areas are closed to public entry.

(~~39~~40) Corral Hollow Ecological Reserve, San Joaquin County.

(A) No person, except as provided in subsection (a)(10), shall enter the reserve.

(~~40~~41) Corte Madera Marsh Ecological Reserve, Marin County.

(A) Boating is permitted, except only lightweight hand-carried boats may be launched within the reserve.

(~~41~~42) Cosumnes River Ecological Reserve, Sacramento County.

(A) Walking is allowed only on established trails, paths or other designated areas.

(B) Horses, except by written permission of the department for grazing management, are prohibited.

(C) Boating is permitted subject to the limitation that only lightweight, hand carried, non-gasoline powered floating devices may be launched and operated from designated launching sites. The department or its designee may further restrict the use and operation of boats to protect resources or provide for the orderly operation of recreational programs. Boating restrictions may include, but are not limited to, seasonal closures.

(D) Fishing is allowed only from a boat on the waters of the main channel of the Cosumnes River and sloughs accessible from the Mokelumne River in accordance with the general fishing regulations and the provisions of subsection (a)(10), related to the protection of wildlife, aquatic life and habitat.

(E) Hunting may be permitted in accordance with general hunting regulations, but only at such times and in specific locations as designated by the department.

(F) Picnicking shall occur only at such times and in those areas designated by the department.

(G) Pets are prohibited from entering the reserve, except when they remain inside a motor vehicle.

(H) The department, the State Lands Commission, the Bureau of Land Management, The Nature Conservancy, Ducks Unlimited, Inc. and the County of Sacramento may carry out management activities necessary for fish and wildlife management, flood control, vector control and public access. Authorized operation and maintenance activities shall include, but not be limited to, use of chemicals, vegetation control, animal control, water control and associated use of equipment.

(I) Grazing may be allowed under permit from the department.

(J) Notwithstanding the provisions of subsections (a)(1), (3), (5), (6) and (12), the department may issue permits to conduct biological or archaeological research. Such research shall be compatible with the primary purpose of the reserve.

(K) Farming may be allowed under permit from the department when such farming is compatible with the primary purpose of the reserve.

(~~42~~43) Crestridge Ecological Reserve, San Diego County.

(A) Non-motorized mountain biking may be allowed on designated roads during designated seasons as determined by the department. Closures may be implemented at the discretion of the department.

(~~43~~44) Dairy Mart Ponds Ecological Reserve, San Diego County.

(A) San Diego County, after consultation with the department, may carry out management activities for vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and associated use of equipment.

(~~44~~45) Dales Lake Ecological Reserve, Tehama County.

(A) Waterfowl hunting shall be permitted in accordance with the general waterfowl regulations per Section 502, Title 14, CCR.

(B) Livestock grazing may be allowed under permit from the department.

(C) The department may carry out management activities necessary for habitat preservation and management. Authorized operations and maintenance activities shall include, but not be limited to, controlled livestock grazing, controlled burning, and chemical and mechanical treatment with the use of associated equipment.

(~~45~~46) Del Mar Landing Ecological Reserve, Sonoma County.

(A) Fishing is permitted for fin fish (those having vertebrae) only. Spear guns may be used for the taking of fin fish.

(B) Swimming, boating, skin and SCUBA diving are permitted.

(~~46~~47) Del Mar Mesa/Lopez Ridge Ecological Reserve, San Diego County.

(~~47~~48) Del Monte Dunes Ecological Reserve, Monterey County.

(~~48~~49) Eden Landing Ecological Reserve, Alameda County.

(A) No person shall enter this reserve except on designated trails without written permission or by posted notice of the regional manager.

(B) No person shall walk, ride horses or bicycles, except on designated trails.

(C) Dogs are restricted to designated trails and designated hunting areas during the waterfowl season. In designated hunting areas, dogs may be off leash only for hunting during waterfowl season and must be under voice control at all times.

(D)Waterfowl hunting shall be permitted, but only at such times and in specific areas as designated by the department. Waterfowl shall be taken in accordance with the general waterfowl regulations.

(E) Fishing shall be permitted from boats and from shore, but only at such times and in specific areas as designated by the department.

(F) Notwithstanding the provisions of section (a)(2), commercial bait fishing for brine shrimp may occur only at such times and in specific areas as designated by the department.

(G) Notwithstanding the provisions of subsections (a)(1), (2), (3), (5), (6), (8), (10), (12) and (20), the department may issue permits to conduct biological research or monitoring compatible with the primary purposes of the reserve.

(~~49~~50) Elkhorn Slough Ecological Reserve (National Estuarine Research Reserve), Monterey County.

(A) Notwithstanding the provisions of subsections (a)(1), (3), (5), (6) and (12), the department may issue permits to conduct biological research projects within the reserve. Such projects shall be compatible with the primary purposes of the reserve.

(B) Fishing shall be conducted from only those specific areas of the reserve designated by the department.

(C) Hunting shall be permitted in accordance with general hunting regulations, but only at such times and in specific areas as designated by the department.

(D) Grazing shall be allowed under permit from the department. The department may restrict the use of horses by grazing permittees.

(E) All designated public access trails are opened to foot access only.

(F) The causing of excessive noise especially that amplified electronically is prohibited.

(G) Picnicking shall be conducted in only those areas designated by the Department.

(~~50~~51) Estelle Mountain Ecological Reserve, Riverside County.

(A) Upland game hunting shall be permitted in accordance with the general hunting regulations.

(~~51~~52) Fagan Marsh Ecological Reserve, Napa County.

(A) Fishing shall be permitted from boats, as well as from shore; only lightweight hand-carried boats may be launched and operated.

(B) Swimming and diving are permitted.

(~~52~~53) Fall River Mills Ecological Reserve, Shasta County.

(~~53~~54) Farallon Islands Ecological Reserve, San Francisco County

(A) Subsections (a)(1) through (a)(21) do not apply.

(B) Except as specifically prohibited under this section, boating, sport and commercial fishing, swimming, and skin and SCUBA diving are permitted within the ecological reserve, which extends one nautical mile from the coastline of Southeast Farallon and North Farallon Islands.

(C) All vessels shall observe a five (5) nautical mile per hour speed limit within 1,000 feet of any shoreline in the reserve.

(D) All commercial abalone and sea urchin diving vessels operating in the reserve shall terminate their vessel engine exhaust system either through a muffler for dry exhaust systems, or below the vessel waterline for wet exhaust systems.

(E) All commercial abalone and sea urchin diving vessels equipped with an open, deck-mounted air compressor system, while operating in the reserve, shall have the air compressor's engine exhaust system terminate below the vessel waterline.

(F) From March 15 through August 15 of each year no vessel shall be operated or anchored less than 300 feet from the shoreline of any of the four islets comprising the North Farallons, including North Farallon, the Island of St. James and the two unnamed islets located between them, all as shown at about 370 46' N, 1230 06' W on the 21st edition of NOAA chart 18645, dated August 11, 1990 and herein incorporated by reference, except in the area beginning at a line extending due west magnetic from the northernmost point of land on North Farallon and continuing clockwise to a line drawn due west magnetic from the southernmost point of land on North Farallon and in the area beginning at a line drawn due west magnetic from the northernmost point of land on the northernmost of the two unnamed islets extending clockwise to a line drawn due south magnetic from the southernmost point of land on that islet.

(G) From March 15 through August 15 of each year no vessel shall be operated or anchored less than 300 feet from the shoreline in the area beginning at the south end of Jordan Channel, westward around Indian Head, then generally northward past Great Arch Rock, then generally following the shoreline to a line extending due west from the northernmost point of land on Sugarloaf Island or in the area from the east end of Mussel Flat, generally southward to the northeasternmost point of land on Saddle Rock (Seal Rock) then generally southwest along the northerly shoreline of Saddle Rock to the southwesternmost point of land on Saddle Rock and continuing generally northward to the west end of Mussel Flat, both areas at Southeast Farallon Island.

(H) Nothing in this section shall prohibit emergency anchorage or vessel operation necessary to protect property or human life.

(~~54~~55) Farnsworth Bank Ecological Reserve, Los Angeles County.

(A) No purple coral (Allopora californica) or geological specimens may be taken.

(B) Subsections (a)(1) through (a)(21) do not apply.

(~~55~~56) Fish Slough Ecological Reserve, Inyo and Mono counties.

(A) Fishing is prohibited within the 20-acre fenced and posted plot of land encompassing two spring areas and an artificial impoundment of 5.6 acres located in the northwest corner of that area known as "Fish Slough," northern Inyo and southern Mono counties.

(B) Hunting shall be allowed in accordance with the general hunting regulations.

(~~56~~57) Fremont Valley Ecological Reserve, Kern County.

(~~57~~58) Goleta Slough Ecological Reserve, Santa Barbara County.

(A) Notwithstanding the provisions of subsections (a)(1), (3), (5), (6) and (12), the department may issue permits to conduct biological research projects within the reserve. Such projects shall be compatible with the primary purposes of the reserve.

(B) No person, except as provided in subsection (a)(10) or designated employees of Santa Barbara Airport, City of Santa Barbara and Goleta Valley Mosquito Abatement District for the purposes of carrying out official duties shall enter this reserve and remain therein except on established trails, paths or other designated areas.

(C) No fishing shall be allowed except at designated areas.

(D) Horses are prohibited.

(E) The department, City of Santa Barbara and the Goleta Valley Mosquito Abatement District may carry out management activities necessary for fish and wildlife management and vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control, minor ditching for mosquito abatement when approved by department and use of associated equipment.

(~~58~~59) Harrison Grade Ecological Reserve, Sonoma County.

(~~59~~60) Headwaters Forest Ecological Reserve, Humboldt County.

(A) Horses are prohibited from entering the reserve.

(B) Bicycles are allowed only on the northern 3.5-mile designated corridor.

(C) Dogs on leash are allowed only on the northern 3.5-mile designated corridor.

(D) Camping may be authorized with written permission from the department or the Bureau of Land Management for research and monitoring.

(E) Swimming may be authorized with written permission from the department or the Bureau of Land Management for research and monitoring.

(F) Aircraft operations and motorized vehicle use may be authorized with written permission from the department or the Bureau of Land Management for emergency operations, monitoring, research and other management activities.

(G) The Bureau of Land Management may carry out operation and maintenance activities necessary for fish and wildlife management and public access. Authorized operation and maintenance activities shall include, but not be limited to use of chemicals, vegetation control, forestry management, controlled burning and use of associated equipment.

(~~60~~61) Heisler Park Ecological Reserve, Orange County.

(A) All fishing is prohibited.

(B) Swimming, boating and other aquatic sports are permitted. Boats may be launched and retrieved only in designated areas and may be anchored within the reserve only during daylight hours.

(~~61~~62) Hidden Palms Ecological Reserve, Riverside County.

(A) No person, except as provided in subsection (a)(10), shall enter this reserve.

(~~62~~63) Indian Joe Springs Ecological Reserve, Inyo County.

(A) Upland game hunting shall be permitted in accordance with the general hunting regulations.

(~~63~~64) Joshua Creek Canyon Ecological Reserve, Monterey County.

(~~64~~65) Kaweah Ecological Reserve, Tulare County.

(A) Grazing may be allowed only under permit from the department.

(B) Hunting shall be allowed in accordance with the general hunting regulations, but only at such times and in specific areas as designated by the department.

(~~65~~66) Kerman Ecological Reserve, Fresno County.

(A) Grazing may be allowed under permit from the Department.

(B) Hunting shall be permitted in accordance with general hunting regulations from July 1 through January 31. Only licensed hunters will be permitted to possess firearms. Shotguns only, discharging not larger than number 2 lead or size T steel shot, will be allowed on the area. Possession of firearms for other than law enforcement purposes will not be permitted on the area, except as provided herein.

(C) No plinking, firearms practice, or target shooting is allowed within the area.

(~~66~~67) King Clone Ecological Reserve, San Bernardino County.

(~~67~~68) Laguna Laurel Ecological Reserve, Orange County.

(~~68~~69) Lake Hodges Ecological Reserve, San Diego County.

(~~69~~70) Lake Mathews Ecological Reserve, Riverside County.

(A) Notwithstanding the provisions of subsections (a)(1), (3), (5), (6) and (12), the department may issue permits to conduct biological research projects within the reserve. Such projects shall be compatible with the primary purposes of the reserve.

(B) No person except as provided in subsection (a)(10) and employees and consultants of Metropolitan Water District and member public agencies of the District, in the performance of customary reservoir maintenance activities or other official duties, may enter or utilize boats, aircraft or motor vehicles within this reserve.

(C) All fishing is prohibited.

(D) Collections may be made by the department for the purposes of fish and wildlife management, or by Metropolitan Water District for the purpose of water quality testing.

(E) The department and Metropolitan Water District may carry out management activities necessary to ensure water quality and the proper operation and maintenance of Lake Mathews as a water supply facility and natural area. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control, rodent control and use of associated equipment.

(~~70~~71) Leek Springs Ecological Reserve, El Dorado County.

(A) No person, except as provided in subsection (a)(10), shall enter this reserve without written permission from the regional manager.

(B) All fishing is prohibited.

(C) Pets are prohibited from entering the reserve.

(D) Vehicles are prohibited, except for use by adjacent landowners and their invitees, United States Forest Service personnel, fire personnel or other authorized persons who may only use the road easement which bisects the property.

(E) Horses and bicycles are prohibited.

(~~71~~72) Limestone Salamander Ecological Reserve, Mariposa County.

(A) No person, except as provided in subsection (a)(10), shall enter this reserve.

(~~72~~73) Little Butte Ecological Reserve, Mendocino County.

(~~73~~74) Little Red Mountain Ecological Reserve, Mendocino County.

(~~74~~75) Loch Lomond Vernal Pool Ecological Reserve, Lake County.

(~~75~~76) Lokern Ecological Reserve, Kern County.

(A) Notwithstanding the provision of subsection (a)(15), grazing may be allowed under permit from the department.

(B) Hunting may be permitted in accordance with general hunting regulations only at such times and in specific areas as designated by the department.

(~~76~~77) Macklin Creek Ecological Reserve, Nevada County.

(A) No person, except as provided in subsection (a)(10), shall enter this reserve without written permission from the regional manager.

(B) All fishing in prohibited.

(~~77~~78) Magnesia Spring Ecological Reserve, Riverside County.

(A) No person, except as provided in subsection (a)(10), and employees of the City of Rancho Mirage in the performance of their official duties shall enter this reserve during the period June 15 to September 30.

(B) The County of Riverside may carry out management activities for fish and wildlife, flood control and vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and use of associated equipment.

(C) Pets are prohibited from entering the reserve except when they remain inside a motor vehicle.

(~~78~~79) Marin Islands Ecological Reserve, Marin County.

(~~79~~80) Mattole River Ecological Reserve, Mendocino County.

(~~80~~81) McGinty Mountain Ecological Reserve, San Diego County.

(~~81~~82) Meadowbrook Ecological Reserve, San Diego County.

(~~82~~83) Moro Cojo Ecological Reserve, Monterey County.

(~~83~~84) Morro Dunes Ecological Reserve, including the Bayview Unit, San Luis Obispo County.

(~~84~~85) Morro Rock Ecological Reserve, San Luis Obispo County.

(A) No person shall enter into or upon this reserve for any purpose except as follows:

1. For the purpose of fishing and sightseeing, persons may enter upon that portion of Morro Rock between the low tide mark and a point ten (10) feet in elevation above the mean high tide mark.

2. Those persons provided for in subsection (a)(10), and employees of the Department of Parks and Recreation may enter the reserve in the performance of their official duties.

(~~85~~86) Napa River Ecological Reserve, Napa County.

(A) Grazing is permitted under a permit from the department.

(B) No person, except as provided in subsection (a)(10), shall enter this reserve between sunset and sunrise.

(C) Swimming is permitted.

(D) The possession and/or consumption of alcoholic beverages is prohibited.

(~~86~~87) North Table Mountain Ecological Reserve, Butte County.

(A) Horses and bicycles are prohibited from entering the reserve.

(B) Livestock grazing for habitat management is permitted under permit from the department.

(C) Hunting is permitted for deer and upland game in accordance with the general hunting regulations through November 15. Hunting is prohibited after November 15 and through the spring turkey season.

(~~87~~88) Oasis Springs Ecological Reserve, Riverside County.

(A) All fishing is prohibited.

(B) Hunting shall be permitted in accordance with general hunting regulations.

(~~88~~89) Offshore Rocks and Pinnacles, coastal counties.

(~~89~~90) Otay Mountain Ecological Reserve, San Diego County.

(A) Hunting shall be allowed in accordance with the general hunting regulations and the Bureau of Land Management's Wilderness Area Restrictions.

(~~90~~91) Owl Creek Ecological Reserve, Humboldt County.

(~~91~~92) Panoche Hills Ecological Reserve, Fresno County.

(A) Grazing may be allowed under permit from the department.

(B) Hunting shall be permitted in accordance with general hunting regulations from July 1 through January 31. Only licensed hunters will be permitted to possess firearms.

(C) No plinking, firearms practice, or target shooting is allowed within the area.

(~~92~~93) Peytonia Slough Ecological Reserve, Solano County.

(A) Fishing shall be permitted from boats as well as from shore.

(B) Swimming, wading and diving shall be permitted within the reserve.

(C) Boats may be operated within the reserve; however, only lightweight, hand-carried boats may be launched within the reserve.

(~~93~~94) Pilgrim Creek Ecological Reserve, San Diego County.

(~~94~~95) Phoenix Field Ecological Reserve, Sacramento County.

(A) No person, except as provided in subsection (a)(10), shall enter this reserve.
(~~95~~96) Pine Hill Ecological Reserve, El Dorado County including the Salmon Falls Unit.
(A) No person, except as provided in subsection (a)(10), shall enter this reserve.
(B) No horses are permitted within the boundaries of the reserve.
(~~96~~97) Pismo Lake Ecological Reserve, San Luis Obispo County.
(A) All fishing is prohibited.
(~~97~~98) Piute Creek Ecological Reserve, San Bernardino County.
(A) Hunting shall be allowed in accordance with the general hunting regulations.
(~~98~~99) Plaisted Creek Ecological Reserve, San Diego County.
(~~99~~100) Pleasant Valley Ecological Reserve, Fresno County.
(A) Grazing may be allowed under permit from the department.
(B) Hunting may be permitted in accordance with the general hunting regulations, but only at such times and in specific areas as designated by the department.
(~~100~~101) Point Lobos Ecological Reserve, Monterey County.
(A) All fishing is prohibited.
(B) Swimming, boating, and other aquatic sports are permitted. Boats may be launched and retrieved only in designated areas and may be anchored within the reserve only during daylight hours.
(~~101~~102) Quail Hollow Ecological Reserve, Santa Cruz County.
(~~102~~103) Quail Ridge Ecological Reserve, Napa County.
(A) No person, except as provided in subsection (a)(10) shall enter this reserve without permission from the department.
(B) Hunting will be permitted only as specially authorized hunts determined by the department.
(~~103~~104) Rancho Jamul Ecological Reserve, including the Headquarters Unit, San Diego County.
(A) Controlled retriever training may be permitted within a designated area. This area shall be clearly posted.
(B) Hunting shall be allowed in accordance with the general hunting regulations, but only at such times and in specific areas as designated by the department.
(C) Within the 50.51 acre Headquarters Unit, the Department may develop facilities and conduct activities consistent with training programs, meeting and storage needs, fire suppression and control, and educational programs under guidelines established by the regional manager.
(D) Uses associated with occupied state housing shall be allowed within the 50.51 acre Headquarters Unit.
(~~104~~105) Redwood Shores Ecological Reserve, San Mateo County.
(A) Fishing shall be permitted from boats as well as from shore; only lightweight, hand-carried boats may be launched and operated.
(B) Swimming, wading and diving shall be allowed within the ecological reserve.
(C) Bicycles are allowed along levee-top road system.
(~~105~~106) River Springs Lakes Ecological Reserve, Mono County.
(A) Hunting shall be permitted in accordance with the general hunting regulations.
(~~106~~107) Saline Valley Ecological Reserve, Inyo County.
(A) Hunting shall be allowed in accordance with the general hunting regulations.
(~~107~~108) San Bruno Mountain Ecological Reserve, San Mateo County.
(~~108~~109) San Diego-La Jolla Ecological Reserve, San Diego County.
(A) Commercial bait fishing for squid, only by use of hand-held scoop net, is authorized offshore west of a line drawn due north from Goldfish Point. All other forms of fishing are prohibited.
(B) Swimming, boating, and other aquatic sports are permitted. Boats may be launched and retrieved only in designated areas and may be anchored within the reserve only during daylight hours.
(~~109~~110) San Diego River Ecological Reserve, San Diego County.
(~~110~~111) San Dieguito Lagoon Ecological Reserve, San Diego County.
(A) Fishing shall be permitted from shore and from the Grand Avenue bridge.
(B) No person, except as provided in subsection 630(a)(10), shall be permitted on the California least tern nesting island.
(C) No person, except as provided in subsection 630(a)(10), shall enter this reserve between 8:00 p.m. and 5:00 a.m.
(D) The County of San Diego, after consultation with the department, may carry out management activities for fish and wildlife, flood control and vector control. Authorized operation and maintenance

activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and use of associated equipment.

(E) Collections of fish, wildlife, water and soil may be made by the Department for the purposes of fish and wildlife management or by San Diego County for the purposes of water quality testing and vector control.

(~~111~~112) San Elijo Lagoon Ecological Reserve, San Diego County.

(A) Notwithstanding the provisions of subsections (a)(1), (3), (5), (6) and (12), the department may issue permits to conduct biological research projects within the reserve. Such projects shall be compatible with the primary purposes of the reserve.

(B) San Diego County, after consultation with the department, may carry out management activities for fish and wildlife management, flood control, vector control and regional park recreational activities. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control, minor ditching and use of associated equipment.

(C) Collections may be made by the department for purposes of fish and wildlife management or by San Diego County for the purpose of water quality testing and vector control.

(~~112~~113) San Felipe Creek Ecological Reserve, Imperial County.

(A) Hunting shall be permitted in accordance with the general hunting regulations.

(~~113~~114) San Joaquin River Ecological Reserve, Fresno and Madera Counties.

(A) No person shall enter into any unit of this reserve except as provided in subsection a(10), or as provided by written permission or by posted notice of the regional manager who will designate appropriate times and/or areas open to public use.

(B) The Department may carry out or cause to be carried out management activities for fish and wildlife, flood control, and vector control. Authorized operation and maintenance activities shall include, but not be limited to, use of chemicals, vegetation control, water control and use of associated equipment.

(C) Boating is permitted, subject to the limitations of subsection (A) above. Except in the execution of law enforcement, emergency services, or official duties of department employees or contractors, only lightweight, hand carried, non-gasoline powered floating devices may be launched and operated from designated launching sites. The Regional Manager or his designee may further restrict the use and operation of boats to protect the resource or provide for the orderly operation of recreational programs maintained on the area. Boating restrictions may include, but are not limited to, seasonal closures.

(D) Angling shall be permitted from boats as well as from shore, subject to the limitations in subsections (A) and (C), above.

(E) Subsection (a)(20) notwithstanding, late night or over-night use for camping and other purposes may be allowed subject to limitations in subsection (A) above.

(F) Subsection (a)(11) notwithstanding, the Department may, for management purposes, introduce or cause to be introduced nonendemic fish species which are naturalized in the San Joaquin River system, primarily to establish and maintain urban sport-fishing opportunities.

(G) Subsection (a)(17) shall not be construed to prohibit aircraft from operating within a normal flight pattern when taking off from or landing at the Sierra Skypark airport located approximately one-quarter mile south of the reserve.

(H) Grazing for vegetation management may be allowed under permit from the department.

(~~114~~115) San Luis Rey River Ecological Reserve, San Diego County.

(~~115~~116) Santa Cruz Long-toed Salamander Ecological Reserve, Santa Cruz County.

(A) No person shall enter the reserve for any purpose except as follows:

1. Those persons provided for in subsection (a)(10), and employees of the departments of Parks and Recreation and Transportation in the performance of their official duties.

(~~116~~117) Santa Rosa Plain Vernal Pool Ecological Reserve, Sonoma County, including the Hall Road, Todd Road, Wikiup and Yuba Drive Units.

(A) No person, except as provided in subsection (a)(10), shall enter this reserve without written permission of the department. Public use of a trail to be constructed on the Hall Road Unit will be allowed under conditions established by the regional manager.

(B) Ecological research and environment education may be conducted with written permission of the department.

(C) Nothwithstanding the provision of subsection (a)(15), livestock grazing may be allowed for habitat management purposes under permit from the department.

(~~117~~118) Santa Rosa Plateau Ecological Reserve, Riverside County.

(A) Notwithstanding the provisions of subsection (a)(18), only those animals assisting visually impaired or disabled persons are permitted.

(~~118~~119) Springville Ecological Reserve, Tulare County.

(A) No person, except as provided in subsection (a)(10), shall enter between sunset and sunrise.

(~~119~~120) Stone Corral Ecological Reserve, Tulare County.

(A) Notwithstanding the provision of subsection (a)(15), grazing may be allowed under permit from the department.

(B) Hunting may be permitted in accordance with general hunting regulations only at such times and in specific areas as designated by the department.

(~~120~~121) Sycamore Canyon Ecological Reserve, Riverside County.

(~~121~~122) Sycuan Peak Ecological Reserve, San Diego County.

(~~122~~123) Table Bluff Ecological Reserve, Humboldt County.

(A) Livestock grazing may be allowed under permit from the department.

(B) The department may carry out management activities for the preservation and expansion of the endangered western lily (Lilium occidentale). Authorized management activities may include, but not be limited to, controlled livestock grazing, controlled burning, chemical treatment and mechanical treatment.

(C) Except as provided in subsection (a)(10) no persons shall enter the fenced western lily area.

(~~123~~124) Theiller Sebastopol Meadowfoam Ecological Reserve, Sonoma County.

(~~124~~125) Thomes Creek Ecological Reserve, Tehama County.

(A) Livestock grazing may be allowed under permit from the department.

(B) The department may carry out management activities necessary for habitat preservation and management. Authorized operations and maintenance activities shall include, but not be limited to, controlled livestock grazing, controlled burning, and chemical and mechanical treatment with the use of associated equipment.

(~~125~~126) Tomales Bay Ecological Reserve, Marin County.

(A) Waterfowl may be taken in accordance with the general waterfowl regulations.

(B) Fishing shall be permitted from boats as well as from shore; only lightweight, hand-carried boats may be launched and operated.

(C) Swimming, wading, and diving shall be allowed within the reserve.

(D) The land area only of the reserve shall be closed to all entry from March 1 through June 30.

(~~126~~127) Upper Newport Bay Ecological Reserve, Orange County.

(A) Fishing shall be permitted from boats. Fishing is also permitted from shore in designated areas. Clamming or wading is not permitted.

(B) Swimming is permitted only in that area bayward from North Star Beach to mid-channel.

(C) Boating is limited to non-motorized craft, with the exception of law enforcement, emergency, and department vessels and authorized operators under permit from the regional manager. Boating shall occur in designated areas only and is limited to five miles per hour.

(D) No person shall walk, or ride horseback except on established trails, paths, or other designated areas.

(E) The County of Orange may carry out management activities for fish and wildlife, flood control and vector control. Authorized operation and maintenance activities shall include, but shall not be limited to, use of chemicals, vegetation control, water control and use of associated equipment.

(~~127~~128) Walker Canyon Ecological Reserve, San Diego County.

(A) Hunting shall be allowed in accordance with the general hunting regulations.

(~~128~~129) Watsonville Slough Ecological Reserve, Santa Cruz County.

(~~129~~130) West Mojave Desert Ecological Reserve, San Bernardino County.

(A) Hunting shall be permitted in accordance with the general hunting regulations from July 1 to January 31. Only licensed hunters shall be permitted to possess firearms.

(B) No plinking, firearms practice or target shooting is allowed within the ecological reserve.

(~~130~~131) Woodbridge Ecological Reserve, San Joaquin County.

(A) No person, except as provided in subsection (a)(10), shall enter this reserve.

(~~131~~132) Yaudanchi Ecological Reserve, Tulare County.

(A) Grazing is permitted under a permit from the department.

(B) No person, except as provided in subsection (a)(10), shall enter this reserve between sunset and sunrise.

(C) No person shall walk except on established trails, paths, or other designated areas.

(D) Horses, except by written permission of the Department for the purpose of grazing, are prohibited.

(~~132~~133) Yorkville Ecological Reserve, Mendocino County.

WILDLIFE CONSERVATION BOARD
Minutes
September 30, 2003

The Wildlife Conservation Board met on Wednesday, September 30, 2003, in Room 4203 of the State Capitol in Sacramento, California. The meeting was called to order at 10:00 A.M. by Chairman Michael Flores. Mr. Flores introduced the Board Members and then turned over the meeting to Mr. Al Wright, Executive Director of the Board.

6. Roll Call

WILDLIFE CONSERVATION BOARD MEMBERS

Michael Flores, Chairperson
President, Fish and Game Commission
Fred Klass, Program Budget Manager
Vice, Steve Peace, Member
Director, Department of Finance
Robert C. Hight, Member
Director, Department of Fish and Game

JOINT LEGISLATIVE INTERIM ADVISORY COMMITTEE

Assembly Member Patty Berg
Kristin Stauffacher,
Vice, Senator Michael J. Machado
Jeff Arthur,
Vice, Assembly Member Hannah-Beth Jackson
Debra Gravert,
Vice, Assembly Member Fran Pavley

EXECUTIVE DIRECTOR

Al Wright

Staff Present: Al Wright, Executive Director
John Donnelly, Assistant Executive Director
Marilyn Cundiff, Public Land Management Specialist
Jenny Smith, Staff Services Analyst
Peter Perrine, Public Land Management Specialist
Bonnie Turner, Public Land Management Specialist
Scott Clemons, Public Land Management Specialist
Tony Chappelle, Public Land Management Specialist
Ajit Bindra, Associate Budget Analyst
Gary Cantrell, Research Analyst
Dave Means, Senior Land Agent
William Gallup, Senior Land Agent
Steven Christensen, Senior Land Agent
Ken Morefield, Research Analyst
Elena Salas, Secretary
Mary Grande, Secretary
Jan Beeding, Office Technician
Maureen Rivera, Executive Assistant

Others Present: Susannah Churchill, Environment California
Melanie Choy, Robinson and Associates
Dottie Jensen, WAMU
Jan Owen, WAMU
Victoria Rome, Natural Resources Defense Council
Joe Caves, Conservation Strategy Group
Paul Martin
Tom Francis, Ballona Wetlands Land Trust
Steve Soboroff, Playa Vista
David Vena, Latham and Watkins
Rorie Skei, Santa Monica Mountains Conservancy
Patti Sinclair, Playa Capital Company LLC
Ruth Lansford, Friends of Ballona Wetlands
Jim Landry, Ballona Wetlands Foundation
and Loyola Marymount University
Rex Frankel, Sierra Club
Mathew Hayden, City of Calabasas
Jared Carter, Pacific Lumber Company
Susan McCabe, McCabe and Company
David Nelson, Playa Capital
Liza Riddle, Trust for Public Land
Catherine Tyrrell, Playa Capital
Marcia Hanscom, Wetlands Action Network
Laurie Collins, Santa Monica Mountains Conservancy
Cara Horowitz, Santa Monica Mountains Conservancy
Leslie Purcell
Debra Gravert, Office of Assembly Member Fran Pavley
Nick Smith, Governor's Office
Others Present: Tami Miller, Platinum Advisors

(Continued) John Stevens, State Assembly
Brian Miller, Resources Agency
Linda Parks, County of Ventura
Rick Rayburn, Department of Parks and Recreation
Jim Metropulos, Sierra Club

2. Ballona Wetlands, Los Angeles County $140,000,000.00

Mr. Wright reported that this proposal was to consider a cooperative project with the State Coastal Conservancy (SCC), the Trust for Public Land (TPL), the Department of Fish and Game (DFG) and the Wildlife Conservation Board (WCB) to acquire approximately 483± acres of private land and property interests in Los Angeles County in order to preserve critical habitat and key open space, including a large portion of what remains of the Ballona Wetlands. The property is located on the western edge of the Los Angeles metropolitan area, in Los Angeles County, just north of Los Angeles International Airport. The subject property is the largest remaining undeveloped and restorable coastal wetland in Los Angeles and consists of three distinct areas identified as Area A (138± acres), B Residential (54± acres) and the Ballona Wetlands Parcel, including the Ballona Creek Channel (291± acres). The total to be conveyed to the State is 483± acres. Mr. John Donnelly described the project and its location.

As part of the transaction, Playa Capital Company, LLC (Playa), the present owner of the property, would also release its right of first refusal to purchase adjacent property identified as Area C. Playa will release its rights to an easement across Area C if relieved of its obligation to construct a road and bridge to connect Culver Boulevard with Playa Vista Drive. A trust currently holds title to Area C for the benefit of the State and legislation has passed to formally transfer title to the State acting by and through the DFG, WCB.

Mr. Donnelly reported that prior to this meeting, a summary paper which discussed several key points of the project, the State's Purchase Agreement and Environmental Site Assessment for this project, were available at the following locations on September 19, 2003:

1. The California Resources Agency, 1416 Ninth Street, Suite 1311, Sacramento, CA 95814 (916) 653-5656
2. Wildlife Conservation Board, 1807 13th Street, Suite 103, Sacramento, CA 95814 (916) 445-8448
3. Los Angeles River Center and Gardens, 570 West Avenue Twenty-six (at San Fernando Road), Los Angeles, CA 90065 (323) 221-9959 Ext. 0
4. Franklin Canyon Park, 2600 Franklin Canyon Drive, Beverly Hills, CA 90210 (310) 858-7272 Ext. 0

Mr. Donnelly explained that the documents and summaries were also available for review on the Internet by accessing the Wildlife Conservation Board's website or the California Resources Agency website.

The subject property is a composition of upland scrub, open salt/mud flat, riparian, coastal dune and grasslands providing habitat for a number of special animal species. A few of the species found on site include Lange's El Segundo dune weevil, Dorothy's El Segundo dune weevil, wandering skipper (federal species of concern), silvery legless lizard, Stevens' California vole (federal and State species of concern), California brown pelican (federally and State-listed endangered), California least tern (federally and State-listed endangered) and Belding's Savannah sparrow (a federal species of concern and State-listed endangered).

Several of the species listed above rely on wetland habitat, which is quickly disappearing. The Ballona Wetlands once consisting of approximately 1,500 acres, has been reduced over time to less than 150 acres. However, several narrow corridors, such as the Ballona Creek Channel connect the subject property with other open areas nearby, including Baldwin Hills to the northeast and a restored dune system at the western end of the Los Angeles International Airport located to the south.

The property will be acquired on behalf of the State and will be under the interim jurisdiction of the DFG. TPL has agreed to pay and provide for management of the property during this interim period (estimated to be approximately five years) which will provide the DFG, SCC and others involved in the transaction, the time needed to complete the planning processes and identify the appropriate entity to manage the property and implement long-term restoration. It is envisioned that restoration will incorporate, as appropriate, Area C, once that property is conveyed to the DFG, and an adjacent fresh water marsh recently restored by Playa as a condition of its present development.

Area A and Area B Residential have been appraised and the value has been reviewed and approved by the Department of General Services (DGS) at $140,000,000.00, with concurrence from the WCB. Playa Capital Company, LLC has agreed to sell these areas at $139,000,000.00, thereby providing a donation to the State. In addition, Playa has agreed to transfer the Ballona Wetlands Parcel and release its rights as described above in Area C to the State at no cost. It is estimated that an additional $1,000,000.00 will be needed for project expenses, including title and escrow company costs, appraisal and the DGS' review charges, bringing the total allocation needed to complete this project to $140,000,000.00.

The proposed acquisition project is exempt from the California Environmental Quality Act (CEQA) pursuant to Class 13 and 25 categorical exemptions. (California Code of Regulations, Title 14, §15313 and 15325) Class 13 of categorical exemptions consists of acquisitions of land for wildlife conservation purposes. Class 25 of categorical exemptions consists of transfers of land in order to preserve open space, habitat or historical resources. Subject to approval by the Board, the appropriate Notice of Exemption will be filed with the State Clearinghouse. CEQA analysis for restoration will be a component of the restoration planning process.

Mr. Wright reported that the Board received numerous letters of support for this project including letters from Senator John Burton; Zev Yaraslovsky, Third District

Supervisor of Los Angeles County; Larry Myers of the Native American Heritage Commission; the Ballona Valley Preservation League, representing 24 individuals and organizations; and Kathy Knight from the Spirit of the Sage Council. Mr. Wright stated that the Board received a rather lengthy email from Tom Francis raising a number of concerns regarding the acquisition.

Ms. Ruth Lansford, President of Friends of Ballona Wetlands, addressed the Board in support of this project. She stated that Friends of Ballona Wetlands is the longest running organization that has been fighting for over twenty-five years to preserve the wetlands. Ms. Lansford went on to read a prepared statement. (See Attachment A)

Mr. John Tommy Rosas, Vice Chair of the Gabrielino/Tongva Indians of California Tribal Council addressed the Board. He stated that the land of this project is theirs, basically and traditionally, which is all documented. Mr. Rosas stated that he has talked with Mr. Wright who provided Mr. Rosas with requested documents.
Mr. Rosas expressed concern that the Native Americans have lost a lot of land, that a lot of land needs to be saved and expressed support for the preservation of the property. He stated that their main objection and concern to this transaction is the way it was proposed and lack of communication with the Tribal Council. Mr. Rosas stated that the Native Americans are protected under CEQA and the Public Resources Code and that those don't seem to work, adding that another burial site was dug up last week at Playa Vista. Mr. Rosas stated that someone cited the letter from Mr. Larry Myers, but in the second sentence of the letter, referring to both the Playa Vista area and Ahmanson Ranch property, both areas contain extremely sensitive Native American cultural sites. He added that in his review of documents faxed to him, there were only two references to historic or cultural resources, yet there was great detail about other aspects of the project and feels they have been left out of the process. He stated that several archeological sites in the Playa Vista area are eligible for listing on the national register for historic places, which usually triggers a 106 consultation, which has not happened. He stated that the area also contains the Ballona Lagoon archeological district, and that district has been determined to be eligible for the national register and is listed on the State register. He stressed the importance of protecting their burial sites and cultural resources and requested they be more involved in the project and their concerns acknowledged ahead of time, and under those conditions they would then lift their opposition to the project. Mr. Rosas provided written comments for the record. (See Attachment B).

At this time Mr. Flores welcomed Assembly member Patty Berg.

Mr. Wright stated that he and Mr. Rosas talked recently and that the Board received a letter from the Native American Heritage Commission in strong support of the acquisition and identifying the area of Playa Vista in total as having cultural resources on it. Mr. Wright stated he is not personally aware of any specific sites on the property that are part of this acquisition, that the State is aware of three

scattered shell sites, and that there may be other information the State is not aware of but is certainly interested in obtaining. Mr. Wright stated that because this project is an acquisition, it does not cause any physical change to the land or the environment does not trigger the 106 consultation requirements that Mr. Rosas has talked about. He added that as Mr. Donnelly discussed in the presentation, one of the primary goals of the restoration that will be led by the State Coastal Conservancy is to protect cultural resource values that may exist on the property. Mr. Wright agreed with Mr. Rosas before the Board meeting that he would convene a meeting in the near future if it was possible to get all of the parties together with the State Coastal Conservancy and the Department of Fish and Game, who would be managing the property, to meet with Mr. Rosas and hear his concerns more specifically so that when the State Coastal Conservancy begins the restoration planning we have made certain that we have incorporated in the public process the concerns of the Native Americans. Mr. Rosas stated that when there are test digs on the property, the soil is going to be disturbed and that is when there are usually archeological finds. He stated there are archeological sites recorded on this property and a number of others that are not recorded and that is why, when they are consulted, the Council can advise the State of those sites, otherwise the sites are confidential. He again stated that is their issue - it is required that they be consulted.

Mr. Hight agreed with Mr. Wright's statements that the Department of Fish and Game will be happy to work with them in resolving their issues. Mr. Rosas expressed appreciation for the opportunity to further discuss their concerns.

Ms. Leslie Purcell addressed the Board and expressed appreciation to the State, the Trust for Public Land and the many people that have worked on saving the Ballona Wetlands. Ms. Purcell stated she is a member of the Sierra Club and that she has worked with many of the local groups in Los Angeles to try to save the wetlands. She expressed support for the State acquiring the land and considering parts of Area D that are not yet entitled. She stated that she is concerned about the amount of money being spent on this proposal comparing it to the amount of money being spent on the Ahmanson Ranch proposal. Ms. Purcell reported that there are toxic issues that have been skimmed over, old oil field gases and residues in that area, and most of the land west of Lincoln Boulevard is a wetlands area that is not very developable. She commented that she understood the State has an appraisal process but when she looked at the Ahmanson and Grizzly Creek properties, the developer was willing to take a substantially less figure and get a tax benefit, $20 million for Ahmanson and $6,300,000.00 for Grizzly Creek, whereas Playa Vista is only taking $1 million off and still trying to get a tax benefit. Ms. Purcell stated that Playa Vista is also released from a traffic mitigation they were supposed to do which was a bridge and road project that would have cost about $10 million. She stated they were also supposed to do the wetland restoration at the west end of the wetlands, maybe $13 million, at the end of the development process they were required to do that restoration. She stated she has been working with several people to save the Ballona west bluff, located above the freshwater marsh. She reported the bluff is being graded at this time and burials are being uprooted and being taken off the site. Ms. Purcell again expressed concern to please consider the bluff area for acquisition.

Mr. Tom Francis, Executive Director of the Ballona Wetlands Land Trust, stated that since 1994, the sole mission of the organization has been to facilitate the acquisition and preservation of the entire Ballona wetlands ecosystem. He reported that the Trust has several concerns about the way the State is approaching this acquisition, but also has suggestions on how, in the future, the State can do a better job on acquisitions, get more land for the taxpayer and therefore do better for the environment. Mr. Francis stated that the Trust supports acquisition of the Ballona Wetlands in concept, but feels the State should be acquiring the entire ecosystem, not just part of it, adding that there are still 350 acres on the other side of the street that are threatened by development and not part of this proposal. He stated that the Trust urges the Board to postpone this acquisition so that the State has an opportunity to renegotiate it so that the taxpayers get a fair deal and the State do something that truly protects the environment from the threat of development. Mr. Francis commented that this acquisition will likely generate significant interest in reevaluating the State's acquisition policy so that the State can stop competing with itself by overpaying for a small part of land that needs protection while leaving other ecosystems to be paved over due to lack of acquisition funds. He stressed the environmental community and the State need to face the fact that we have a small amount of money relative to the amount of land that needs to be purchased and there is a need to reevaluate how we approach purchases.

Mr. Jim Metropulos, representing the Sierra Club California, addressed the Board and read a prepared statement in support of this proposal. (See Attachment C)

Mr. Rex Frankel, President of the Ballona Ecosystem Education Project, addressed the Board in support of the proposed preservation of this area and expressed concern regarding the purchase price of the property. He stated that the Ballona Ecosystem Education Project is the second oldest group that has been working on the Ballona Wetlands issue and that he has been working since 1985 to save the Ballona Wetlands, uplands and open space around it. Mr. Frankel stated he is also a member of the Executive Committee of the Sierra Club of Los Angeles. He praised Governor Davis for his support of this proposal. Mr. Frankel expressed concern regarding the amount of money the State was paying for this acquisition thereby possibly hindering the State's ability to acquire other properties, including Ballona Bluffs, Palos Verdes Peninsula and Santa Clarita Valley in the Newhall area. Mr. Frankel stated that Ballona Bluffs and the Newhall Ranch area face imminent threat of development while the Ballona properties being considered today face enormous regulatory hurdles to build anything, have no permits and may take many years of litigation. He stated that it will take years for permits to be issued and therefore they are concerned that the purchase price may be excessive for the amount of property being acquired in comparison to the Ahmanson Ranch proposal. Mr. Frankel commented that he felt Playa Vista and their supporters are using the panic of the recall to press Governor Gray Davis into making a bad deal for the taxpayers even if it is good for the environment. Mr. Frankel stated that the Board should reconsider the transaction and urge Playa Vista to accept a fair price and save more land.

Ms. Marsha Hanscom, Executive Director of the Wetlands Action Network, addressed the Board in support of this project. She reported that she also serves on the National Board of Directors of the Sierra Club and wanted to clarify that Mr. Jim Metropulos was the official spokesperson from the Sierra Club regarding this proposal. She reported that their National Board of Directors passed a resolution in support of this acquisition last week at its annual meeting. She stated that Wetlands Action Network is one of the cofounders of the Citizens United coalition to save all of Ballona Wetlands, with 110 groups participating in that coalition. She stated that over the past 30 years, thousands of people have been involved in various ways to protect the Ballona Wetlands. Ms. Hanscom addressed Mr. Frankel's and Mr. Francis' comments regarding issues about entitlements and that the developers could never get permits on this land. She stated that those comments were not entirely accurate and that there are some entitlements on the property from a settlement several years ago and that there is an underlying land use plan where the Coastal Commission would have been required to permit hundreds of houses, a marina and residential units to be built on this land. She added that while there have been some changes in the law or clarifications in the law, there is no question in her mind that after attending many Coastal Commission hearings, the developers would get permits to build something on this land. She stated that development on this land is not acceptable and that it should be protected for the public. She again expressed their support for this proposal and that the management of the property will improve under the Department of Fish and Game and the Trust for Public Land and not stay the same as was mentioned earlier. She stated that they wanted to make sure, before closing escrow, that all of the agreements that are detailed in the purchase agreement are made available to the public; all of the agreements about the parking lots that were originally built for the 1984 Olympics are still there. She commented that today's proposal regarding Grizzly Creek is related to Ballona Wetlands because the Marbled Murrelet, the endangered bird that nests at the top of the redwoods, has actually been seen on several occasions at Marina Del Rey adjacent to the Ballona Wetlands, and that if we restore these wetlands and give the birds more space, we are helping endangered species that travel up and down the Pacific Flyway. She commented that these two acquisitions will be a legacy to Governor Davis and his administration.

Mr. Hight thanked Ms. Hanscom for seeing the connection between the two parcels and that the Department of Fish and Game is very excited about the combination of the two acquisitions.

Ms. Victoria Rome, Policy Analyst with the Natural Resources Defense Council (NRDC), addressed the Board in support of this proposal. On behalf of California's 110,000 members, she asked the Board to approve this proposal. She submitted for the record a copy of a Commentary by Mark Gold and Joel R. Reynolds, Southern California colleagues, which appeared in the Los Angeles Times on July 21, 2003, and provides further detail on all of the reasons why the NRDC supports acquisition of this property and Ahmanson Ranch. (See Attachment D)

Mr. Reed Holderman, Vice President and Regional Director for The Trust for Public Land (TPL), addressed the Board in support of this proposal. Mr. Holderman stated that the TPL is the only national nonprofit land conservation organization dedicated to conserving land for people, no matter where they live. Mr. Holderman stated that

The Trust for Public Land has been in existence for over 30 years and saved over 1.5 million acres in the United States and over 250,000 acres here in California. Mr. Holderman stated that over the past two years his organization has had the pleasure of working with the Board staff, the Department of General Services, Playa Capital and the environmental community to create an opportunity for public purchase of the Ballona Wetlands. This opportunity has been over 20 years in the making, involving studies, land use and public hearings, appraisals and lawsuits. Mr. Holderman stated that the Ballona Wetlands is probably the most analyzed and thought over property in the State and believes that the proposal offers the best chance of saving the portion of Playa Capital's ownership that can be reclaimed and restored as a fully functioning wetland. He added that most groups and elected officials at all levels of government support the Board's acquisition of this property. He stated that the overwhelming support stems from the fact that the Los Angeles area has experienced incredible growth and urbanization without providing the necessary open space and outdoor recreational opportunities to meet the social, recreational and spiritual needs of the community. Mr. Holderman reported that in 1950, the population of New York City was eight million people and Los Angeles County had four million people, and in 2000, New York City still had eight million people, but Los Angeles County had grown to ten million people, an increase of 150 percent. He stated Los Angeles is now known as one of the most "park poor" cities in the United States and the natural areas in Los Angeles are disappearing at an alarming rate. He explained that Southern California has lost all but 10 percent of its historic wetlands and Los Angeles County has been even harder hit with only two to three percent of Los Angeles County's wetlands remaining. He commented that this acquisition is so important to the fragile chain of wetlands dotting California's coast because it will more than double the current wetland supply in Los Angeles by making approximately 500 acres available for wetland restoration. Mr. Holderman stated that the purchase of Ballona Wetlands is arguably the most significant wetland acquisition on the south coast during the last twenty years. He stated this acquisition will also reaffirm a commitment made by Governor Davis to create and expand open space. He reported that the land use plan for the subject properties was approved twice by the City and County of Los Angeles and the California Coastal Commission calls for intensive residential, commercial and visitor serving development on these graded and historic wetlands. The California Coastal Commission signed an agreement a few years ago to expedite project permits and has already approved several infrastructure projects that reference the larger unbuilt development on the subject properties. Mr. Holderman stated that if the Board did not approve today's proposal, Playa Capital will proceed with efforts toward development. He added that The Trust for Public Land enthusiastically supports the recommendation to approve this proposal.

Ms. Susannah Churchill, Preservation Advocate with Environment California, addressed the Board in support of this proposal. She stated that they have been involved in the effort to save Ballona Wetlands since 1996. On behalf of Environment California, she expressed appreciation to the Davis administration, Senator Bowen and Assembly member Nakano for taking action to preserve Ballona Wetlands. She commented that they believe these lands will be valuable as wildlife habitat and as open space in a part of the State where over 95 percent of the wetlands have been destroyed by development. She added that they also believe $140 million is a lot of money, that protecting the land is priceless and urged the Board to approve this proposal. She presented for the record a Position Statement representing over 40 groups and individuals in support of this acquisition. (See Attachment E) Ms. Churchill also submitted for the record a response to the Ballona Land Trust Position Paper outlining why the State is justified in moving forward on this proposal. (See Attachment F)

Dr. James Landry, representing Ballona Wetlands Foundation, expressed support for this proposal and their desire to assist the State, especially through the expertise of their science advisory board in the planning and eventual restoration of the salt marsh. He stated that he also represented Loyola Marymount University and expressed the University's support of the acquisition of this land, both as a neighbor and community member. Dr. Landry stated that for many years they have been involved in a variety of activities in the wetlands, from workshops to research, and will be happy to provide assistance to the State in the restoration of the wetlands. He stated that they viewed the wetlands as a great site and opportunity to help education and train their scientists as well as all of their students about the importance of the wetlands and environment in their lives.

Mr. Flores asked if there were any further comments or questions.

Mr. Hight stated that in 1985 Governor Davis, at that time State Controller, became involved in this project and has been heavily involved ever since with the goal in mind of trying to figure out how to preserve and restore as much of the wetlands as possible. Mr. Hight stated that this area has been appraised and reappraised and that he is exceedingly comfortable with the appraised value and that it is fair, just and equitable. He thanked the local activists who have worked through the years and spent many hours to get to this point.

Mr. Flores requested Mr. Wright address some of the issues regarding toxics, Area D, full disclosure of documents, etc. Mr. Wright discussed the property value and stated that no one wants to pay more for the property than they have to, including the Wildlife Conservation Board. He reported that the State must adhere to strict processes in order to make value determinations. He stated that the Trust for Public Land contracted for an appraisal and once that appraisal was done, the Wildlife Conservation Board contracted with another private contractor, also licensed by the State to review the appraisal. Once the review was done, both documents were given to the Department of General Services, who has authority and the mandate to approve all appraisals for the State before we approve the acquisitions. After consultation with others, Mr. Wright felt it would be appropriate for the State to contract with yet another contractor for another appraisal. Another appraisal was done, the fair market value was determined by that appraiser, which came in $10 million less than the first appraisal that was contracted by The Trust for Public Land. Mr. Wright addressed issues regarding toxics that may or may not exist on the property. He stated that The Trust for Public Land paid for an extensive environmental site assessment done by a contractor, URS, and that report has been made available for public review. Mr. Wright has asked the contractor to update the site assessment for better interpretation of the data contained in the report and may ask URS to do additional sampling. He stated that, from what is known at this time, there is nothing on the property that would cause the Board concern, that we would ask Playa Capital to pay for remediation since everything we know about the property relative to toxics occurred on the property long before their ownership. He stated there are hydrocarbons in the soils because of the approximate 22 old oil wells, most are currently operated by Southern California Gas Company, either as monitoring or as wells, to inject and withdrawn natural gas from the property and they will have continuing responsibilities in that area. Mr. Wright stated there is an issue about an old agricultural dump and sampling in that area. He stated that from what we know about it today, they have not detected any pesticides even though apparently a pesticide was used on the celery grown in the area and fuel oil might have been used as the celery was discarded to reduce the amount of odor. He stated that none of those contaminants were found in the testing and URS is continuing to evaluate whether or not they need to go in and resample those sites. He added that there were also some heavy metals found, and it is believed some of that is a result of dredge spoils on the property. Mr. Wright stated there is also the issue of soil gases, the methane gas, which some believe would preclude Playa Capital from developing the property and ultimately reducing the value of the property. Mr. Wright passed around a map showing soil gases from a survey of the property and he stated most of the soil gases are in Area D, where Playa Capital is presently developing and very little is found or known to exist on the areas that are the subject of this acquisition. Mr. Wright stated that he has spoken to Southern California Gas Company staff because there have been allegations over the years from people that the gas reservoir that exists 6,000 feet under the ground is leaking and there are gases coming to the surface. In addition to the gas company and Playa Capital investigating that, the City of Los Angeles has also investigated the issue and everybody has come to the conclusion that there is no connection between the underground gas reservoir and the soil gases which is natural occurring methane that appears in several areas in Southern California. Mr. Wright pointed out that the worst gas occurrences are in Area D, and both the city and the county have building codes that provide for construction in those areas by the use of mitigation measures such as venting and impervious soil membranes so that they protect people that live in those areas. He stated that both the Board and the appraiser feel that would have no impact on the value. Mr. Wright addressed zoning and planning. He referred to previous testimony by one of the speakers where they stated there are no entitlements on the property and other speakers have said there are.

Mr. Wright reported that one of the issues in the first appraisals was whether or not there was adequate investigation with the permitting authorities about entitlements and the risk that Playa Capital or the landowner was taking in proceeding with building. Mr. Wright stated that the appraiser discovered in his review regarding entitlements, and by speaking with city and county staff, also talking with the Executive Director, Chair and voting members of the Coastal Commission, that in 1984 there was a land use plan that was approved and it has been resubmitted to the Coastal Commission and accepted by the City of Los Angeles and the County of Los Angeles. He stated that everybody recognizes this will be a difficult place to develop. In addition to that, because of legal challenges, there was a settlement agreement in 1994, Friends of Ballona Wetlands vs. the California Coastal Commission, in which there were specific agreements reached about building density, building heights and several other things. Mr. Wright stated that these were all taken into consideration by the appraiser in developing the highest and best use scenario of the properties. Mr. Wright stated the appraiser made certain that the proposed development scenario was also compliant with the Bolsa Chica decision.

Mr. Wright stated that discussions with and correspondence from the City and County indicate that they believe that once the applications are perfected, that permits would be issued within a period of about 18 months. Mr. Wright stated that he talked with the appraiser this morning on the issue of litigation because in a conversation with one of the speakers a couple of days ago they raised the issue of how could one assume the litigation would be resolved in a year to a year and a half, and therefore asked what he took into consideration to come to that conclusion. The appraiser advised him that he recognized this is a difficult property to develop, but no more difficult than Area D, where special construction techniques are being used now by Playa Capital to construct. There was a boat basin proposed in one development scenario and this appraiser took that out. He stated that there was a cluster of wetlands, the appraiser drew a line around those wetlands and put a 100 foot buffer on it and assumed that most of the rest of the property could be developed. The wetlands delineations that have been approved previously totaled approximately 25 acres on Area B residential and on Area A this appraiser set aside a total of about 65 acres, so the appraiser believes he has created plenty of room to protect wetlands, provide buffers and open space that are necessary, and if there is mitigation required as a result of the proposed development scenario that he assessed, it could be done on site. Mr. Wright stated that in the end, the appraiser said that in the event litigation went beyond the estimated period, the profit margin that he built into the appraisal would still take care of the additional litigation time. Mr. Wright explained that, in other words, if someone were to go to Playa Capital today and offer them what the State is proposing to pay and they develop this out to where they have a lot ready to sell on the open market to build, there is a huge profit margin built into the appraisal. Mr. Wright went on to say that the appraiser believes that even though this property is appraised at $140 million, we are dealing with the Los Angeles market and he believes it is a very reasonable value which was approved by the Department of General Services. Mr. Wright acknowledged that when this large amount of money is taken out of a source to purchase and do restoration work, it will have an impact on our ability to purchase other properties in Los Angeles. He stated the funds are coming out of Prop 50 money designated specifically for Los Angeles and Ventura Counties. He stated that another issue that was raised is why we don’t buy other lands that Playa Capital may be proposing to develop or other lands that may be held by other parties. Proposition 50 specifically states that we will only purchase land from willing sellers and buyers. Mr. Wright stated that, as far as he knows, this Board has never tried to force a landowner to sell something they don’t want to sell and that we are in the business to work with willing sellers and we try to negotiate fair deals for the State and the public, and for the landowners as well. Addressing Ms. Hanscom’s question regarding whether or not all of the agreements will be available for the public to view before we close escrow, Mr. Wright stated that once we complete those licenses, which the Department of Fish and Game will be working with Playa Capital and the WCB on, he did not see any reason why we could not make those available to the public.

Mr. Wright stated that it will be important that we have a strong partnership with the Department of Fish and Game, they are going to need a lot of local support and we hope they will continue to be there after we acquire the property. He added that this acquisition presents a tremendous opportunity to save a large open space in Los Angeles and that the planning and management is done so that there is consensus about how we move forward.

Mr. Flores requested clarification regarding full public access. Mr. Wright stated public access would be decided by the planning process. The Department of Fish and Game will have many discussions regarding that aspect and he assured everything possible would be done to make the property available for public access. Mr. Hight stated there are issues regarding safety and the adjacent Ballona canal, but he assured they would work on providing as much public access as possible. Mr. Wright reported that during his site visits to the wetlands, he observed many students in the area, that there is already a lot of environmental education going on in the community and he expects to continue to see that in the future.

Staff recommended that the Board approve the acquisition of Area A, B Residential and Ballona Wetlands Parcel as proposed; allocate $140,000,000.00 from the Water Security, Clean Drinking Water, Coastal and Beach Protection Fund of 2002 (Prop. 50), Section 79572(b) to cover acquisition and project expenses; authorize acceptance of any and all interests in Area C, the freshwater marsh, and the expanded wetland parcel, as appropriate; authorize transfer of the property to the appropriate managing entity as identified at the end of the restoration planning process; authorize staff to enter into appropriate agreements as necessary to accomplish this project; and authorize staff and the Department of Fish and Game to proceed substantially as planned.

It was moved by Mr. Robert Hight that the Board approve the acquisition of Area A, B Residential and Ballona Wetlands Parcel as proposed; allocate $140,000,000.00 from the Water Security, Clean Drinking Water, Coastal and Beach Protection Fund of 2002 (Prop. 50), Section 79572(b) to cover acquisition and project expenses; authorize acceptance of any and all interests in Area C, the freshwater marsh, and the expanded wetland parcel, as appropriate; authorize transfer of the property to the appropriate managing entity as identified at the end of the restoration planning process; authorize staff to enter into appropriate agreements as necessary to accomplish this project; and authorize staff and the Department of Fish and Game to proceed substantially as planned.

Motion carried.

Mr. Wright expressed appreciation to the many people who worked on this project.

3. Ahmanson Ranch, Ventura County $135,000,000.00

Mr. Wright reported that this was a proposal to consider the allocation of a grant to the Santa Monica Mountains Conservancy (SMMC) to assist in the cooperatively funded acquisition of 2,958.76± acres of land for the protection of wildlife habitat and corridors to promote the recovery of rare and sensitive species. Other partners in this project include the State Coastal Conservancy (SCC) and the Mountains Recreation and Conservation Authority (MRCA), a Joint Powers Authority. The property is located on the southern facing slopes of the Simi Hills, at the easternmost edge of Ventura County, just north of Calabasas. Mr. Dave Means described the project and its location.

The SMMC is seeking to acquire the property to expand protection of critical habitat within the Simi Hills and maintain habitat corridors with other adjoining mountain ranges and ecosystems. This includes the protection and restoration of sensitive and declining plant communities, protection of the Malibu Creek watershed (a coastal stream) and to provide accessible open space parkland opportunities for the greater Los Angeles metropolitan area.

The Simi Hills run 16± miles east to west, bounded by the 23 Freeway and Thousand Oaks on the west, the San Fernando Valley on the east, the 101 Freeway to the south and the 118 Freeway to the north. The hills are situated in the middle of a series of mountain ranges running east to west in southern California, containing Mediterranean type ecosystems. To the north are the Santa Susana and Big Mountains. These two ranges essentially merge together to form one range of mountains that extends east to west, 20± miles between Moorpark on the west and Santa Clarita on the east. North of this range are larger national forest areas, including the Los Padres National Forest and the Angeles National Forest, located within the San Gabriel Mountains. Running parallel and south of the Simi Hills are the Santa Monica Mountains, coastal mountains that extend east to west, 40± miles between the Oxnard plain on the east and Hollywood on the west, with southerly slopes extending down to the Pacific Ocean coastline.

The location of the Simi Hills provides critical habitat linkage that allows migration of species back and forth between the coastal ranges, up into the larger national forest areas to the north and east. In 1989 the National Park Service commissioned a study that concluded the existing sub-populations of many of the larger mammals in these coastal ranges were too small to be self-sustaining. The linkages provided by the Simi Hills allow for the migration and replenishment of mammals between the different ranges. Without these linkages, the species, especially in the Santa Monica Range, could become isolated and suffer detrimental effects in terms of health and numbers. Adding to this potential impact is the fact that most of the areas separating the Simi Hills from the other two ranges are already developed and separated by major roads and freeway improvements.

As part of this acquisition the SMMC will also obtain rights to an open space easement encumbering Crummer Canyon that abuts the southeast corner of Ahmanson Ranch and extends approximately one mile south to the 101 Freeway.

Crummer Canyon is one of the only two existing protected habitat corridors remaining between the Simi Hills and the Santa Monica Mountains. Eventually a habitat underpass (tunnel) will need to be constructed under the 101 Freeway in order to link up with the Las Virgenes View park open space, located on the south side of the freeway. From here the open space connects with the Malibu Creek State Park and the Malibu Creek watershed, a protected wildlife corridor that extends out to the Pacific Ocean.

Other public held open space within the Simi Hills includes the Santa Susana Pass Historical Park; the 625 acre Sage Ranch; the 2,566 acre Las Virgenes Canyon open space abutting the eastern boundary of the Ahmanson Ranch; the 300 acre Liberty Canyon North Open Space, that also provides the only other protected corridor link between the Simi Hills and the Santa Monica Mountains; the 1,792 acre Cheeseboro Canyon located west of the Las Virgenes Canyon; and the 2,308 acre Palo Comado Canyon National Park. Located in the western portions of the Simi Hills are a combination of county and MRCA open space areas managed by the Conejo Open Space Conservation Agency, encompassing approximately 15,000 acres.

In addition to protecting critical linkages, Ahmanson Ranch will also expand core habitat areas within the Simi Hills. By abutting and linking with the Las Virgenes Canyon open space, the majority of the Las Virgenes Creek watershed, a major tributary of Malibu Creek, will be protected.

The topography of Ahmanson Ranch ranges from the relatively flat Laskey Mesa, to gentle slopes and rolling hills, to the rugged rock lands at the northern boundary of the property. East Las Virgenes Creek flows east to west through the center of the property connecting to the main fork of the Las Virgenes Creek that makes up the western border of the property.

For most of its history the property has been used as ranch. As a result, there is still an abundance of native habitat and wildlife found on the property. Habitat types include valley oak savannah, coastal sage scrub, chaparral, riparian woodland, California walnut woodland, southern willow riparian vegetation and native bunch grasses and grasslands. Wildlife includes a high level of both common and rare species. Listed species of note include the red-legged frog, San Fernando spineflower and the southwestern willow flycatcher. The population of red-legged frogs found on the property is thought to be one of the last remaining viable populations of the federally listed red-legged frog in Southern California; the extremely rare San Fernando Valley spineflower, discovered in 1999 by consultants on the ranch was thought to be extinct at one time and was last observed in the area in 1929; and the southwestern willow flycatcher observed on the property, is both a State and federally listed bird.

The Ahmanson Ranch is also part of the historical range of the California condor and the southern steelhead. It is hoped that preservation of the property will lead to reestablishment of these species on site. Other sensitive species and wildlife found on the property include the loggerhead shrike, two-striped garter snake, American Badger, southern California rufous-crowned sparrow and the yellow warbler. Fifteen species of raptors have been observed on the ranch, nine of which are considered sensitive by the State. Bats use the property for foraging, including the three sensitive listed species. Large mammals include the mountain lion, mule deer, bobcat, coyote, long-tailed weasel, raccoon and ringtail cat. The ranch also supports a full compliment of reptile, rodent and bird species.

Approval of the Ahmanson Ranch development was conditioned on the transfer to MRCA of approximately 7,316 acres of land offsite and 2,633 acres of what was once the western portion of the ranch for parkland, for a total of 9,949 acres which has been completed.

The property has been appraised and the value has been approved by the Department of General Services (DGS) at $170,000,000.00. The purchase price as negotiated is $150,000,000.00. The WCB will fund $135,000,000.00 toward the purchase price, with the remaining $15,000,000.00 funded by the SCC and the SMMC. The transaction and transfer of the property will involve two purchase agreements. The first is a purchase agreement between the MRCA and the current owners. Immediately after this transaction has been completed, the MRCA will transfer and sell the property to the SMMC. Because the transaction between the SMMC and MRCA requires the Public Works Board (PWB) approval, disbursement of WCB funds will be conditioned on approval by the PWB, scheduled to occur subsequent to WCB approval.

For management purposes, title to the property will be transferred to SMMC. Management objectives include: 1) protection of core habitat and wildlife corridors; 2) protections and restoration of sensitive and declining plant communities; 3) protection of listed and sensitive species; 4) nature education and interpretation uses, including the possible conversion of a residence on the property to a nature interpretation center; 5) protection of coastal stream watershed; and 6) public use for low impact recreation, including hiking, biking and nature-related studies.

The terms and conditions of the proposed grant require the PWB approval, as mentioned above, and provide that staff review and approve all documents pertaining to the Grantee’s acquisition, including any appraisals, preliminary title reports, entitlements on the property, property and tax assessments, agreements for purchase or sale, escrow instructions and the instruments of conveyance prior to disbursement of funds.

The proposed acquisition is exempt from California Environmental Quality Act requirements under Section 15313, Class 13 as the acquisition of land for wildlife conservation purposes and under Section 15325, Class 25 as the transfer of ownership in land to preserve open space, habitat or historical resources. Subject to approval by the Board, the appropriate Notice of Exemption will be filed with the State Clearinghouse.

Mr. Wright reported that the Board received several letters of support from Senator Sheila Kuehl; Assembly member Fran Pavley; Assembly member Hannah-Beth

Jackson; Zev Yaroslavsky, Los Angeles County Third District Supervisor; Frances Alet, President, Malibu Canyon Community Association; David Brown, Conservation Chair, Santa Monica Mountains Sierra Club; Phillip Rundell, UCLA Professor; Eugene Jones, Cal State Fullerton; Richard Ambros, UCLA; Jim Edmonson, Southern California Steelhead Coalition and approximately thirty letters from citizens, one of those letters contained 20 signatures.

Mr. Means reported that Ms. Linda Parks, Ventura County Second District Supervisor, was in the audience, also staff from the Santa Monica Mountains Conservancy, including Executive Director Joe Edmiston, Deputy Director Rorie Skei and Staff Counsel Laurie Collins should there be any questions.

Supervisor Parks addressed the Board and, as a member of the Santa Monica Mountains Conservancy as well as the Ventura County Transportation Commission and the Ventura County Board of Supervisors, expressed appreciation for this acquisition. She stated that from the point of view of the SMMC, she felt this acquisition was a great deal. As a member of the Ventura County Transportation Commission, she stated that this acquisition is less expensive than having to put extra lanes on the 101 Freeway and it will save the commuters of that region. She pointed out that the acquisition of the Ahmanson Ranch is supported by the major and minor environmental organizations such as the Sierra Club, Save Open Space, Rally to Save Ahmanson Ranch, Heal the Bay and others, the legislators who represent the area, the cities of Thousand Oaks, Agoura Hills, Westlake Village, Malibu, Los Angeles, Calabasas, as well as the County of Los Angeles. She commented that we are very fortunate to save a large expanse of open space in the middle of a major metropolitan area and that the voters intended for Prop 50 funds to be spent in this type of acquisition. She also pointed out that the Board members might look back on this vote with pride and that this is one of the most important votes they could make. She again expressed appreciation for the Board’s support.

Mr. Joe Edmiston, Executive Director of the Santa Monica Mountains Conservancy, expressed appreciation to the Board and Executive Director Wright for their work on this project, and stated that final approval for this acquisition lies with the Public Works Board at its regularly scheduled meeting. He stated that the appraisal and agreements have been reviewed by numerous people. Mr. Edmiston commented that it is appropriate that we deal with Prop 50, because the proposition requires the funds to be used in close proximity to urban areas of high resource value. He stated there is no other property, with the exception of Ballona Wetlands, in Los Angeles and Ventura Counties, which better meets the criteria and there are no other willing sellers of as significant a property in Los Angeles and Ventura counties. Therefore, all the criteria are combined in this one property. He stated that the last acquisition approved by the Public Works Board for the Santa Monica Mountains Conservancy was an area in Glendale for $70,000 per acre and stated that the Ahmanson Ranch area is a much higher value community, the market is red hot and that we’re considering about $50,000 per acre for this acquisition.

Mr. Flores requested clarification regarding public access to the project area.

Mr. Edmiston explained that there are two roads that access the property, there is a trailhead at the end of Los Virgenes that serves the current open space that was dedicated that will also serve as the principal trailhead into the property and all they have to do is cut off the no trespassing sign that Ahmanson has on it and the property is open. Mr. Edmiston stated there will have to be a management plan because of the sensitive and endangered species on site, with public input and a ranger will move onto the property to guide the public and make sure there is public access but also public access that also protects the sensitive resources.
Mr. Edmiston stated they are ready to open it to the public because the SMMC already manages the adjacent property.

Mr. Metropulos, representing Sierra Club California, stated the Sierra Club supports the recommendation of staff to approve the purchase of Ahmanson Ranch, which will complete protection of a unique block of core habitat but it will also be an important step in completing a habitat linkage that will connect wildlife populations and protected lands in the Santa Monica Mountains to the south, to wild lands in the Santa Susanna and the San Gabriel Mountains to the north, in addition to a critical part of the upper watershed of Malibu Creek which is one of the largest protected coastal streams south of Big Sur. He stated that Lower Malibu Creek is within Malibu Creek and supports the southernmost run of the endangered southern steelhead and Malibu Laguna at its mouth is the last remaining laguna in Los Angeles. Protection of Ahmanson Ranch will provide watershed protection to these unique wetland and riparian resources downstream.

Ms. Marsha Hanscom, Executive Director of the Wetlands Action Network, addressed the Board and expressed appreciation for those involved in this project. She stated that the headwaters for the Los Angeles River is located on this property, which created the estuary Ballona Creek and Ballona Wetlands. She wanted to honor those activists who have worked hard in promoting this proposal. She also thanked the Governor for recognizing the importance of the linkages in this area.

Ms. Victoria Rhome, representing the Natural Resources Defense Council, addressed the Board and stated they are very concerned about environmental degradation that could occur in this area if Ahmanson Ranch were to be developed and therefore, were in strong support of the proposal.

Mr. Flores requested clarification from Mr. Edmiston regarding plans for environmental education, particularly for children, on the property. Mr. Edmiston explained that Mr. Howard Ahmanson had a beautiful vacation home on this property and that will be turned into an education center. Mr. Edmiston reported that there are plans in the works for a permanent endowment to make sure there is money for children all over Southern California, particularly from the heavily impacted urban core, to visit this property. He stated they have an existing program called The Recreational Transit Program, that brings children from the inner city to all of the parks within the Santa Monica Mountains Conservancy and that will include this property.

Ms. Debra Gravert, representing Assembly member Fran Pavley, read a statement from the Assembly member strongly supporting this project. (See Attachment G)

Mr. John Tommy Rosas stated that the Native American group feels they should have been consulted regarding this project. He stated he is familiar with this land and that the land is shared by the Chumash and their people and that many of the Native American sites on the property are theirs. He stated they have concerns because there was no consultation and they were not involved with the process. At this time he also addressed that Board in support of agenda item 5 regarding Grizzly Creek.

Mr. Jeff Arthur, representing Assembly member Hannah-Beth Jackson, whose district includes parts of Santa Barbara and Ventura counties, read a statement from the Assembly member strongly supporting this acquisition. (See Attachment H)

Staff recommended that the Board approve this project as proposed; allocate $135,000,000.00 from the Water Security, Clean Drinking Water, Coastal and Beach Protection Fund of 2002 [$580,000.00 from Section 79572(a) and $134,420,000.00 from Section 79572(b)] to fund the grant amount; authorize staff to enter into appropriate agreements as necessary to accomplish this project; and authorize staff and the Department of Fish and Game to proceed substantially as planned.

It was moved by Mr. Fred Klass that the Board approve this project as proposed; allocate $135,000,000.00 from the Water Security, Clean Drinking Water, Coastal and Beach Protection Fund of 2002 [$580,000.00 from Section 79572(a) and $134,420,000.00 from Section 79572(b)] to fund the grant amount; authorize staff to enter into appropriate agreements as necessary to accomplish this project; and authorize staff and the Department of Fish and Game to proceed substantially as planned.

Motion carried.

4. Salton Sea Habitat Planning and Restoration Project, Imperial and Riverside Counties — $20,000,135.00

Mr. Wright reported that this proposal was to consider a cooperative project with the Department of Water Resources (DWR) to develop feasibility studies and restoration options for the restoration of the Salton Sea. The sea is located in the southeast corner of California in Riverside and Imperial Counties. Mr. Scott Clemons described the project and its location.

The Salton Sea was created by accident nearly 100 years ago when water diversion dikes inadequately built along the Colorado River collapsed during a flood. For about a year and a half the Colorado River, flooding the channel now occupied by the New River, emptied into the ancient Salton Basin before finally being brought under control and redirected into Imperial Valley irrigation canals or down to the Gulf of Mexico. This accidental flood created what is now California's largest lake, based on surface area.

The Salton Sea is a desert lake with no outlet, with agricultural runoff from diversions from the Colorado River as its primary source of inflow. This runoff has been sufficient to maintain the sea's water level over the years. The sea's salinity has been increasing since its creation, due to concentration of salts through evaporation. Although its present salinity is about 25 percent saltier than ocean water, the sea supports a highly productive fishery and more than 400 species of resident and migratory birds. The endangered desert pupfish is the only native fish species in the sea. Introduced fish species, dominantly tilapia, Gulf croaker, orangemouth corvina and sargo, sustain an important sport fishery and provide the food base for millions of birds. The sea supports many species, including the endangered brown pelican, and significant populations of eared grebes and American white pelicans. There are more than 50 birds listed as special status species (i.e., endangered, threatened, fully protected, or species of concern) at the sea and its environs.

Unless actions are soon taken to control its salinity, the sea will, perhaps within a decade, become too saline to support its present fishery and associated avian populations. With conversion of some 98 percent of California's historical wetlands to other land uses, preservation of this remaining Pacific Flyway habitat area is of major importance. In an effort to determine the best way to restore this valuable resource, the Salton Sea Reclamation Act of 1998 was enacted, which directed the U.S. Department of Interior to complete a feasibility study of sea restoration by 2000 and to report the results to Congress. The federal study indicated that preserving the entire Salton Sea as it now exists (current salinity levels and associated fish and wildlife resources) would be infeasible, due to the sheer volumes of water and salt that would have to be managed to save the whole sea.

Since then, State efforts have focused on evaluating alternatives for sea restoration and preservation not covered in the federal effort – alternatives for restoration and preservation at a smaller scale. Complex negotiations are currently underway associated with the Colorado River Quantification Settlement Agreement (QSA). Parties involved in this effort include Imperial Irrigation District, Coachella Valley Water District, Metropolitan Water District and the San Diego County Water Authority, as well as all interested State and federal agencies, including the Department of Fish and Game, and many non-governmental organizations. The QSA is intended to provide a mechanism for California to manage the reduction from its historical deliveries of Colorado River water to the State's basic interstate apportionment. Agricultural to urban water transfers are part of this approach and, in some instances, would result in reduction of agricultural runoff to the Salton Sea. Reductions in water supplied to the sea would result in an increase in the rate of change of the sea's salinity and could accelerate the habitat degradation of the ecosystem. One of the goals of the QSA is to improve habitat values of the sea. Funding authorized by the Board for this project will not be encumbered until the QSA is signed.

To facilitate progress in the QSA negotiations and to ensure timely preservation of the sea's unique resources, this project will provide feasibility studies to guide the restoration and permanent protection of the wildlife habitat of the Salton Sea. Specifically, the studies will evaluate pilot-scale testing of components of proposed alternatives, and would include such components as embankment design, desalination pre-treatment, aeolian erosion control and wildlife habitat design. The study and the resultant programmatic environmental impact report/statement are to be completed by March 31, 2006. The goal of the State study is to identify an approach that provides the greatest diversity and quantity of fish and wildlife resources consistent with financial feasibility. Once these studies are complete, and the preferred restoration alternatives have been identified and approved, funding available pursuant to pending legislation (including the Salton Sea Restoration Act) and other available State and federal funding will be used to begin implementation of the habitat restoration.

The 2003 Budget Act (Item 3640-301-6031) provides $32,500,000.00 under the Colorado River Acquisition, Protection and Restoration Program. Of this, $10,000,000 as identified in the Act, and an additional $10,000,000 from that same source, shall be made available to the DWR for feasibility studies and related expenses to guide the restoration and permanent protection of wildlife habitat of the Salton Sea and for the reduction of impacts on the sea resulting from water transfers related to the QSA; the treatment, desalination and reuse of a portion of agricultural wastewater and runoff flowing into the sea; the maintenance of stable shorelines for recreational access; and the preparation of an adaptive management process for the long-term conservation of the fish and wildlife species of the sea.

In addition to the costs listed above, an additional $135.00 will be required for Department of General Services' review costs, bringing the allocation necessary for the Board's portion of the project to $20,000,135.00. The Department of Fish Game has reviewed this proposal and recommends it for funding by the Board. These studies will provide the basis for environmental documents that will be prepared for the resultant restoration activities in the sea. The DWR will acquire any necessary permits.

Mr. Hight reported that yesterday the Governor signed three bills authorizing the quantification settlement agreement to go forward and the Salton Sea restoration process to go forward. He stated that the entire process involves transferring water from the Imperial Irrigation District to San Diego and that transfer process will leave the Salton Sea with less water. Through this process, we will have the ability to figure out options to restore the Salton Sea into an exceedingly valuable wildlife area, which was one of the key elements the Governor was concerned about in the entire Colorado River negotiations, that the Salton Sea be dealt with and restored to its greatest capacity. Mr. Hight stated that the agreement also provides $300 million for that restoration and this money will go to the development of alternative plans.

Ms. Marsha Hanscom, representing the Wetlands Action Network, addressed the

Board in support of this project and explained why developing feasibility studies and restoration options are very important and should be considered. Mr. Hight stated that during the planning process the Department of Fish and Game will look at every conceivable option and welcomes their comments.

Mr. Jim Metropulos, representing the Sierra Club, addressed the Board in support of this project. He clarified information in the staff report regarding the creation of the Salton Sea. He pointed out that prior to the event where the dikes collapsed during a flood, which is where the current Salton Sea is now, the Colorado River was not contained by a dam, and water flowed freely through the area and collected in that basin. He also commented that he hoped the feasibility study done by the Bureau of Reclamation would not be a starting point for the feasibility study that the Department of Fish and Game will be doing with the DWR and believes they should start out new and look at various restoration options for the sea. He expressed appreciation to Governor Davis, Director Hight, Secretary Nichols, Richard Katz, Director Hannigan and Deputy Director Michael Spear, Acting Director for the Department of Water Resources, for their efforts in working on the QSA, having the environmental groups involved and getting the legislation signed and passed. He also expressed appreciation to Joe Caves for his efforts with the legislation and looking at ideas for the Salton Sea.

Mr. Joe Caves addressed the Board and on behalf of the National Audubon Society, expressed support for this project stating that this is a critical first step in looking at the Salton Sea and the Colorado River ecological system in a new way. He stated that the Governor's Office and the Administration has provided incredible leadership in putting together this package and urged the Board's support.

Staff recommended that the Board approve this project as proposed; allocate \$20,000,135.00 from the Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002 (Prop. 50), Section 79568; authorize staff to enter into appropriate agreements necessary to accomplish this project; and authorize staff and the Department of Fish and Game to proceed substantially as planned.

It was moved by Mr. Fred Klass that the Board approve this project as proposed; allocate \$20,000,135.00 from the Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002 (Prop. 50), Section 79568; authorize staff to enter into appropriate agreements necessary to accomplish this project; and authorize staff and the Department of Fish and Game to proceed substantially as planned.

Motion carried.

5. Grizzly Creek Forest, Expansion 1, Humboldt County \$18,300,000.00

Mr. Wright reported that this was a proposal to consider the acquisition of 691± acres of land as an expansion of the Grizzly Creek Forest for the protection of old growth redwoods and mixed conifer forest along with portions of the riparian corridors of Grizzly Creek and the Van Duzen River. The property is located within the Van Duzen River drainage, about 20 miles easterly of the City of Fortuna on State Highway 36. The town of Bridgeville is located about 20 miles southeast of the project area. Mr. William Gallup described the project and its location.

Acquisition of the Grizzly Creek Forest began in 1999 pursuant to Assembly Bill 1986 as set forth in Chapter 615 of the Statutes of 1998 of the State of California to purchase designated lands within the Grizzly Creek Marbled Murrelet Conservation Area (MMCA). Consequently, the Wildlife Conservation Board approved the first acquisition in 1999 consisting of approximately 716± acres. The Department of Parks and Recreation (DPR) owns and manages the Grizzly Creek Redwoods State Park located adjacent to the subject property, and if this project is approved, the subject, along with the initial 716± acres, will be transferred to the DPR. The property will be owned and managed by State Parks.

The Department of Fish and Game (DFG) has identified this expansion as being critical to the protection of the old growth coniferous forest which is extremely important for recovery of the marbled murrelet, a federally threatened and State endangered species. The marbled murrelet is a small seabird in the alcid family found along the Pacific Coast from Alaska to California. At sea, it feeds by diving for small fish in near-shore waters, typically within 5 km of the coastline. The marbeled murrelet is unique among seabirds in that it nests up to 40 km inland in old growth coniferous forests. In California, it nests almost exclusively in redwoods greater than 200 years old. The marbeled murrelet is a long-lived slow-reproducing species, laying only one egg per year. Given these demographic characteristics, the vast majority of the population consists of breeding adults, whose survival is critical to sustaining the species.

The marbeled murrelet’s total California population is estimated at 6,450 individuals. The vast majority breed in the coastal redwoods of Del Norte and Humboldt counties. A relatively isolated population of approximately 500 birds breeds in the Santa Cruz Mountains of central California. Acquisition of the subject property will increase the likelihood that this species will survive by maintaining current nesting opportunities that are available within the MMCA.

In addition to providing quality marbled murrelet habitat, the subject property also includes nice stands of riparian habitat along Grizzly Creek and the Van Duzen River and provides habitat for additional listed species including Cooper’s hawk, northern spotted owl, coho salmon, chinook salmon and steelhead trout as well as other animals including deer, black bear, mountain lion and raccoon, just to name a few.

The DFG Office of Spill Prevention and Response (OSPR) and the U.S. Fish and Wildlife Service (USFWS) along with other natural resource trustee agencies have been assessing injuries to natural resources, including those to marbled murrelets as a result of the Kure oil spill in 1997 and the Stuyvesant oil spill in 1999. Pursuant to the federal Oil Pollution Act (OPA), its implementing regulations, and the State Lempert-Keene-Seastrand Oil Spill Prevention and Response Act, the OSPR and the USFWS are authorized to collect damages for the injuries to marbled murrelets and to use that money to develop and implement restoration projects for marbeled murrelets, after public input. One of the preferred marbled murrelet restoration projects under consideration by the OSPR, the USFWS, and the other trustees is the acquisition and protection of the subject property. However, timing is an issue. To date these cases have not been settled, nor is there a judgment to provide the funding for such an acquisition. The DFG has concluded that this parcel has the most significant unprotected habitat available for immediate protection.

Funds earmarked for marbled murrelet habitat acquisition acquired through a settlement or civil judgment can be used to replace and/or supplement funds placed in escrow by the Board to purchase the subject property. The OSPR has advised that any use of such recovered funds would be conditioned upon compliance with the OPA's requirement for "adequate public notice, opportunity for a hearing, and consideration of all public comments," prior to finalizing and implementing a restoration plan.

In addition, any settlement of the trustees' claims for natural resource damages will be set forth in a judicial consent decree, subject to public comment, before the court enters it as a judgment. Furthermore, the National Environmental Policy Act (NEPA) and the California Environmental Policy Act (CEQA) apply to the approval of the Restoration Plan, of which a project(s) to address the MMCA injury would be a component.

This proposed acquisition is exempt from California Environmental Quality Act under Section 15313 Class 13 as the acquisition of land for wildlife conservation purposes and under Section 15325 Class 25 as the transfer of ownership in land to preserve open space, habitat or historical resources. Subject to approval of the Board, the appropriate Notice of Exemption will be filed with the State Clearinghouse.

The Department of General Services (DGS) has reviewed and approved the appraisal of the property at $24,600,000.00. The owner has agreed to sell the property for $18,200,000.00; consequently any value over the approved appraised value will be considered a donation to the State. It is anticipated that an additional $100,000.00 will be needed to cover administrative expenses including appraisal and DGS' review costs, bringing the total proposed allocation for this project to $18,300,000.00. However, as discussed above, the funding the Board may expend on the acquisition may be replaced or supplemented as described above for all or part of its acquisition costs. Any such funds received will be used for future Proposition 40 qualifying projects.

Earlier in the meeting, Mr. John Tommy Rosas expressed his support for this proposal. He stated that the redwoods are getting damaged from logging and that the logging should stop and the land restored.

Mr. Wright reported that he received a note from Assembly member Patty Berg that she regretted she was not able to stay for the remainder of the meeting and that the entire community supports the purchase. Mr. Wright stated that the Board received letters of support from Joe Blum of the National Marine Fisheries Service, the U.S. Fish and Wildlife Service and Kate Anderton of Save the Redwoods League.

Mr. Flores asked if there were any questions or comments. There were none.

Staff recommended that the Board approve this acquisition as proposed; allocate $18,300,000.00 from the California Clean Water, Clean Air, Safe Neighborhood Parks and Coastal Protection Bond Fund (Prop. 40), Section 5096.650, for the acquisition and related expenses; authorize future replacement of funding for this acquisition pursuant to settlement or civil judgment; accept a portion of the approved appraised value as a donation from the landowner; authorize transfer of the Grizzly Creek Forest property to the Department of Parks and Recreation for inclusion into the Grizzly Creek Redwoods State Park; authorize staff to enter into agreements as necessary to carry out this acquisition as described; and authorize staff and the Department of Fish and Game to proceed substantially as planned.

It was moved by Mr. Michael Flores that the Board approve this acquisition of up to 691± acres as proposed; allocate $18,300,000.00 from the California Clean Water, Clean Air, Safe Neighborhood Parks and Coastal Protection Bond Fund (Prop. 40), Section 5096.650, for the acquisition and related expenses; authorize future replacement of funding for this acquisition pursuant to settlement or civil judgment; accept a portion of the approved appraised value as a donation from the landowner; authorize transfer of the Grizzly Creek Forest property to the Department of Parks and Recreation for inclusion into the Grizzly Creek Redwoods State Park; authorize staff to enter into agreements as necessary to carry out this acquisition as described; and authorize staff and the Department of Fish and Game to proceed substantially as planned. Motion carried.

Mr. Wright thanked the many staff who worked very hard to prepare these projects for the Board's consideration. He also thanked Ms. Nancy Templeton, Staff Counsel, Mr. Stanley Young, Communications Director for the Resources Agency and Mr. Paul Mosley, a private attorney that has been counsel to the State and working specifically on the Ballona Wetlands project. Mr. Hight also expressed his appreciation to the staff.

Mr. Flores also thanked the Board staff for their work and to the audience for attending and providing input on the proposed projects.

With no further business to discuss, the meeting adjourned at 12:10 P.M.

Respectfully submitted,

Al Wright

Executive Director

Attachments

PROGRAM STATEMENT

At the close of the meeting on September 30, 2003, the amount allocated to projects since the Wildlife Conservation Board's inception in 1947 totaled $1,537,807,956.30. This total includes funds reimbursed by the Federal Government under the Accelerated Public Works Program completed in 1966, the Land and Water Conservation Fund Program, the Anadromous Fish Act Program, the Sport Fish Restoration Act Program, the Pittman-Robertson Program, and the Estuarine Sanctuary Program.

The statement includes projects completed under the 1964 State Beach, Park, Recreational and Historical Facilities Bond Act, the 1970 Recreation and Fish and Wildlife Enhancement Bond Fund, the Bagley Conservation Fund, the State Beach, Park, Recreational and Historical Facilities Bond Act of 1974, the General Fund, the Energy Resources Fund, the Environmental License Plate Fund, the State, Urban and Coastal Park Bond Act of 1976, the 1984 Parklands Fund, the 1984 Fish and Wildlife Habitat Enhancement Bond Act, the California Wildlife, Coastal and Park Land Conservation Act of 1988, Cigarette and Tobacco Products Surtax Fund of 1988, California Wildlife Protection Act of 1990, the Safe, Clean, Reliable Water Supply Act of 1996, the Natural Resources Infrastructure Fund, the Harbors and Watercraft Revolving Fund, Forest Resources Improvement Fund, the Safe Neighborhood Parks, Clean Water, Clean Air, and Coastal Protection Bond Act of 2000, Safe Drinking Water, Clean Water, Watershed Protection, and Flood Protection Act of 2000, California Clean Water, Clean Air, Safe Neighborhood Parks, and Coastal Protection Fund, Water Security, Clean Drinking Water, Coastal and Beach Protection Fund of 2002 and the Wildlife Restoration Fund. In addition to projects completed with the above funding sources, this statement includes tax credits awarded under the Natural Heritage Preservation Tax Credit Act of 2000. The tax credits are not reflected in the total amount allocated to projects.

A. Fish Hatchery and Stocking Projects		$16,006,219.06
B. Fish Habitat Preservation, Development & Improvement		24,602,180.88
Reservoir Construction or Improvement	$ 5,518,592.00	
Stream Clearance and Improvement	14,788,961.69	
Stream Flow Maintenance Dams	542,719.86

Total Allocated to Projects $1,537,807,956.30

BALLONA WETLANDS OVERVIEW AND SUMMARIES
LOS ANGELES COUNTY

Introduction

The Ballona Wetlands are the last, undeveloped and restorable wetlands of their kind in Los Angeles County. This is of particular importance since some 98% of coastal wetlands in Southern California have been destroyed or degraded. The Ballona Wetlands serve as a last refuge for several species of birds, animals, and plants and is possibly the last remaining area in the county that has the soil characteristics, hydrology, and seed bank that allow for successful wetland restoration.

The 1,087± acres of the original wetlands, once owned by industrialist Howard Hughes and serving as his private airport and birthplace of the famous “Spruce Goose” airplane, is currently owned by Playa Capital Company, LLC (Playa) or its affiliates. Stretching from the San Diego Freeway to the sea, this land has been a source of contention for well over 20 years between the landowners and those concerned about increased congestion and environmental degradation.

In 2001, the Trust for Public Land (TPL) optioned 192± acres of Playa’s property located west of Lincoln Boulevard (138 acres depicted as "Area A" and 54± acres as "Area B Residential"). The project also includes 291± acres shown on the attached map as Ballona Wetlands Parcel, including 83± acres in the Ballona Creek. The total to be conveyed to the State is 483± acres.

The proposed acquisition provides congested Southern California with open space and important habitat for endangered and threatened species including the California brown pelican and Belding's savannah sparrow. The area is also a local nesting site of the great blue heron and habitat for at least ten species of reptile and amphibian species. Acquisition of the property, which the parties currently anticipate will occur 60 days following approval by the Wildlife Conservation Board, will set the stage for a comprehensive five-year restoration planning process led by the State Coastal Conservancy that will actively include members of the public.

Purchase Agreement Summary

The Purchase Agreement calls for Playa Capital Company, LLC (Playa) to convey properties in the City and County of Los Angeles located along the Ballona Creek for $139 million to the State government. The Purchase Agreement between Playa and the State of California specifies which properties are being acquired and includes terms and conditions of the transaction.

The transaction relates to approximately 483 acres of real property and other real property rights located along the Ballona Creek, as shown on the attached map, including:

> ***Areas A and B Residential -*** *Approximately 192 acres of fee property located west of Lincoln Boulevard. Approximately 138 acres of the fee property is labeled on the attached map as Area A and approximately 54 acres of the fee property is labeled on the map as Area B Residential. The entire 192± acres of fee property will be conveyed to the State for the purchase price.*

Ballona Wetlands - *Approximately 291± acres of fee property labeled on the attached map as the Ballona Wetlands Parcel. Of the 291 acres to be conveyed, approximately 83± acres lie within the Ballona Creek and approximately 208± acres lie outside the creek. The Ballona Wetlands Parcel will be conveyed to the State for no payment beyond that paid for Area A and Area B Residential.*

Release of Purchase Rights on Area C - *A release by Playa of all remaining purchase rights it has in the property labeled Area C on the attached map. A trust currently holds Area C approximately 64 acres for benefit of the people of the State. Legislation will formally transfer title of this property to the State.*

Roadway Rights on Area C - *A future release by Playa of an easement it holds on Area C to build a road across Area C to connect Culver Boulevard with Playa Vista Drive across a bridge to be built over the Ballona Creek. Playa is presently obligated to build the road and accompanying bridge in order to alleviate traffic resulting from its present development. Playa is attempting to obtain special relief from this obligation and will release its easement across Area C if, but only if, it obtains such relief prior to September 30, 2005. If Playa obtains relief prior to September 30, 2005, it will relinquish its easement for the road for no payment beyond that paid by the State for Area A and Area B Residential.*

The property is to be conveyed by Playa to the Department of Fish and Game, Wildlife Conservation Board. Fish and Game will be the initial steward of the land.

The $139 million negotiated purchase price is payable at closing, which is scheduled to occur 60 days following approval of the acquisition by the California Wildlife Conservation Board. The Purchase Agreement provides for possible extensions of the closing to December 31, 2003 if necessary to address specified title or survey issues, or to satisfy specified conditions to the close of escrow.

Appraisal:

The State contracted for, and the California Department of General Services approved, an independent appraisal of the portion of the property to be purchased, Area A and Area B Residential. The appraisal was performed by qualified independent appraisers licensed by the State of California, in conformance with the Uniform Standards of Professional Appraisal Practice. The appraisal is further discussed in the Summary of Appraisal, below.

Tax Benefit Sought:

Playa believes the negotiated purchase price for Area A and Area B Residential is below the value of such portions of the property and intends to seek a tax benefit for this conveyance. Playa also intends to seek a tax benefit for the conveyance of the Ballona Wetlands Parcel for no additional consideration. The amount of any charitable gift will be determined by relevant government authorities. The State will acknowledge Playa's intent to make a charitable contribution and accept such gift of the property to the extent the fair market value of all the property conveyed exceeds the purchase price. The State is making no guarantee regarding the tax treatment of the transaction.

Freshwater Marsh:

Although not a part of this transaction, in connection with its development of adjacent property, Playa has created a freshwater marsh located at the Southwest corner of Lincoln and Jefferson Boulevards. The area within which the freshwater marsh has been created is approximately 38 acres and is labeled on the attached map. Playa continues to own the marsh and approximately 22 acres next to the marsh, which additional property is labeled on the attached map as the Expanded Wetlands Parcel. In connection with its previous option to purchase Area C, Playa agreed to convey both the freshwater marsh and the Expanded Wetlands Parcel (approximately 60 acres in the aggregate) to the State of California. This agreement is still in effect even though the option in favor of Playa has expired. If the State elects not to accept the conveyance, then Playa must offer to convey these properties to the City of Los Angeles. It is anticipated that the State will accept the conveyance and that the conveyance will occur in early 2004. After conveyance, Playa must either maintain or provide for maintenance of the freshwater marsh in perpetuity.

Southern California Gas Parcel:

Playa owns fee title to a small property adjacent to the Ballona Wetlands Parcel labeled on the attached map as the Southern California Gas Company parcel. Southern California Gas Company holds a perpetual right to occupy the parcel for purposes of accessing an underground natural gas storage facility, and presently maintains above ground storage tanks and other facilities used to store and distribute natural gas. The rights held by Southern California Gas Company were originally sold *to its predecessors by the U.S. government after World War II when the federal government divested itself of petroleum reserves condemned for use during the war. Southern California Gas Company also holds other easements for oil and gas wells in the area, including easements for gas wells located on the property to be conveyed by Playa to the State. Gas wells are presently used to monitor the underground natural gas storage facility and, in some instances, to pump natural gas into and out of the storage facility.*

The State may not take ownership of the land occupied by Southern California Gas Company in connection with this transaction.

Playa has informed the State that it intends to transfer its fee interest in the Southern California Gas Company parcel to the Southern California Gas Company concurrently with its conveyance to the State of Area A, Area B Residential and the Ballona Wetlands Parcel, so long as negotiations provide for the State's ability to acquire this property at no cost should the Southern California Gas Company ever offer the property for sale. If unsuccessful, the property may be transferred to the State as part of this transaction.

Parties' Obligations and Conditions:

The parties' obligations to close the transaction are subject to conditions, including:

The State must approve title of the property and be reasonably satisfied with matters disclosed by surveys of the property, including environmental surveys, and be satisfied that existing lawsuits and judgments affecting the property do not impose obligations upon the property for which the State will have responsibility following the conveyance.

The State must receive and approve a commitment from the Trust for Public Land, or a similar organization, to provide initial stewardship of the property for a period of up to five years following the conveyance, during long term restoration planning for the property.

Except as specified in the Purchase Agreement, the State is acquiring the property in its current condition.

No Release of Playa's Liability:

The State is not releasing Playa from any liability for the clean up of hazardous materials, if any, required under applicable law. Southern California Gas Company is liable under existing law for contamination on the property, if any, associated with its wells and operations.

Environmental Surveys:

Various environmental surveys of the property, including an environmental site assessment, have been performed to evaluate the suitability of the property for development. An updated environmental site assessment is being performed in accordance with current professional (ASTM) standards, which updated assessment will be available for review and approval by the State prior to the conveyance. The following environmental conditions are known to exist on the property:

Naturally occurring soil gases, including methane, have been detected on the property. Levels of methane detected on the property are generally lower than levels detected on adjacent property where residential development is underway.

Historic oil and natural gas wells exist on the property, including wells that have been abandoned and wells that are presently used by Southern California Gas Company to monitor and operate its underground natural gas storage facility.

Portions of the property have been used in the past as (i) a repository for sludge dredged from the Marina Del Rey harbor, (ii) a landfill for agricultural waste, and (ii) a gun club.

Testing of both soil and groundwater on the property, including testing intended to address the historical uses of the property, has identified localized areas on the property where minor amounts of contaminants are present. The updated environmental assessment will further evaluate the risk associated with the identified contaminants.

Special Tax (Mello-Roos District) Issues:

The portion of the property referred to as Area B Residential is presently located within the boundaries of a Mello-Roos Community Facilities District known as CFD No. 5, which district is under the jurisdiction of the City of Los Angeles. Property located within the boundaries of CFD No. 5 may be assessed a special tax to pay for the construction of streets, sewers and other infrastructure in the district. Playa has represented that all but approximately one-half of one acre of the property to be conveyed to the State is exempt from taxation by the district. The Purchase Agreement requires that Playa provide evidence of the exemption to the State prior to the conveyance. The district has not yet issued any bonds, and no special tax is currently payable. However, Playa has agreed to pay any special tax levied against the property and to cause the property to be removed from the boundaries of the district within five years. If removal is not accomplished within five years, then Playa has committed to provide to the State cash collateral that may be used to pay all future levies, if any, payable by the State with respect to the property.

Existing Rights and Leases:

Various parties have acquired from Playa, and from Playa's predecessors, rights to occupy small portions of the property. The State will take the property subject to these rights, including:

Leases granted by Playa to the County of Los Angeles for parking for the County Sheriff and for the Department of Beaches and Harbors upon a small portion of Area A. These leases may be terminated by the State.

A lease granted by Playa to the County of Los Angeles Flood Control District to access the Ballona Creek from Area A to remove trash and debris. This lease may also be terminated by the State.

A license granted by Playa to a group known as Friends of Ballona Wetlands who perform work to restore sand dunes located in the Ballona Wetlands Parcel. This license is presently being modified by Playa and the Purchase Agreement allows the State to accept or reject the license in its modified form.

A license to the Ballona Wetlands Foundation allowing the Foundation (in association with Loyola Marymount University) to restore habitat and perform other educational functions within a portion of the Ballona Wetlands Parcel. This license is also being modified by Playa and the Purchase Agreement allows the State to accept or reject the license in its modified form.

Licenses granted to several business owners along Culver Boulevard for minor encroachments upon the Ballona Wetlands Parcel. These licenses are all terminable and are subject to review by the State prior to closing.

Easements running in favor of Southern California Gas Company for gas wells to monitor its natural gas storage facility and to inject and remove natural gas from its storage facility.

Easements running in favor of a majority of homeowners located along the Western boundary of the Ballona Wetlands Parcel for small encroachments.

Easements running in favor of Playa for the widening of Culver and Lincoln Boulevards and for the installation of other infrastructure relating to the Playa Vista Development.

Approval by State:

The Purchase Agreement is subject to approval by the California Wildlife Conservation Board, which will be considered at a public meeting, and by the Director of the California Department of General Services following WCB action.

Appraisal Summary

An independent appraisal analysis was performed on Area A and Area B Residential by Members of the Appraisal Institute (MAIs) who are also Certified General Real Estate Appraisers licensed by the State of California. The appraisers certify that they have no financial interest in the property, nor do they have any bias with respect to the parties involved in the transaction. The valuation report and analysis conform to the Uniform

Standards of Professional Appraisal Practice (USPAP), the supplemental requirements and Code of Professional Ethics of the Appraisal Institute, and generally accepted appraisal practice.

The property appraised contains approximately 192 acres (Area A & Area B Residential) and has prior approvals from the California Coastal Commission and local jurisdictions, but the prior plan requires modification and the property requires further significant approvals from each of the jurisdictions including the Coastal Commission before any development could occur. There are also sensitive environmental resources that would limit the development footprint ultimately approved for the property. After thorough interviews and analysis, the appraisers determined that the highest and best use of the property is future development with primarily residential uses, and on-site preservation and enhancement of wetland and buffer areas. About 65 acres of the property was projected to be set aside as open space. Therefore, if the property were developed to its highest and best use, little or no off-site mitigation would be required. Also reflected in the valuation are 3 ½ - 4 ½ years of entitlement and projected litigation delays prior to development.

In preparing the appraisal, the appraisers performed the following tasks:

> The property and surrounding area were inspected several times by the appraisers, including an inspection with the property owners and representatives of the Wildlife Conservation Board on June 10, 2003;
>
> The physical, legal, and economic characteristics of the property were investigated, including review of numerous public and consultant documents.
>
> Representatives of City, County, and State planning and land use departments and commissions were consulted, as were documents including relevant planning and land use regulations and maps. A partial list of individuals interviewed for this appraisal includes members of neighborhood/preservation groups, staff (planning and scientific) of the California Coastal Commission, the Executive Director of the Coastal Commission, the Chair of the Coastal Commission, the Director of the California Department of Fish and Game, Southern California Gas Company representatives, City and County planning officials, property owner representatives and consultants, and attorneys for both the State and property owner;
>
> The relevant regulations relating to wetlands and other environmentally sensitive areas were investigated, particularly in light of the Coastal Commission jurisdiction and Bolsa Chica appellate decision;
>
> Both the ‘sales comparison’ and ‘subdivision development analysis’ approaches were used in valuing the property. These two approaches are commonly relied upon by market participants for a property such as the land in question. There are no other approaches that would be relevant in this case and the two approaches were reconciled into a final conclusion of fair market value for the

entire property;

The Department of General Services (DGS) reviewed the appraisal and concluded that the content, analysis and conclusions stated in the report are in compliance with the applicable (DGS) standards and requirements of the USPAP. DGS also approved the fair market value opinion stated in the appraisal report.

Interim Management

As part of this transaction, the Trust for Public Land (TPL) has agreed to provide initial stewardship of the property consistent with the stewardship Playa has been providing at the Ballona Wetlands for the last decade. This obligation would begin at the close of escrow and last for not more than five years, while long-term restoration planning is underway. The goal of interim management would be to preserve the property in its existing condition. Stewardship activities would include security, maintenance and repair of existing property fencing, weed abatement and trash removal, and invasive non-native species control.

The California Department of Fish and Game will designate a contact person for the property and act as a liaison between TPL and the public.

The State asked TPL to provide interim property stewardship to bridge the gap between the State taking ownership and the completion of the comprehensive long-term restoration planning (summarized below) which the State Coastal Conservancy has agreed to fund and lead. The Conservancy estimates that this planning (including environmental (CEQA) review and permitting) will take approximately five years, a fact that was central to determining the duration of the interim stewardship period. The plan will be the means by which the State determines the final disposition for ownership and management.

Summary of Long-Term Restoration Planning for Ballona Wetlands

The natural resource goals for the long-term restoration planning for the Ballona Wetlands are:

restore tidal circulation to the extent feasible;

provide the range of freshwater, brackish and saltwater wetland habitat that is typically associated with a coastal estuary; and

provide significant new habitat area for a variety of native species of plants and animals, including migratory birds.

Additional long-term restoration planning goals include:

providing for cost-effective flood management;

protecting cultural resources; and

providing appropriate public access, public recreation, educational and interpretive opportunities.

A collaborative planning process will be organized to develop the technical studies necessary to design long-term restoration plans and meet these goals in a timely and cost-effective manner. A project management team will be organized under the leadership of the Southern California Wetlands Recovery Project (SCWRP) and will be composed of seventeen State and federal agencies including the U.S. Fish and Wildlife Service, National Marine Fisheries Service, and the California Coastal Commission. The California Coastal Conservancy will provide the initial funding for this planning initiative.

In order to ensure the development of a scientifically sound and public supported plan, the project team will establish a technical advisory panel and actively engage all stakeholders including regulatory agencies, conservation groups, local governments and regional planning entities such as the Santa Monica Bay Restoration Commission. This substantial new public acquisition will enable all prior planning to be extended and refined, with frequent opportunities for organizations, agencies and individuals to become involved in the planning process. Completion of the initial stage of scientific studies and engineering feasibility analyses is currently anticipated within two to three years.

Information regarding the Ballona Wetlands Restoration project, including meeting notices, technical studies and project updates, will be made available at a future date to the public through the SCRWP website, www.coastalconservancy.ca.gov/scwrp.

Public Availability of Purchase Agreement and Environmental Surveys

Copies of the full Purchase Agreement, and the environmental surveys of the properties proposed to be acquired are available for viewing by the public during regular business hours at the following locations:

1. Wildlife Conservation Board

LIST OF FIGURES

1. INTRODUCTION

In 2004, the State of California took title to 600-acres of the remaining Ballona Wetlands in Los Angeles (Figure 1-1). The property is owned by two state agencies, the Department of Fish and Game (DFG) and the State Lands Commission. The State Coastal Conservancy (Conservancy) has funding for planning and restoring the property. Together, the three agencies are working with stakeholders, scientists and other agencies to develop a plan to restore this extraordinary resource. The Conservancy is providing funds for the planning effort and manages the work plan, budget, and schedule. DFG would be the applicant for any permits needed for the restoration project and the lead agency for purposes of CEQA. A restoration plan would be developed for all of the lands owned by the state. Planning is being conducted within the landscape and watershed context, incorporating adjacent and ecologically related resources.

This document characterizes the differences between five preliminary alternatives for the Ballona Wetlands Restoration Plan developed and refined by the Project Management Team (PMT), with the advice of the Ballona Wetlands Working Group, Science Advisory Committee, Agency Advisory Committee, and the consultant team. The aim is to provide a consistent set of information for each alternative using measures of change developed from the project's Goals and Objectives (Appendix A). These measures of change provide the ability to objectively determine how each alternative moves towards a specific project objective from the existing baseline conditions. The PMT would use this information to screen out infeasible or undesirable alternatives from advancing to the EIS/EIR process.

While the report is structured around five alternatives, they are discussed for each subarea within the Ballona Wetlands when appropriate, allowing the preferred alternative(s) to be developed from a combination of alternatives from different subareas. Area A refers to the portion of the Ballona Wetlands north of Ballona Creek to the west of Lincoln Boulevard. Area B refers to the portion south of Ballona Creek. Area C refers to the area north of Ballona Creek and east of Lincoln Boulevard.

Chapter 2 of the report provides an overview of the five alternatives, highlighting the changes from the existing conditions of the site, as well as the habitat restoration and public access objectives accomplished by each alternative. The alternatives encompass a reasonable range of options for restoring estuarine habitat within each of the different subareas (see Appendix B for habitat descriptions). These options include:

- Enhance existing habitat with minimal grading
- Muted tidal wetland restoration within existing constraints
- Full tidal wetland restoration, supporting all associated habitat types, and requiring significant site alteration

- Full tidal wetland and subtidal habitat restoration, providing a connection between these habitats with the project site, and requiring significant site alteration.
- Realignment of Ballona Creek, allowing interaction between the creek and wetland, and providing much more habitat and functional connectivity; and, requiring significant site alteration.

For each habitat restoration alternative, a public access alternative has been developed which includes trails, gateway entrances, overlooks and pullouts.

Chapter 3 applies information from existing sources, in particular the Existing Conditions Report and hydrodynamic modeling (Appendix C), to compare the potential effects of the restoration alternatives based on the measures of change. The main themes of the feasibility assessment are:

- Habitat Acreages
- Quality of Habitat
- Habitat Connectivity (Regional and Local)
- Biodiversity
- Hydrology (Tidal Circulation and Flood Protection)
- Sediment and Water Quality
- Sustainability
- Public Access, Recreation and Safety
- Phasing and Relative Costs

These themes are based on the goals and objectives for the project. Each theme is discussed in terms of how different site conditions might improve or effect desired characteristics of the theme. The evaluation is summarized in a Chapter 4 which describes the main characteristics of each alternative. The information provided in this section can then be used as an objective basis to determine how each of the alternatives accomplishes these project objectives. A summary is provided that compares the alternatives to each other based on a list of common, favorable characteristics. This summary also describes some of the trade-offs between the different approaches to restoration. A ranking of each alternative on a scale from 1 to 5 is given. These rankings are based on the best judgment of the Project Management Team, with input from the Science and Agency Advisory Committees.

Ballona Wetlands Restoration

Project Area

Proj. # 1793

PWA

2. DESCRIPTION OF ALTERNATIVES

2.1 ALTERNATIVE 1 - ENHANCE EXISTING HABITAT WITH MINIMAL GRADING

Alternative 1 (Figure 2-1) proposes minimal change relative to the existing conditions of the site. As such, this alternative emphasizes enhancement of existing upland habitats, in particular coastal sage scrub (CSS) and native grassland habitats, over creation or restoration of coastal wetland habitats. Alternative 1 would convert an area of freshwater marsh in the southeast portion of Area B to muted tidal marsh by replacing the existing Freshwater marsh culvert with a daylighted tidal channel that connects to Ballona Creek. This would provide one additional source of tidal influence to the project area. Existing tide gates would be modified to increase the muted tidal waters entering the southwest portion of Area B. Alternative 1 proposes little change to existing infrastructure such that the project area would remain fragmented and isolated by roads, Ballona Creek, berms and levees. Existing dune habitat, the constructed freshwater marsh and recreational facilities in Area C would be retained.

Area A would be managed to include seasonal wetland habitat, tidal low marsh and channel, transition zone and enhanced upland. The existing tidal connection to Berth H in Marina del Rey would not be changed.

Area B would remain similar to existing conditions with the following exceptions:

1. A small triangle of land located south of Culver Boulevard and west of proposed muted mid-marsh habitat that is currently mapped as non-tidal salt marsh/brackish marsh would be converted to CSS and transitional habitats.
2. The closing elevation of the tide gates that allow limited tidal influence in this area would be increased to admit lower high tides into the area. This would expand the area of muted tidal marsh.

Area C includes the highest elevations of the project area. Under Alternative 1, little excavation of this area is proposed. Instead, existing recreational facilities would be retained and enhanced CSS and native grassland habitat, and a small treatment wetland would be constructed.

In terms of Public Access (Figure 2-2), Area A would have a loop trail on the existing Gas Company access road, and a larger loop trail would provide access to the seasonal wetland area via a boardwalk. Gateway entrances, overlooks and a formal parking/staging area would be developed. For Area B, public access would include periphery trails, along Cabora Drive, and pedestrian crossings for a fully integrated trail network. Gateway entrances, overlooks and formal parking would be provided. Linkages between the east and west portions of Area B would be provided by two pedestrian crossings on Culver Boulevard. A pedestrian bridge located near the historic rail crossing would link Area B to Area A. Public access features in Area C would include two loop trails originating from the gateway entrances at La Villa Marina and near the Little League fields. A parking area would continue to be located at the Little League fields.

2.2 ALTERNATIVE 2 - A SMALLER AREA TIDAL WETLAND RESTORATION

Alternative 2 (Figure 2-3) includes a departure from existing conditions through excavation of fill to create fully tidal channels, low marsh, and mid-high salt marsh. Alternative 2 would also convert an area of freshwater marsh in the southeast portion of Area B to muted tidal marsh by replacing the existing Freshwater Marsh culvert with a daylighted tidal channel that connects to Ballona Creek. This would provide one additional source of tidal influence to the project area. Existing connections would be modified by adjusting the setting of the existing tide gates to increase the muted tidal waters entering the southwest portion of Area B. The connection under Dock 52 to Marina del Rey would be enhanced, creating a full tidal marsh in Area A. Alternative 2 proposes little change to existing infrastructure such that the project area would remain fragmented and isolated by roads, Ballona Creek, and berms and levees. Existing dune habitat, constructed freshwater marsh and recreational facilities would be retained.

Area A would be modified to include fully tidal channels, low and mid-high marsh, and associated transition zone habitats. This would be accomplished by increasing the tidal connection under Dock 52 to create an open culvert with a cross-sectional area of 100 ft^2. The remainder of Area A would be converted to enhanced CSS and native grassland habitat.

The southeast portion of Area B (Area B southeast) would be modified to include fully tidal channels, low and mid-high marsh, and associated transition zone habitats. In Area B southwest, the degree of tidal influence would be increased through modification of the existing tide gates. A new culvert with a cross-section of 100 ft^2 would provide a new fully tidal connection to Area B southwest. Like Alternative 1, a small triangle of land located south of Culver Boulevard that is currently mapped as non-tidal salt marsh/brackish marsh would be converted to CSS and transition zone habitats

Alternative 2 would create a small, deeper extension of Fiji Ditch in Area C beneath Lincoln Boulevard resulting in an incremental increase in fully tidal channel, low and mid-high marsh habitats and transition zone habitat beyond that proposed in Alternative 1. The recreational facilities, CSS and native grassland habitat would be retained and small areas of seasonal wetland and treatment wetlands created.

In Area A, a loop trail on the existing Gas Company Road, and a perimeter trail, around the new wetlands, connecting the gateway entrance along Fiji Way to the Ballona Creek Bicycle trail along the north levee would be developed (Figure 2-4). Boardwalk spur trails at the Fiji Way and Fisherman’s Village gateway entrances would provide access to overlooks. Public access features in Area B would be similar to Alternative 1. Public access features in Area C would include two loop trails originating from the gateway entrances at La Villa Marina and near the Little League fields. A parking area would continue to be located at the Little League fields. An overlook would be located near the seasonal wetland area.

2.3 ALTERNATIVE 3 - A LARGER AREA TIDAL WETLAND RESTORATION

Alternative 3 (Figure 2-5) would create additional estuarine habitat relative to Alternative 2 resulting in further increases in fully tidal channel, low marsh and mid-high marsh habitats and associated transition zone habitat. Culver Boulevard, Jefferson Boulevard and the Gas Company road in Area B would be improved by raising the roads on levees or piles; these would provide greater hydraulic connectivity through larger culverts or between piles. Portions of the project area would remain fragmented and isolated by Ballona Creek and Jefferson Boulevard. Existing dune habitat, constructed freshwater marsh and recreational facilities would be retained.

Area A would be modified to include fully tidal channels, low marsh and mid-high marsh and associated transition zone habitats. This would be accomplished by increasing the tidal connection under Dock 52 to create an open culvert with a cross-sectional area of 160 ft^2. The remainder of Area A would be converted to enhanced CSS and native grassland habitat.

In Area B, Alternative 3 would increase the degree of tidal influence in the southwest wetland by replacing the SRT with a 100 foot wide breach. The alternative also includes extension of existing fully tidal channels and raising Culver Boulevard on pilings or levees and removal of the berm south of Culver Boulevard. Most available area would be converted to fully tidal habitats and transition zone habitat. The southeast wetland would be connected as in Alternative 2.

Alternative 3 would create a small, deeper extension of Fiji Ditch in Area C and excavation of a small tidal marsh resulting in an incremental increase in fully tidal channel habitat and an increase in transition zone habitat beyond that proposed in Alternative 2. The recreational facilities, CSS and native grassland habitat would be retained and two small areas of seasonal wetland would be created.

Key provisions for public access (Figure 2-6) in Area A are a looping perimeter trail along the banks of the restored wetland. This trail links gateway entrances along Fiji Way to those along the north levee. Gateway entrances would be located at the existing parking area near Fisherman's Village, along Fiji Way, and two along the Ballona Creek Bicycle Path. Boardwalk spur trails at the Fisherman's Village and Fiji Way gateway entrances would provide access to overlooks. These overlooks would provide both an easily accessible viewing point and a key location for interpretive and educational signage. A formal parking/staging area would be developed at the gateway entrance near Fisherman's Village. In Area B, roadside vehicular pullouts would be provided along Culver and Lincoln Boulevards. A link between the east and west portions of Area B would be provided by a pedestrian crossing located on Culver Blvd. A pedestrian bridge located near the historic rail crossing would link Area B to Area A. Formal parking areas would be located at the gateway entrance behind Gordon's Market and along Jefferson Blvd at the Freshwater Marsh. Public access features in Area C would include two loop trails originating from the gateway entrances at La Villa Marina and near the Little League fields. A parking area would continue to be located at the Little League fields. Overlooks would be located at viewing points for the seasonal wetland area near the Little League fields and north of Culver Blvd at the restored estuarine wetland area.

2.4 ALTERNATIVE 4 - A LARGE AREA TIDAL WETLAND RESTORATION WITH SUBTIDAL COMPONENT

Alternative 4 (Figure 2-7) resembles Alternative 3 with the exception of a larger connection with Marina del Rey and creation of shallow subtidal and intertidal habitats in Area A. This increased excavation would create a shallow subtidal basin and increased intertidal mudflats, while shifting the excavation to the northwest edge of Area A would allow for the creation of a more diverse marsh plain. Culver Boulevard and the levee system south of Culver Boulevard would be improved by raising the road on piles or a levee, these would provide greater hydraulic connectivity through larger culverts or between piles. Portions of the project area would remain fragmented and isolated by Ballona Creek and Jefferson Boulevard. Existing dune habitat, constructed freshwater marsh and recreational facilities would be retained.

Area A would be modified to include a shallow subtidal embayment, tidal channels, intertidal mudflat, low salt marsh, mid-high marsh and associated transition zone habitats. This would be accomplished by increasing the tidal connection under Dock 52 to create an open culvert with a cross-sectional area of 500 ft^2. A narrow, linear strip adjacent to Ballona Creek would be converted to enhanced CSS habitat.

In Area A there would be a loop trail on the existing Gas Company Road, and a perimeter trail along the southern edge of the restored estuarine wetland, portions of which would be boardwalk (Figure 2-8). Gateway entrances would be located at the existing parking area near Fisherman's Village and along the Ballona Creek Bicycle Path. The loop and perimeter trails would link the gateway entrance near Fisherman's Village to the Ballona Creek trail located along the north levee and the two gateway entrances along Ballona Creek. Overlooks would be located near the Fisherman's Village gateway entrance and along the perimeter trail. A formal parking/staging area would be developed at the gateway entrance near Fisherman's Village. Public access features in Area B and C would be the same as Alternative 2.

2.5 ALTERNATIVE 5 - A REALIGNMENT OF BALLONA CREEK

Alternative 5 (Figure 2-9) proposes the greatest amount of change to the project area, including the greatest degree of fully tidal wetland creation. The most obvious change would be the removal of the Ballona Creek flood control channel levees and creation of a sinuous natural creek and associated tidal basins through the site. The site would be interconnected across all areas, with shallow subtidal and mudflats grading through all marsh habitats to higher wetland-upland transition habitat. The channel would be free to migrate across the tidal floodplain, limited where necessary by buried rock protection. The existing Ballona Creek channel would be filled where necessary. The intersection of Culver and Jefferson Boulevards would be moved westward, closer to Lincoln. Culver and Lincoln Boulevard would be raised on pilings above the fully tidal marshlands. The gas/oil monitoring facilities in Area A and recreational facilities in Area C would be minimized and converted to fully-tidal channel, low, and. mid-high marsh, transition zone and enhanced CSS. The constructed freshwater marsh and existing dunes would be retained.

Phasing would be an important aspect of this alternative. Phase 1 would lower the levees and surface elevations and excavate the main channel in Area A; Phase 2 would extend the channel into Area B; Phase 3 would extend the channel into Area C following the raising of Lincoln Boulevard.

Areas A, B and C would be modified to include the reengineered fully-tidal Ballona Creek, two shallow tidal ponds, tidal channels, low salt marsh, mid-high marsh and associated transition zone habitats. The northern breakwater of Ballona Creek would be lowered to allow flood flows to spill into Marina Del Rey. Buried rock protection would be provided along the south east edge to prevent the channel meandering too far west. A narrow, linear strip in the north and west portions of the area would be converted to enhanced CSS habitat.

A perimeter trail would be constructed along Fiji Way and gateway entrances located at the existing parking area near Fisherman's Village and along Fiji Way (Figure 2-10). A boardwalk containing an overlook would link the two gateway entrances as well as overlooks located at both gateway entrances. A vehicular pullout would be located along Culver Blvd and would also provide an overlook. Linkages within Area A would be provided through two pedestrian crossings located along Lincoln Blvd. A formal parking/staging area would be developed at the gateway entrance near Fisherman's Village. Area B gateway entrances would be located behind Gordon's Market, along the southern bank of Ballona Creek, along Lincoln Blvd, and along Jefferson Blvd at the entrance to the Freshwater Marsh. Boardwalk spur trails leading to overlooks would be located along the Freshwater Marsh Trail and at a vehicular pullout along Culver Blvd. Overlooks would also be located at the existing Boy Scout Overlook Platform, at the gateway entrance along the south levee, and along the Cabora Drive trail at Pershing Drive. Linkages throughout Area B would be provided by three pedestrian crossings located on Culver Blvd. An upland area along Lincoln Boulevard provides for a possible visitor center location. Formal parking areas would be located at the gateway entrance behind Gordon's Market, at the visitor center, and along Jefferson Blvd at the Freshwater Marsh.

Public access features in Area C would include a perimeter trail from the La Villa Marina gateway entrance to the Lincoln Blvd pedestrian crossing to Area A. Regional trail connectivity would be preserved by connecting the Ballona Creek Bicycle Trail (previously located on the north levee) to a dual pedestrian and bicycle trail along the southern boundary of Area C. This trail would continue both to the north along Lincoln Blvd and to the south along Culver Blvd. Since both roads would be improved within this restoration alternative, improved bicycle lanes would facilitate this regional connectional. A pedestrian bridge would cross Ballona Creek connecting this new trail alignment to the existing Ballona Creek Bicycle Trail. An overlook would be located at the La Villa Marina gateway entrance.

3. MEASURES OF CHANGE

3.1 HABITAT

The Ballona Wetlands historically covered over 2000-acres and likely included a mix of fluvial, tidal, deltaic and dune habitat types. Today this wetland has been reduced to less than 170 acres within the project area and the hydrology of the watershed has been severely altered by extensive development. Remnant areas of the historic wetland complex include Del Rey Lagoon, Ballona Lagoon, Grand Canal, Oxford lagoon, Marina Del Rey, and the Venice Canals. Given the significant alteration, restoring Ballona Wetlands to its historic condition is infeasible; however, the opportunity to recreate a vibrant wetland system would still require consideration of the mix of habitat types that would benefit the ecological functioning.

This section provides a brief description of the different habitat types that would be restored under each of the alternatives (for more detail see Appendix B). A number of broad habitat types are identified in the alternatives: shallow subtidal and open water habitats, intertidal channels and mudflat habitats; low, mid and high marsh and salt pan habitats; wetland-upland transition habitat; brackish marsh; seasonal wetland habitat; freshwater marsh and riparian scrub habitats; and coastal dune, coastal sage scrub and native grassland habitats. Estuarine intertidal wetland habitat includes shallow subtidal, intertidal channels, mudflats, and low, middle and high marsh, salt pan, and transition zone habitats. Each component is necessary to recreate the Ballona Ecosystem and without each component the estuarine wetlands within the system would not function properly. Some components are currently absent from Ballona, and may be important additions in the restoration of Ballona Wetlands.

Tidal Wetlands

Given the estuarine location of the site, the degree of tidal inundation would be a major factor in influencing the habitat type. The period, depth, and frequency of inundation by tidal water are dependent upon the tidal range, density of soil, degree of slope, and ground elevation.

Shallow subtidal habitats include channels, embayments, basins and other features, which at extreme low water do not drain with the outgoing tides. This estuarine water regime results in permanently flooded habitats and permanent open water bodies. These habitats are generally considered truly aquatic systems and are adjacent to and downslope from tidal estuarine wetlands. Estuaries with extensive subtidal habitat areas often support extensive intertidal low marsh and mudflat habitats, providing refugia for fish during low tides, and feeding opportunities for wetland birds.

Intertidal channels and creeks play a critical role in salt marshes as they convey tidal waters and associated nutrients and dissolved gases. They also support a complex assemblage of plants and animals. Estuarine channels and creeks are subjected to a wide variety of environmental conditions. Typically, tidal flushing is greatest at the tidal inlet and decreases with distance from the inlet. This general gradient, in turn influences, water movement, salinity, temperature, nutrients, and dissolved gases. These environmental factors influence the species composition, distribution, and population dynamics of the channel fauna.

Intertidal mudflats are situated low in the intertidal zone, between subtidal open water and vegetated salt marsh (low marsh), at the open water edge and along channel banks. Mudflats are inundated and exposed during most tide cycles. Mudflat habitat support invertebrate population and provides valuable foraging habitat, particularly for shorebirds.

Intertidal salt marsh ranges from low marsh, dominated by California cordgrass (*Spartina foliosa*), to a diverse mosaic of species that comprises the mid-marsh, to very high marsh species that transition to upland. Salt marsh vegetation changes gradually with elevation. Nearly every species has its peak occurrence at its unique elevational band and the vegetation forms a continuum rather than a set of zones. However, the presence of shrub-like succulents at the uppermost elevations and tall cordgrass at the lowest elevations helps to delineate low to high marsh.

Low salt marsh is regularly inundated by tides and is dominated by California cordgrass that forms dense monotypic stands. At its lower elevation, cordgrass intergrades with mudflat habitat; at its upper elevation it intergrades with a mosaic of mid-marsh species. This highly productive species decomposes to form the base of the detrital food chain that supports many lower order estuarine consumers. Many of the animals of the low marsh are adapted to periods of frequent inundation.

Intermediate elevations within the salt marsh are inundated irregularly by tides but at a greater frequency than are higher elevations. As a result, the plant species that inhabit this elevation are adapted to highly saline soil conditions due to long periods of exposure. The animals of the mid-marsh are abundant and diverse. Food is abundant in the form of algae and the epifaunal invertebrates and insects that feed on algae. In addition, when flooded by the tides, fish move into the marsh plain to forage on these abundant invertebrates. Several bird species such as the Beldings' savannah sparrow and light footed clapper rail also forage in this zone.

High marsh habitats are also irregularly to intermittently inundated by tidal water and generally range from saline to hypersaline conditions. The vegetation varies depending on the density of the soil (i.e. ratio of clay to sand), which often is correlated with salinity.

Salt pans form in the high marsh where drainage is poor. These higher elevation areas along the upland edge are only inundated during the highest spring tides and typically have no tidal channels. As a result, ponded areas are formed that become hypersaline as water evaporates, thereby inhibiting vegetation establishment. These salt pans provide habitat diversity and have habitat value for foraging and refugia.

The wetland transitional zone represents that area where the halophytic (salt-tolerant) and hydrophytic salt marsh vegetation overlaps with upland communities. Scrub-shrub plant species of the transition zone overlap with the highest of the salt marsh species. The animals at the higher elevations of the transition zone are primarily terrestrial species. The transitional zone may also include nontidal palustrine habitats both salt influenced and non-saline types. Seeps from perched water tables on deltas and the toe of slopes and along dune transitions often support a variety of palustrine emergent and scrub-shrub types. Seasonal wetlands also occur in this area, especially in low-gradient deltaic deposits and may include salt pans. Transitional zones provide refugia during extreme weather or tides, as well as foraging opportunities. These areas also support a unique set of plant species, which may only occur or coexist in the habitat conditions provided in these transition zones.

Muted tidal habitats are created by the installation of gate structures and flow restrictions, which typically reduce tidal flows and the tide range compared to a fully tidal wetland. Muted tidal wetlands may support subtidal, mudflat, and vegetated wetland habitats. Hydraulic control structures have proven to severely limit fish passage, decrease tidal flushing, and restrict the diversity of habitat of a restored tidal wetland. A muted tidal system typically limits the creation of upper marsh and transitional habitat.

Additional habitats, which either occur on the site or are included in the alternatives consist of, brackish marsh, seasonal wetlands, freshwater and riparian habitat, and upland habitats, including coastal dune, coastal sage scrub and native grassland habitats. Some of these additional habitats are important to the restoration of the tidal wetland system; they may provide buffers from human disturbances, refugia during extreme weather or tides, or complementary habitats. These habitat types may also be significantly impacted in the region due to limited range along the coast.

Brackish conditions, with intermediate salinities, occur where freshwater mixes with seawater. This phenomenon is less frequent in southern California where many estuaries are less influenced by runoff from rainfall than in more northerly latitudes. Local influence from seeps and springs and seasonally impounded stream and river-mouths can produce brackish environments that support emergent vegetation and aquatic bed species.

Non-tidal Wetlands

Seasonal wetlands are non-tidal wetlands and transitional habitats that are flooded to varying degrees by seasonal rainfall and runoff. If there are sufficient salts in the soil, the seasonal wetland may support plant species more typical of coastal salt marsh. If the soils do not contain salts, the seasonal wetlands may support freshwater marsh species and a mixture of weedy opportunists. “Vernal pools” and seasonal saline wetlands in transition zones can occur on alluvial and deltaic deposits adjacent to estuarine habitats and are known to support special-status plants and invertebrate animals. A majority of the existing seasonal wetlands at Ballona occur on saline dredge spoils from the excavation of Marina del Rey. These habitats only support common intertidal plant species in a severely degraded state, and provide little habitat for wildlife. Some of the alternatives include the creation of seasonal wetlands in areas that do not support salt marsh plant species; in these areas freshwater seasonal wetlands may be created that could support vernal pool habitat.

Riparian scrub and woodland occurs in small groves or in riverine corridors that drain into estuaries. As with other riparian habitats, riparian scrub supports a diverse assemblage of wildlife species, especially passerine bird species. Mammal assemblages are similar to those found in freshwater marsh habitats as the two often intergrade. In an undisturbed estuarine system, wouldow scrub habitat would generally occur upstream of tidal influence as wouldows are very sensitive to salt. Like freshwater marsh, this habitat is dependent upon a constant source of freshwater.

Uplands

Most of the peripheral uplands of estuaries have been disturbed in southern California. Historically, upland communities of the systems were likely comprised of coastal dunes, scrub, or grasslands, and woodlands in some cases.

Dune habitat represents a form of transition zone between the land and the sea and includes Coastal Dune Scrub and Dune Herb vegetation. Coastal dune habitats have been largely lost due to development in southern California. Prior to development, plants stabilized the loose sand, and the dunes were thereby anchored. Following human disturbance, many of the native plants were eliminated and exotics, such as sour-fig (*Carporotus edulis*) and sea rocket (*Cakile maritima*) invaded or were planted.

Coastal sage scrub can be described as low, soft to woody shrubs and subshrubs that occur in a variety of situations and are characterized by a variety of dominant plant species. Coastal Sage Scrub is now generally rare along the coast. This vegetation community is typically dominated by coastal sagebrush (*Artemisia californica*) and California buckwheat (*Eriogonum fasciculatum*), together with laurel sumac (*Malosma laurina*), white sage (*Salvia apiana*) and others. Other forms of upland coastal scrub include, for example, Delta Scrub and Baccharis Scrub, which can be transitional to wetland scrub types. A variety of terrestrial animals, including amphibians, reptiles, mammals and birds are supported by coastal scrub habitat.

Native grasslands were a common upland vegetation associated with estuarine ecosystems in southern California. Existing conditions within coastal ecosystems often include extensive areas of non-native annual grassland and forblands generally dominated by introduced species. The function and importance of perennial and annual grasslands, however, are often similar for the support of small mammals and the raptors that prey upon them.

The proposed creation of treatment wetlands provide a means of cleaning contaminated water before it enters the wetlands. Treatment wetlands require periodic maintenance, including harvesting of wetland plants and removal of sediments as they accumulate contaminants. Thus, treatment wetlands are not considered valuable for their structure, but for their function.

3.1.1 Habitat Acreages

Each of the alternatives would make changes to the existing distribution of habitats. In some places there would be enhancement of the existing habitat, either by management or by increasing tidal inundation (for the case of muted tidal areas). In some places, there would also be replacement of existing habitat by a different habitat type, which would generally involve the regrading of the existing ground elevation and introduction of tidal flows.

For each alternative the area for each habitat type was calculated. Where the alternative did not change the existing habitat then that habitat was assumed to remain. Where a muted tidal regime has been proposed, the distribution of low, mid and high marsh has been defined by the specified tidal inundation regime.

Table 3-2 shows the acreage of each habitat type by subarea and alternative. Table 3-3 show the area of habitat type by alternative. Totals are given for estuarine, freshwater/riparian and upland habitats. These show the shift in emphasis from upland and muted tidal habitat, in the existing situation, to increasing proportion of fully tidal estuarine habitat. Alternatives 3, 4 and 5 each create over 450 acres of estuarine habitat. Included in Table 3-3 is the acreage of shallow subtidal habitat adjacent to mudflat habitat for each alternative. As noted earlier, extensive dredging and development along the southern California coastline has reduced the amount of functional subtidal habitat adjacent to mudflats and wetlands. Alternatives 4 and 5 are the only alternatives that create subtidal habitat adjacent to mudflats, each with over 40 acres.

3.1.2 Quality of Habitat

Each of the proposed restoration alternatives implies varied degrees of improvement over the current existing conditions. Alternative 1, for example, proposes minimal grading and creation of wetland habitats; however, it offers enhancement of existing uplands and seasonal wetlands, resulting in an increase in the quality of the existing habitats (CSS and palustrine wetlands on fill). For the purposes of this document, quality of habitat is described based on a variety of factors: the regional “rarity” of each habitat; the characteristics of habitat patches; the connectivity between habitats both within the project site and with adjacent complimentary habitats; the relationship to adjacent developed areas; and the degree of transition from wetland to upland habitats.

3.1.2.1 Regional Rarity

One important factor in prioritizing habitats for restoration is to identify those habitats that are rare in the region. This includes habitat types that have been lost due to development as well as habitats that require a specific combination of natural processes so that they can only be created in a few, specific places. Regional rarity, which may be considered both in terms of local (Santa Monica Bay or Los Angeles County) or regional (Southern California coast) extent of habitats, can be used to aide in this selection.

Estuarine Wetlands

Due to the dredging of wetlands and the expansion of harbors, subtidal habitat is not regionally rare; but it is often severely degraded. Shallow subtidal habitat connected to functioning wetland habitat is rare.

Estuarine wetlands, including vegetated tidal marsh, intertidal channels, mudflats and salt pans, are a regionally rare habitat that can only be restored in very specific locations. The Ballona Wetlands has long been identified as a significant regional opportunity for estuarine wetland restoration. The Southern California Wetlands Recovery Project, identifies tidal wetland restoration as a key priority in their Regional Strategy. The Regional Strategy states tidal wetlands can only be established within a small elevation range and a compatible geologic setting, and the region's rugged topography and extensive development restricts opportunities for restoration of tidal wetlands in Southern California. The project site represents the only opportunity to restore a large tidal wetland in Santa Monica Bay, and fills a large gap in the chain of wetlands along the Southern California coast.

Transitional zones provide a rare habitat due to the unique conditions created as tidal wetlands convert to uplands with increasing elevation. These habitats are regionally rare and have been significantly impacted as tidal wetlands have been lost.

Brackish marsh habitat is found at the transition of freshwater and intertidal marsh. These habitats are regionally rare and have been significantly impacted as tidal wetlands have been lost.

Non-tidal Wetlands

The seasonal wetlands in Ballona are on saline dredge spoils and are not a naturally occurring habitat type. However, seasonal wetlands may be created that could support vernal pool habitat of much more significant value. Vernal pool habitat has been nearly extirpated from Los Angeles County. These unique habitats support plant and wildlife species that rarely occur elsewhere.

Freshwater marsh and riparian scrub/woodland have also been severely degraded throughout southern California. These habitats require a consistent surface or subsurface freshwater input. While there are additional sites in the region to restore riparian and freshwater habitat, few occur in the vicinity of the Ballona Wetlands.

Upland Habitats

Coastal dunes habitats once stretched from Torrance to Santa Monica. Some of the small remaining patches are currently being restored along the south bay. Dune habitats are also rare in the sense that they require sandy substrate and specific physical processes (wind) to be maintained. Given impacts of the development surrounding the project area, there are limited opportunities to restore functioning dune systems and there may be better opportunities for coastal dune restoration adjacent to the coast.

Coastal sage scrub habitat is considered sensitive by the CDFG, but it is much more common in southern California than coastal wetland habitats. The bluffs immediately adjacent to the site and the nearby Baldwin Hills provide significant areas for potential restoration of coastal sage scrub.

Grassland habitats provide essential foraging habitat, and much of this habitat has been lost or severely impacted along the southern California coast. Restoration of upper marsh and transitional zones may provide equivalent foraging opportunities.

3.1.2.2 Habitat Patch Characteristics

The number, size and shape of habitat patches can determine the long-term stability of the created ecosystem. Restoration plans that incorporate numerous, small patches of different habitats are less likely to be self-sustaining in the long term due to edge effects. Edge effects may include colonization by invasive exotic plant species and/or competition with dominant plant species from other nearby created native habitats. Edge effects may also be reduced in habitat patches of similar area with smaller perimeters (edges). Small patches are also more susceptible to disease as fewer individual plants or clones may equate to reduced genetic diversity. Additionally, specialized pollinators may not be supported by small habitat patches. In general, larger more genetically diverse patches are more likely to survive in the long term without active management.

Edge to area ratio and edge to area index for each alternative is presented in Table 3-4. Patches have been defined by combining together all connected estuarine habitats. Edge to area ratio is simply the ratio of perimeter length to habitat patch size. Alternatives with larger patch sizes would have a lower edge to area ratio. Edge to Area Index is the ratio of the shape's edge-to-area ratio compared to the edge-to-area ratio for a circle of the same total area. The lower the index the closer patch shape is to a circle; the shape that maximizes area and minimizes edge length.

3.1.2.3 Connectivity Between Habitat Patches

Habitat connectivity includes the connection between similar habitats, as well as the connection between complementary habitats. The degree of habitat connectivity within each restoration alternative is an important factor to determine the quality of habitat which may result. Connectivity of similar habitats allows for local migration of plant and animal species providing alternative sites for these species when conditions of one site or patch become unsuitable, i.e., during drought. While bird and insect species may be able to migrate across roads and waterways, terrestrial animals, such as reptiles, amphibians and mammals, are prevented or discouraged from by these barriers. Tidal exchange is an important component of connectivity in a wetland system. Tidal exchange provides diurnal replenishment of gases and nutrients; conveys pelagic eggs and larvae of marine organisms, and distributes floating propagules of salt marsh and other plant species. Connectivity of wetland and to transitional or upland habitat is also important to the quality of a restored wetland, allowing migration terrestrial species to migrate to dry areas during high tides. Thus, habitat connectivity can be measured on at least three scales within a restoration project: 1) connectivity of similar habitats within the project area, 2) hydraulic connectivity between wetland/estuarine habitats and the ocean, and 3) connectivity between wetland habitats and the uplands or transition zones.

Roads or levees can affect the connectivity within the project area. They bisect habitat areas, restrict movement of species, increase the area of disturbed habitat and force channels through culverts. Alternatives 1 through 4 contain 3 miles of roads and 3.8 miles of levees, while Alternative 5 has 2.2 miles of roads and no levees within the project area.

3.1.2.4 Relationship to Adjacent Developed Areas

Transition zones affect the species diversity and function of both the intertidal wetland and the adjacent upland. This habitat supports a unique assemblage of both plants and animals that may not exist in either the adjacent upland or wetland. Thus, the inclusion of transitional habitats in restoration projects is highly desirable. Table 1 gives the areas of transitional habitat for each alternative. The approximate slopes for transitional habitats in the alternatives is about 1:50 to 1:100.

In addition to a wetland-upland transition zone, buffer areas are important for various wetland functions, such as area for transgression, sediment filtration or retention, pollution retention, habitat and food web support, and flood protection. These would improve the quality of the wetland habitat.

Typically, southern California wetlands are bounded by homes, roads and levees that create abrupt, narrow transitions from wetland to upland. This adjacency does not allow animal species the refugia needed during some tides and introduces human disturbances to the wetlands. For example, during extreme high tides, species like light-footed clapper rail are subjected to predation by cats as they are forced from their preferred low marsh habitat into adjacent uplands. In some cases, adjacent developed areas provide habitat for desirable species. For example, non-native cedar trees located to the north of the Area A provide nesting habitat for a small colony of great blue herons. These herons may forage in the wetland and upland habitats of Ballona, but it is the adjacent habitat that serves as the rookery.

3.1.3 Connectivity

Connectivity may be measured in terms of geographical position of the restored wetland relative to other similar or complimentary habitats, locally and regionally.

3.1.3.1 Connectivity Within the Greater Ballona Ecosystem

Within the greater Ballona system there exist areas of complimentary habitat. These include Del Rey Lagoon, Grand Canal, El Segundo Dunes, Oxford Lagoon, adjacent bluff areas, nearshore and beach habitat, Ballona Creek and Marina del Rey jetties and breakwater, and the Pacific Ocean. Some of these sites are hydraulically connected and support a limited wetland component; those that are not provide upland habitat primarily for avian and insect species.

Connectivity within the greater Ballona ecosystem can be accomplished, via improved hydraulic connection, for fish and other aquatic species and for wetland and upland plants. This allows exchange of nutrients gases; transportation of eggs, larvae, juveniles and adult aquatic organisms; provides habitat for avian species and a pathway for water-dispersed seed. Connection by air is possible for flying insects and birds, as well as wind-dispersed seeds. The ability to access similar habitats within the greater system provides refugia for animal species during times of environmental instability; provides greater genetic variation and a greater potential foraging area.

3.1.3.2 Regional Connectivity to Other Southern California Wetlands

A further measure of connectivity is the position of the restored wetland to other wetlands in southern California, such as Mugu Lagoon and Upper Newport Bay. Such connectivity applies primarily to avian and fish species. It may also apply to aquatic plankton and nekton and plant propagules, as these are transported tidally. Certain habitats, such as mudflat, may be created in order to facilitate the connectivity between these wetland systems by providing a string of mudflats along the southern Californian coast.

3.1.4 Tables

Table 3-1. Tidal Habitat Types with Elevation Limits and Inundation Regime
(Based upon Ferren et al, 2007)

Habitat Type	Lower	Upper	Lower	Upper
	NAVD ft	NAVD ft	% time tide exceeds	% time tide exceeds

* Edge to Area Index is the ratio of the shape's edge-to-area ratio compared to the edge-to-area ratio for a circle of the same total area.

3.2 BIODIVERSITY

Habitat restoration provides opportunities for the preservation of the region's plant and animal species as well as the opportunity for the recovery of lost or declining biodiversity. The biological communities of coastal southern California have experienced a decline in species richness, or diversity, as a result of loss of over 90% of their wetland habitat following urban and agricultural development. Declining biodiversity includes plant and animal species that are listed as threatened or endangered, many of which are associated with wetland habitats. Restoration of Ballona wetlands offers the opportunity to create refuges for these species and habitats for other species to recover locally and potentially act as a "seed" source for other nearby wetland systems. Because a major goal of this restoration project is to restore estuarine habitats and processes, diversity of species supported by estuarine habitats would be of particular interest. Therefore, for the purpose of this document, biodiversity is discussed in terms of the sustainable richness of representative interdependent native estuarine habitats along with their associated and expected species biodiversity. The diversity of species dependent upon other habitat types (eg. freshwater wetland or coastal dune habitats) included in the alternatives is also noted.

The five restoration alternatives for Ballona range from preservation and enhancement of large areas of upland habitat with limited wetland habitat to restoration and creation of large areas of wetlands with less upland habitat. Upland-dominated restoration should increase the biodiversity of the existing upland habitats. This would primarily benefit woody vascular plants and associated animals at the expense of opportunities to increase diversity of wetland plant and animal groups. Wetland-dominated restoration would benefit non-vascular aquatic plants, vascular plants, aquatic invertebrates, aquatic vertebrates, terrestrial invertebrates and terrestrial vertebrates.

Biodiversity is discussed at the level of large taxonomic groups. Some specific examples are given; however, not all species that may be supported by each of the restoration alternatives are discussed. For the purposes of this document, taxonomic groups are defined as vascular and nonvascular plants; terrestrial invertebrates (insects); terrestrial vertebrates (birds, herpetofuana, mammals); aquatic invertebrates (infauna and epifauna); and aquatic vertebrates (fish).

Estuarine Wetlands

Maximizing shallow subtidal habitat would benefit the biodiversity of the system especially for birds and fishes. Non-vascular plants (e.g., phytoplankton) would presumably be most functional in the upper water column where light penetration is greatest and thus would not necessarily benefit from deeper water. Similarly, vascular plants, insects, benthic invertebrates, herpetofuana and small mammals would not directly benefit from deeper salt water.

Fishes, primarily those associated with the nearshore ocean habitat, would be supported by deeper waters with a connection to the open coast. Such species as Queenfish (*Seriphus politus*), white croaker (*Genyonemus lineatus*), northen anchovy (*Engraulis mordax*) that inhabit the mid- to upper water column would increase the biodiversity of the system as would demersal species such as California halibut and shovel-nose guitarfish (*Rhinobatos productus*).

Gulls and terns, including California least tern and such species as double-crested cormorant (*Phalacrocorax auritus*) and brown pelican (*Pelicanus occidentalis*) would be supported by increased fish diversity and abundance. Osprey (*Pandion haliaetus*) may also forage for fish in the subtidal areas.

As more tidal wetland habitat is included in an alternative, additional taxonomic groups are supported. Creation of channel, low and mid-high marsh would support non-vascular aquatic plants, vascular plants, aquatic invertebrates, aquatic vertebrates, terrestrial invertebrates and terrestrial vertebrates.

Non-vascular plants include phytoplankton, micro-algae, and macro-algae, that are found in the channels and marsh habitats. Salt marsh micro-algae are dominated by diatoms. Macro-algae include green algae and blue-green algae. Tidal influence, light penetration and nutrients are factors that can limit salt marsh algal populations.

Vascular plants that inhabit a typical Southern California tidal salt marsh include the perennials Pacific cordgrass (*Spartina foliosa*), common pickleweed (*Sarcocornia pacifica*) and fleshy jaumea (*Jaumea carnosa*), as well as annual pickleweed (*Salicornia bigelovii*). They occur in narrow elevation zones determined by the frequency of tidal inundation, salinity, duration of saturated soil, and temperature. These plants, along with non-vascular algae, contribute to the complex food web that supports the high productivity of coastal wetlands. The detritus of vascular and non-vascular plants provides food for aquatic invertebrates, including both infauna (organisms that live within the sediment) and epifauna (those that live on the surface of the sediment).

Common infauna associated with mud or sand bottoms of channel and low marsh habitats include polychaete worms and filter-feeding bivalves, such as California jackknife clam (*Tagelus californica*), littleneck clam (*Prototheca staminea*) and bent-nose clam (*Macoma nasuta*). Common epifuana of channels include detritivores, such as California horn snail (*Cerethidia californica*), bubble snail (*Bulla gouldiana*), and *Nassarius* sp., and omnivores such as lined shore crab (*Pachygrapsus crassipes*) and yellow shore crab (*Hemigrapsus oregonensis*).

Restoring intertidal mudflat area would increase the biodiversity of benthic infauna, including polychaetes, which in turn would support a higher diversity of wading birds. Perhaps the most conspicuous animals of the intertidal mudflats are the shorebirds that feed and rest there during low tide. Many of their invertebrate prey items are widely distributed, from the subtidal channels to the lower limit of the salt marsh. Wading shorebirds, such as western sandpiper (*Calidris mauri*), semipalmated sandpiper (*C. pusilla*) and dowitchers (*Limnodromus* spp.) would be expected to forage on the mudflats during their migration.

Cordgrass associated with low marsh habitat provides structure, and possibly food, for insect species, such as the larvae of *Incertella* and *Cricotopus* species, the beetle *Coleomegilla fuscilabris* and the plant hopper (*Prokelesia* sp.). The longjaw mudsucker (*Gillichthys mirabilis*) forages in the low and mid-high marsh, especially along creek banks during high tides. Mid-high marsh habitat provides food and structure for California horn snails, amphipods, and snails of the genus *Assiminea*. Water boatmen (*Trichocorixia* spp.) feed on algae in pools and in turn provide food for California killifish (*Fundulus parvipinnis*) that feed in the marsh during high tides

The wetland-dominated restoration alternatives would create/restore large blocks of habitat that would be connected via channels and tidal flows. These large blocks of habitat would be more sustainable in the long-term as they would be less susceptible to edge effects of invasive species. They would also be less susceptible to human disturbance, as many areas would be inaccessible.

Creation of channels and mudflats provides habitat for breeding and foraging for estuarine fishes. Some, such as gobies (Gobiidae), complete their life cycle in southern California estuaries, attaching their eggs to the burrows of commensal invertebrates. Other common wetland fish species, such as topsmelt (*Atherinops affinis*), attach their eggs to filamentous algal mats that also shelter their larvae and post-larvae. Species such as California halibut spawn offshore but spend the first few years of life in protected coastal waters. Still others, such as striped mullet (*Mugil cephalus*) live their lives in protected inshore habitat but spawn offshore. In general, the channels and low marsh habitats of southern California coastal wetlands act as nursery grounds for coastal fisheries.

Larger aquatic benthic invertebrates, such as snails and crabs, as well as fish, are preyed upon by a number of bird groups, including herons and egrets, wading birds and terns and gulls. Southern California coastal wetlands support dozens of species and many thousands of individual birds that migrate along the Pacific flyway. Herons, egrets, gulls, terns, shorebirds, ducks, geese, coots, gallinules and rails occur in southern California wetlands throughout most of the year. Most of these birds appear to prefer intertidal flats to salt marsh habitats for foraging and other activities. However, marsh habitats contribute to the support of birds by: providing food (either directly or indirectly), cover from predators, and structure for nesting and roosting. Birds of the low marsh include rails, such as Virginia rail (*Rallus limicola*), sora (*Porzana carolina*), and the endangered light-footed clapper rail (*Rallus longirostris levipes*).

Common bird species of the mid-high marsh include wading species such as willet (*Catoptrophorus semipalmatus*), marbled godwit (*Limosa fedoa*), long-billed curlew (*Numenius americanus*) and great blue heron (*Ardea herodias*). These species prey upon fishes and aquatic invertebrates and, in the case of herons, upland terrestrial animals such as small mammals and herpetofauna.

Terns and gulls observed in southern California coastal wetlands occur primarily in intertidal flats and on the adjacent beaches; however, some taxa do utilize salt marsh habitats. Western gull (*Larus occidentalis*) and ring-billed gull (*Larus delawarensis*) forage and roost in intertidal salt marsh habitats while the endangered California least tern (*Sterna antillarum browni*) forages in intertidal channels. Forster's tern (*Sterna forsteri*) and elegant tern (*S. elegans*) can use a variety of wetland habitats, including salt marsh. Most of the bird groups, with exception of a few small species, forage and roost in southern California wetlands but breed elsewhere.

The mid-high marsh provides structure for some nesting birds, including the state endangered Belding's Savannah sparrow (*Passerculus sandwichensis beldingi*). This small songbird builds its nest low to the ground under marsh vegetation, such as pickleweed. Belding's Savannah sparrows forage on insects, often at the interface of marsh and channel.

Small mammals associated with southern California tidal wetlands include the western salt marsh harvest mouse (*Reithrodontomys megalotis limicola*) and meadow mouse (*Microtus californicus stephensi*). Harvest mice are granivorous, while meadow mice are primarily herbivorous. While little is known about their diets, neither feeds on pickleweed, the most common vascular plant species at Ballona.

Both upland-dominated and intermediate tidal restoration alternatives preserve areas that are currently muted-tidal wetlands. Muted-tidal wetlands provide functions similar to fully-tidal wetlands, but reduced in terms of biodiversity. For example, muted tidal channels may have similar species composition and densities of phytoplankton and benthic micro-algae but may support fewer salt marsh vascular plant species than do fully tidal channels. Similarly, fewer fish species might occur in muted tidal systems. With less tidal influence, muted tidal areas would be susceptible to periodic fresh water inflows. Conversely, during neap tides, muted tidal systems may be subjected to prolonged drying and increased salinity, unless they impounded water continuously, in which case, they would not support vascular plants. Thus, muted tidal systems are likely to be less sustainable than fully tidal systems.

Creation of wetland habitats allows for creation of transitional habitats, which would increase the regional diversity of vascular plants and terrestrial vertebrates. Examples of transition zone vascular plants include boxthorn *(Lycium californicum)*, bush seepweed *(Suaeda nigra)*, coast golden bush (*Isocoma menziesii*), and Parish's glasswort (*Arthrocnemum subterminale*). These overlap with the highest elevation salt marsh species including, for example, saltgrass, alkali weed *(Cressa truxillensis)*, and shoregrass *(Monanthochloe littoralis)*. Boxthorn is a common perch for birds and various small mammals and herpetofauna burrow beneath it or use it for shade.

The transition zone of southern California wetlands, such as Carpenteria salt marsh, have a euryhaline zone that fluctuates between wet season low salinities and dry season hypersaline conditions. The habitat is characterized by winter annual plant species such as salt marsh daisy (*Lasthenia glabrata* ssp. *coulteri*), salt marsh sand-spurry (*Spergularia marina*), toad rush (*Juncus bufonius*), and hutchinsia (*Hutchinsia procumbens*), which tolerate the fluctuating salinities by growing in the wet season.

The animals of the higher elevations of the transition zone are primarily terrestrial species. These include various snakes, lizards, small mammals and birds. Herpetofauna may include California kingsnake *(Lampropeltis getulus californiae)*, San Diego gopher snake *(Pituophus melanoleucus annectens)* and side-blotched lizard *(Uta stansburiana)*. Common mammals of the shrub-dominated transition zone include western harvest mouse, deer mouse *(Peromyscus maniculatus)*, pocket gopher (*Thomomys* sp.), and California ground squirrel *(Spermophilus beechyi)*. The small mammals are preyed upon by a variety of birds including northern harrier *(Circus cyaneus)* and white-tailed kite *(Elaneus caeruleus)*. Ground-nesting bees that pollinate salt marsh bird's-beak (*Cordylanthus maritimus* spp. *maritimus*) live above the high tide in this habitat.

Non-tidal Wetlands

It is anticipated that brackish marsh would develop in areas where fresh water marsh and salt marsh intergrade. This habitat supports many of the taxa associated with both of those habitats, although species that cannot tolerate either extreme are likely to be absent. Brackish water marsh habitat has a range of conditions from briefly fresh to briefly hypersaline and would provide a small increase in the biodiversity of the wetlands. For example, *Juncus acutus* is regionally rare and can thrive where soil is at least briefly brackish; tall tules can provide critical cover for rails during high tide.

Seasonal wetlands would support regional biodiversity of non-vascular and vascular plant species, herpetofauna, birds and small mammals. However, much of the existing seasonal wetlands are on saline fill soils that would not support biodiversity. Vascular plants that might be supported include common pickleweed (*Sarcocornia pacifica* = *Salicornia virginica*), alkali weed (*Cressa truxellensis*), and alkali heath (*Frankenia salina*). Smaller areas of freshwater seasonal wetlands would provide breeding grounds for toad and frog species, such as Pacific chorus frog (*Pseudacris regilla*) and California tree frog (*Hyla cadaverina*). Ponded water provides nesting and foraging habitat for American avocet (*Recurvirostra americana*), black-necked stilt (*Himantopus mexicanus*) and killdeer. Small mammals common to upland habitats could also use seasonal wetlands.

Creation of vernal pool habitat has been proposed as part of upland-dominated restoration schemes. Vernal pools are regionally rare habitats, and adding water-holding depressions would increase the biodiversity of the Ballona ecosystem. Vernal pools are formed over impervious substrates, such as a soil with a subsurface clay layer that impounds seasonal rainfall. Such topography and soils are lacking from Ballona upland areas. Creation of vernal pools would benefit primarily non-vascular and vascular plants, aquatic invertebrates, and herpetofauna, although small mammals and birds may also benefit. Non-vascular species that inhabit vernal pools include diverse phytoplankton, green and blue-green micro-algae, and occasional macro-algae. These are food sources for a number of invertebrates, including fairy shrimp (*Branchinecta* spp.), several species of which are listed as endangered. Many of the vascular plants associated with vernal pools are unique in their adaptations to water levels that fluctuate widely over short periods of time. These range from fairly common species, such as isoetes (*Isoetes* spp.) to the endangered San Diego mesa mint (*Pogogyne abramsii*). Herpetofauna, such as discussed above, would benefit from vernal pools, although survival through metamorphosis depends on the amount of rainfall and the duration of impoundment.

Created vernal pools, especially those requiring importation of clay to line the pools so they would hold water for the appropriate duration, would not only be difficult build but subject to invasion by unwanted species once wetted. Imported soils often contain plant propagules, such as non-native grasses, that could invade the proposed restoration. Furthermore, small vernal pools would be subject to edge effects. Pools that dry early in the growing season of vernal pool vascular plants would be subject to invasion by non-desirable species, such as non-native grasses.

Fresh water marsh and riparian habitats would, in some way, provide support to all of the taxonomic groups. Detritus from vascular plants, such as cattail (*Typha* spp.) and bulrushes (*Scirpus* spp.), and a variety of non-vascular algae would provide food for aquatic invertebrates, including gastropods, copepods, amphipods and decapods, and insects, such as beetles (Coleoptera), flies (Diptera) and true bugs (Hemiptera). These taxa provide food for passerine birds, such as blackbirds (*Agelaius* spp.), wrens (*Cistothorus* spp.), rails (*Rallus* ssp.) and waterfowl; fishes, primarily non-native species; herpetofauna, including Pacific chorus frog and California tree frog, and snakes, such as two-striped garter snake (*Thamnophis couchi hammondi*); and small mammals. Larger mammals, such as raccoon (*Procyon lotor*), may forage directly on invertebrates and fish.

Treatment wetlands could support similar species as fresh water marsh habitat. However, these areas would require active management and removal of sediments, contaminants, and invasive plants, all of which would limit their value for biodiversity support.

Upland Habitats

Existing disturbed uplands would be preserved and their biota enhanced through the removal of exotic plant species and planting of native coastal sage scrub and native grassland species. Coastal sage scrub habitat (CSS) would be enhanced through planting of species such as coastal sagebrush (*Artemisia californica*), California buckwheat (*Eriogonum fasciculatum*), deerweed (*Lotus scoparius*), sage species (*Salvia* spp.) and lemonadeberry (*Rhus integrifolia*). Planting of these vascular plant species would, in turn, provide nesting and foraging habitat for a number of migratory and non-migratory terrestrial passerine bird species, including the federally-listed threatened coastal California gnatcatcher (*Pilioptila californica californica*), towhees (*Pipilo* spp), wrens (*Troglodytes* spp.), and finches (*Cardeulis* spp.). Many of these passerine birds rely on insects and seeds for food. CSS enhanced by more diverse flowering plants would support insects that provide forage for the above birds. Enhanced CSS would also support insect pollinators, including bees and flies. The diversity of other insects, such as butterflies and moths, would be enhanced by providing plant species that serve as larval foods and adult nectaring plants.

Native grassland habitat would be created from disturbed upland habitat through the removal of exotics and planting with a variety of native grasses and annual forbs. Examples include purple needlegrass (*Nassela pulchra*), nodding needlegrass (*N. cernua*), bluegrass (native *Poa* spp.) goldenstar (*Bloomeria* spp.), brodiaea (*Brodiaea* spp.), clarkia (*Clarki*a spp.) and valley tassels (*Castilleja attenuata*). Populations of these vascular plant species would enhance nesting and foraging habitat for passerine birds such as western meadowlark (*Sternella neglecta*) and grasshopper sparrow (*Ammodramus savannarum*), and also wading birds such as killdeer (*Charadrius vociferous*) and owls, including burrowing owl (*Athene cunicularia*). Grasslands are important foraging grounds for raptors including red-tailed hawk (*Buteo jamaicensis*) and white-tailed kite (*Elanus leucurus*). Like coastal sage scrub, this upland habitat would increase the diversity of flowering plants which, in turn, would support a variety of insects.

A number amphibians and reptiles occur in upland habitats, including Gilbert's skink (*Eumeces gilberti rubricaudatus*), western toad (*Bufo boreas*), spadefoot toad (*Scaphiphus hammnodi*), western fence lizard (*Sceloporus occidentalis*), side-blotch lizard (*Uta stansburiana*), rosy boa (*Charina trivirgata roseofusca*), gopher snake (*Pituophis catinefer*), horned lizard (*Phrynosoma coronatum*) and various species of rattle snake (*Crotalus* sp.). Enhancement of the existing habitat would increase foraging and breeding habitat for these and other herpetofauna.

Upland habitats also support numerous small mammals. Examples include shrews (*Sorex* sp.), deer mice (*Peromyscus* spp.), voles (*Microtus* sp.), rabbits (*Sylvilagus* spp.), and skunks (*Mephitis mephitis*). These small mammals are preyed upon by larger upland mammals, such as coyote (*Canis latrans*) and grey fox (*Urocyon* sp.), and birds of prey, such as red-tailed hawk and northern harrier (*Circus cyaneus*).

The existing disturbed upland habitats at Ballona are dominated by non-native vascular plant species, such as crown daisy (*Chrysanthemum coronarium*), mustard (*Brassic*a spp.), wild radish, fennel, castor bean, pampas grass and brazillan pepper tree. Seeds of many of these and other invasive plants are wind dispersed and off-site sources are numerous. Non-native animal species, such as Virginia opossum (*Didelphis virginianus*) and house mouse (*Mus mus*) are also common. Non-native animals that are adapted to humans are also likely to disperse into created upland habitats, competing for food with native species. Additionally, upland predators, including red fox and feral cats, can significantly affect birds nesting in the wetland as well as small mammals. Because restored upland habitats are highly susceptible to invasion by non-native plants and animals, their sustainability is constrained by the urban landscape.

All alternatives include the preservation and enhancement of coastal dune habitat at Ballona. Similar to CSS and native grassland, coastal dunes would support flowering vascular plants, such as lupines (*Lupinus* sp.), which would support and benefit from insect pollinators and provide larval and adult food sources. Coastal dune habitats provide habitat for reptiles, including horned lizard (*Phrynosoma* spp.) and California silvery legless lizard (*Anniella pulchra pulchra*). Passerine birds and small mammals could forage on seeds produced by vascular plants.

3.3 HYDROLOGY

The hydrology of each of the alternatives would have a significant impact on the functioning of the habitats. The depth and period of tidal inundations is a major influence on the type of habitats that would each alternative would support. The flow of water would erode, deposit and transport sediment. The period of time water stays on the wetlands and the amount it mixes with water from other water bodies would affect water quality. The hydrology of each alternative also affects the flood protection for existing infrastructure surrounding the wetlands. Hydrology is one of the main processes that link both the different project areas with each other and with Ballona Creek and Marina del Rey. The hydrology of the site would be sensitive to climate change and sea level rise in particular; the sustainability of the alternatives is discussed in Section 3.5.

Each restoration alternative proposed for the project has varying degrees of tidal inundation in terms of area and tidal range. Alternative 1 has minimal grading and most of the tidally inundated areas have a muted tidal range in portions of Area B. Alternative 2 and 3, by contrast, have fully tidal wetlands covering significant portions of Areas A and B. Alternative 4 has a large subtidal component connected to Marina del Rey. Alternative 5 has the greatest hydraulic connectivity with the main channel and between the restoration areas, due to the removal of levees. The degree of tidal inundation has a fundamental impact on the vertical and horizontal distribution of habitat types that would be supported.

The degree of tidal inundation inside the wetlands would also change the way the wetlands interact with Ballona Creek and Marina Del Rey. Larger, fully tidal wetlands would have larger tidal prisms which would have a greater impact on the surrounding water bodies, in particular on the amount of mixing. The location of the tidal connections is also important; a location inside Basin H, with its smaller tidal prism, would have a greater local effect on mixing than one connected to the main channel of Marina del Rey, which has a very large tidal prism.

3.3.1 Muted Tidal System versus Full Tidal System

A fully tidal wetland at Ballona would experience a tidal range equivalent to the oceanic tide in Santa Monica Bay. Mean Lower Low Water (MLLW, the long term average of the lowest tide each day) is -0.21 ft NAVD, Mean Higher High Water (MHHW, the long term average of the highest tide each day) is 5.29 ft NAVD and the diurnal tidal range (MHHW-MLLW) is 5.49 feet. The land area between the upper and lower limits of tidal range is the total area of intertidal habitat.

A muted tidal wetland experiences a more limited tidal range than a fully tidal wetland. Existing muted tidal wetlands at Ballona have Self-Regulating Tide gates (SRT), which close when the water surface elevation reaches a set height. Muted tidal systems would tend to compress the vertical range of wetland habitat types and would cause intertidal habitats to be created at lower elevations. Connections through culverts, open breaches and removal of levees are intended to allow the full oceanic tide to enter the site.

Inundation regime is the percentage of time that a given water level is exceeded during a Neap-Spring tidal cycle. It a useful parameter for characterizing the tidal inundation at a particular location with a specific elevation. The inundation regime for the unrestricted tidal system in the Santa Monica Bay is shown in Table 3-3; for example 2 ft NAVD is exceeded for 80% of the time and 4 ft NAVD for 38% of the time.

The inundation regime in some of the alternatives can be modified by setting the closure of the SRT in Area B at different elevations, which limits the maximum tidal elevation but maintains the rate of rise and fall of the tide. The inundation regimes were estimated for three SRT closure elevations using hydraulic modeling. The existing gate is set to close at 3.6 ft NAVD. Two additional closure elevations were modeled at 4.9 ft NAVD and 6.6 ft NAVD.

Table 3-3 shows how the inundation regime varies with different closure elevations. The inundation regime for lower elevations stays roughly the same between gate settings (e.g. 2 ft NAVD is exceeded about 77% of the time in all cases, which is comparable to the 80% for Santa Monica Bay). The effect of the muting is more pronounced at higher elevations (e.g. 4 ft NAVD is exceeded 38% of the time in Santa Monica Bay, but only 6% with a gate that closes at 4.9 ft NAVD). The inundation regime for intermediate closure elevations can be estimated by interpolation.

The vertical zonation of intertidal habitats can be estimated from the inundation regime. Different species would favor being inundated for different frequencies. For instance, high marshes are inundated approximately 28 to 50% of the time, while for low marsh the range of frequencies are 74 to 90%. Table 3-4 shows the inundation regime for intertidal habitats and the corresponding elevations for the oceanic tide in Santa Monica Bay (based on Ferren *et al*, 2007 in Appendix B). Each of the marsh habitat types covers a vertical range of about one foot.

Habitat zonations for the muted tidal regimes have been derived by determining the muted tidal elevation that has the same inundation regime as the open ocean. Table 3-4 shows the expected habitat distribution for different closure elevations for the SRT. Muting can also be achieved by undersized culverts that constrict the flow. These change the rate at which the tide rises in the site such that maximum elevation would not be the same on each tide. However, undersized culverts cause problems of erosion, backwater effects, and drainage.

For muted tidal systems the elevation range for the intertidal habitats is compressed which in turn limits the areal extent of these habitats compared to fully tidal alternatives. The zonation for intermediate closure elevations can be estimated by interpolation. This compression is most significant for the highest zones of the marsh (e.g. high marsh, transition zone). For instance, with the existing SRT closure elevation of 3.6 ft NAVD, mid marsh has the same vertical range as in a fully tidal system (1 foot) but occurs 0.3 feet lower. However, for the same SRT setting, the high marsh has a much reduced vertical range of 0.3 ft (between elevations 3.2 -3.5 ft NAVD).

In summary:

- varying the SRT closure elevation would mute the inundation regime in a predictable manner in Area B;
- vertical zonation of habitat would be compressed, particular at higher elevations, by muting of the tidal inundation;
- habitat area would be limited by the reduced vertical range of habitats.

3.3.2 Tidal Prism

The tidal prism is the volume of water entering the wetland on each tide. The tidal prism is a function of the topography and the tidal range of the site. For example, Alternatives 2 to 5 include substantial grading which would increase the volume of tidal water entering the site on each tide. If the tidal range is muted, the tidal prism would be reduced. The tidal prism was evaluated for each restoration area and for each of the main water connecting water bodies (Basin H, Marina Del Rey and Ballona Creek).

The tidal prism is important both within and outside the wetland:

- the tidal prism would influence the channel geometry and channel network properties.
- the tidal prism would influence the source of tidal water (as it affects the excursion length) and the residence time.

Table 3-5 shows the tidal prism of Ballona Creek in relation to the southwest wetland of Area B. In this case the main variable is the type of connection, either a SRT (Alt 1) or open breach (Alt 3). The muted tidal wetland has a tidal prism of about 30 ac-ft. Replacing muted tidal wetlands in Area B with fully tidal wetlands (Alt 3), connected to the creek by a breach, adds about 150 ac-ft to the existing tidal prism. One effect of increasing the tidal prism of Ballona Creek would be to increase the potential for scour at the mouth, in the vicinity of the jetty heads. Increased scour at the mouth has both positive and negative implications. It may reduce the need for dredging of Ballona Creek, improving the flood conveyance of the channel; however, it may also remobilize contaminated sediment that has settled at the mouth and there is the potential for undermining the breakwater as the channel readjusts to the larger tidal prism.

Table 3-6 shows the variation of tidal prism in relation to the southwest wetland of Area B. For a muted tidal wetland in this area the tidal prism is about 15 ac-ft. A tidal wetland created in this area in Alternatives 2 to 4 has a tidal prism of about 30 ac-ft.

Table 3-7 shows the variation of tidal prism for Area A. For those alternatives that connect to Marina del Rey, the tidal prism across the mouth of Basin H was used as a measure as this allows the effect of restoring the wetland tidal prism on Basin H water quality to be assessed. The larger the combined tidal prism, the greater the turnover of water in Basin H. The existing tidal prism of Basin H is about 12 acre-feet. A 38 acre wetland in Area A (Alt 2) increases the tidal prism by about 25 ac-ft, a 73 acre wetland (Alt 3) adds about 46 ac-ft, and the large subtidal pond and wetland in Alternative 4 adds about 330 ac-ft. The same alternatives connected to Marina del Rey at Via Venetia do not have a significant effect on the overall tidal prism as the tidal prism of Marina del Rey is so large.

Alternative 5 has the largest tidal prism of all of the alternatives at 600 ac-ft. This is nearly three times the existing tidal prism and it is expected that tidal flow velocities through the mouth of Ballona Creek would increase.

In summary:

- in the southwest wetland of Area B, an open breach and full tide would have a tidal prism about 100 ac-ft greater than a muted tidal option;
- southeast wetland would have a tidal prism of about 30 ac-ft;
- a tidal connection from Area A at Dock 52 has a large impact on the circulation of Basin H, but no alternative has a tidal prism sufficiently large to impact the much larger Marina del Rey channel.
- Alternative 5 has the largest tidal prism at 600 ac-ft.

3.3.3 Connections

The nature of the connection between open water and the wetland would greatly influence tidal conditions within the wetland. Four types of connections are present in at least one of the five alternatives:

- open (non-gated) culverts,
- gated culverts (e.g. self-regulating tide gate (SRT) and flood gates)
- open breach, and
- complete levee removal

The large pipes which penetrate levees to convey water between Ballona Creek and the inundated areas are referred to as culverts. Conveyance through a culvert is limited by its dimensions, particularly its cross-sectional area. Flow through culverts can be controlled by different types of gates that prevent flow through the culvert. SRT include a mechanism to close itself when water levels reach a specified elevation. Manual flood gates can be closed manually as dictated by conditions. Gated culverts can be used to prevent contaminants entering the site from Ballona Creek or Marina del Rey or to reduce peak flood elevations. The SRT has an advantage of being adaptable so that the desired water surface elevation within the site may be controlled.

The second type of connection through a levee is a breach. Breaches would be sized to the same width and depth as the connecting marsh channel and would have no top boundary. Breaches would therefore convey water with negligible restriction during normal tides and much more effectively during flood conditions. Breaches may be combined with lowering of the levee to about marsh plain elevation, thereby allowing higher tides to enter the site. This would mimic the flood routing of natural overmarsh tides and restore the hydraulic connection between the creek and the marsh plain. Controlling regular tidal flows or flood events is not possible with either a breach or levee removal.

The capacity of connections would vary. The SRT and culvert would have fixed capacity dependent upon their physical dimensions. A breach, depending on the nature of the material in which it is excavated, may be able to erode wider or deeper. Sizing levee breaches and connecting channels to the predicted tidal prism is generally necessary to limit how much the channel and breach erode. Tidal exchange and sediment supply to a wetland would be limited if the levee breaches or channels are undersized compared to the tidal prism. As the breaches or slough channels erode in response to the large tidal prism, tidal exchange and sediment supply would increase. Levee removal provides the most complete connection for water exchange and sediment supply between wetlands and the tidal source.

The location of the connections would have an impact on the evolution of the wetland, in particular the channel network. The alternatives have been developed to maximize opportunities for creating a single unified channel network within each marsh unit rather than multiple smaller networks, each with their own connection to open water. Using two connections for a hydrologic unit may increase the circulation in subtidal areas if there is sufficient head difference between the two entrances; this would be most effective in Alternative 4, which has a large open water area. For intertidal channels, flow may occur preferentially through only one of the entrances. Ideally, each marsh unit should be large enough to sustain its own network, containing a range of channel sizes and habitat. The southwest wetlands in Area B have the only remnant channel system that could be rejuvenated.

The use of structures as part of the connection, while increasing control, does have a number of issues:

- Gates and trash grilles, common on such structures, can impede the movement of sediment, seeds, fish and fish larvae. These restrictions would not be present with breaches.
- Culverts and gates generally have a smaller cross-section than natural channels and flow velocities within the structures would generally be higher. Scour would therefore be expected in the vicinity of the structure, especially in the channels leading into the wetlands.
- The potential for blockage is greater for gates and culverts, compared to an open breach, due to the smaller size of the opening and the presence of moving parts.
- Failure of a gate in the open position, due to trapping of debris or the failure of the control mechanism, may allow increase the potential for flooding. Failure of a gate in the closed position could delay drainage of tidal habitats.

3.3.4 Channel Network

Vegetated wetlands are typically drained by a complex network of dendritic and sinuous tidal channels. A dendritic sinuous tidal channel network is expected to provide better habitat and support a wider range of wetland functions than linear channels. For examples, channel bends provide sheltered foraging habitat for birds. Each tidal channel within the channel network drains and fills an area of marsh or "tidal watershed." Marsh drainage areas in natural marshes are distinguished by very subtle changes in marsh plain elevation and inundation patterns. The channel size adjusts to the flow to and from the marsh drainage area (i.e., the tidal prism of the marsh drainage area). Tidal channels may scour or fill in with sediment (shoal) in response to changes in the tidal prism and/or sediment dynamics.

In a natural system, as mudflats accrete to intertidal elevations, mudflat tidal channels form and become fixed as vegetation establishes and the marsh plain develops. Within this channel network, the tidal channel geometry at any given point is mainly dictated by the tidal prism of the watershed upstream. If the channel geometry is too small for the tidal prism, current speeds would increase and erode a larger channel. If the channel geometry is too large for the tidal prism, current speeds would decrease, allowing sedimentation to decrease the channel geometry.

Much of the natural channel system in Ballona Wetlands has been lost and a new channel networks would be constructed in tidal marsh restoration areas using the same tidal prism channel geometry relations found in natural channels. Larger tidal channels may be graded by excavating channels with dimensions that closely mimic channels in natural tidal marshes. The smallest channels may only be partially excavated, allowing these channels to develop over time through channel scour. Channel dimensions would be sized relative to the tidal prism of the marsh drainage area. Table 3-8 shows the channel network characteristics expected for each alternative, including tidal prism, channel length and order of channels. The method of calculation is described in Appendix C.

Channel networks constructed within the Ballona restoration are expected to be relatively stable, with limited potential for channel scour or shoaling. Tidal habitat would be restored by excavating fill and grading the site to elevations suitable for high, mid, and low marsh plain; mudflat; and subtidal habitat. The restored marsh plain would be graded with gentle slopes from the channel edge to upland areas to allow for the transgression of tidal habitats with sea level rise (see Section 3.5.1 below). Sedimentation rates within restored marsh areas are expected to be slow due to low sediment supply from the urbanized Ballona Creek watershed. The tidal prism of the restored marsh is therefore not expected to change rapidly after construction. The constructed tidal prism and channel dimensions are expected to maintain a relatively stable equilibrium condition. Also, as the restored marsh would be graded to higher marsh elevations, the tidal prism would be less than for lower elevation tidal areas. The potential for channels to form through channel scour is therefore expected to be low.

The presence of roads and levees within the site somewhat constrain the channel pattern as flow through this infrastructure must be routed through culverts. These culverts would set both the location and capacity of the channel at that place, reducing the ability of the channels to evolve over time. The culverts should be oversized in anticipation of larger tidal prisms in the future to increase the sustainability of the wetlands.

Permanent ponds in the marsh plain may be constructed to increase the amount of subtidal habitat. These would be connected to the channel network. These ponds would be shallow, well-defined, persistent depressions, 1 to 2 ft deep, that contain about 0.5 ft of standing water at all stages of the tide. They would receive tidal inflow on most tides.

3.3.5 Residence Time

Residence time is an estimate of how long water would remain in a flooded area before it is replaced by water from outside the wetland. A shorter residence time indicates a faster rate of turnover of the water. For this study, the residence time is estimated as the fraction of volume exchanged each tidal period, calculated by dividing the total volume in the flooded area by the tidal prism.

The residence time would depend on the proportion of tidal prism to total (subtidal plus intertidal) volume. Intertidal areas with an open connection to the ocean would have a residence time equal to the average tidal period because they dry out each tide. In areas with a large subtidal volume relative to intertidal volume (such as in Area A in Alternative 4), the residence time can be as long as several tidal periods. Short residence times indicate rapid and continuous exchange with the ocean water, with positive effects, for example, on exchange of gases, nutrients, fish larvae, sedimentation and water quality. Longer residence times indicate delayed exchange with the ocean.

The method for estimating residence time is an average for the entire flooded area and range of tides. Actual residence time would vary across the site. For example, residence times would be longer for regions of the flooded areas which are far from the exchange outlet or during periods of reduced tidal prism, such as neap tides. Similarly, actual residence times would be shorter for regions of the flooded areas which are close to the exchange outlet or during periods of increased tidal prism, such as spring tides.

3.3.6 Excursion Length

Excursion length is an estimate of the distance traveled by water during a tidal period. It is analogous to dropping a buoy in the water and measuring how far the buoy travels during a single tide. Excursion length provides an indication of the spatial extent of water movement within the tidal timeframe. As a first approximation, the water within an excursion length of a particular location is the source of inflowing water, the destination for departing water, and the volume of water that would most rapidly mix with that location's water. Water within an excursion length can be categorized as hydraulically well-connected to that location.

A major influence on excursion length is the addition of intertidal area upstream of a location which increases the flow of water past that location. In accordance with increasing flow, current speeds and hence, excursion length, also increase. Alternatives with the largest intertidal area would yield the largest excursion lengths.

Water in Ballona Creek, at the western side of the project area, exchanges with Santa Monica Bay on each tide. In contrast, water at the eastern side of the project area remains in Ballona Creek for more than a single tide. The different outlets from Area B are just a bit further than an excursion length of each other, indicating that water that exits one flooded area would typically take at least two typical tidal cycles to enter into another flooded area. The outlets from Area A to Marina del Rey and the outlets from Area B to Ballona Creek are separated by approximately three times the excursion distance and pass through a portion of Santa Monica Bay. This indicates that Area A and Area B are not well connected by Alternatives 1-4. Only Alternative 5 would closely connect Area A and Area B.

3.3.7 Flooding

Increasing tidal inundation within the Ballona wetlands may also affect the potential for flooding. Potential changes to the flood hazard as a result of the alternatives were evaluated.

Flood hazard was considered to arise from two sources – stormwater discharge from the Ballona Creek watershed and elevated ocean water levels in Santa Monica Bay. The watershed of Marina del Rey is small and its stormwater contribution is not considered a significant flood hazard. Flood events are typically characterized by their likelihood of occurrence, where the likelihood is expressed as a return interval. For this study, the selected stormwater discharge event has a return interval of 50 years or a 2% chance of occurring in any one year. The hydrograph of this 50-year stormwater discharge, which relates the rate at which water enters Ballona Creek as a function of time, was developed by the U. S. Army Corps of Engineers (2008). This hydrograph was developed by combining: (1) modeling of the transformation of rainfall into runoff and (2) frequency analysis of past discharge events.

The second source of flood hazard, elevated ocean water levels, arises from meteorological events acting at the regional or global scale. Regional meteorological events which elevate water levels include low atmospheric pressure associated with storm systems and wind setup. El Niño is the global meteorological event which leads to elevated ocean water levels along the entire western coastline. Since a detailed frequency analysis of elevated ocean water levels has not yet been conducted, this study relied upon an event selection approach to identify typical increases in ocean water level. Water levels at the Port of Los Angeles during 12 large storm events increased an average of 1.1 ft above expected water levels (USACE Hydrology Report).

These sources of water, stormwater discharge and elevated ocean water levels, interact with the ground surface elevation to determine the depth and spatial extent of flooding. Because of the existing levees which bound Ballona Creek, flooding is also a function of hydraulic connection. By adding tidal connections, the restoration alternatives alter the potential for flooding while decreasing the peak water levels within Ballona Creek. Within the flooded areas, flood exposure increases because of additional conveyance through the new tidal connections. However, the exposure within these flooded areas can be managed to acceptable levels by configuring the tidal connections and/or the flood hazard to infrastructure can be mitigated by structural means. The input of flood waters into the flooded areas acts to reduce the flood hazard within Ballona Creek itself. Because the flooded areas provide additional storage for flood waters, flood peak water levels along Ballona Creek, downstream of the tidal connection, are reduced.

Infrastructure that is exposed to flood hazard as a result of its location within or adjacent to the project area can be protected in several ways. The infrastructure itself can be raised above peak flood levels. For instance, roadways which cross the project site could be raised on structures or earthwork to elevate them above anticipated flood levels. Flood risk for infrastructure adjacent to the project area can be mitigated by constructing new levees or improving existing levees to constrain the flooded area extent.

Alternatives 1 and 2, which have muted tidal systems, have flood peaks at or below the closure elevation. If the rate at which the water level rises is rapid then the gate may close when elevations within the site are lower. For those alternatives that allow a full tide, flood peaks in the wetland channels are generally about a foot lower than in Ballona Creek. For instance, with the 50-year storm, Ballona Creek has a flood elevation of about 8.9 ft NAVD; for the same storm conditions the southeast wetland in Area B records 7.1 ft NAVD, and the southwest marsh was 7.6 ft NAVD.

Flood peaks also lower along Ballona Creek. At the seaward end of the channel, the existing peak flood elevation is predicted to be 8.9 ft NAVD. Predictions under Alternatives 1 and 2 have similar elevations as existing conditions. Alternatives 3 and 4 exhibit a 0.5 ft reduction in peak levels because of storage in the restored wetlands. Alternative 5 has slightly less of a reduction of 0.3 ft, due in part to the channel configuration and roughness of the vegetated floodplain.

3.3.8 Tables

Table 3-3. Inundation Regime of the SRT Gates in Area B, Showing Percentage of Time Tidal Water at or Above a Given Elevation

Elevation	% of time tides at or above given elevation				
ft NAVD	Santa Monica Bay (open ocean)	SRT closes at 3.6 ft NAVD	SRT closes at 4.9 ft NAVD	SRT closes at 6.6 ft NAVD	
7.5	0%				Inundation muted
7.0	1%				
6.5	4%				
6.0	8%				
5.5	14%			0%	
5.0	19%			4%	
4.5	28%		0%	16%	
4.0	38%	0%	6%	29%	
3.5	51%	23%	42%	44%	
3.0	65%	56%	58%	57%	
2.5	74%	69%	72%	70%	
2.0	80%	76%	78%	77%	Inundation similar
1.5	85%	82%	83%	82%	
1.0	90%	87%	88%	87%	
0.5	95%	100%	91%	91%	
0.0	98%	100%	97%	97%	
-0.25	100%	100%	100%	100%	

Note: all these examples use the existing 39 ft^2 culvert; with the gate set to close at 6.6ft NAVD the tide range is damped due to the lack of capacity of the culvert.

Table 3-4. Habitat Zonation in Terms of Inundation Regime and Elevation for Full and Muted Tidal Regimes

Habitat type	Inundation regime	Elevation range, ft NAVD			
	%r	Santa Monica Bay (open ocean)	SRT closes at 3.6 ft NAVD	SRT closes at 4.9 ft NAVD	SRT closes at 6.6 ft NAVD

3.4 SEDIMENT AND WATER QUALITY

Water and sediment quality are key to the proper functioning of wetland systems. Contaminants associated with poor sediment and water quality can have an effect on the health of wetland plant and animal communities and to the long-term sustainability of any restoration efforts. Accumulated contaminants may also pose a human health risk. A healthy wetland depends on the continuing flow of non-impacted tidal waters and sediment into and out of the restored areas.

Contaminants that have been detected in the water column in Ballona Creek above the water quality criteria include copper, lead, zinc, bacteria indicators, polyaromatic hydrocarbons (PAHs), and several pesticides. These contaminants are generally associated with urban runoff that may contain heavy metals, PAHs and pesticides. These constituents generally are adsorbed to, and carried by, fine-grained soils (clays) and organic materials. These materials then settle out when the water flow velocity decreases such as in a wetland. Continuous flushing through adequate circulation and channel flows would reduce the accumulation of impacted sediments; in a muted tidal system there may be periods of high water slack where increased sedimentation may occur.

Evaluation of sediments in both the Ballona tidal prism and in Marina del Rey has indicated benthic impacts and in some cases toxicity responses to aquatic organism. As indicated by the toxicity testing and benthic studies, these constituents may have negative impacts to the benthic and aquatic organisms within the wetland. Certain metals such as selenium and mercury can bio-accumulate in the wetland environment and are carried up the food-chain. Organic compounds such as PAHs and pesticides such as DDT can also bio-accumulate in organisms in the wetlands resulting in a long-term impact.

Through the Total Maximum Daily Load program, pollutant load reduction is required to reduce these impacts to the benthic and aquatic communities. TMDL implementation is, however, in its initial phases which include developing an implementation plan and identifying source of pollutants. Due to the challenges of reducing pollutant loads from highly urbanized watersheds, improvements in water quality and significant reduction in potential impacts may take twenty years or more. Therefore, alternative for the wetland restoration need to consider the potential impacts from storm flows within this projected timeframe.

Water quality in Ballona Creek may improve as a result of efforts to meet TMDL targets. The need for restricted wet weather flows would diminish compared to the importance of water quality within the wetlands achieved through adequate circulation and residence time that would require less restriction of flow in and out of the wetland

Alternatives are compared by evaluating the sediment and water quality issues associated with different sources of tidal and fresh water flows, which include Ballona Creek, tidal waters and urban storm water runoff. These issues form the criteria for which the alternatives can be assessed to assure a healthy and sustainable wetland.

3.4.1 Ballona Creek Flows

Historical and current water quality data indicate that dry weather flows from Ballona Creek exceed water quality objectives for bacteria indicators, metals, and other constituents. Dry weather flows may result in pollutant loading to the restored areas. Any alternative that increases the connection of the creek to the wetlands, through larger culverts and breaches, may increase this loading.

Storm water flows frequently exceed water quality objectives for bacteria, metals, PAHs, and pesticides in Ballona Creek. Alternatives that allow for the use of flood gates can prevent the inflow of contaminated storm water into the wetlands and reduce pollutant loading. Restricted connections, for example culverts, may reduce inflow from the Creek but would also restrict drainage leading to ponding of polluted waters on the wetlands. Unrestricted storm flows from Ballona Creek, through larger breaches and levee removal, would allow the greatest exchange of water between the Creek and wetlands. Compared to muted tidal systems this would maximize the area exposed to pollutants but this may be mitigated by the improved circulation and flushing of the system.

3.4.2 Tidal Water from Ballona Estuary and Marina del Rey

In general the oceanic water quality is better than in Ballona Creek or Marina Del Rey. In Ballona Creek the tidal influence extends up to Centinela Creek and water quality reduces further away from the ocean as a result of less mixing (a function of tide and fresh water flow). Water in Marina del Rey also exceeds the water quality objectives for bacteria indicators, metals and other constituents. However, the magnitude and frequency of these exceedances are lower in comparison to Ballona Creek. The main channel of Marina del Rey has better water quality than the back basins due to greater circulation, proximity to the ocean, and less direct input from urban runoff.

Accessing the cleaner oceanic water is dependent upon the location of the tidal connection and the excursion length of the waters in the wetlands. Alternatives that have inlets or breaches closer to the ocean would provide water of higher quality to the restored areas. Alternatives that have greater excursion lengths, through larger tidal prisms, would draw from more distant, higher quality waters. Water quality within the wetlands, compared with the muted tidal systems, would also be improved by adequate circulation and lower residence time.

3.4.3 Suspended Sediment Loading

Suspended sediment and organic matter in urban runoff attract and provide the mechanism to transport constituents such as heavy metals (copper, lead, zinc), bacteria, pesticides, PAHs and other organic compounds to receiving waters. These sediments then settle out as velocity decreases when storm flows meet tidal waters or enter into the wetlands.

Historical and current data indicate long term accumulation of these constituents in sediments in Ballona estuary and at the tide gates into Area B; sediment testing has indicated toxic effects on aquatic organisms. Suspended sediments from Ballona Creek and from local resuspension during storms, may continue to enter the wetlands and impact sediment quality.

Marina del Rey also has impacted sediments in the main channel and in several of the back basins. The sources of the impacted sediments may include the Ballona estuary, resuspension of coastal sediments during storms, storm water discharges directly into Marina del Rey and human activities within the Marina.

Alternatives that restrict flows into the wetlands during and, for a period, after storm events may reduce the supply of sediment to the wetlands but increase the potential for settling of finer material due to longer slack periods. In the long term, restricted flow and import of sediment would limit sediment cycling. This may further reduce the already limited sediment supply from the urbanized watershed.

Other storm water inflows are at the ends of Falmouth and Pershing Drives and along Lincoln Boulevard and Marina Freeway. Continued loading of these constituents into the existing wetland areas has resulted in localized impacts to sediment. All the alternatives include storm water treatment wetlands to reduce the pollutant loading. Treatment wetlands can be effective in removing heavy metals, sediment and organic compounds that adsorb to fine-grain soil particles and organic matter. The effectiveness of these systems depends on the retention time that flows entering the wetlands and the maintenance of the plants and sediments. These wetlands may only be able to reduce loads from a portion of storm water flows due to the constraints of size, through flow, and number of inflow locations.

3.4.4 Sediment Impacts

Within the project area there are contaminated soils in the creek and wetland channels. Grading of the site for an alternative may make these contaminants bioavailable. All the alternatives would alter the local flow patterns within the wetlands, either by altering the path or velocity of the flow. As a result there would be localized accretion and erosion of the existing sediment as the channels adapt to the new flow regime. This may result in the mobilization of contaminated soils which may be deposited within the site or transported out to the Creek or Marina del Rey.

Culverts and other constrictions should be sized to reduce the flow velocity below that for significant erosion. Alternatives may also include structures that reduce the velocity at locations of high flow.

3.5 SUSTAINABILITY AND MAINTENANCE

All natural systems have a certain amount of variation or trends that occur over different time scales. In a tidal wetland, these variations may include floods or droughts over the short term or changes in climate over the long term. These variations can cause stress to the system, which may be anticipated and accommodated within the design of a restoration project. Climate change, for example, would affect not only sea level but also temperature and precipitation.

In addition to long term changes, there would also be individual events that would stress the system. Variations in timing and frequency of storms are difficult to predict, as is the accidental release of contaminants. The uncertainty in the timing and magnitude of these stressors makes the operation and maintenance (O&M) of the system to unexpected changes important.

3.5.1 Long-term Sustainability - Sensitivity to Climate Change

Long-term sustainability of the restored wetlands is evaluated as the sensitivity to climate change and other long-term trends, including sea level rise and also changing rainfall patterns and sediment supply within the watershed.

Tidal wetlands exist within a very narrow vertical range, set primarily by the tidal frame. A small change in the tidal frame due to sea level rise would result in movement of the vertical distribution of tidal habitats. The response of tidal wetland to sea level rise depends primarily on:

1. sediment supply to the wetland and the associated rate of wetland accretion, and
2. the availability of space for the transgression of wetland habitats to higher elevations.

If sediment is readily available, vertical accretion may keep pace with sea level rise and the spatial distribution of tidal habitats may not change significantly. If sediment supply is low, as in Ballona Creek, accretion rates may be slower than sea level rise and habitats would transgress landward. In Alternatives 2, 3, 4 and 5, tidal wetlands would be graded to elevations that support the desired vegetation, as it is assumed accretion rates would be slow.

As sea level rises, habitats that are higher in the tidal frame would be converted to habitats that are lower in the tidal frame (e.g., high marsh is converted to low marsh, low marsh is converted to mudflat, and mudflat is converted to open water). If the transitional zone has a shallow slope, higher tide levels due to sea level rise would inundate transitional and upland habitats and convert these areas to high marsh. The space provided by shallow upland slopes allows tidal habitat to transgress up the slope with sea level rise, thereby maintaining similar acreages of habitat. If the transitional slope is steep, higher elevation habitat acreages would decrease as open water and lower elevation habitats transgress landward.

The tidal wetland habitats in Alternatives 2, 3, 4 and 5 include broad transitional slopes (1:50 to 1:70) that allow habitat transgression and can accommodate 2 to 3 feet of sea level rise. These shallow slopes would also provide valuable interim transitional habitat and act as a buffer from the surrounding urban activity. Where space is constrained and shallow slopes are not feasible, particularly where wetlands are located close to levees or roads, the transgression process would still occur but the higher elevation marsh habitat would be compressed against the slope of the levee into a narrow horizontal band. There may be loss of some wetland in the future due to the steep transitional slopes in these locations.

Alternatives 1 and 2, which include culverts or gates, allow some control of the water surface elevation. In these alternatives, a muted tidal regime would be implemented that limits the maximum water surface elevation. The result would likely be a vertical and horizontal compression of the higher elevation habitats (high marsh and transition zones). The culverts and gates would be designed to accommodate expected sea level rise.

Current assessments of climate change in California do not indicate a clear trend or significant change in precipitation patterns. Higher temperatures are expected to cause a significant shift from snow to rain in the mountains, but coastal California is relatively unaffected by snow. Significant changes in precipitation and streamflow in coastal watersheds are therefore not currently predicted. There is the potential for decreased precipitation and more severe droughts. Small changes in water balance for sensitive habitats, such as seasonal wetlands and brackish marsh, may result in temporary or permanent changes in the salinity regime of these areas. Those areas that are already fully tidal wetlands may not be directly affected but they may still be influenced by changes in occasional freshwater inputs. In this respect, wetland areas connected to Ballona Creek and its watershed would be more sensitive than those connected to Marina del Rey.

3.5.2 Operations and Maintenance (O&M)

The alternatives require varying levels of ongoing operations and maintenance (O&M). Fully tidal wetlands in Alternatives 3, 4, and 5 would be designed to be self-maintaining and are expected to require little O&M. Muted tidal wetlands in Alternatives 2 and 3 would require regular and ongoing O&M of tide gates.

In addition to routine O&M for typical conditions, there would always be unforeseen or difficult to predict events – a large flood, the accidental release of a pollutant, the failure of a mechanical structure. Ideally the alternatives should be flexible enough to accommodate such unknowns and allow the opportunity for intervention. The muted tidal wetlands in Alternatives 1 and 2 provide the ability to occasionally close off the wetlands from its main tidal source, which could prevent high flows or contaminants from entering the site. A flood or tide gate may be added to a culvert with relative ease; however, it is much more difficult to close off the breaches and lowered levees in Alternatives 3, 4, and 5 from Ballona Creek. On the landward side, preventing flows from entering the site is more difficult due to the number of potential inflows and the difficulty of rerouting the flows to the ocean. For fully tidal wetlands in Alternatives 3, 4, and 5, the breaches may allow better flushing of contaminants entering from either the creek or adjacent land.

If controls are used as part of the management of the alternative, planning should include system response if the control fails. For instance, if a tide gate fails to operate then the impact it would have on the wetlands would differ depending on whether it failed open or shut, at high or low water. Ideally the tide gate should not be the only protection against excessive water levels, there should be redundant measures such as additional ebb culvert barrels and landward levees.

Another consideration is the reversibility of an alternative. All alternatives would have an adaptive management plan in which it may be desirable to manipulate conditions. Changing the operation of an existing gate has less risk than changing the tidal inundation by removing a section of the levee. If conditions change and the system does not respond as required then the ability to revert to the former state may be desirable. Another example may be the enhancement of existing uplands, where changes envisioned in Alternative 1 and 2 are mainly related to management rather than structural changes and could more easily be reversed.

3.5.3 Vectors

Mosquitoes occur in wetland ecosystems where certain species can be vectors for viral diseases such as forms of encephalitis and more recently West Nile Virus. Understanding the life cycles and habitat requirements of the species that can be disease vectors is important in their control. Mosquitoes breed in standing water. Mosquitoes rarely occur in significant numbers in areas of tidal wetlands that are regularly inundated and drained over the tide cycle. Problems can occur in areas of tidal wetlands that are not well drained, such as ponds and pans that are infrequently or seasonally inundated, densely vegetated areas that pond water between tides, or locations where tidal drainage has been interrupted. Maintenance (e.g., spraying) may be required to address vector issues for poorly drained areas of tidal marsh.

For muted tidal wetlands, the designs should provide the ability to drain areas of standing water when required. This could be accomplished by operating gated culverts to drain the wetland on an occasional basis. Open areas of standing water should be large enough to allow wind waves to disturb the surface and dense vegetation around the edges should be avoided.

Additionally, wide buffers between wetlands and residential areas can reduce the likelihood of vector issues. The design of the alternatives should provide access points for mosquito surveillance and control.

3.5.4 Invasives

Biological invasions by exotics represent one of the most serious threats to ecosystem integrity and functioning. Invaders can detrimentally alter habitats, eat native species, and act as disease agents. Millions of dollars are spent annually in combating exotic plant pests just within southern California. Managing exotic species is complicated, as invaders are living organisms that can adapt to their new environments and have diverse, cascading effects. Invasive species may become established in restored upland and wetland habitats, requiring costly removal and maintenance efforts.

Salt marshes in southern California have been relatively free from invasions of wetland plants. Some localized exceptions include a mangrove (*Avicennia marina*) intentionally introduced into Mission Bay, San Diego, a sea lavender (*Limonium ramosissimum provinciale*) in Carpinteria salt marsh in Santa Barbara and *Tamarix* which has invaded the high marsh at Tijuana Estuary in San Diego County.

Upland area in southern California have some particularly troublesome plant invaders including giant reed (*Arundo donax*), which forms dense stands in riparian, brackish and fresh water wetlands, and salt cedar (*Tamarix* spp.), which have invaded riparian habitats, uplands, transition zones and high salt marsh. The major invaders at Ballona include , wattle (*Acacia* spp.), myoporum (*Myoporum laetum*), Russian thistle (*Salsola tragus*) mustard (*Brassica* spp.), garland daisy (*Chrysanthemum coronarium*), wild radish (*Raphanus sativus*), castor bean (*Ricinis communis*), pampas grass (*Cortaderia jubata*), fennel (Foeniculum *vulgare*), brazillian pepper tree (*Schinus terebinthifolia*), slender fan pam (*Washingtonia robusta*), non-native spurge (*Euphorbia* spp.), multiple varieties of ice plant (*Aizoaceae*) and non-native grasses have invaded disturbed upland areas and continues to spread.

Important vertebrate invaders that may affect restoration efforts include cowbirds, which are nest parasites that affect the endangered Least Bell's Vireo, and predatory red fox and house cats. These primarily upland invaders can also enter the wetland areas, impacting the native species. Estuarine and marine invaders include the clam-smothering mussel (*Muscalista senhousia*) and the carnivorous yellowfin goby (*Acanthogobius flavimanus*), the "killer" alga *Caulerpa taxifolia*, the salt-marsh destroying crustacean *Sphaeroma quoyanum*, and the mud-flat invading cordgrass *Spartina alterniflora*.

Alternatives with greater area of upland habitats would have greater impacts from invasive species and provide more opportunities for them to impact the adjacent wetland habitats. Alternatives 3, 4 and 5 provide the greatest area of contiguous wetland habitat (see Table 3-3), while Alternative 5 provides a significantly smaller edge to area ratio (Table 3-4).

3.6 PUBLIC ACCESS, RECREATION AND SAFETY

The goal of the public access plan is to provide "enhanced access to and within the Ballona Ecosystem consistent with ecosystem preservation and restoration values in a safe, consistent, coherent and functional manner," as per project objectives in the Ballona Wetland Restoration Plan Goals and Objectives (Appendix A). Public access features would be developed in concert with habitat restoration efforts to ensure maximum resource protection while providing a valuable recreational experience for the community. Providing public access and interpretive features about habitat restoration in turn provides increased public education, awareness, and support of local biological and physical resources present within the Ballona Wetlands. Providing strategically-placed public access features and limiting the intensity and duration of recreational use at the Ballona Wetlands would reduce impacts to the wetlands and enhance opportunities to involve the public in restoration and monitoring efforts.

The proposed public access and recreation features include a system of trails and overlooks, gateway entrances, interpretive stations, pedestrian bridges, bicycle parking, parking areas, boardwalks, vehicular pullouts, and visitor center. These would provide a diversity of public access and recreation opportunities for a wide range of users. The goal for the future design of these features would be to integrate all aspects of the project into a coherent system of restoration and public access that provides a clear sense of place within the context of the Ballona Wetlands and surrounding landscape.

The California Fish and Game Commission has designated the majority of the project area as a State Ecological Reserve. The purpose of the designation is to provide protection for rare, threatened or endangered native species. Public entry and recreational use of ecological reserves is subject to general rules and regulations to ensure that recreation is compatible with the primary purpose of resource protection.

In order to protect natural resources on the site and limit impact to wetland areas, a controlled and appropriate level of access to the Ecological Reserve would be provided as part of restoration. The public access strategy would focus on managing and concentrating recreation use within the site. The restoration and public access design would accommodate an appropriate level of fishing, boating, walking, and other activities consistent with the Ecological Reserve designation and ecosystem restoration values:

- **Walking**. Currently, access to the Ecological Reserve for walking or hiking is authorized on a case-by-case basis, and the site is not yet open to the general public. However, there is a public trail and self-guided interpretive tour located along the perimeter of the Freshwater Marsh. Walking or hiking would likely be the predominant recreational use of the site.

- **Biking**. Several local and regional bicycle routes are located near the Ballona Wetlands. No formal off-road or trail bicycle paths exist within the wetlands. The Ecological Reserve designation permits biking only on the designated bicycle path located on the north bank of Ballona Creek. Bicycle use is not permitted within the Ecological Reserve or Freshwater Marsh area.

- **Fishing**. Fishing currently occurs on both sides of Ballona Creek and from the downstream pedestrian bridge. The Ecological Reserve designation permits fishing with barbless hooks from the shoreline of Ballona Creek or from boats within the Ballona Creek channel. Fishing within the wetland area is restricted and by permit only.

- **Boating**. The Ballona Creek channel is currently used for both motorized and non-motorized boating. The University of California Los Angeles and Loyola Marymount University rowing teams use the Ballona Creek channel for crew practice. The Ecological Reserve designation permits boating within the Ballona Creek channel. Boating within the wetland area, however, is restricted and by permit only.

- **Other Recreational Uses**. Playa Vista Little League currently plays baseball on three fields located within the Ecological Reserve (Area C).

Public access and recreation features would provide a variety of settings, including access to the estuarine environment and retreat from urbanized areas, and would provide recreation opportunities for a variety of visitors. Access would be designed to be as barrier-free as possible to provide access for visitors of varying abilities and to comply with the Americans with Disabilities Act. In some locations, trails may be designed to accommodate vehicular use in order to provide access for security or maintenance. Raised boardwalks would be strategically located to maximize interpretive and educational opportunities related to the site and ongoing restoration activities. Exact trail locations and characteristics would be further developed when the preferred alternative is identified.

Table 3-9 details the number, length and location of public access features.

The Ballona Wetlands are also an important crossroad within the regional trail network. Both the coastal South Bay Bicycle Trail and the Ballona Creek Bicycle Trail run along the boundary of the site. Running north/south, the South Bay Bicycle Trail is a 22-mile paved trail that runs from Will Rogers State Beach in the north to Torrance County Beach in the south. Running east/west, the Ballona Creek Bicycle Trail runs along the south boundary of Area A and concludes in Culver City. The project is an opportunity to increase regional connectivity by developing an integrated trail network within the project site that connects to the surrounding regional trail network. The Alternatives would both preserve and enhance regional connectivity through connections of loop trails within the project area to the regional network. These connections would provide regional and local trail users with a range of opportunities and destinations.

Providing public access and interpretive features regarding habitat restoration in turn provide increased public education, awareness, and support of local biological and physical resources present within the Ballona Wetlands. Interpretive stations would be developed at strategic locations such as at gateway entrances, overlooks, or along the trail network within the project area. Educational signage and interpretive panels would facilitate a greater understanding and appreciation of the landscape. A potential visitor center and other opportunities for outdoor education and interpretation would provide a rich diversity of public access and recreation opportunities for a wide range of users. The goal for the future design of these features would be to integrate all aspects of the project into a coherent system of restoration and public access that provides a clear sense of place within the context of the Ballona Wetlands and surrounding landscape.

The prehistoric resources within and near the Ballona project area, including LAN-54, contain human remains and other materials that are of extremely high heritage value and sensitivity to the contemporary Gabrielino/Tongva Native American groups. Efforts to enhance cultural awareness of these resources and Native American lifeways in general should therefore be closely coordinated with the California Native American Heritage Commission and those groups identified as having specific concerns for the Ballona area.

As outlined in the Ballona Wetland Early Action Plan, interpretive panels would highlight habitat characteristics and diversity, watershed history, and Native American site usage through clear, consistent and attractive displays (Conservancy 2007). Overlooks or viewing platforms would be located at vista points where important features of the landscape can be viewed and/or opportunities for wildlife viewing and birding exist. Associated interpretive information would be provided at these facilities based on the opportunities provided at the facility sites.

Public access within Ballona Wetland would be developed in a manner that is “safe, consistent, coherent and functional” for the safety of the public, long-term management, and maintenance of the site. The separation of incompatible uses, such as bikers and walkers or bikers and cars is important for public safety and security in the area. The Ballona Wetlands are located in a densely population area surrounded by busy roads and popular regional bike paths. The Ecological Reserve designation provides clear guidance on allowable recreational uses within the site.

The most common unauthorized uses within the project area are BMX biking, dog walking, homeless encampments, dumping, and off-trail walking. Unauthorized use of the site can have an adverse impact on the landscape. Therefore, controlling these uses is critical to successful habitat restoration. Wetland restoration would inherently preclude access to portions of the site by creating deepwater and wetland habitat.

Lincoln Boulevard, Jefferson Boulevard, and Culver Boulevard, as well as street ends to the west and north, provide site access for automobiles. Current on-site parking includes an unimproved lot behind Gordon’s Market in Area B, paved on-street parking along Jefferson Boulevard at the Freshwater Marsh, and a paved parking lot at the Little League baseball fields in Area C. Safe traffic access would be provided by designating parking areas, creating roadside pullouts to provide formalized automobile access and viewing locations, and discouraging unauthorized roadside parking.

3.6.1 Tables

Table 3-9. Public Access Features Comparison

Public Access & Recreational Features	Alternative 1 (length/ number)	Alternative 2 (length/ number)	Alternative 3 (length/ number)	Alternative 4 (length/ number)	Alternative 5 (length/ number)
Trails					
Area A: Trails	8,800 feet	8,000 feet	9,450 feet	3,550 feet	4,450 feet
Area B: Trails	29,600 feet	29,600 feet	27,000 feet	27,000 feet	16,200 feet
Area C: Trails	7,200 feet	6,700 feet	7,150 feet	6,550 feet	2,250 feet
Boardwalks	1,900 feet	1,450 feet	1,350 feet	3,650 feet	3,850 feet

3.7 PHASING AND COSTS

This section describes the probable construction costs for the five selected alternatives as described in Chapter 2. In determining an opinion of probable construction costs appropriate to conceptual level design, several assumptions were required. These assumptions included:

- construction methods
- unit costs
- project sequencing and phasing
- permitting
- property acquisition

Table 3-10 is included to illustrate the level of accuracy and amount of contingency which is typically included in cost estimation for construction projects at various levels of design. This table is from the Cost Estimate Classification System, developed by the Association for the Advancement of Cost Estimating (AACE, 1997). As shown in the table, a particularly wide range in accuracy is assumed inherent for project design at the conceptual level. In addition, contingency is a large percentage of the estimated project costs, decreasing as the level of design is increased.

The “estimates of probable costs” are summarized in Table 3-11. Appendix D contains detailed cost estimates for each alternative by area and supporting information. It is important to note that these are large scale construction projects and that the alternatives involve significant intervention, and hence would require further detailed analysis and engineering design that would likely lead to additional refinements. Consequently, at this conceptual design phase, a cost contingency of 35% is included. We anticipate that actual construction costs could be reduced significantly through more detailed engineering. This is particularly true of the unit costs identified for fill placement; if a major fill element is included in the project, there is an opportunity to develop a construction methodology with a lower cost. Also, land costs are not included. At this stage, it is anticipated that all construction can be accomplished on publicly-owned land, and land and easement purchase costs are therefore not included. Also, costs associated with environmental restrictions of construction including timing and phasing are not explicitly treated.

These estimates are subject to refinement and revisions as the design is developed in future stages of the project. The cost tables summarize the cost of construction, and do not include estimated project costs for additional studies, permitting, detailed design, construction observation, monitoring and ongoing maintenance. Estimated costs are presented in 2008 dollars, and would need to be adjusted to account for price escalation for implementation in future years. This opinion of probable construction costs is based on: PWA’s prior experience, prices from similar projects, and consultation with contractors and others involved in comparable projects.

Note these estimates of probable construction costs and the actual costs at the time of construction may vary. The cost of construction would be impacted by the availability of construction equipment and crews and fluctuation of supply prices at the time the work is bid. PWA makes no warranty, expressed or implied, as to the accuracy of such opinions as compared to bids or actual costs.

3.7.1 Notes on Cost Estimate Assumptions

Quantities were estimated conservatively (high). For the grading of the subtidal, mudflats and marsh plain, it is assumed the grading was to the desired elevation and volumes were calculated using the "average end area method." For channels, it is assumed that only the largest channels (order 3, 4 and 5) would be excavated, and that these channels would be excavated to their modeled, equilibrium dimensions. Quantities of material used in levees were increased to account for settlement.

Appendix D (Table D-2) includes the unit costs and assumptions used in the cost estimate. The cost of excavation is the most expensive item in Alternatives 2 to 5. The cost used for excavation is $15/CY, which may be high. The use of scrapers or other efficient construction methods may have a lower unit cost. However, in this case, over-excavation and/or ripping of the soil may be required to give a suitable substrate for wetland restoration. This additional work would increase costs. Therefore, lower unit costs are not recommended for use in the cost estimate without further analysis of engineering and constructability considerations.

Onsite trucking and placement of excavated material is included as a separate item in the cost estimate. The cost estimate assumes that as much material as possible is reused within the same area to construct levees. Even so, each alternative generates more material than can be reused on site. There is no requirement to move material from one area to another, with the exception of Alternative 1. In Alternative 1, material excavated in Area A would be trucked to Area B and used as fill for levee construction along the daylighted culvert. It is assumed that the excess quantity from each area will be placed on site in stockpiles, at least until the material is disposed of off site. Table 3-12 lists the volume of excess material to be stockpiled (Appendix D, Table D-4 includes a rough calculation of possible stockpile areas).

Options for disposal may include:

Option 1 / 2. Remove sediment, barge sediment to the Port of Los Angeles (POLA), and unload dredged material at POLA (Option 1) or dispose material at a confined disposal facility (CDF) at POLA (Option 2).

Option 3. Remove sediment, barge sediment to POLA, and truck to landfill for beneficial use as landfill cover.

Option 4. Remove sediment, barge sediment to POLA, and dispose contaminated material at a hazardous waste landfill. The level and extent of on-site contamination is presently unknown.

Option 5. Remove sediment, barge sediment offshore, and dispose sediment offshore (Offshore Disposal).

Option 6. Remove sediment and dispose sediment on a nearby beach (Beach Disposal).

POLA identified and evaluated disposal Options 1 to 4. A preliminary draft cost estimate table prepared for POLA by Weston (Weston, undated) for these options was provided. There are uncertainties associated with the preliminary draft table and conceptual-level cost estimates. Disposal costs were not estimated for this report. The POLA/Weston cost estimate information was used to estimate the costs for Options 1 to 3. Mobilization (8%) and a 35% contingency were added to the disposal cost estimates for consistency with the estimates in this report and to account for uncertainties. Cost estimates for Option 4 are not included because information on contamination is not currently available.

For offshore disposal (Option 5) and beach disposal (Option 6), a range of costs is included in the estimate. On the lower end of the range, the costs for offshore disposal (Option 5) and beach disposal (Option 6) may be as low as the costs for disposal at POLA (Option 1 / 2). The upper end of the range for offshore disposal (Option 5) may be as high as the unit cost for dredging and offshore disposal at Upper Newport Bay provided by the SCC (G. Gauthier, SCC, pers. comm.) This unit cost is $28 per cubic meter for dredging and disposal about three to five miles offshore (S. Brodeur, County of Orange, pers. comm.). For beach disposal (Option 6), the upper end of the unit cost may be about $10/CY higher than the costs for Option 1 / 2. The cost estimates for disposal options should be updated at the next opportunity. Table 3-13 summarizes the disposal option cost estimates for each alternative.

3.7.2 Phasing

Areas A and C and Area B are not hydraulically connected in Alternatives 1 to 4 and so their construction may be phased in either order. In addition, it would be possible to construct Area A prior to Area C in each of these alternatives. Since each area generates more than enough material to construct levees, there is no need to stockpile material for use in later phases.

Alternative 5 is shown as being constructed in three phases (see Figure 2-9). A breakdown of the cost estimate between phases is included in Table 3-11. Excavation of Area A and removal of the Ballona Creek levees downstream of Lincoln Boulevard would occur first. This would require the construction of a temporary levee across the northern part of Area B and adjacent to Culver Drive. This temporary levee would increase the costs of phasing Alternative 5 compared to the cost estimated for Alternative 5 without phasing. The second phase would consist of restoring the remaining portion of Area B once the first phase habitat had been successfully established. Finally, Area C would be restored in the third phase. The advantage of phasing would be to spread costs over a longer period of time and take advantage of the timing of other projects, such as the widening of Lincoln Boulevard. The project could be stopped at the end of any of the phases and still leave a functioning system.

3.7.3 Tables

Table 3-10. Levels of Cost Estimate Accuracy and Contingency for Different Levels of Design

Design Completion Level	Cost Estimate Accuracy	Contingency
Conceptual (order of magnitude costs)	-30% to +50%	35–50%
Preliminary (30%)	-15% to +30%	20-25%
40 to 70% complete	-15% to +30%	15-20%
70 to 100% complete	-5% to +15%	10-15%

Table 3-11. Summary of Engineer's Estimates[1] for Alternatives 1 to 5 (cost in Millions of Dollars)

Alternative	Area A	Area B	Area C	Total
1	$4.0	$2.6	--	**$6.6**
2	$42.6	$16.0	$3.3	**$61.8**
3	$69.3	$55.5	$5.2	**$130.0**
4	$108.4	$55.5	$5.2	**$169.0**
5	$99.8	$59.0	$50.4	**$209.3**
	Phase 1	**Phase 2**	**Phase 3**	
5 [2]	$110.4	$48.8	$50.5	$209.7

Notes:

1 - Estimated construction costs include a 35% contingency

2 - The cost estimate for phasing Alternative 5 is higher due to the construction of a temporary levee

Table 3-12. Estimated Volumes of Excess Material to Be Stockpiled.

	Stockpile Volume (ac-ft)			
	Area A	**Area B**	**Area C**	**Total**
Alternative 1	50	-	-	**50**
Alternative 2	590	120	60	**770**
Alternative 3	1,040	600	90	**1,730**
Alternative 4	1,700	600	90	**2,390**
Alternative 5	1,650	760	840	**3,250**
	Phase 1	**Phase 2**	**Phase 3**	
Alternative 5	1,790	570	830	**3,190**

Table 3-13. Summary of Estimated Costs[1] for Disposal Options. Costs in Millions of Dollars

							Alt 5 with Phasing [2]			
		Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Phase 1	Phase 2	Phase 3	Total [2]
On-Site Work		$6.6	$61.8	$130.0	$169.0	$209.3	$110.4	$48.8	$50.5	$209.7
Disposal Volume (CY)		86,400	1,241,440	2,789,580	3,853,140	5,231,600	2,889,960	923,500	1,344,600	5,158,060
Off-Site Disposal Options										
Option 1 / 2	Unload Dredged Material at POLA / Disposal at CDF at POLA	$1.3	$19.1	$43.0	$59.4	$81.0	$44.5	$14.2	$20.7	$81.0
Option 3	Beneficial Use - Landfill Cover	$4.2	$59.7	$134.1	$185.2	$252.6	$138.9	$44.4	$64.6	$252.6
Option 4	Disposal at Hazardous Waste Landfill [3]									
Option 5	Offshore Disposal (low end of range)	$1.3	$19.1	$43.0	$59.4	$81.0	$44.5	$14.2	$20.7	$81.0
	Offshore Disposal (high end of range)	$3.6	$51.0	$114.6	$158.3	$216.	$118.7	$37.9	$55.2	$216.0
Option 6	Beach Disposal (low end of range)	$1.3	$19.1	$43.0	$59.4	$81.0	$44.5	$14.2	$20.7	$81.0
	Beach Disposal (high end of range)	$2.7	$38.3	$86.0	$118.7	$162.	$89.1	$28.5	$41.4	$162.0

Notes

1 - Estimated construction costs include a 35% contingency

2 - The cost estimate for phasing Alternative 5 is higher due to the construction of a temporary levee

3 - Estimate not included for Beneficial Use - Landfill Cover, contamintant report pending

4. SUMMARY

1. The project goal is to create functional estuarine habitat, including shallow subtidal, mudflats, fully tidal wetlands, salt pan and transitional habitats. Extensive enhancement of muted tidal wetlands or upland habitat, such as coastal sage scrub, grassland and saline seasonal marsh, does not achieve the project goal. However, upland habitat may provide some support for functioning estuarine habitat. Alternatives 3, 4 and 5 create the largest areas of fully tidal estuarine habitat while Alternatives 1 and 2 have larger areas of upland and muted tidal habitat. As discussed in Section 3.1, tidal estuarine habitats would benefit vascular and non-vascular plants, small mammals, a diverse community of aquatic invertebrates and many bird species known to utilize other southern California wetlands. Alternatives 4 and 5 create large areas of shallow subtidal habitat adjacent to mudflat. This would provide spawning and nursery habitat for pelagic and demersal fish species; these may disperse to the adjacent nearshore habitat and to other regional wetlands.

2. Transitional habitats, between tidal wetlands and upland, support a unique assemblage of vascular plant species and provide additional support for terrestrial species such as snakes, lizards, small mammals and birds. Transitional habitats also provide refuge for wildlife during periods of high water, serve as buffers against human activity, and allow for transgression of wetland habitats with rising sea levels. Alternatives 3, 4 and 5 provide the widest and largest area of transitional habitat. Muted tidal systems, as in Alternatives 1 and 2, have a reduced tidal range and therefore a compressed vertical range of habitats, limiting the area of transitional habitat that can be created.

3. Upland areas would support populations of vascular plants and provide foraging and nesting habitat for a number of bird species. Upland areas would also provide breeding and foraging habitat for insect pollinators, butterflies and moths, birds, herpetofauna and some mammals. All alternatives provide some upland habitat; however, there is a trade-off between the acreage of estuarine habitat and upland habitat. Alternatives 1 and 2 have the most upland habitat and the least change to the existing habitat mix. Freshwater seasonal wetlands, including vernal pool habitat, would benefit specific vascular and non-vascular plants, aquatic invertebrates and herpetofauna uniquely adapted to this environment, Alternatives 2, 3 and 4 create vernal pools.

4. Alternatives with larger, contiguous, areas of wetland habitat are more likely to sustain populations of associated species. Alternatives 3, 4 and 5 have larger areas of contiguous wetlands with fewer roads, wider transitions and more channels. These alternatives would have a higher quality of wetland habitat because they would be more remote from noise, lights, cars, and other human impacts. Alternatives with larger areas of contiguous wetland would also have fewer impacts from, and require less active management for, invasive plant and animal species.

5. Fully tidal systems allow for greater tidal circulation and reduced residence time. This would lead to a more rapid exchange of water with the ocean, and positive effects on exchange of gases, nutrients, fish larvae, sedimentation and improved water quality. Alternatives 1 and 2 have large areas of muted tidal wetland; Alternatives 3, 4 and 5 create fully tidal wetlands. The large intertidal areas of Alternative 2, 3 and 5 would have the shortest residence times, completely draining on most tidal cycles. Alternative 4 has a substantial subtidal volume, which would flush over several tidal cycles.

6. A complex tidal channel system allows water, sediment and nutrients to reach all parts of the wetland and provides diverse habitats. The complexity of the channel network depends on the area of the wetland and its tidal prism. Alternatives 3, 4 and 5 have large tidal prisms and would support an extensive and complex channel network with a large range of channels sizes.

7. The higher quality sources of tidal water are the ocean and Marina del Rey. The ability to bring this water into the wetlands would depend on the location of the tidal connection and the tidal excursion length. Alternatives 2, 3 and 4 improve tidal connections between Area A and higher quality water in Marina del Rey; this would also benefit habitat connectivity for fish species. All alternatives have some connection to Ballona Creek, which has poorer water quality. Longer excursion lengths increase the mixing of water on each tidal cycle, improving water quality. Alternatives 3, 4 and 5, with the largest tidal prism, have excursion lengths extending to the ocean.

8. The form of the tidal connection would affect the connectivity and function of habitat by influencing the movement of sediment, seeds, gases, nutrients, fish and fish larvae. Tide gates in Alternatives 1 and 2 would control water surface elevations within the wetlands but would limit connectivity with Ballona Creek and Marina del Rey, reducing diversity, and limiting primary productivity. Gates can also control pollutant loading, especially during storm events, although muted tidal systems would have a longer residence time allowing greater settling of pollutants. Gates would require regular maintenance and management as failure could impact habitat and cause flooding. Fixed structures, such as gates and culverts, need to accommodate both scour and sea level rise in their design.

Breaches in Alternatives 3 and 4 allow for full tidal range, movement of larger fish and greater seed dispersal. Open breaches would allow greater tidal circulation, reduced residence times and would be able to adapt to rising sea levels. Levee removal in Alternative 5 has the advantages of breaches and increases the interaction between the wetlands and the Creek - creating gradients of inundation and salinity across the site, letting the morphology evolve and allowing for periodic disturbance by flooding and scouring.

9. All of the alternatives would maintain the existing level of flood protection. Alternatives 1 and 2 have muted tidal systems, which would maintain the existing flood levels. These

alternatives rely on tide gates. Alternatives 3, 4 and 5 can accommodate higher flood levels by the construction of new levees and provide additional flood storage, reducing peak flood elevations.

10. All the alternatives would include principles of adaptive management in their Operation and Maintenance strategy. Alternative 1 has little change from the present situation and the risk associated with implementation is low. The restoration of wetlands in Alternative 2, 3 and 4 could be undertaken in distinct hydrologic areas which would allow for adaptive management and experimentation. Alternative 5 restores a large, contiguous area of habitat connecting a number of existing hydrologic units with Ballona Creek. This alternative makes the greatest change to the site, would be the hardest to reverse and consequently has the most risk. This risk may be mitigated to an extent by phasing the implementation.

The following tables have been developed from the above summary. They indicate favorable characteristics in terms of habitat, hydrology and public access. Check marks indicate which alternatives have these characteristics and the number of check marks indicates the relative degree. The number in brackets refers to the relevant summary paragraph above.

4.1 TABLES

Table 4-1. Summary of Habitat Characteristics

	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5
Large areas of fully tidal estuarine habitat (1)		√	√√	√√√	√√√
Large areas of mudflat (1)			√	√√	√√
Large areas of shallow subtidal habitat, adjacent to mudflats (1)				√√	√√
Extensive channel network (6)	√	√	√√	√√	√√√
Wide transitional habitat (2)		√	√√	√√	√√
Large areas of enhanced upland habitats (3)	√√	√√	√	√	
Allows for dynamic interaction between Ballona Creek and the Wetlands					√
Larger and more hydraulic connections between wetland habitats, Ballona Creek and the ocean (5, 7, 8)		√	√√	√√	√√√
Hydraulic connection to Marina del Rey (7)		√	√	√√	
Fewer culverts and tide gates; more breaches and levee removal (7, 8)			√	√	√√
Larger contiguous areas of estuarine habitat with fewer roads and more channels (4)			√	√	√√

Table 4-2. Summary of Hydrology, Sediment and Water Quality Characteristics

	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5
Full tidal range (1)		√	√√	√√√	√√√
Large channel network (6)		√	√√	√√	√√√
Daylights culverts, creates breaches (8)	√	√	√√	√√	√√
Large tidal prism (5, 7)		√	√√	√√√	√√√√
Short residence time (5)		√√	√√	√	√√√
Long excursion length (7)		√	√√	√√√	√√√
Control of flows by gates (8)	√	√			
Maintains existing flood levels (9)	√	√			
Increase in flood storage (9)			√√	√√√	√√√
Stormwater wetlands	√	√	√	√	√
Hydraulic connection to Marina del Rey (7)		√	√	√√	

4.2 RANKING OF ALTERNATIVES

Ranking is based upon the ability of each alternative to meet the project goals: the creation of functioning estuarine habitats, tidal circulation, connectivity of habitat areas, ability to address sediment and water quality, sustainability and maintenance. The alternatives are ranked from 1 to 5, with 1 being the highest rank.

In order to protect natural resources on the site and limit impact to wetland areas, a controlled and appropriate level of access to the Ecological Reserve would be provided as part of restoration. The alternatives are not ranked according to public access; each alternative can be modified to accommodate varying degrees of access as described in the feasibility analysis.

<u>Alternative 1 – Rank 5</u>
Alternative 1 is ranked the lowest because this alternative:

- does not achieve the project goals of creating a functional estuarine habitat;
- maintains existing upland habitat and does not provide fully tidal habitat;
- does not address existing problems of invasive species, limited buffers, poor tidal circulation, poor connectivity between habitat areas, and supports only a limited number of targeted wetland species;
- has upland areas that would require continuous management for a muted tidal system, invasive species and human impacts; and
- accommodates sea level rise through tidal muting.

<u>Alternative 2 – Rank 4</u>
Alternative 2 is ranked 4th because this alternative:

- creates fully tidal areas with better connections to Marina Del Rey although existing muted tidal areas remain;
- maintains significant upland areas;
- does not take advantage of whole site;
- does not address existing problems of invasive species, limited buffers, tidal circulation restricted by levees, poor connectivity between habitat areas;
- has upland areas that would require continuous management for a muted tidal system, invasive species and human impacts; and
- accommodates sea level rise through tidal muting.

<u>Alternative 3 – Rank 3</u>
Alternative 3 is ranked 3rd because this alternative:

- creates fully tidal areas across the whole site;

- creates complex channel networks;
- improves tidal circulation with breaches and larger connection to Marina del Rey water;
- creates large contiguous areas of habitat and large buffer areas;
- has poor connectivity between habitat areas across the site; and
- accommodates sea level rise through transgression.

Alternative 4 – Rank 2

Alternative 4 is ranked 2rd because this alternative:

- creates fully tidal areas across the whole site;
- creates complex channel networks;
- improves tidal circulation with breaches and larger connection to Marina del Rey water;
- creates large contiguous areas of habitat and large buffer areas;
- has poor connectivity between habitat areas across the site;
- includes subtidal habitat adjacent to wetlands using Marina Del Rey water ;
- has longer residence time in subtidal areas; and
- accommodates sea level rise through transgression.

Alternative 5 – Rank 1

Alternative 5 is ranked the highest because this alternative:

- is the most likely to create a functional estuarine habitat as per the project goals;
- creates the largest complex channel network;
- improves tidal circulation through a direct connection to Ballona Creek;
- has the largest tidal prism, lowest residence time, and greatest tidal excursion;
- creates the largest contiguous area of wetland;
- has the greatest connectivity across the site;
- allows interaction between the wetlands and the Creek;
- restores gradients in salinity and inundation;
- allows periodic disturbance by flooding and scouring; and
- accommodates sea level rise through transgression.

5. LIST OF PREPARERS

This report was prepared by:

Sean Bergquist, Santa Monica Bay Restoration Commission

and the following PWA staff:

Jeremy Lowe
Nick Garrity, P.E.
Matt Brennan, P.E.
Louis White
Bob Battalio, P.E.
Jeff Haltiner, P.E.

with:

Kerry McWalter, EDAW

Chris Nordby, Nordby Biological Consulting (formerly with Tierra Environmental)

David Pohl, Weston Solutions

APPENDIX A.
GOALS AND OBJECTIVES, OPPORTUNITIES AND CONSTRAINTS

Appendix A

Ballona Wetlands Restoration Plan
Goals and Objectives,
Opportunities & Constraints

The purpose of this document is to identify key characteristics of the project area that present opportunities for achieving the restoration planning goals and objectives as well as those that may limit (or place constraints on) the achievement of those goals and objectives. The ideas listed below tend to be generalized, this document is an effort to take information about the existing conditions of the area and assess what that information tells us about achieving the project's goals and objectives.

This table does not evaluate the relative importance of specific opportunities or constraints and there are internal inconsistencies among the opportunities and constraints identified. Inherent in some of the opportunities are preferences, priorities and approaches to wetland restoration and because of these differences, some conflict with one another. The purpose of this document is not to resolve these potential conflicts, but rather to be sure there is a common understanding of the project area's potential for achieving the fullest range of goals.

Goal 1: Ecosystem Restoration: Restore, enhance, and create estuarine habitat and processes in the Ballona Ecosystem to support a natural range of habitat and functions, especially as related to estuarine dependent plants and animals.

Sub-goal 1. Habitat: Preserve, restore, enhance, and create a variety of functional wetland, estuarine and other habitats representative of the Ballona Ecosystem.

Objectives:

a. *Support existing and future habitat based on identified regional needs*

b. *Create spatial connectivity within the site*

c. *Create appropriate edge habitat and connectivity to adjacent areas of the Ballona Ecosystem*

d. *Provide landscape-level function at a regional scale addressing habitat/landscape patches, corridors, connectivity and mosaics landscapes. Provide habitat for migratory birds, fish nurseries, etc.*

Opportunities	Constraints
Preserve, restore, enhance, and create multiple habitats historically associated with both the Ballona Wetlands and the region.	Because the size of the site is limited, it may not be possible to incorporate large enough patches of all historic habitat types to ensure their viability.
Restore and create fully tidal wetland habitat	Habitats are fragmented by the existing roads, infrastructure and surrounding development
Preserve and enhance seasonal ponding areas	Existing habitats on site could be displaced by future enhancement, such as the restoration of tidal inundation
Create regional habitat linkages and corridors	Site has been filled, existing soil types may not be appropriate for reestablishment of all historic habitats
Incorporate adjacent upland habitats along with transitional habitats linking wetlands and uplands.	
Restore diverse habitats based upon gradients of elevation, hydroperiod and salinity	

Sub-goal 2. Biodiversity: Preserve and increase the native biodiversity of the Ballona Ecosystem. Identify and protect multiple levels of diversity (e.g. species, habitats, biogeographic provinces and trophic structure).

Objectives:

a. *Increase diversity and populations of rare and endangered plant and animal species.*

b. *Establish and maintain diverse native plant communities, including vascular plants, algae, and diatoms.*

c. *Support a diverse complement of species including: birds, fish, amphibians, reptiles, native aquatic and terrestrial invertebrates.*

Opportunities	**Constraints**
Restore biodiversity historically associated with the region, including common, rare and locally extirpated species.	Implementation of restoration efforts will entail impacts to existing species to some degree and may need to be mitigated in some way
Strategically design habitat to ensure recruitment and survival of targeted species	Site may too small and isolated to support some species
Restore microhabitats that support various life stages of species	May become a biological sink as a result of invaders, predators or other impacts
	Restricted tidal connection could limit the species of fish that can be established

Sub-goal 3. Physical/Chemical Processes: Maintain and establish physical and chemical processes consistent with the restoration goals.

Objectives:

a. *Improve tidal circulation and enlarge the amount of area that is tidally inundated.*

b. *Manage surface and subsurface freshwater inflows to support desired on-site habitats.*

c. *Establish and maintain a sediment transport regime that supports the desired wetland functions.*

d. *Re-establish a dynamic range of hydrologic conditions (intensity and duration) to support natural ecosystem processes.*

e. *Establish and maintain biogeochemical processes representative of natural wetland ecosystems.*

Opportunities	Constraints
Increase tidal flow into the site	Flood conveyance in Ballona Creek Channel needs to be maintained
Improve tidal connectivity within the site by enlarging existing channels and culverts, and creating new channel networks	Existing tidal connections are insufficient to create and maintain a significant area of natural tidal wetland
Improve management of tide gates to create a muted tidal system with long-term management of water levels	Elevations are too high, fill disposal will be difficult
Change the roads and berms to improve habitat connections, reduce flood hazards and accommodate sea-level rise	Existing infrastructure may limit hydrologic connections within the site
Include distributary channels in the bluff deltas for coarse sediment distribution where feasible	Urban watershed negatively impacts sediment supply, water quality and hydrograph of potential freshwater sources
Restore a more natural tidal slough system linking freshwater areas to tidal marsh	Natural channel formation may be limited due to lack of tidal scour, high elevations, soil type and absence of antecedent channel network
Enhance historic Centinela Creek in Area B by increasing freshwater flows.	Limited supply of fine sediments to the site may limit march evolution over time
Reduce current flooding problems around the project area	Low-lying properties around the periphery of the site may need to be protected from flooding
Daylight outlet culvert of the Freshwater Marsh	The upstream reach of Centinela Creek has been diverted.

Physical/Chemical Processes, continued

Opportunities	Constraints
Modify Ballona Creek levees by realignment or changing the form of the bank	
Coordinate the management of tide gates in the Ballona Ecosystem (Del Rey Lagoon, Ballona Lagoon & Ballona Wetlands)	

Sub-goal 4. Sustainability: Facilitate the conservation and restoration of natural resources in a manner that maintains and improves the ecological integrity, function, diversity and productivity for future generations.

Objectives:

a. *Accommodate potential sea level rise for transitional habitat provide appropriate elevations to accommodate habitat shifts*
b. *Use self-sustaining, low maintenance systems where possible*
c. *Minimize future adverse effects of nuisance species, including non-native, invasive species, feral predators and disease vectors.*
d. *Protect the wetlands from adverse impacts caused by contaminants in influent water or sediment.*
e. *Plan for the longterm management of the site*

Opportunities	Constraints
Accommodate rising sea level by using site slope to allow habitat migration	Future development of surrounding areas
Provide sufficient tidal flow to maintain channel system	Maintenance and management resources have not been identified
Incorporate principles of adaptive management in restoration design to phase implementation and test different methods	Some sources of water and sediment to the site may be contaminated, those contaminants may accumulate in the restoration area
Utilize (or employ) existing organizations to maintain and implement stewardship activities at the site	Accumulation of contaminants or pollutants on the site: including trash and aerial deposition
Use low maintenance processes to improve water quality of urban runoff entering the wetlands	Site vulnerable to invasive species, onsite and from local area
Design site to minimize the impacts of streetlights, traffic noise and other urban characteristics on habitat values	Rising sea level may inundate low lying areas
Reduce management costs associated with tide gates	Infrastructure, such as gas facilities, needs to be maintained

Goal 2: Social and Socioeconomic Values: Create opportunities for aesthetic, cultural, recreation, research and educational use of the Ballona Ecosystem that are compatible with the environmentally sensitive resources of the area.

Sub-goal 1. Public Access: Design enhanced access to and within the Ballona Ecosystem consistent with ecosystem preservation and restoration values in a safe, consistent, coherent and functional manner.

Objectives:

a. *Develop gateway entrances that attract, welcome and inform ecosystem visitors.*

b. *Phase-out inappropriate or uncontrolled access points.*

c. *Create public outreach, education and interpretive opportunities for visitors, organizations and institutions.*

d. *Develop appropriate signage that enhances visitor understanding of wetland restoration efforts; increase public awareness of local biological and physical resources present within Ballona Wetlands.*

e. *Develop overlooks and connections accessible to pedestrian, bike and bus users and provide the appropriate signage to facilitate such access.*

f. *Provide potential opportunities for the public to participate in restoration and monitoring efforts.*

Opportunities	**Constraints**
Develop parking areas and designated entry points for the public on currently disturbed or developed areas.	Informal access points and associated unauthorized and uncontrolled uses
Develop interpretative components to educate the public on the values of wetland functions and habitat, build on existing educational programs	Public access areas reduce the area available for restoration
Design access with buffers between people and sensitive habitat areas	
Install facilities to serve visitors of the site	
Improve overlook points. For example, potential to use sediment material onsite to create high points	
Install consistent signage	

Public Access, continued

Opportunities	Constraints
Provide access that serves people with disabilities	
Incorporate educational and stewardship activities into the Little League program	

Sub-goal 2. Cultural Access and Preservation: Initiate formal and informal consultation with representatives of the Gabrielino/Tongva Tribal Council to develop guidelines that contribute to the preservation of sacred and cultural sites.

Opportunities	Constraints
Provide access for cultural use of the site by native people	Protection of cultural resources on site may constrain site design
Preserve cultural resources onsite	
Educate the public regarding archaeological and historic resources	

Sub-goal 3. Recreational Use: Design site to accommodate an appropriate level of fishing, boating, walking, and other activities consistent with the Ecological Reserve Designation and ecosystem restoration values.

Objectives:

a. *Provide public trails and viewing areas around the perimeter of the wetlands with interpretive displays at selected locations.*

b. *Concentrate potentially incompatible human activities in non-sensitive areas*

Opportunities	Constraints
Develop a recreational plan compatible with the Ecological Reserve designation	Existing unauthorized uses, such as BMX use and dog walking, may be incompatible with Ecological Reserve designation
Integrate existing trails, features and disturbed areas into the designated trail network.	
Integrate trail network with local and regional trails, bikeways and transportation systems	

Sub-goal 4. Public Safety and Security: Design public access so that the wetlands are a safe place to visit.

Objectives:

a. *Design access to minimize maintenance costs*
b. *Provide access points at locations responsive to the needs of law enforcement.*
c. *Create and maintain access points in a manner that minimizes safety concerns and hazards.*

Opportunities	Constraints
Provide for a safe visitor experience through site design	Major roadways cross the site, fast moving traffic, limited places for parking
Consolidate Gas Company facilities, separate from habitat areas and public access	Poorly secured site, hard to control all unauthorized access in an urban setting
Improve traffic-related safety concerns through crosswalks, walkways and safe parking areas	Unknown extent of methane or other potentially harmful substances
Improve emergency access to the site	Need to protect public health by limiting disease vectors (such as mosquitos)

APPENDIX B.
HABITAT DESCRIPTIONS FOR RESTORATION ALTERNATIVES

Draft

BALLONA WETLAND RESTORATION PROJECT: HABITAT DESCRIPTIONS FOR RESTORATION ALTERNATIVES

**Prepared by Wayne R. Ferren Jr.,
John C. Calloway, Joy B. Zedler, and the
Ballona Wetland Restoration Science Advisory Committee**

I. INTRODUCTION

The Ballona Wetlands Restoration Project seeks to restore ecosystem structure, function, and processes at Ballona Wetlands, in particular those related to the support of biodiversity. A method of organizing biological diversity information for the Ballona Wetland Restoration Project is to group plants and animals by the "habitat" in which they are most likely to be sustained under improved conditions. One measure of progress toward achieving habitat restoration goals, therefore, is a determination of whether or not these targeted organisms are supported by the manipulated habitats to a measurable and acceptable level of sustained occurrence. Performance criteria can be established to measure establishment of species populations in these habitats. Physical parameters of the environmental also can be monitored and compared against data from reference sites or expected conditions to determine if the restored areas are performing within a range of anticipated values.

The following are generalized groups of habitats (organized by category and type) with information regarding characteristics such as structural feature, ecosystem function, and landscape process as well as dominant or characteristic plant species, characteristic animal species, and presumed extirpated or rare or endangered species that could be candidates for translocation and recovery experiments or goals within the Ballona Ecosystem.

The categories and subcategories of habitats are arranged from estuarine deepwater habitats and wetlands to palustrine wetlands, followed by uplands within the Ballona Ecosystem and within the estuarine category from subtidal (deepwater) and intertidal open water and non-vegetated types of habitats to vegetated types, generally going from lower elevation and hence more frequently flooded types to less frequently flooded types, an important distinction when assessing habitat characteristics. Habitat restoration design as it relates to the potential for significant sea level rise due to global climate change is an important consideration for the Ballona Wetland Restoration Science Advisory Committee during the evaluation of restoration alternatives for the Ballona Ecosystem.

II. LIST OF HABITAT CATEGORIES AND TYPES

Habitat Category I – Estuarine Open Water: Non-vegetated Habitats and Flooded Substrates:

1. Deepwater Habitats (mud and sand substrates) – Open Water Subtidal Conditions

2. Deepwater Subtidal and Wetland Intertidal Channels (cobble/gravel and riprap substrates) – Open Water Subtidal, Intertidal, and High Tide Conditions

3. Intertidal Wetland Habitats (sand and mud substrates) – Intertidal and High Tide Conditions

Habitat Category II - Estuarine Non-vegetated Intertidal Wetland Habitats

4. Intertidal Margins, Beds, Banks, and Benches (mud and sand substrates) - Low Tide Conditions

5. Intertidal Channels (cobble/gravel and riprap substrates) - Low Tide Condition

6. Mudflats

7. Hyperhaline Salt Flats

Habitat Category III - Estuarine Vegetated Wetlands:

8. Aquatic Bed Wetlands

9. Cordgrass (Low) Marsh

10. Marsh Plain (Middle Marsh)

11. High Marsh (clay/mud or sand/loam substrates)

12. High Marsh Transition Zone (including Euryhaline and Hyperhaline Habitats)

13. Brackish Marsh (an associated Open Water Habitat)

Habitat Category IV - Palustrine Nontidal Wetlands:

14. Transitional Emergent Wetlands (delta distributaries and margins of estuaries)

15. Freshwater Marsh

16. Seasonal Palustrine Wetlands (including Haline Vernal Wetlands)

17. Palustrine Scrub/Shrub Wetland (= DFG "Riparian Scrub")

18. Palustrine Forested Wetland (= DFG "Riparian Woodland"?)

Habitat Category V - Upland Habitats:

19. Grasslands (= DFG Non-native Herbaceous Vegetation)

20. Coastal Scrub (including Coastal Bluff Scrub)

21. Coastal Dune Scrub and Dune Herbs (including Foredunes)

22. Forests, Woodlands, Groves, and Tree Rows (including DFG "Eucalyptus Grove")

III. HABITAT DESCRIPTIONS

Habitat Category I – Estuarine Open Water: Non-vegetated Habitats and Flooded Substrates:

In the estuarine system, deepwater habitats are characterized by the subtidal water regime and wetlands are characterized by various non-storm-influenced intertidal water regimes including irregularly exposed, regularly flooded, and irregularly flooded regimes.

1. Deepwater Habitats (mud and sand substrates) – Open Water Subtidal Conditions

Narrative (refer to other open water habitats for additional information): Subtidal deepwater habitats include channels, bays, basins, and other features, which at extreme low water do not drain with the outgoing tides. The subtidal estuarine water regime results in permanently flooded habitats and permanent bodies of open water. These habitats are generally considered truly aquatic systems and are adjacent to and down-slope from tidal estuarine wetlands. Estuaries with extensive deepwater habitat areas often support adjacent areas of intertidal mudflat and low marsh wetland habitats.

The "plants" of channels and creeks, both intertidal and subtidal, are generally nonvascular taxa, but under brackish conditions may include various aquatic bed and emergent vascular species. The non-vascular plants include phytoplankton (e.g., diatoms) and macroalgae, which, along with the detritus from decomposed Cordgrass (*Spartina foliosa*), are often direct links in the estuarine food chain (i.e., are directly consumed by higher order consumers). Benthic invertebrates are the most visible consumers of detritus, algae and plankton. Crabs and snails graze on detritus and macroalgae, while bivalve mollusks filter feed on phytoplankton. Polychaete worms inhabit the fine sediments of tidal creeks, while fish exploit the water column and substrate surface.

Fish use of subtidal habitats can be categorized by various functional groups or guilds including, for example, (1) adult and juvenile marine fish, such as Leopard Sharks (*Triakis semifasciata*), Grey Smoothhounds (*Mustelus californicus)*, and Stripped Mullet (*Mugil cephalus*) that enter estuaries with incoming tides to forage in estuaries, (2) adult marine fish such as Round Rays that feed and mate in estuaries; (3) marine fish such as California Halibut (*Paralichthys californicus*) that use flooded estuarine habitats especially channels as nursery habitat for young-of-the-year juvenile populations; (4) estuarine restricted fish such as Long-jawed Mudsuckers (*Gillichthys mirabilis*) that spend their entire life cycle in estuaries; (5) estuarine fish such as Tidewater Gobies (*Eucyclobius newberryi*) that are restricted to particular types of estuaries with brackish water but that survive under marine conditions during floods and return to estuaries under reduced runoff conditions; (6) anadromous fish such a Steelhead Trout (*Oncorhynchus mykiss*) that live under marine conditions as adults but enter estuaries to spawn either in estuaries or in rivers and streams on adjacent watersheds. In general most estuaries do not support all of the fish guilds, but collectively, southern California estuaries as a whole provide functions for each guild.

Estuarine open water habitats such as those provided by permanently flooded conditions are important foraging areas for birds from other habitats. Of note is the endangered California Least Tern (*Sterna antillarum browni*), which breeds on sandy habitats adjacent to marine and estuarine wetlands and forages on small fish, primarily Top Smelt *(Atherinops affinis)* and Northern Anchovy *(Engraulis mordax)* in the relatively shallow water of estuaries. Shallow water habitat also is important for foraging by wading birds [e.g., Snowy and Great Egrets (*Egretta thula*, *Casmerodias albus*) and Green, Black-crown Night, and Great Blue Herons (*Butorides virescens*, *Nycticorax nycticorax*, *Ardea herodias*], wading shore birds [e.g., Willet (*Catoptrophorus semipalmatus*)], diving birds including grebes, mergansers, and many ducks. The endangered Brown Pelican (*Pelecanus occidentalis*) is a frequent forager in estuarine open water habitats such as those provided by permanently, semi-permanently flooded, and intertidal water regimes. Open waters also provide low-tide refuges for species that move on to the mudflat and marsh plain during high tide.

Structural features: bays, lagoons, channels.

Deepwater habitats: Estuarine Unconsolidated Bottom and Rocky Bottom, and Estuarine Streambed Deepwater Habitats.

Physical processes: estuarine hydrology including tidal hydraulics; fluvial hydrology in river and creek mouth estuaries; marine and shoreline processes associated with estuary mouth dynamics; sediment transport; biogeochemistry.

Water regime/hydrology: subtidal, permanently flooded (i.e., deepwater habitats).

Salinity: haline to mixohaline.

Dominant/characteristic plant(s): diatoms, algae.

Associated plant(s): *Zostera marina*, *Potamogeton pectinatus, Ruppia maritima*, *Ruppia chirrosa* in various types of Estuarine Aquatic Bed Deepwater Habitat.

Characteristic animals: perhaps over 35 species of fish depending on type of estuary and guild of fishes present; suites of benthic and epibenthic invertebrates including various mollusks, crustaceans, worms, etc.; wading birds; dabbling and diving waterfowl; foraging Osprey.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; resident and migratory bird resting and foraging habitat, source populations of marsh-plain fish species (e.g., California Killifish, Long-jaw Mudsuckers); nutrient removal (denitrification at anoxic-soil/oxic-water interface; also P removal with sediment deposition); maintain predictable environment by maintaining hydrological connectivity and reducing extremes of drought (hypersalinity) and/or freshwater flooding (hyposalinity).

Recovery opportunities: foraging habitat for California Least Tern (*Sterna antillarum browni*), California Brown Pelican (*Pelicanus occidentalis californicus*), and Osprey (*Pandion haliaetus*); flat fish nursery habitat including California Halibut (*Paralichthys californicus*), Starry Flounder (*Platichthys stellatus*), and Diamond Turbot (*Hypsopsetta guttulata*).

Management Issues: water quality.

2. Deepwater Subtidal and Wetland Intertidal Channels (cobble/gravel and riprap substrates) – Open Water Subtidal, Intertidal, and High Tide Conditions

Narrative (refer to other open water habitats for additional information): Estuarine channels and creeks play a critical role in salt marshes as they convey tidal waters and associated nutrients and dissolved gases. They also support a complex assemblage of plants and animals, and are particularly diverse when cobble beds provide surfaces for attachment by some invertebrates (e.g., mussels, oysters, barnacles, and limpets) and protective habitats for others (e.g., crabs, gobies). This substrate differences separates this habitat type (#2) from type #3 (sand and mud substrates).

Estuarine channels and creeks are subjected to a wide variety of environmental conditions including fluctuations in salinity and depth of tidal inundation. Typically, tidal flushing is greatest at the tidal inlet and decreases with distance from the inlet. This general gradient, in turn influences, water movement, salinity, temperature, nutrients, and dissolved gases. These environmental factors influence the species composition, distribution, and population dynamics of the channel fauna.

Structural features: marine cobble deltas, cobble channel beds and bars, riprap.

Deepwater Habitats and Wetlands: Estuarine Streambed and Unconsolidated Shore and Bottom (cobble/gravel) Wetlands and Estuarine Rocky Shore and Rocky Bottom (boulder) Wetlands and Estuarine Deepwater Habitats.

Physical processes: estuarine hydrology including tidal hydraulics; fluvial hydrology in river and creek mouth estuaries; marine and shoreline processes associated with estuary mouth dynamics; sediment transport; biogeochemistry.

Water regime/hydrology: subtidal, permanently flooded (i.e., deepwater habitats); intertidal irregularly exposed, regularly flooded, irregularly flooded.

Salinity: haline and mixohaline.

Dominant/characteristic plant(s): micro-algae (e.g., diatoms, cyanobacteria); macro-algae (e.g., *Ulva* and *Enteromorpha*).

Associated plant(s): none.

Characteristic animals: oysters; mussels; crustaceans including Shore, Mud, and Fiddler Crabs; possibly over 70 species of invertebrates in cobble beds; wading birds; dabbling and diving waterfowl; foraging Osprey. Many estuarine fish species also use these channels depending on the type of estuary and habitat.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; biofiltration (e.g., bivalve filtration from mussels, oysters, etc.), nutrient cycling/biogeochemistry; N and P removal as above; carbon removal by shell forming mollusks.

Recovery opportunities: *Ostreola conchaphila* (native oyster) on cobble-gravel and other hard substrates; foraging habitat for California Least Tern, California Brown Pelican, and Osprey.

Management issues: water quality including sedimentation; loss of habitat due to dredging in some estuaries; expansion of habitat in other estuaries due to ongoing accretion of marine deltas.

3. Intertidal Wetland Habitats (sand and mud substrates) – Intertidal and High Tide Conditions

Narrative (refer to other open water habitats for additional information): Intertidal channels and creeks play a critical role in salt marshes as they convey tidal waters and associated nutrients and dissolved gases. They also support a complex assemblage of plants and animals. Estuarine channels and creeks are subjected to a wide variety of environmental conditions. Typically, tidal flushing is greatest at the tidal inlet and decreases with distance from the inlet. This general gradient, in turn influences, water movement, salinity, temperature, nutrients, and dissolved gases. These environmental factors influence the species composition, distribution, and population dynamics of the channel fauna.

Structural features: intertidal channels, creeks, basins, banks, benches, marsh plain, as well as margins of deepwater habitats in bays, lagoons and subtidal channels, natural creek levees and back-levee depressions (pools).

Wetlands: Estuarine Unconsolidated Bottom, Unconsolidated Shore, Streambed, Aquatic Bed, and Emergent wetlands.

Physical processes: estuarine hydrology including tidal hydraulics; fluvial processes in tidal river and stream channels; marine and shoreline processes in estuary mouths; sediment transport; biogeochemistry.

Water regime/hydrology: intertidal **–** semi-permanently flooded, irregularly exposed, regularly flooded, irregularly flooded.

Salinity: haline or mixohaline.

Dominant/characteristic plant(s): diatoms.

Associated plant(s): none or *Spartina foliosa* and *Sarcocornia pacifica* (*Salicornia virginica*), and other species as appropriate on flooded habitat margins and the marsh plain; channel banks provide substrate for germination of *Ulva* spp. spores, which then grow into blades that break free and become highly productive floating mats.

Characteristic animals: perhaps over 35 species of fish depending on type of estuary and habitat; suite of benthic and epibenthic invertebrates including Ce*rithidea californica* (California Horn Snail) and various clam genera including *Tagelus, Macoma*, *Protothaca*; wading birds including egrets and herons; dabbling and diving waterfowl; and foraging Osprey.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; resident and migratory bird resting and foraging habitat, source populations of marsh-plain fish species (e.g., killifish, mudsuckers); nutrient cycling/biogeochemistry; N and P removal.

Recovery opportunities: flat fish habitat including California Halibut, Starry Flounder, and Diamond Turbot; foraging habitat for California Least Tern, Brown Pelican, and Osprey.

Management issues: water quality including sedimentation; loss of habitat due to dredging in some estuaries; expansion of habitat in other estuaries due to ongoing accretion of marine deltas.

Habitat Category II
Estuarine Non-vegetated Intertidal Wetland Habitats

4. Intertidal Margins, Beds, Banks, and Benches (mud and sand substrates) - Low Tide Conditions

Narrative: Within the intertidal wetland portion of estuaries and in addition to mudflat features for those estuaries that support flats, other non-vegetated structures, including channel beds, banks and benches, often occur that can have similar functions to mudflats exposed at low tide conditions. These structures are group together here when lacking aquatic bed or emergent wetland vegetation cover.

Structural features: bay and lagoon margins and beds, bottoms, banks, and benches of estuarine channels and creeks.

Wetlands: Estuarine Streambed, Unconsolidated Shore, and Unconsolidated Bottom Wetlands.

Physical Processes: estuarine hydrology including tidal hydraulics; biogeochemistry.

Water regime/hydrology: irregularly exposed, regularly flooded.

Salinity: haline and mixohaline.

Dominant/characteristic plant(s): diatoms.

Associated plant(s): none or *Spartina foliosa*, *Sarcocornia pacifica* (*Salicornia virginica*) on margins; channel banks provide substrate for germination of *Ulva* spp. spores, which then grow into blades that break free and become highly productive floating mats.

Characteristic animals: suite of benthic and epibenthic invertebrates including C*erithidea californica* (California Horn Snail) and various clam genera including *Tagelus, Macoma, Protothaca*; wading and shore birds (foraging); polychaetes; oligochaetes.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; biofiltration, food chain support and nutrient cycling, N and P removal, C removal by bivalves.

Recovery opportunities: channel bench and similar habitat for Fiddler Crabs (*Uca crenulata*).

Management issues: water quality and sedimentation issues.

5. Intertidal Channels (cobble/gravel and riprap substrates) - Low Tide Conditions

Narrative: Estuarine channels and creeks play a critical role in salt marshes as they convey tidal waters and associated nutrients and dissolved gases. They also support a complex assemblage of plants and animals, and are particularly diverse when cobble beds provide surfaces for attachment by some invertebrates (e.g., mussels, oysters, barnacles, and limpets) and protective habitats for others (e.g., crabs, gobies). Estuarine channels and creeks are subjected to a wide variety of environmental conditions including fluctuations in salinity and depth of tidal inundation. Typically, tidal flushing is greatest at the tidal inlet and decreases with distance from the inlet. This general gradient, in turn influences, water movement, salinity, temperature, nutrients, and dissolved gases. These environmental factors influence the species composition, distribution, and population dynamics of the channel fauna.

Structural features: marine cobble deltas, cobble channel beds and bars, riprap.

Wetlands: Estuarine Unconsolidated Shore and Bottom (cobble/gravel) and Estuarine Rocky Shore and Rocky Bottom (boulder).

Physical processes: estuarine hydrology including tidal hydraulics; fluvial hydrology in river and creek mouth estuaries; marine and shoreline processes associated with estuary mouth dynamics; biogeochemistry.

Water regime/hydrology: intertidal irregularly exposed, regularly flooded, irregularly flooded.

Salinity: haline and mixohaline.

Dominant/characteristic plant(s): micro-algae (diatoms, cyanobacteria); macro-algae.

Associated plant(s): none.

Characteristic animals: oysters and mussels (hard substrates) crustaceans including Shore, Mud, and Fiddler Crabs; possibly over 70 species of invertebrates in cobble beds.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; low tide resting habitat for resident and migratory birds and foraging habitat for shorebirds and clapper rail; biofiltration (by bivalves), nutrient cycling/biogeochemistry; food chain support.

Recovery opportunities: *Ostreola conchaphila* (native oyster), shore bird feeding habitat.

Management issues: water quality including sedimentation**.**

6. Mudflats

Narrative: Extensive mudflats generally occur in estuaries that have gradually sloping shorelines and are sufficiently large enough to support a extensive open water and low marsh habitats or that are flooded for long periods due to closure of the estuary mouth or reduced tidal flow, presenting development of a vegetated marsh plain. Many estuaries that lack extensive mudflat habitat support functions for shore bird foraging and maintenance of invertebrate biodiversity because tidal channel beds and banks that are exposed at low tide provide similar habitat areas.

Structural features: down slope from low marsh and the marsh plain.

Wetlands: Estuarine Unconsolidated Shore and Unconsolidated Bottom Wetlands, and Estuarine Aquatic Bed Wetland (Irregularly Exposed).

Physical processes: extended periods of inundation prevent vascular plant growth.

Water regime/hydrology: regularly (daily) flooded by high tides.

Salinity: haline.

Dominant/characteristic plant(s): micro-algae, especially diatoms (over 100 species identified at some estuaries in s. CA).

Associated plant(s): at lowest tides, Eelgrass (*Zostera marina*) may be exposed (Estuarine Aquatic Bed Wetland, Irregularly Exposed) if present in estuary; macroalgae (e.g., *Ulva* spp.).

Characteristic animals: invertebrates: crabs, shrimp, clams, etc. (some are listed above regarding intertidal creeks] and shorebirds.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; nitrogen fixation by microalgae, sediment accumulation (and P removal), nutrient cycling, denitrification, invertebrate habitat, shorebird foraging.

Recovery opportunities: shorebird feeding habitat.

Management issues: mudflat is a very limited in most southern California estuaries. Sedimentation elevates the mudflat to levels that can support vascular plants; once vascular plants are established, the habitat is less suitable for shorebird feeding.

7. Hyperhaline Salt Flats

Narrative: Whereas intertidal mudflats occur at low elevations, permanently hypersaline salt flats are an important part of continuum from upland to low marsh. Salt flats but generally form only when the elevational gradient of the marsh plain is sufficient low for this evaporate zone to form at the higher levels of infrequent tidal inundation. As with restoration of all tide influenced habitats, establishment of hyperhaline salt flat and adjacent euryhaline marsh habitats require careful consideration of elevation, frequency and duration of inundation, and substrate texture. Salt flats alternate between flooded and drought conditions, which prevent most plants from occurring or from developing closed canopies if they are present. The open flat, with an occasional subshrub (e.g., *Arthrocnemum* (*Salicornia*) *subterminale*), offers certain shore birds a rare habitat that allows both feeding and refuge from predators.

Structural features: shallow depressions of upper marsh plain, banks, upper tidal deltas

Wetlands: Estuarine Unconsolidated Shore (Irregularly Flooded)

Physical processes: Estuarine processes including tidal hydraulics; geochemical processes including formation of evaporate deposits; salt concentration so that soils prevent invasion by exotic plants.

Water regime/hydrology: irregularly flooded by tides; < 25% of high tide.

Salinity: hyperhaline **-** 200 g/L or more in dry season.

Dominant/characteristic plant(s): none; scattered *Arthrocnemum subterminale.*

Associated plant(s): none.

Characteristic animals: Staphylinid beetles; shorebirds use these areas as refugia.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; resting and foraging areas for migratory birds, especially during high tides when other habitats are inundated.

Recovery opportunities: Tiger beetles (?); Elegant Tern (*Sterna elegans*) roosting habitat.

Management issues: Naturally occurring salt flat habitats, such as along the margins of estuarine deltas, were often some of the first areas filled in and developed in southern California estuaries. The Ballona Ecosystem supports habitat on dredge spoil in areas that were previously lower elevation habitats on the marsh plain. Preservation of salt plat habitat and functions may require relocation of the habitat if existing conditions are altered as part of a restoration plan.

Habitat Category III
Estuarine vegetated wetlands:

8. Aquatic Bed Wetlands

Narrative: This habitat category as described herein includes a number of different types depending on the structure of the habitat and the dominant organism, such as algae, bluegreen algae, vascular plants, etc. For example, nutrient-rich, estuarine channels are likely to be dominated by floating *Enteromorpha intestinalis* whereas nutrient-rich, exposed mud flats may be characterized by *Enteromorpha clathrata.* Lagoons, channels, and flooded marsh depressions with haline salinities may support dense, submersed colonies of *Ruppia maritima,* whereas similar areas that are mixohaline are likely to be characterized by *Ruppia cirrhosa* and other vascular aquatic-bed species.

Structural features: depressions in marsh plain, intertidal and subtidal channels, lagoons, and bays; haline vernal wetlands.

Wetlands: Estuarine Aquatic Bed Algal; Estuarine Aquatic Bed Rooted Vascular.

Physical processes: Estuarine processes including hydraulics.

Water regime/hydrology: variable depending on class of wetland and type of estuarine system; includes permanently flooded, semi-permanently flooded; intermittently exposed, regularly flooded, irregularly flooded.

Salinity: haline; mixo-haline.

Dominant/characteristic plant(s): Algae – various species represented including Enteromorpha, *Ulva*, *Porphyra*, etc, but many examples are not large enough or provide a dense enough cover to warrant distinction as a wetland type; Rooted vascular plants – various species depending on conditions, including *Ruppia maritima* (haline or euryhaline) and *Potamogeton pectinatus*, *Ruppia cirrhosa*, and *Zannichellia palustris* (mixohaline). Floating vascular plants – e.g., *Lemna gibba* (mixohaline).

Associated plant(s): as noted above or various emergent species in adjacent wetlands.

Characteristic animals: food and habitat for aquatic invertebrate species and for small fish species, including Tidewater Goby (*Eucyclogobius newberryi*) under mixohaline conditions.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; food chain support for waterfowl such as dabbling ducks; bio-assimilation of nutrient pollution; nutrient cycling/biogeochemistry; N and P removal.

Recovery opportunities: Mixohaline (i.e., brackish) environments that support *Ruppia cirrhosa* are frequently habitat for populations of Tidewater Goby (*Eucyclogobius newberryi)*, a federal endangered and state fish of concern.

Management issues: water quality.

9. Cordgrass (Low) Marsh

Narrative: Low salt marsh is regularly and daily inundated by tides and is dominated by California Cordgrass (*Spartina foliosa*) that forms dense monotypic stands, primarily along channel edges and adjacent to mudflats. At its lower elevation, cordgrass intergrades with mudflat habitat; at its upper elevation it intergrades with a mosaic of mid-marsh species. California Cordgrass is a highly productive species. It decomposes to form the base of the detrital food chain that supports many lower order estuarine consumers. The tall canopy provides cover for birds such as Curlew and Pintail Duck, which forage during migration.

Many of the animals of the low marsh are adapted to periods of frequent inundation. These include California horn snail, Lined Shore Crab *(Pachygrapsus crassipes)*, Yellow Shore Crab *(Hemigrapsus oregonensis)*, and Fiddler Crab *(Uca crenulata)*. The best-studied animal of the low marsh is the federal and state-endangered Light-footed Clapper Rail (*Rallus longirostrus levipes*). This species generally nests in the cordgrass that grows in the low marsh and feeds on fishes and crustaceans in adjacent tidal creeks. It also nests in pickleweed on the marsh plain and in bulrushes in brackish marsh vegetation.

Structural features: lower edge of the marsh plain, tidal channel margins

Wetlands: Estuarine Emergent Persistent Wetland (Regularly Flooded)

Physical processes: Estuarine processes including tidal hydraulics; sediment accumulation.

Water regime/hydrology: regular (daily) flooding by tides

Salinity: hypersaline and saline to brackish

Dominant/characteristic plant(s): *Spartina foliosa;* also patches of *Batis maritima.*

Associated plant(s): *Salicornia bigelovii.*

Characteristic animals: *Pachygrapsus crassipes; Hemigrapsus oregonensis; Uca crenulata;* California Horn Snail (*Cerithidea californica).*

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; sediment accumulation and reduced erosion along channel edges; nutrient cycling/biogeochemistry; N and P removal; C sequestration; high rates of primary productivity and food web support; invertebrate habitat; fish habitat when flooded by tide water.

Recovery opportunities: *Spartina foliosa* (where it previously existed or to compensate for areas where its population is declining); Light-footed Clapper Rail (Fed. & State endangered bird).

Management issues: potential impacts from native and introduced predators of marsh nesting birds (Light-footed Clapper Rail); excessive sedimentation.

10. Marsh Plain (Middle Marsh)

Narrative: Intermediate elevations within the salt marsh are inundated irregularly by tides but at a greater frequency than are higher elevations. As a result, the plant species that inhabit this elevation are adapted to occasional prolonged inundation. The dominant plant is Pickleweed [*Sarcocornia pacifica* (*Salicornia virginica*)] a perennial with the broadest elevation range of all salt marsh species. Other common mid-marsh species include Saltwort (*Batis maritima*), Arrow-grass (*Triglochin concinnum*), Estero Sea-blite (*Suaeda esteroa*), and Jaumea (*Jaumea carnosa*). An important feature of the marsh plain is its topographic heterogeneity, which includes creeks, creek banks, levees, and shallow depressions. The creeks provide habitat for Longjaw Mudsucker (*Gillichthys mirabilis*);

creek levees tend to support more plant species than the plain (e.g., Estero Sea-blite is especially abundant near creeks), and the shallow depressions (5-10 cm) tend to reduce biomass of perennial pickleweed. When this dominant is subdued, the annual pickleweed (*Salicornia bigelovii*) can establish and persist. Deeper depressions ($\geq$10 cm) retain tidal water and become feeding oases for the California Killifish (*Fungulus parvipinnus*); shallow depressions develop algal growths that support dense populations of invertebrates that are suitable prey for fish.

The animals of the mid-marsh are abundant and diverse. Food is abundant in the form of algae and vascular plant detritus. Animals that feed directly on algae include Ephydrid flies, amphipods, and snails such as the Olive Snail (*Melampus olivaceus*) in marsh vegetation and California Horn Snail (*Cerithidea californica*) in open flats and channels. A variety of birds forage in the mid-marsh, especially during higher tides when mudflats are under water, including Willet *(Catotrophorus semipalmatus)*, Marbled Godwit *(Limosa fedoa)*, Long-billed Curlew *(Numenius americanus)*, Great Blue Heron *(Ardea herodias)*, and Great Egret *(Ardea alba)*. The state endangered Belding's Savannah Sparrow *(Passerculus sandwichensis beldingii)* inhabits the marsh plain where it prefers to nest in pickleweed in mid and high marsh conditions.

Structural features: mid-marsh plain, rivulets, tidal pools, creek-side levees and back-levee depressions.

Wetlands: Estuarine Emergent Persistent Wetland (Irregularly Flooded).

Physical processes: estuarine processes including tidal hydraulics and maintenance of sediment and elevation.

Water regime/hydrology: irregularly flooded by tides (ca. 50% of high tides).

Salinity: saline to hypersaline.

Dominant/characteristic plant(s): *Sarcocornia pacifica* (*Salicornia virginica*).

Associated plant(s): *Frankenia salina, Jaumea carnosa, Distichlis spicata, Suaeda esteroa, Triglochin concinna.*

Characteristic animals: *Fundulus parvipinnis* (California Killifish); *Melampus* olivaceus; polychaetes; oligochaetes.

Ecosystem functions: plant diversity support (the mash plain is potentially diverse in native halophytes), habitat for rare, endangered, and special interest species; insect support, nutrient cycling/biogeochemistry; N and P removal; primary productivity and detrital food web support.

Recovery opportunities: Belding's Savannah Sparrow (State endangered bird); Long-billed Curlew (*Numenius americanus*); Estero Seep-weed (*Suaeda esteroa*); Northern Harrier (*Circus cyaneus*).

Management issues: sedimentation (increase in elevation and loss of shallow depressions that form pools and create feeding oases, or erosion (decrease in elevation); potential impacts to marsh nesting birds (Belding's Savannah Sparrow).

11. High Marsh (clay/mud or sand/loam substrates)

Narrative: High marsh habitats are irregularly to intermittently inundated by tidal water and generally range from saline to hypersaline conditions. Plants that comprise the high marsh include the Parish's Glasswort [*Arthrocnemum subterminale* (*Salicornia subterminalis*)], Shoregrass (*Monanthochloe littoralis)*, Alkali Heath (*Frankenia salina*), and Sea Lavender *(Limonium californicum)*. The vegetation varies depending on the drainage and density of the soil (i.e., ratio of clay to sand), which often is correlated with salinity. Vegetation in dense, hypersaline (salinity greater than seawater) or euryhaline (fluctuating salinity, seasonal hypersalinity) is quite different than loose, sandy soils. The endangered Salt Marsh Bird's Beak *(Cordylanthus maritimus* spp. *maritimus)* occurs in high marsh and is more abundant in sandy soils. Likely the open canopies of sandy areas allow seeds to germinate after rainfall while also offering roots for this hemiparasite to parasitize. High marsh vegetation provides habitat for Belding's Savannah Sparrow, staphylinid beetles, the snail *Assiminea transluscens*, and other estuarine restricted species.

Structural features: upper marsh plain, slopes of berms and banks; upper tidal deltas.

Wetlands: Estuarine Emergent Persistent Wetland (Irregularly Flooded).

Physical processes: Estuarine processes including tidal hydraulics; also Aeolian-influenced processes if adjacent to dune systems, or fluvial-influenced if on a delta.

Water regime/hydrology: Irregularly flooded by tides (< 50% of high tides.

Salinity: saline, hyperhaline, euryhaline.

Dominant/characteristic plant(s): *Arthrocnemum subterminale*; *Monanthochloe littoralis.*

Associated plant(s): *Sarcocornia pacifica, Limonium californicum, Distichlis spicata, Spergularia macrotheca, Atriplex watsonii, Frankenia salina*

Characteristic animals: *Asiminea transluscens* (snail); Belding's Savannah Sparrow; Cottontail; Ground Squirrels.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; high tide refuge for Light-footed Clapper Rail and Belding's Savannah Sparrow.

Recovery opportunities: Light-footed Clapper Rail (Fed. & State endangered bird); Belding's Savannah Sparrow (State endangered bird); Northern harrier (*Circus cyaneus*) foraging habitat; *Cordylanthus maritimus* ssp. *maritimus* (Fed. & State endangered plant)

Management issues: Loss of historic habitat due to filling and development. Vulnerable to invasion by many introduced invasive plant species including introduced species of *Limonium* (Sea Lavender), are less likely to invade lower elevations habitats, and introduced grass species such as Rabbit's Foot Grass (*Polypogon monspeliensis*), Sicklegrass (*Parapholis incurva*), Italian Ryegrass (*Lolium multiflorum*) because it is rarely tidal and can have very low salinities at least seasonally.

12. High Marsh Transition Zone (including Euryhaline and Hyperhaline Habitats)

Narrative: The transition zone represents that area where the halophytic and hydrophytic salt marsh vegetation overlaps with upland communities. Storm-surge high tides may flood habitats transitional to upland habitats, including various palustrine wetlands adjacent to high marsh estuarine wetlands; however, they are generally considered to be located beyond the limits of estuarine wetlands, but within the more broadly defined "estuarine" ecosystem (e.g., the Ballona Ecosystem). At relatively undisturbed southern California estuaries, examples of Estuarine Scrub Shrub Wetland may occur in the transition zone and may include Boxthorn *(Lycium californicum)*, Bush Seepweed *(Suaeda nigra)*, Coast Golden Bush (*Isocoma menziesii*), Parish's Glasswort (*Arthrocnemum subterminale*), and Quail Bush (*Atriplex lentiformis*). These overlap with the highest elevation salt marsh species including, for example, Saltgrass *(Distichlis spicata)*, Alkali Weed *(Cressa truxillensis)*, and Shoregrass *(Monanthochloe littoralis)*. *Lycium* is a common perch for birds and various small mammals burrow under it. The fact that it is deciduous shrub that greens up whenever there is water available makes it an indicator of sewage spills or other off-season sources of water.

The animals of the higher elevations of the transition zone are primarily terrestrial species. Those associated with shrubby uplands such as portions of the transition zone include, for example, various species of snakes, lizards, small mammals and birds. Herpetofauna may include California Kingsnake *(Lampropeltis getulus californiae)*, San

Diego Gopher Snake *(Pituophus melanoleucus annectens)* and side-blotched lizard *(Uta stansburiana)*. Common mammals of the shrub-dominated uplands include Western Harvest Mouse *(Reithrodontomys megalotis)*, Deer Mouse *(Peromyscus maniculatus)*, Pocket Gopher (*Thomomys* sp.), Opossum *(Didelphis virginianus)*, Striped Skunk (*Mephitis mephitis)*, and California Ground Squirrel *(Spermophilus beechyi)*. The small mammals are preyed upon by a variety of birds including Short-eared Owl *(Asio flammeus)*, Northern Harrier *(Circus cyaneus)*, and White-tailed Kite *(Elaneus caeruleus)*. Ground-nesting bees that pollinate Salt Marsh Bird's-Beak (*Cordylanthus maritimus* spp. *maritimus*) live above the high tide in this habitat. Boxthorn (*Lycium californicum*) offers a tall perch site for various birds, and its thorns can deter human intrusion.

One of the more interesting habitats is the euryhaline zone with fluctuating salinities between wet season low salinities and dry season hypersaline conditions. The habitat is characterized by winter annual plant species such as Salt Marsh Daisy (*Lasthenia glabrata* ssp. *coulteri*), Salt Marsh Sand-sperry (*Spergularia marina*), Toad Rush (*Juncus bufonius*), and Hutchinsia (*Hutchinsia procumbens*), which are adapted to the fluctuating salinities. The euryhaline zone is generally located upslope from hyperhaline salt flats and down-slope from nontidal palustrine wetland or grassland habitats and is perhaps the habitat most representative of Mediterranean climate estuarine wetlands.

The transition zone may also include nontidal palustrine habitats both salt influenced and non-saline types. Seeps from perched water tables on deltas and the toe of slopes and along dune transitions often support a variety of palustrine emergent and scrub-shrub types. Characteristic non-saline or slightly brackish species may include shrubs such as Mule Fat (*Baccharis salicifolia*) and herbaceous species such as spiny-rush (*Juncus acutus*), Willow-Dock (*Rumex salicifolia)*, and Alkali Ryegrass (*Leymus triticoides*). Seasonal palustrine wetlands also occur in this area, especially in low-gradient deltaic deposits and may include salt-influenced types supporting a variety of native annual species such as Alkali Barley (*Hordeum depressum*). Belding's Savannah Sparrows use the taller shrubs of this habitat during the non-nesting season.

Structural features: alluvial plain, upper deltas, banks.

Wetlands: Estuarine Emergent Persistent and Nonpersistent Wetland (Irregularly Flooded); Estuarine Scrub Shrub Wetland (Broadleaved Deciduous and Evergreen).

Physical processes: estuarine processes including tidal hydraulics; fluvial-influenced if on a delta; geochemical processes including formation of evaporate deposits.

Water regime/hydrology: (irregularly flooded by tides; i.e., < 20% of tides); and adjacent storm-tide influenced wetlands, palustrine wetlands, and uplands.

Salinity: fluctuating from mixohaline and saline to hyperhaline (more saline than sea water) and euryhaline (fluctuating salinity) and upslope to potentially non-haline.

Dominant/characteristic plant(s): *Arthrocnemum subterminale, Monanthochloe littoralis, Lycium californicum.*

Associated plant(s): winter annuals including *Spergularia marina, Juncus bufonius, Hordeum depressum, Lasthenia glabrata* ssp. *coulteri, Hutchinsia procumbens.*

Characteristic animals: (see animals discussed above regarding the high marsh habitat).

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; foraging areas for upland animals; resting areas for migratory birds; high tide refuge for Light-footed Clapper Rail; pollination support.

Recovery opportunities: *Lasthenia glabrata coulteri* (CNPS rare); *Hutchinsia procumbens* (locally extirpated); Tiger beetles (?); Northern Harrier (*Circus cyaneus*) foraging areas.

Management issues: Loss of historic habitat due to filling and development. Vulnerable to colonization by many introduced invasive plant species. This transitional habitat [and the high marsh as noted above] is highly susceptible to invasive species such as Rabbit's Foot Grass (*Polypogon monspeliensis*), Sicklegrass (*Parapholis incurva*), Italian Ryegrass (*Lolium multiflorum*), and other grasses because it is rarely tidal and can have very low salinities at least seasonally, especially during unusually wet winters and in areas that receive substantial anthropogenic freshwater inputs.

13. Brackish Marsh (and associated Open Water Habitat)

Narrative: Sites where freshwater mixes with saline seawater produce brackish conditions with intermediate salinities. This phenomenon is less frequent in southern California where many estuaries are less influenced by runoff from rainfall than in more northerly latitudes. In southern California, brackish sites vary seasonally, with dilution during the wet season and concentration of salts during the dry season. Local influence from seeps and springs and seasonally impounded stream and river-mouths can produce brackish environments that support emergent vegetation characterized, for example, by Prairie Bulrush [*Bolboschoenus* (*Scirpus*) *maritimus*], and Southern Cattail (*Typha domingensis*), and aquatic bed species including (*Potamogeton pectinatus)* and Ditchgrass (*Ruppia* spp.). The biggest difference in plant composition between brackish and salt marshes is often at the lower elevations in the marsh -- higher elevation areas of Mediterranean-climate brackish marshes tend to be similar to the mid-marsh plain or high marsh habitats of salt marshes. Tidewater Goby (*Eucyclogobius newberryi),* a Federal listed endangered species, occurs in systems or habitats within systems characterized by brackish water conditions.

Structural features: channels, depressions, basins, seeps and springs.

Wetlands: Estuarine Emergent Persistent and Nonpersistent Wetland (Semi-permanently Flooded); estuarine Aquatic Bed Wetland (Floating and Rooted Vascular; Algal).

Physical processes: Estuarine processes including tidal hydraulics; also fluvial-influenced if associated with a river channel and artesian-influenced if associated with seeps or springs from groundwater.

Water regime/hydrology: Tidally influenced with a wide range of tidal inundation frequencies depending on elevation and distance from the tidal inlet; seasonal dilution from surface water (runoff).

Salinity: brackish (mixohaline).

Dominant/characteristic plant(s): Prairie Bulrush [*Bolboschoenus* (*Scirpus*) *maritimus*]*;* California Bulrush, Tule [*Schoenoplectus* (*Scirpus*) *californicus*]; American Bulrush [*Schoenoplectus* (*Scirpus*) *americanus*]; Southern Cattail (*Typha domingensis*).

Associated plant(s): Salt Marsh Bulrush [*Bolboschoenus* (*Scirpus*) *robustus*] (unknown from Ballona?); Spiny Rush (*Juncus acutus*).

Characteristic animals: rails; bittern; wrens, Redwing Blackbird.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; biofiltration of freshwater runoff; nutrient cycling/biogeochemistry; N and P removal; C sequestration; sediment accumulation; very high rates of primary productivity in the lower portions of brackish and freshwater marsh areas; food web support.

Recovery opportunities: Light-footed Clapper Rail (Fed. & State endangered); Tidewater Goby (threatened); Brackish Water Snail (*Tyonia imitator*).

Management issues: Influence of stormwater runoff on formation of and impacts to brackish marshes; water quality; excessive sedimentation from upstream disturbances.

Habitat Category IV
Palustrine Nontidal Wetlands:

14. Transitional Emergent Wetlands (delta distributaries and margins of estuaries)

Narrative: The toe of slopes along estuary margins often provide opportunities for the formation of fresh or brackish water seeps and springs, including examples with well-developed dune fields containing freshwater lenses, deltas of rivers with shallow aquifers, and alluvial fans with artesian wells. These features can be the sites of estuarine brackish marshes and palustrine freshwater marshes. They also can support the development of palustrine emergent wetlands that are transitional in nature and similar to habitat type No 12 – High Marsh Transition Zone, but are distinctly palustrine and adjacent to estuarine habitats within coastal ecosystems.

Structural features: margins of dunes, deltas, banks, bluffs, alluvial fans and plains.

Wetlands: Palustrine Emergent Persistent Wetland.

Physical processes: Fluvial and/or groundwater hydrology.

Water regime/hydrology: (Permanently?), seasonally, temporarily, or intermittently saturated; temporarily or intermittently flooded.

Salinity: Freshwater to euryhaline. Due to brackish nature of water, salt spray, or rare storm-tide influences, or even concentration of salts by plants, soil salinity may increase during dry periods and may include formation of surface precipitates.

Dominant/characteristic Plant(s): Alkali Ryegrass (*Leymus triticoides*); Saltgrass (*Distichlis spicata*); Western Goldenrod (*Euthamia occidentalis*); Salt Marsh Baccharis (*Baccharis douglasii*).

Associated plant(s): Alkali Barley (*Hordeum depressum);* Seaside Heliotope (*Heliotropium curassavicum);* Coast Golden Bush (*Isocoma menziesii);* Western Sea-Purslane (*Sesuvium verrucosum);* Common Sedge (*Carex praegracilis*); Yerba Mansa (*Anemopsis californica*); Baltic Rush (*Juncus balticus*); Small-leaved (Petunia parvifolia); Sticky Conyza (*Conyza coulteri*).

Characteristic animals: small mammals including voles, harvest mice, field mice, gophers; herpetofauna.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; hydrology (seasonally saturated, temporarily flooded).

Recovery opportunities: foraging habitat for White-tailed Kite and other raptors; potential habitat for Ventura Marsh Milk-vetch (*Astragalus pycnostachys* var. *lanosissimus* - Fed and State listed endangered plant); Wandering Skipper (butterfly); Southern Salt Marsh Shrew (*Sorex ornatus salicornicus*).

Management issues: invasion by Giant reed (*Arundo donax*) and Myoporum (*Myoporum laetum*).

15. Freshwater Marsh

Narrative: Freshwater marshes occur in saturated, organic rich or sometime mineral soils. The dominant plants are generally emergent monocots such as cattails (*Typha* spp.) and bulrushes [e.g., *Schoenoplectus (Scirpus) californicus*], although aquatic-bed species, such as pondweeds (*Potamegeton* spp.), may also be common. Redwing Blackbirds (*Agelaius phoeniceus*) and Marsh Wrens (*Cistithorus palustris*) commonly breed in the tall, dense vegetation. Common mammals include Raccoon (*Procyon lotor*), Striped Skunk and Opossum. Freshwater marsh habitat may also support the Light-footed Clapper Rail, although this is not considered optimal breeding or foraging habitat. These marshes may provide refugia for rails and other bird species during extreme high tides and rive floods. Creation and maintenance of freshwater marsh habitat is dependent upon a continual source of freshwater. Some coastal wetland restoration plans have incorporated freshwater and brackish marshes due to historical evidence of springs adjacent to intertidal areas

Structural features: river and stream channels; ponds; seeps and springs

Wetlands: Riverine Nonpersistent Emergent Wetland; Palustrine Emergent Persistent Wetland (Permanently or Semi-permanently Flooded, Irregularly Exposed).

Physical processes: Fluvial and/or groundwater.

Water regime/hydrology: Permanently flooded; intermittently flooded; seasonally flooded; permanently and seasonally saturated.

Salinity: fresh water to slightly brackish (groundwater conditions).

Dominant/characteristic Plant(s): Broadleaved Cattail (*Typha latifolia*); Bur-reed (*Sparganium eurycarpum*); California Bulrush (*Schoenoplectus californicus*); Southern Cattail (*Typha domingensis*).

Associated plant(s) - Representative: Basket Rush (*Juncus textilis*); Spiny Rush (*Juncus acutus*); Spike-rush (*Eleocharis spp*.), Hooker's Evening Primrose (*Oenothera elata* ssp. *hookeri*); Horsetails – Common Scouring Rush (*Equisetum hyemale* ssp. *affine*), Smooth Scouring Rush (*E. levigatum*), Giant Horsetail (*E. telmateia*); Western Goldenrod (*Euthamia occidentalis*); Willow Dock (*Rumex salicifolius* vars. *crassus*); Willow Herb (*Epilobium ciliatum* ssp. *ciliatum*); Yerba Mansa (*Anemopsis californica*); American Bulrush (*Schoenoplectus americanus*); Three-square Bulrush (*Schoenoplectus pungens*); Cinquefoil (*Potentilla anserina*); Monkey-flower (*Mimulus guttatus*).

Characteristic animals: Western Pond Turtle, Red-legged Frog; rails, waterfowl, Red-winged Blackbird (*Agelaius phoeniceus*); many passerine birds.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; nutrient cycling/biogeochemistry; N and P removal; C sequestration; sediment accumulation; high rates of primary productivity; habitat for breeding birds.

Recovery opportunities: Western Pond Turtle (*Clemmys marmorata*); California Red-Legged Frog (*Rana aurora draytonii*); Light-footed Clapper Rail and other rail species known to use freshwater marshes adjacent to estuaries in southern California; Least Bittern (*Ixobrychus exilis*); Northern Harrier (*Circus cyaneus*); Spiny Rush (*Juncus acutus*).

Management issues: excessive sedimentation; subject to shrub invasion (e.g., willow invasion). Sites that are less frequently flooded can have substantial problems with non-native grasses such as Rabbitsfoot Grass. Also, Giant Reed and Pampas Grass are large perennial grasses that can be problematic.

16. Seasonal Palustrine Wetlands (including Haline Vernal Wetlands)

Narrative: Seasonal wetlands are non-tidal wetlands and transitional habitats that are flooded to varying degrees by seasonal rainfall and runoff. If there are sufficient salts in the soil, the seasonal wetland may support plant species more typical of coastal salt marsh, such as Pickleweed [*Sarcocornia pacifica* (*Salicornia virginica*)], Saltgrass (*Distichlis spicata*), and Alkali Weed (*Cressa truxillensis*). If the soils do not contain salts or alkaline substances, the seasonal wetlands may support freshwater marsh species and a mixture of weedy opportunists. “Vernal pools” and saline vernal wetlands of transition zones can occur on alluvial and deltaic deposits adjacent to estuarine habitats and are known to support special concern plants and invertebrate animals (e.g., fairy shrimp species).

Seasonal wetlands can be important to a number of bird species that feed on the insects, algae and aquatic invertebrates that develop in these temporary habitats. Amphibians, such as western toad (*Bufo boreas*) and Pacific Tree Frog (*Pseudacris regilla*) have been noted to breed in this habitat. These areas also attract mammals, such as Coyote, Raccoon, Striped Skunk and Opossum. In areas where water pools deeply enough, waterfowl species such as Mallard (*Anas platyrhynchos*), Cinnamon Teal (*Anas cyanoptera*) and American Coot (*Fulica Americana*) have been observed. Seasonal wetlands may also used by shorebirds such as Killdeer (*Charadrius vociferus*) and Black-necked Stilts (*Himantopus mexicanus*).

Structural features: depressions in deltas and fill deposits often associated with other palustrine wetlands adjacent to estuarine wetlands

Wetlands: Palustrine Emergent Wetland, persistent and non-persistent types, seasonally flooded and generally euryhaline

Physical processes: natural examples influenced by fluvial and coastal (storm) processes and anthropogenic effects from disturbances including infilling, dredging, grading, etc.

Water regime/hydrology: Seasonally flooded

Salinity: Fresh water or euryhaline (low salinity when flooded and higher salinity when dry)

Dominant/characteristic Plant(s): Haline vernal wetland examples – Alkali Barley (*Hordeum depressum*); Pickleweed (*Sarcocornia pacifica*); Salt Marsh Daisy (*Lasthenia glabrata* ssp. *coulteri*); Salt Marsh Sand-Sperry (*Spergularia marina*); Toad Rush (*Juncus bufonius* ssp. *halophilus*?). Freshwater examples – Meadow Barley (*Hordeum brachyantherum* ssp. *brachyantherum).*

Associated plant(s): Alkali Mallow (*Malvella leprosa*); Alkali Weed (*Cressa truxillensis*); Sea-Purslane (*Sesuvium verrucosum*); Horned Sea-blite (*Suaeda calceoliformis*); Seaside Heliotrope (*Heliotropium curassavicum*); Slim Aster (*Symphyotrichum subulatum*); Sticky Conyza (*Conyza coulteri*).

Characteristic animals: planktonic (e.g., rotifers, crustaceans including copepods, cladocerans) and macroscopic (e.g., aquatic insect larvae) invertebrates.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; shorebird foraging habitat.

Recovery opportunities: Silver Scale (*Atriplex argentea* var. *mohavensis*) (extirpated?); Hutchinsia (*Hutchinsia procumbens*) (extirpated?); Southern Tarweed (*Centromadia*. *parryi* ssp. *australis*); fairy shrimp species?

Management issues: impacts (e.g., cover and thatch) from introduced annual weeds including Brass Buttons (*Cotula coronopifolia*), Mediterranean Barley (*Hordeum marinum*), Italian Ryegrass (*Lolium multiflorum*), Rabbitsfoot Grass (*Polypogon monspeliensis*), and Sicklegrass (*Parapholis incurva*).

17. Palustrine Scrub/Shrub Wetland (= DFG "Riparian Scrub")

Narrative: Willow scrub is characterized by dense broad-leafed, winter-deciduous riparian thickets dominated by several willow shrub and tree species (*Salix* spp.). Riparian trees also may occur with the association and may include, for example, scattered Fremont's Cottonwood (*Populus fremontii*), and Western Sycamore (*Platanus racemosa*). Riparian woodland also may occur in small groves or in riverine corridors that drain into estuaries. As with other riparian habitats, riparian scrub supports a diverse assemblage of wildlife species, especially passerine bird species. The endangered Least Bell's Vireo (*Vireo bellii pusillus*) and Southwestern Willow Flycatcher (*Epidonax traillii extimus*) as well as other sensitive species, such as Yellow Warbler (*Dendroica petechia brewsteri*) and Yellow-breasted Chat (*Icteria virens*) all depend on riparian woodlands for breeding. Mammal assemblages are similar to those found in freshwater marsh habitats as the two often intergrade. In an undisturbed estuarine system, willow scrub habitat would generally occur upstream of tidal influence as willows are very sensitive to salt. Like freshwater marsh, this habitat is dependent upon a constant source of freshwater.

Structural features: bluff and dune seeps or spring, floodplains.

Wetlands: Palustrine Scrub/Shrub Wetland (Broadleaved Deciduous and Evergreen).

Physical processes: fluvial and/or groundwater hydrology; sediment transport.

Water regime/hydrology: seasonally and permanently saturated; temporarily flooded; phreatophytic.

Salinity: fresh water.

Dominant/characteristic Plant(s): Arroyo Willow (*Salix lasiolepis*); Mule Fat (*Baccharis salicifolia*); Sandbar Willow (*Salix exigua*).

Associated plant(s): Basket Rush (*Juncus textlis*); California Rose (*Rosa californica*); Coyote Brush (*Baccharis pilularis*); Salt Marsh Baccharis (*Baccharis douglasii*); American Dogwood (*Cornus sericea* ssp. *occidentalis*)?; Hoary Nettle (*Urtica dioica* ssp. *holosericea*).

Characteristic animals: resident and migratory passerine birds, such as Common Yellowthroat (*Geothlypis trichas*) and Blue grosbeack (*Guiraca caerulea*), and those listed herein (habitat no. 18); herpetofauna and mammals of various guilds.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; refuges for estuarine wildlife species and wildlife corridors linking upland sites with coastal wetlands.

Recovery opportunities: Least Bell's Vireo (*Vireo bellii pusillus*) and Southwestern Willow Flycatcher (*Epidonax traillii extimus*) as well as other sensitive species, such as Yellow Warbler (*Dendroica petechia brewsteri*) and Yellow-breasted Chat (*Icteria virens*).

Management issues: Impacts from invasive plant species including Giant reed (*Arundo donax*), Pampas Grass (*Cortaderia selloana*); Myoporum (*Myoporum laetum*).

18. Palustrine Forested Wetland (= DFG "Riparian Woodland"?)

Narrative: Palustrine Forested Wetland as discussed herein is generally characterized by isolated stands of trees or tall shrubs that occur at seeps, toe-of-slopes, ponded areas, along streams and rivers, and at other sites with shallow water tables. Arroyo Willow (*Salix lasiolepis*) is the most common representative but other native species such as additional willow species, Black Cottonwood (*Populus balsamifera* ssp. *trichocarpa*), and Western Sycamore (*Platanus racemosa*) are also represented. Riparian corridors along streams and rivers are no longer well developed due to impacts from urbanization, but portions of the original drainage of Centinela Creek still support riparian vegetation. In the riparian setting, trees in upland and wetland habitats may be included in mapped examples of this vegetation where the distinction among hydric (i.e., wetland), mesic, and xeric (i.e., upland) types of riparian vegetation are often not distinguished. A number of exotic species also may be represented including Myoporum (*Myoporum laetum*) and various species of *Eucalyptus*, especially Blue Gum (*Eucalyptus globulus*).

Structural features: bluff seeps, floodplains, margins of dunes and dune swales.

Wetlands: Palustrine Forested Broadleaved Deciduous Wetland.

Physical processes: fluvial and/or groundwater hydrology; sediment transport.

Water regime/hydrology: permanently, seasonally, temporarily, or intermittently flooded; permanently, seasonally saturated; phreatophytic.

Salinity: freshwater.

Dominant/characteristic Plant(s): Black Cottonwood (*Populus balsamifera* ssp. *trichocarpa*); Western Sycamore (*Platanus racemosa*); Arroyo (*Salix lasiolepis*).

Associated plant(s): Blue Elderberry (*Sambucus mexicana*); Coast Live Oak (*Quercus agrifolia*); White Alder (*Alnus rhombifolia*); Red Willow (*Salix laevigata*); Shining Willow (*Salix lucida* ssp. *lasiandra*); Black Willow (*Salix goodingii*); California Walnut (*Juglans californica*); various riparian shrubs and vine species and herbaceous plants including Stinging Nettle (*Urtica dioica* ssp,. *holosericea*).

Characteristic animals: Passerine birds including resident and migratory birds such as those sensitive species listed below; herpetofauna; shelter and corridor for mammals including raccoon, skunk, and coyote.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; breeding bird habitat.

Recovery opportunities: Southwestern Willow Flycatcher (*Empidomax trallii extimus*); Least Bell's Vireo (*Vireo belli pusillus*); Western Yellow Warbler (*Dendroica petechia brewsteri*); Yellow-breasted Chat (*Icteria virens*).

Management issues: vulnerable to invasion by Giant Reed (*Arundo donax*) and various exotic vines (e.g. Cape Ivy), shrubs (Tamarisk), and tree species (e.g., *Eucalytus* spp.); restore connectivity of stands when appropriate and feasible.

Habitat Category V
Upland Habitats:

19. Grasslands (= DFG Non-native Herbaceous Vegetation)

Narrative: Grasslands are illustrated on historic maps of the Ballona region and are likely to have occurred on alluvial deposits on the periphery of the coastal wetland ecosystem, mixed with various forms of coastal scrub. DFG recently used the designation "non-native herbaceous" for the category of vegetation that represents the existing conditions of "grassland", "meadow", or "prairie" vegetation within the Ballona Ecosystem. In a restored state, the vegetation could include native grass species and a diverse number of native herbaceous and sub-shrub species as noted above, with small colonies and scattered individuals of coastal scrub species to provide perches and shelter for animals that characterize grassland and adjacent scrub and wetland habitats.

Structural features: upland alluvial deposits, graded spoil deposits,

Physical processes: potentially a fire-maintained community.

Dominant/characteristic Plant(s): in an upland context - California Barley (*Hordeum brachyantherum* ssp. *californicum*); Purple Needlegrass (*Nassella pulchra*); Salt Grass (*Distichlis spicata*); Alkali Ryegrass (*Leymus triticoides*).

Associated plant(s): Alkali Heath (*Frankenia salina*); Coast Golden Bush (*Isocoma menziesii*); Common Tarweed (*Dienandra fasciculata*); Telegraph Weed (*Heterotheca grandiflora*); Deerweed (*Lotus scoparius*), Spanish Clover (*Lotus purshianus*), Owl's Clover (*Castilleja exerta*); White Cudweed (*Gnaphalium canescens*); Common Verbena (*Verbena lasiostachys*); California Poppy (*Eschschulzia californica*); Pitseed Goosefoot (*Chenopodium berlandieri*); Arroyo Lupine (*Lupinus succulentus*); Bicolor Lupine (*Lupinus bicolor* var. *microphyllus*); Fascicled Milkweed (*Asclepias fasciculata*); Bush Aster (*Lessingia filaginifolia*); Fiddleneck (*Amsinckia menziesii*); Western Ragweed (*Ambrosia psilostachya*); Gum Plant (*Grindelia robusta*); California Goldenrod (*Solidago californica*); Popcorn Flower (*Cryptantha inermedia*); Miniature Sun Cup (*Camissonia micrantha*); Rattlesnake Weed (*Euphorbia albomarginata*); Pygmy Stonecrop (*Crassula connata*).

Characteristic animals: resident and migratory grassland bird species including Horned Lark; herpetofauna including lizards and snakes, such as California King Snake and Gopher Snake; and small mammals including voles, mice, shrews, and moles.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; host plants for butterfly larvae including the Wandering Skipper Monarch (*Danaus plexippus*) butterflies; habitat for native small mammals; foraging habitat for raptors such as White-tailed Kite and Northern Harrier and egrets (Great Egret) and herons (Great Blue Heron).

Recovery opportunities: South Coast Marsh Vole (*Microtus californicus stephensi*); San Diego Black-tailed Jackrabbit (*Lepus californicus bennettii*); California Horned Lark (*Eremophila alpestris*); White-tailed Kite (*Elanus caeruleus*); Northern Harrier (*Circus cyaneus*).

Management issues: Maintenance of grassland habitat to prevent it becoming coastal scrub (using fire, grazing, or mowing techniques?); control of invasive plant species.

20. Coastal Scrub (including Coastal Bluff Scrub)

Narrative: The general category "coastal scrub" includes a number of shrub-dominated plant communities in the context of a variety of land forms. Coyote Brush and California Sage Brush form colonies on alluvial and disturbed soils and can occur within the context of grassland and other herbaceous vegetation. Upland delta scrub can be quite rich in shrub species and occurs in alluvium adjacent to wetland forms of delta scrub often dominated by Mulefat (*Baccharis salicifolia*). Coastal Bluff Scrub is limited to coastal bluffs where salt tolerant species including Wooly Sea-Blite (*Suaeda taxifolia*) and Quail Bush (*Atriplex lentiformis*) are characteristic but occurs in different forms depending on proximity to salt spray. Within the bluff community, sparsely-vegetated areas or areas with low vegetation also can support a wide variety of herbaceous species, some of which are also associated with coastal dunes. Coastal Dune Scrub is treated separately herein. No Maritime Chaparral occurs in the Ballona Ecosystem.

Other forms of upland coastal scrub include, for example, Delta Scrub and Baccharis Scrub, which can be transitional to wetland scrub types.

A variety of terrestrial animals, including amphibians, reptiles, mammals and birds are supported by coastal scrub habitat. For instance, Coastal Sage Scrub is the preferred breeding habitat of the coastal California Gnatcatcher (*Pilioptila californica californica*).

Structural features: alluvial deposits, berms and banks; coastal bluffs.

Physical processes: fluvial, erosional, (and anthropogenic).

Dominant/characteristic Plant(s): Coyote Brush (*Baccharis pilularis*); California Sagebrush (*Artemisia californica*); *Mugwort (Artemisia douglasiana***);** Quail Bush (*Atriplex lentiformis*); Douglas' Nightshade (*Solanum douglasii*); Lemonade Berry (*Rhus integrifolia*); Seacliff or Dune Buckwheat (*Eriogonum parvifolium*).

Associated plant(s): Laurel Sumac (*Malosma laurina*); Cliff Aster (*Malacothris saxatilis*); Deerweed (*Lotus scoparius*); Black Sage (*Salvia mellifera*); Wild Morning-glory (*Calystegia macrostegia*); Melic Grass (*Melica imperfecta*); Foothill Needlegrass (*Nassella lepida*); California Brome (*Bromus carinatus*); Mock Heather (*Ericameria ericoides*); Bladderpod (*Isomeris arboreus)*; Elderberry (*Sambucus mexicanus*); Wild Cucumber (*Marah macrocarpus*); Giant Ryegrass (*Leymus condenstatus*); California Encelia (*Encelia californica*); Suffrutescent Wallflower (*Erysimum insulare* ssp *suffrutescens*); Coastal Prickly Pear (*Opuntia littoralis*); California Buckwheat (*Eriogonum fasciculaum*); Milk Vetch (*Astragalus trichopodus*); Branching Phacelia (*Phacelia ramosissima* var.

austrolittoralis); Bush Mallow (*Malacothamnus fasciculatus*); Lewis' Evening Primrose (*Camissonia lewisii*); Toyon (*Heteromeles arbutifolia*); Chaparral Nightshade (*Solanus xanti*); Wooly Sea-blite (*Suaeda taxifolia*).

Characteristic animals: Loggerhead Shrike (Lanius ludovicianus) perching; California Gnat Catcher (*Polioptila californica californica*) endangered; resident and migratory passerine birds including Luzuli Bunting (*Passerina amoena*) and Blue Grosbeak (*Guiraca caerulea*); small mammals.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; breeding bird habitat; refuge for resident estuarine birds.

Recovery opportunities: Pacific Pocket Mouse (*Perognathus longimembris pacificus*); Loggerhead Shrike (*Lanius ludovicianus*) perching; California Gnat Catcher (*Polioptila californica californica*) breeding habitat; Suffrutescent Wallflower (*Erysimum insulare* ssp. *suffrutescens*); Lewis' Evening Primrose (*Camissonia lewisii*); Coastal Dunes Milkvetch (*Astragalis tener* var. *titi*).

Management issues: plan for connectivity among sites; invasive species such as Pampas Grass.

21. Coastal Dune Scrub and Dune Herbs (including Foredunes)

Narrative: Dune habitat represents a form of transition zone between the land and the sea and includes Coastal Dune Scrub and Dune Herb vegetation. Coastal dune habitats have been largely lost due to development in southern California. Prior to development, plant species such as dune lupine (*Lupinus chamissonis*), Mock Heather (*Ericameria ericoides*), dune primrose *(Camissonia cheiranthifolia)*, sand verbena *(Abronia maritima)* and dune ragweed *(Ambrosia chamissonis)* stabilized the loose sand, and the dunes where thereby anchored. Following human disturbance, many of the native plants were eliminated and exotics, such as sour-fig *(Carporotus edulis)* and sea rocket *(Cakile maritima)* invaded or were planted.

Dunes are important habitats for several species of rare insects including Globose Dune Beetle *(Coelus globosus)*, the Sandy Beach Tiger Beetle *(Coelus hiticollis gravida)*, and Sand Dune Tiger Beetle *(C. latesignata latesignata)*. The San Diego Horned Lizard and Silvery Legless Lizard *(Anniella pulchra pulchra)* were once common; the later still occurs within the Ballona Ecosystem. The endangered California Least Tern *(Sterna antillarum browni)* and Western Snowy Plover *(Charadrius alexandrinus nivosus)* are associated with dune habitat but generally nest in the upper beach environment, which is no longer connected to the dunes.

Structural features: coastal dunes

Physical processes: aeolian transport and deposition of sands; storm influenced.

Dominant/characteristic Plant(s): Dune Lupine **(***Lupinus chamissonis*); Dune Buckwheat **(***Eriogonum parvifolium***)**; Beach Bur (*Ambrosia chamissonis*); Beach Evening Primerose (*Camissonia cheiranthifolia*); Common Sand Verbena (*Abronia umbellata*).

Associated plant(s): California Croton (*Croton californicus*), Tall Stephanomeria (*Stephanomeria virgata*), Mock Heather (*Ericameria ericoides*), Yellow Pincushion (*Chaenactis glabriuscula*), California Sun Cup (*Camissonia bistorta*), Lewis' Evening Primrose (*Camissonia lewisii*), Miniature Sun Cup (*Camissonia micrantha*), Coastal Dunes Milkvetch (*Astragalis tener* var. *titi*).

Characteristic animals: Silvery Legless Lizard (*Anniella pulchra pulchra*); Globose Dune Beetle (*Coelus globosus*); Ciliated Dune Beetle.

Ecosystem functions: maintenance of biodiversity; habitat for rare, endangered, and special interest species; source of freshwater seeps along interface with salt marsh habitat.

Recovery or protection opportunities: Silvery Legless Lizard (*Anniella pulchra pulchra*); El Segundo Blue Butterfly (*Euphilotes battoides allyni*); Dorothy's El Segunda Dune Weevil (*Trigonoscuta dorothea dorothea*); Globose Dune Beetle (*Coelus globosus*); Lande's El Segundo Dune Weevil (*Onychobaris langei*); Suffrutescent Wallflower (*Erysimum insulare* ssp. *suffutescens*); Beach Spectaclepod (*Dithyrea maritima*), Lewis' Evening Primrose (*Camissonia lewisii*)

Management issues: Remnant dunes are disjunct from coastal processes that formed them hence no natural disturbance regime, and beach related habitats are missing from the complex. Vulnerable to introduced invasive plant species.

22. Forests, woodlands, groves, and tree rows (including DFG "Eucalyptus Grove")

Narrative: Oak woodlands, characterized by Coast Live Oak (*Quercus agrifolia*), are characteristic along slopes, bluffs, and banks adjacent to various estuaries in southern California but may not have been located within or in proximity to the Ballona Ecosystem. Nonetheless, Coast Live Oaks may have been in the more xeric portions of riparian forests that included stands of Western Sycamore (*Platanus racemosa*). Current conditions include a number of groves and stands of planted or naturalized, largely exotic trees (e.g., Blue Gum, *Eucalyptus globulus*) within the Ballona Ecosystem. Some of these sites have important ecosystem functions such as nesting areas for great Blue Herons, whereas others (e.g., Myoporum and Acacia) may be less important depending on the site and role in the ecosystem.

Structural features: cultivated areas; roadsides; yards; banks and bluffs.

Physical processes:

Dominant/characteristic Plant(s): *Eucalyptus* spp.; Myoporum (*Myoporum laetum*).

Associated plant(s): numerous species of planted and naturalized trees including Acacia (*Acacia baileyana*); California Walnut (*Juglans californica*); Peruvian and Brazilian Pepper Trees (*Schinus molle* and *S. terebinthifolia*); Canary Island Date Palm (*Phoenix canariensis*); Slender Fan Palm (*Washingtonia robusta*); Carob (*Ceratonia siliquia*); Sweet Gum (*Liquidambar styraciflua*); Olive (*Olea europea*); Velvet Ash (*Fraxinus velutina*); Fremont Cottonwood (*Populus fremontii*); Chinese Elm (*Ulmus parvifolia*).

Characteristic animals: resident and migratory passerine birds; roosting and possibly nesting raptors; roosting and nesting herons.

Ecosystem functions: habitat for rare, endangered, and special interest species; perches for raptors.

Recovery opportunities: Preservation/expansion of Great Blue Heron rookery; potential for Monarch Butterfly over-wintering habitat in groves of Blue Gum (*Eucalyptus globulus*).

Management issues: Monarch Butterflies use exotic Eucalyptus trees as winter roosts. Need to retain butterfly habitat (if Eucalyptus trees are targeted as butterfly habitat at Ballona), while not encouraging spread of exotic tree species.

APPENDIX C.
HYDRODYNAMIC MODELING

APPENDIX C – NUMERICAL MODELING OF BALLONA WETLAND RESTORATION ALTERNATIVES TECHNICAL APPENDIX

Hydrodynamic modeling was conducted in support of the development and evaluation of restoration alternatives for the Ballona Wetlands Restoration Project. The Environmental Fluid Dynamics Code (EFDC) hydrodynamic model was selected because of its capacity to model the relevant physical processes, its compliance with regulatory standards, and its availability in the public domain at no cost.

This appendix documents the development, calibration, and alternative implementation of the EFDC model. It also provides supporting documentation for specific model results discussed in the Feasibility Report. This appendix is not a stand-alone report and should be reviewed in conjunction with Section 3.3 (Hydrology) of the Feasibility Report.

Because the EFDC model uses metric units, some of the model results in this appendix are presented using metric units. However, the discussion in the Feasibility Report uses English units to follow local convention. As a result, this appendix presents some results in metric units and some in English units.

Sections C-1 and C-2 were prepared as stand-alone memos. Section C-1 discusses the EFDC model development and calibration. Section C-2 discusses the representation of marsh channel networks within the model. Section C-3 shows overview plots of model bathymetry for each alternative. Section C-4 provides supporting documentation for model results discussed in Section 3.3 (Hydrology) of the Feasibility Study.

C-1. LOWER BALLONA CREEK MODELING – EFDC MODEL DEVELOPMENT AND CALIBRATION

1. INTRODUCTION

This section presents the calibration process for the Environmental Fluid Dynamics Code (EFDC) hydrodynamic model developed for the Ballona Creek Wetland Restoration Project. The EFDC model was configured such that predicted water levels accurately replicate observed water levels from a two-week calibration period. Typically, predicted water levels agree to within 5 cm of the observed water levels. Having calibrated the EFDC model, it is ready to characterize the hydrologic response of the proposed restoration actions for feasibility assessment purposes.

This section includes details of the model development and calibration. The section on model development describes the EFDC model in general and summarizes how the model was configured to represent the Lower Ballona Wetland system. The section on calibration describes the calibration approach and compares model predictions and field observations.

2. MODEL DEVELOPMENT

The EFDC model was chosen to simulate the Lower Ballona Wetland system after discussion between the Project Management Team, the Science Advisory Committee and the LA District, Corps of Engineers. Benefits of this model include its capacity to model the relevant physical processes, its compliance with regulatory standards, and its availability in the public domain at no cost.

After briefly describing EFDC's general characteristics, this section describes the application of the model to the Lower Ballona Wetland system, including the model's domain, boundary conditions, initial conditions and model execution. The linked Lower Ballona Wetland system includes lower Ballona Creek; Ballona Wetland Restoration Areas A, B, and C; Marina Del Rey; Del Rey Lagoon; Ballona Lagoon; the Grand Canal; and a portion of Santa Monica Bay. The uncertainties with respect to the model predictions are discussed.

2.1. MODEL DESCRIPTION

EFDC is a numerical model designed for simulating flows in open water systems. The model was originally developed at the Virginia Institute of Marine Science and receives continuing support from the U.S. EPA. A complete description of the model assumptions, governing equations and approximations, including the space discretization, time integration, and numerical solution methods is presented in Hamrick (1992). Tetra Tech (2002) provides guidance in using the model as well as references to successful applications of EFDC for a variety of tidally-influenced systems.

The physical processes represented in the model include important aspects of the Lower Ballona Wetland system:

- unsteady tidal flow,

- boundary wetting and drying, and
- hydraulic control structures.

EFDC solves the physical equations for fluid flow on a staggered, finite-difference grid. The modeling domain is defined by a curvilinear flexible mesh, enabling the grid to follow dominant terrain features. At present, the model has been configured to predict two-dimensional (2D) depth-averaged flow. Although not implemented for this study, the model can be extended to simulate three-dimensional (3D) flows and the transport of salt, sediment, and/or contaminants.

2.2. MODEL DOMAIN

The model domain defines the portion of the physical environment that is included in the model. Its extent should include the system's relevant components and processes between these components. Additionally, the boundaries of the system should be sufficiently far from the region of interest such that boundary conditions do not overly constrain flow in the region of interest. When constructing the model's horizontal grid that defines the domain, these factors must be balanced against model execution time. The vertical component of the model domain is defined by the system's bathymetry. Further information about the physical setting within the model domain can be found in PWA (2006).

2.2.1. Model extent

The model domain extends from where Ballona Creek passes under Sawtelle Boulevard to Santa Monica Bay, as shown in Figure 1. The upstream boundary is beyond the range of tidal influence and coincides with a discharge monitoring station. Placing the downstream boundary within Santa Monica Bay provides ample distance and tidal volume between the specified tidal boundary condition and the region of interest. Between the upstream and downstream boundaries, the model domain includes:

- lower Ballona Creek;
- Ballona Wetland Restoration Areas A, B and C;
- Marina Del Rey, including Oxford Basin;
- Del Rey Lagoon;
- Ballona Lagoon, including the Grand Canal downstream of Washington Boulevard; and
- a portion of Santa Monica Bay roughly 1.3 km by 2.5 km.

2.2.2. Horizontal grid generation

EFDC employs a curvilinear orthogonal grid to represent the physical domain. The grid is analogous to a rubber sheet of graph paper. Its curvilinear aspect allows the grid to be stretched and transformed so that it aligns with the major topographic features of the model domain. However, orthogonality requirements dictate that the grid maintains nearly perpendicular intersections at cell boundaries.

The grid generation tools available within the EFDC modeling environment are somewhat limited in their functionality. Instead, DELFT3D's grid generation software (WL | Delft Hydraulics, 2006b) was used to create the grid. DELFT3D's graphical user interface provides robust tools for grid orthogonalization, manipulation, and merging. After creating the grid with the DELFT3D software, the grid files were converted to EFDC format using MatLab programs. The grid cell sizes average 10 m across in most of the model domain, resulting in approximately 42,000 active cells within the domain.

2.2.3. Bathymetry

The bathymetry, or spatial map of surface elevations, is represented in the model as a single elevation value at the center of each grid cell. Multiple sources of bathymetric data were compiled to cover the entire model domain. The sources of bathymetry data for each region are listed below:

- *Ballona Creek:* Channel centerline elevations and width from the channel's design drawings (Los Angeles County Flood Control District, 1959).
- *Ballona Wetland Areas A, B and C*: Ground surface elevations from the R.J. Lung & Associates aerial survey in April 1998, supplemented with spot elevations, marsh channel cross sections, and culvert invert elevations collected by PWA in 2006.
- *Marina Del Rey*: Elevations in the main stem of the marina from unpublished USACE dredging surveys in March 2006 and elevations in the mooring basins extrapolated from the adjacent main channel elevations.
- *Del Rey Lagoon:* Spot elevations from bathymetric survey drawings (City of Los Angeles, 2003) interpolated across the lagoon.
- *Ballona Lagoon and the Grand Canal*: Elevations from cross section surveys (Coastal Frontiers Corporation, 1989) and Ballona Lagoon Enhancement Project design drawings (City of Los Angeles, 1997).
- *Santa Monica Bay*: Bathymetric survey data from the National Oceanic and Atmospheric Administration (1997).

All elevation data were converted to the same horizontal datum (UTM Zone 10N) and vertical datum (NAVD88) using Corpscon software (U.S. Army Corps of Engineers, 2004). The data sets were then imported into the DELFT3D bathymetry generation software (WL | Delft Hydraulics, 2006a) and smoothly interpolated at the boundaries between data sets. The compiled bathymetric surface was converted into EFDC-specific input files using the EFDC_Explorer graphical user interface (Criag, 2004). To refine features such as wetland channels and elevated road bed that have widths on the order of the 10 m grid cell size, a MatLab program was used to inscribe these features into the bathymetry. This procedure ensures that these features are hydraulically contiguous, but yields a stair-step appearance as the features traverse diagonally across the grid. The compiled bathymetry for the model extent is shown in Figure 1. Figure 2 displays a portion of the bathymetry within the western portion of Area B that includes wetland channels and road bed. This figure demonstrates the implementation of these features as contiguous sets of grid cells.

2.3. BOUNDARY AND INITIAL CONDITIONS

Boundary and initial conditions describe the external forcing applied to the model and starting values for the predicted variables, respectively. Boundary conditions consist of:

- the tidal boundary within Santa Monica Bay,
- the freshwater inflows from the Ballona Creek watershed,
- culvert discharges, and
- bed roughness.

Initial conditions must be specified for the water surface elevation and velocity field when the model begins a simulation.

2.3.1. Tidal boundary

Comparison between the NOAA continuous tide gauge station at the Port of Los Angeles (Station ID 9410660) and water surface measurements in Ballona Creek collected by Nearshore and Wetland Surveys (2006) show good agreement with minimal amplitude differences or phase lag. For example, observations in Ballona Creek (Nearshore and Wetland Surveys, 2006) and at the Port of Los Angeles are shown in Figure 3. Because of the agreement between the two data sets, the Port of Los Angeles water surface elevation data was applied as the open tidal boundary condition at the model's western edge in Santa Monica Bay. This tide station is well established and it can provide boundary condition data for a wide range of time periods. The northern and southern boundaries of the model grid in Santa Monica Bay are linked by a periodic boundary condition. This type of boundary condition minimizes the influence of these boundaries on model results.

2.3.2. Freshwater inflow

The primary freshwater inflow into the Lower Ballona system comes from Ballona Creek itself. The upstream model boundary coincides with the County of Los Angeles, Department of Public Work's discharge station at Sawtelle Blvd (Station ID F38C-R). Observations from this station were used as a discharge boundary condition into the model.

2.3.3. Culvert and gate discharges

Culverts and gates regulate flow into and out of the Area B wetland, Fiji Ditch, Del Rey Lagoon, and Ballona Lagoon. Culvert flow is represented in the model as water-level-dependent discharge between a pair of grid cells. Discharges through all but one culvert are implemented in the EFDC model through an input file that specifies the discharge as a function of the difference in water levels at the ends of each culvert.

A slightly more complex specification was used for the gate that conveys water from Ballona Creek to the Area B wetland. Flow through this gate is governed by a self-regulating tide gate that closes automatically once the water level in Ballona Creek reaches a predetermined level. For this culvert, the discharge was modeled as a function of both the upstream and downstream water levels and the discharge was set to zero when the upstream water level in Ballona Creek equal or exceeds the water level which triggers gate closure.

Observed water levels within the Area B wetland (Nearshore and Wetland Surveys, 2006) slowly increase even after the self-regulating tide gate has closed. This increase may result from leakage through either of the tide gates and/or seepage from the headlands to the south of the wetland. The exact source remains a point of discussion. To replicate these slowly increasing water levels, a constant discharge of 0.16 m^3/s was added as a source to the wetland. This rate was estimated from the observed rate of water level increase after the self-regulating tide gate has closed (Figure 5) and the area of inundated wetland during higher high water. If future investigation clarifies and quantifies the source of this water level increase, it can be more explicitly included in the model.

2.3.4. Bed roughness

Bed roughness relates the flow velocity to the frictional loss of momentum as the flow moves over the bed. EFDC parameterizes the bed friction's effect on flow through a roughness height, z_0, based on the assumption of a logarithmic velocity profile. A typical, constant z_0 value of 0.002 m was applied across the entire domain (Blumberg and Mellor, 1987). Sensitivity analysis of water levels to variations in z_0 confirms that water levels are relatively insensitive to this parameter.

2.3.5. Initial conditions

Model start times were selected to coincide with slack tide when current speeds can be initialized to zero. Initial water levels throughout the model domain were set to a uniform value equal to the open boundary condition. The model was spun up for four days of simulation time to remove initial transients from the model results and enable water levels and velocities to equilibrate to the prescribed boundary conditions.

2.4. MODEL EXECUTION

For the model configuration described above, model testing indicates that stable and accurate predictions are achieved with a time step of two seconds. With this time step, simulations execute on a 3.6 GHz PC workstation at speeds approximately eight times faster than real time.

2.5. MODEL UNCERTAINTY

EFDC is a widely used modeling tool for estuarine simulations and has been validated in numerous studies (Tetra Tech, 2002). However, numerical models inherently rely on approximations that introduce sources of uncertainty in the model results. Uncertainties may be present both spatially and temporally, and may result from a variety of factors, including:

- physical characteristics of the model domain,
- specification of boundary conditions, or
- limitations in the model's numerical formulation.

For the specific application of a hydrodynamic model of the Lower Ballona system, it is important to assess the modeling uncertainties and assumptions made in applying the model to understand the extent to which these uncertainties affect model predictions.

The largest uncertainties affecting model performance for the Lower Ballona model are the accuracy and resolution of available bathymetry and the grid resolution used in the model to resolve this bathymetry. To the extent possible, the model has made use of the most recent and best available bathymetric data and datum conversion tools (Section 2.2.3). However, when the bathymetric data is sampled onto the model grid, additional filtering of the bathymetric data occurs which limits the capacity of the model to resolve small-scale bathymetric features. The grid resolution for the model was selected to be as fine as possible, subject to the computation time restraints. The nominal grid cell size of 10 m prevents the model from accurately resolving the bathymetry in the smallest channels. However, since the volume of these small channels represents a small fraction of the overall domain, their exclusion is not likely to significantly alter the model's predictions.

The model solves the 2D depth-averaged approximation of the hydrodynamic flow equations. The use of 2D simulations significantly reduces the computational time required for the model simulations but also introduces additional model uncertainty in the hydrodynamic predictions. This uncertainty is constrained because the wetland's shallow depths and limited freshwater inputs minimize the impact of 3D flow effects.

Model uncertainties are also introduced through the specification of boundary conditions and model parameterizations, such as bed roughness. Additionally, any field data used either to force the model or to calibrate the model has some associated uncertainty due to instrument calibration and errors, instrument location, field corrections, and data noise.

3. MODEL CALIBRATION

The model was calibrated to observed water levels, primarily by adjustment of culverts and gate discharge rates. As presently calibrated, the model predicts water levels to within 5 cm of observations for nearly all of the calibration period. The sections below describe the calibration approach, summarize the observation data, compare predicted and observed water levels, and outline future refinements to the model.

3.1. CALIBRATION APPROACH

Calibrating a model involves adjusting model parameters or model formulation in order to match model predictions and field observations at known locations. Initially, the calibration process can verify that each of the specified model inputs and boundary conditions are working properly. Subsequent iterations of the calibration process enhance agreement between model predictions and observations. The model is run for a known set of input conditions, and its output is compared to a known set of observations. The discrepancies between the model predictions and the observation data help determine which aspects of the model are not adequately capturing the physical processes. This may lead to adjusting some model parameters to improve agreement between predictions and observations.

Adjustments to model parameters are made until the model's response to the specified inputs replicates the field measurements as closely as possible. The goal of the calibration process is to identify the areas and processes of highest interest, and maximize the model's predictive capability in those areas, while ensuring reasonable behavior in the rest of the model predictions.

The model was calibrated to optimize agreement between observations and predictions of water levels. Calibration to water levels indicates that the model is correctly predicting the volumes of water that are exchanged between each region of the model. Calibration of Ballona Creek water levels required no adjustments to model parameters beyond the model setup described above in Section 0. To calibrate water levels at the other four observation stations, all of which are upstream of culverts, a coefficient scaling the discharge through the culverts was adjusted. Comparison between this calibrated discharge and the discharge estimated by the U.S. Geological Survey Culvert Analysis Program (CAP; Fulford, 1998) exhibit good agreement.

3.2. OBSERVATION DATA

The water level observations used for calibration were collected by PWA and Nearshore and Wetland Surveys (2006) in July and August, 2006. A representative spring-neap cycle from July 5 to July 20 was selected from this observation record as the calibration period to simulate. The five locations at which water levels were observed are shown in Figure 1. In addition to water levels in Ballona Creek, which is directly exposed to the tidal action, the other four stations are located in regions where the tidal flows are controlled by flow through gates and culverts.

3.3. WATER LEVEL COMPARISON

Time series of predicted water levels at five stations and the corresponding observed water levels are plotted in Figure 4 to Figure 8. For most of the two-week simulation period, these time series demonstrate agreement within 5 cm between the model predictions and observations. Differences larger than 5 cm between predictions and observations are typically caused by mechanisms beyond the scope of the model that are insignificant in comparison to the changes expected from restoration. Explanation for these larger differences between observations and predictions are discussed below:

- During several of the lowest tides in the middle of the simulation period, the observations bottom out at constant values that are above the predicted values (Figure 4 to Figure 7). This is because the instruments were mounted such that water levels during these lowest tides fell below their sensors and exposed the sensors to the atmosphere during these periods.
- As discussed above in Section 2.3.3, an unknown water source causes water levels to rise in the Area B wetland after the tide gates between Ballona Creek and the wetland close. The observed water levels consist of a rapidly rising section while the tide gate is open and then a slowly rising section once the tide gate closes (Figure 5). In the absence of data, the unknown source was modeled as a constant discharge to the wetland. This approximation of the source is sufficient to

reproduce the typical rising water levels during high tides. However, the source's actual discharge rate probably varies in time, causing the differences between the observed and the modeled water levels.

- In Fiji Ditch (Figure 6), high frequency oscillations in the water level observations are consistent with the 6 to 8 second water level oscillations observed visually during instrument installation. It is hypothesized that these water level oscillations result from ocean swell that propagates through the marina and culvert. The model does not include the physical processes which create this type of water level oscillation since this process does not transport significant amounts of water.
- Below 0.25 m NAVD, predicted water levels in Del Rey Lagoon fall more rapidly than observed water levels (Figure 7). This difference may be the result of the representation of the lagoon's bathymetry in the model, which was created by interpolation from relatively few spot elevations. Since the predictions at all other times and locations otherwise demonstrate good agreement with the observed water levels and the lagoon is only a small feature located outside the project area, the current implementation is sufficient for assessment of the restoration alternatives. If specific questions regarding circulation within the lagoon are of interest, the model's representation of the lagoon's bathymetry should be improved.
- The tide gates regulating flow into Ballona Lagoon (Figure 8) are manually adjusted to restrict flow during spring tides, e.g. from July 7 to July 14. This operational practice prevents flooding upstream of the gates. Since records of the actual gate settings are not maintained (Mariposa Landscaping, personal communication), no attempt was made to model the Lagoon's water levels during this period. Hence, during the spring tides, the predicted water level continues to span nearly the full range of water levels in Ballona Creek while the observed water level within Ballona Lagoon was muted.

3.4. FUTURE WORK

Although the model is sufficiently calibrated to provide a feasibility assessment of the proposed restoration alternatives, additional calibration should be conducted for future stages of alternative design or evaluation of more complex processes, such as sediment transport or water quality. These additional steps include:

- Calibration to observed current velocity data
- Calibration to observed salinity data
- Validation to water levels during high Ballona Creek discharge

C-2. MARSH CHANNEL REPRESENTATION IN LOWER BALLONA EFDC MODEL

1. INTRODUCTION

This section outlines the methodology implemented to represent tidal channel morphology and layout in the Lower Ballona Wetlands EFDC numerical model. The purpose of the numerical model is not to model fine scale hydrodynamics or velocities in the tidal channels (existing or future), but to describe the hydraulic characteristics and flushing of each restoration parcel. The procedure is based on the methods presented in the "Design Guidelines for Tidal Channels in Coastal Wetlands," prepared by PWA in January 1995 for the U.S. Army Corps of Engineers. The guidelines present empirical relationships between morphologic characteristics of marsh channels (channel top width, depth, and cross sectional area) and diurnal tidal prism. Characteristics of marsh morphometry (channel order, length, sinuosity, drainage density, etc.) are also tabulated. The tidal prism dataset includes sites from San Diego Bay (Chula Vista) and San Francisco Bay (Novato, Corte Madera, and Newark Slough). The marsh morphometry dataset includes a more extensive analysis of sites from southern California, north San Francisco Bay, and south San Francisco Bay.

The approach taken to implement the appropriate channel characteristics in the model was to first determine what the detailed tidal channel characteristics would be, and then to aggregate these for inclusion into the model, given the grid cell size limitations. A general outline of the procedure is presented below:

1. Approximate channel order, length, and number of channels based on channel morphometry relationships with marsh area (Section 2).
2. Approximate channel geometry (width and thalweg depth) based on tidal prism using hydraulic geometry relationships (Section 3).
3. Aggregate channel morphology and morphometry for inclusion into the model (Section 4).

2. CHANNEL MORPHOMETRY

Marsh morphometry refers to the plan view features of tidal marshes, such as channel length, sinuosity, channel order, and density of channels. The general outline presented in the Design Guidelines is reproduced below:

1. Determine the order of the drainage system that can be accommodated within the site based on the marsh area.
2. Calculate the total channel length based on an assumed drainage density (typically 0.01-0.02 ft/ft^2).
3. Estimate the number of channels of each order.
4. Partition the length among the different order channels.

The results for Area B East Wetland are presented below as an example of the methodology and assumptions used in the analysis.

1. For a given marsh area of approximately 35 acres, Figure 7.1-4 of the design guidelines was used to select a maximum channel order of 4 for the parcel.
2. Drainage densities at numerous California marshes tend to fall between 0.01-0.02 ft/ft^2. A drainage density of 0.01 ft/ft^2 was selected to minimize construction costs and allow for natural evolution of the site. From this drainage density, a total length of channels of 15,250 ft was determined.
3. The number of channels of each order was determined assuming a bifurcation ratio of 3.5. This ratio predicts 1 fourth-order channel, 4 third-order channels, 12 second-order channels, and 43 first-order channels, although not all orders can be represented in the model due to grid cell size limitations.
4. Table 7-6 and Figure 7.3-1 of the Design Guidelines give typical channel distributions for California marshes. The following distribution of channel length was assumed for the 4th through 1st order channels: 10%, 15%, 30%, and 45%. The total length of channels was used with the channel order distributions to determine the length of each order channel.

3. HYDRAULIC GEOMETRY

The term hydraulic geometry refers the empirical relationships between channel discharge and channel geometry. The hydraulic geometry relationships presented in the Design Guidelines relate diurnal tidal prism with channel width, depth, and cross sectional area. A predicted tidal prism of 25 acre-ft was determined to represent the diurnal tidal prism for the 35-acre Area B East Wetland parcel using Figure 5.2-1. The top width and depth of the 4th order channel were determined assuming this tidal prism. For the lower order channels, the total tidal prism was distributed incrementally based on the bifurcation ratio, after subtracting out the intertidal storage volume of the next higher order channel. The partitioned tidal prism was used in the hydraulic geometry relationships for each channel order.

4. IMPLEMENTATION OF CHANNEL MORPHOLOGY IN MODEL BATHYMETRY

For each channel order, the predicted top width was compared to the grid cell size of the EFDC model grid, nominally equal to 9 m (29.5 ft). The predicted top widths of the 3rd and 4th order channels were 28 ft and 54 ft, roughly equivalent to one and two cell widths, respectively. The model tidal prism was calculated as the total intertidal channel storage volume for a diurnal tide range of 5.49 ft (LA tide gage, #9410660). The resulting tidal prism was 19 acre-ft, 24% less than the predicted tidal prism of 25 acre-ft. This is due to the lack of first and second order channels in the model. To account for the remaining 6 acre-ft, 4 of the 12 second-order channels were implemented at a width of one grid cell. The number of grid cells for each channel order was determined by dividing the length per channel by the nominal grid size. An idealized channel layout was then overlaid on the existing topography grid based on the widths, depths, and lengths determined from the Design Guidelines. The bed elevation of the highest-order channel is constant along its length. Along-channel bed elevations of lower-order channels were linearly interpolated from the channel junction to the channel end (i.e., from the predicted elevation of the higher-order channel to the predicted elevation of the lower-order channel). Elevations of the future marshplain (non-channel regions within the wetland footprint) were set at MHHW (1.61 m NAVD).

The channel layout was adjusted iteratively to correctly reproduce the expected future tidal prism for the marsh restoration parcel. The model tidal prism was confirmed by comparing the total intertidal channel storage volume to the predicted diurnal tidal prism for the given marsh area. Future model refinement could be to develop a more detailed bathymetry grid in the region of tidal channels.

C-3. LOWER BALLONA EFDC MODEL – ALTERNATIVES BATHYMETRY

Sections C-1 and C-2 above describe the model development and calibration procedures. Figure 9 through Figure 14 show the model bathymetries for each alternative.

C-4. SUPPORTING DOCUMENTATION FOR SECTION 3.3 HYDROLOGY

Section 3.3 of the Lower Ballona Creek Restoration Feasibility Study discusses the expected hydrology for each proposed alternative. The text and figures below provide supporting documentation for the specific model results discussed in the report as well as related model results not explicitly discussed in the Feasibility Study. The section numbers below correspond to the relevant subsections of Section 3.3 (Hydrology).

Section 3.3.1 - Muted Tidal System versus Full Tidal System

Inundation regime is the percentage of time that a given water level is exceeded during a neap-spring tidal cycle. It is a useful parameter for characterizing the tidal inundation at a particular location with a specific elevation. The inundation frequency curves corresponding to Table 3-7 are shown in Figure 15.

Section 3.3.2 - Tidal prism

Tidal prism is the volume of water passing through a channel cross section on each tide (ebb or flood). Tidal prism was evaluated for each restoration area at four cross sections: (1) mouth of Ballona Creek, (2) mouth of Marina Del Rey, (3) Basin H entrance, and (4) Marina del Rey above Basin H. Tidal prism was estimated by integrating the discharge time series at each cross section for each tide (flood or ebb). The mean tidal prism of all floods and all ebbs was estimated for all runs that spanned the full spring-neap cycle. The results are shown in Table 1.

Section 3.3.3 – Connections

Area B southwest wetland SRT and culvert connection

Figure 16 shows a sample water level comparison for the culvert sizing and SRT optimization for the Area B southwest wetland. Two culvert geometries are tested: (1) 2 x 5 ft culverts and (2) 3 x 5 ft culverts. Three elevations are tested for the SRT: 3.6 ft, 4.9 ft, and 6.6 ft NAVD. Increasing the culvert area increases the tide range within the wetland and improves drainage from the wetland to Ballona Creek. The effect of the SRT in limiting high water within the site is seen once the Ballona Creek water levels reach the closure elevation.

Area B southeast wetland, Area A small marsh, Area A large marsh, Area A subtidal

Figure 17 illustrates the procedure adopted to size the culvert connections to each wetland. The number of culverts was increased until the tide range within the wetland approximately matched that of Ballona Creek. As can be seen in Figure 17, once the number of culverts increases beyond six 5-ft culverts, there are very small incremental gains in tide range for relatively large increases in culvert cross sectional area. The same procedure was followed to size the culverts for the small and large marshes and subtidal portion of Area A, shown in Figure 18, Figure 19, and Figure 20, respectively.

Area B southwest breach

The Area B breach was sized with a similar objective to the culvert sizing described above. The breach was sized to allow full conveyance of the tidal signal to the wetland (i.e. no tidal damping or muting). A sample water level comparison is shown in Figure 21.

Section 3.3.4 - Channel Network

Section 3.3.4 of the Feasibility Report discusses the expected channel network characteristics for each alternative. See Appendix C-2 (Marsh channel representation in Lower Ballona EFDC model) for a more detailed explanation of the methodology used to develop the channel networks.

Section 3.3.6 - Excursion Length

Section 3.3.6 of the Feasibility Report provides a qualitative discussion of tidal excursion lengths and implications for hydraulic connectivity and mixing in Ballona Creek. Excursion length was examined at the same cross sections locations as for the tidal prism analysis: (1) mouth of Ballona Creek, (2) mouth of Marina del Rey, and (3) Entrance to Basin H. For this application, excursion length was calculated by integrating the velocity time series over each tidal cycle to obtain the tidal excursion for each flood or ebb tide. The median tidal excursion lengths for flood and ebb were then tabulated for each model run. The results are shown in Table 2.

Section 3.3.7 – Flooding

50-yr hydrograph

The Ballona Creek Ecosystem Restoration Feasibility Study Hydrology Appendix (USACE 2008) presents results of a flood frequency analysis and rainfall-runoff model for the Ballona Creek watershed. A discharge-frequency relationship for Ballona Creek at Sawtelle Boulevard for the period 1928-2005 was developed to predict the hydrograph for the 50-yr discharge event (Figure 22). Ballona Creek hydrographs for the 50-year event were provided to PWA by the USACE. PWA then used these hydrographs to estimate the discharge from Sepulveda Channel and from Centinela Channel. These estimates were used as boundary conditions for the model.

50-yr flood water levels

The restoration alternatives were evaluated under flood conditions by using the EFDC model to predict water levels resulting from the 50-yr flood. The predicted peak water levels near the SRT for existing conditions (Figure 23) compare well with the USACE predictions at the same location. Overall changes to the system under Alternative 1 and Alternative 2 are minimal, resulting in nearly identical water level predictions in Ballona Creek as for Existing Conditions (Figure 24, Figure 25). Because of flow through the culverts is limited, water levels within the southeast wetlands peak at lower values than within Ballona Creek and also take longer to drain off with the falling flood water levels (Figure 25). Alternative 3's peak water levels in Ballona Creek were lower than the Existing Conditions peak because the large expanse of wetlands in this alternative provides storage for the flood waters (Figure 26). For floods under Alternatives 1-3, predicted water levels in Area A are not altered since these wetlands are not connected to Ballona Creek. Therefore, Alternative 4, which is identical to Alternative 3 except for the subtidal region of Area A, was not modeled with flood conditions. For Alternative 5, water levels were assessed both upstream near Area C and at the SRT. While the upstream water levels are higher as a consequence of the channel and water surface slope, Alternative 5's upstream water levels are below that of existing conditions (Figure 27). This suggests that flood hazard is unlikely to increase with restoration.

Storm Surge Analysis

Water levels at the Port of Los Angeles were examined using an event selection approach to identify typical storm surge events (super-elevation of water levels above astronomical tides). Events were selected based on events identified in the Ballona Creek Ecosystem Restoration Feasibility Study Hydrology Appendix (USACE 2008), since coastal storms often exhibit high precipitation and storm surge. Typical surges ranged from 0.5 to 1.5 ft above astronomical tides, with a maximum of 1.65 ft during the 1997-1998 El Niño winter. Storm surge events lasted approximately 3-7 days. Table 3 shows a summary of the event-based analysis.

Additional Model Runs

Additional model runs were conducted for each alternative to inform the culvert sizing, SRT closure elevations, and other aspects of the model setup. The full run catalog is shown in Table 4.

Average Surge	**1.1**

* Events were selected based on the COE Ballona Creek Ecosystem Study Appendix F3 Hydrology.
* Peak surge determined from the max residual between observed and predicted water level at NOAA Station #9410660 Los Angeles
** Dates and times are given in local standard time (LST)
*** Approximate storm durations were determined by visually examining the residual time series for each event

APPENDIX D.
DETAILED COST ESTIMATES AND SUPPORTING INFORMATION

Table D-1. Summary of Engineer's Estimates[1] for Alternatives 1 to 5. Costs in Millions of Dollars

Alternative	Area A	Area B	Area C	Total
1	$4.0	$2.6	--	**$6.6**
2	$42.6	$16.0	$3.3	**$61.8**
3	$69.3	$55.5	$5.2	**$130.0**
4	$108.4	$55.5	$5.2	**$169.0**
5	$99.8	$59.0	$50.4	**$209.3**
	Phase 1	**Phase 2**	**Phase 3**	
5 [2]	$110.4	$48.8	$50.5	**$209.7**

Notes

1 - Estimated construction costs include a 35% contingency

2 - The cost estimate for phasing Alternative 5 is higher due to the construction of a temporary levee

Table D-2. Estimated Volumes of Excess Material to Be Stockpiled and Rough Calcuation of Possible Stockpile Areas and Number of Truck Loads.

	Stockpile Volume (CY)				Stockpile Volume (ac-ft)				5-ft High Stockpile Areas (ac) [1]				10-ft High Stockpile Areas (ac) [1]				No. Truck Loads [2]
	Area A	**Area B**	**Area C**	**Total**	**Area A**	**Area B**	**Area C**	**Total**	**Area A**	**Area B**	**Area C**	**Total**	**Area A**	**Area B**	**Area C**	**Total**	**Total**
Alternative 1	86,400	-	-	86,400	50	-	-	**50**	11	-	-	**11**	6	-	-	**6**	**8,640**

Alternative 3	1,684,880	963,700	141,000	2,789,580	1,040	600	90	**1,730**	211	122	19	**352**	108	63	10	**182**	**278,958**
Alternative 4	2,748,440	963,700	141,000	3,853,140	1,700	600	90	**2,390**	344	122	19	**485**	176	63	10	**249**	**385,314**
Alternative 5	2,665,700	1,218,100	1,347,800	5,231,600	1,650	760	840	**3,250**	334	155	171	**659**	170	80	88	**338**	**523,160**
	Phase 1	**Phase 2**	**Phase 3**		**Phase 1**	**Phase 2**	**Phase 3**		**Phase 1**	**Phase 2**	**Phase 3**		**Phase 1**	**Phase 2**	**Phase 3**		
Alternative 5	2,889,960	923,500	1,344,600	5,158,060	1,790	570	830	**3,190**	362	116	169	**647**	185	60	87	**332**	**515,806**

Notes

1- Assumes circular stockpile with 5:1 (h:v) side slopes. Area calculation uses insitu volume and does not account for losses, bulking, or compaction.

2- Assumes 10 CY per truck load as an order of magnitude index

Table D-3. Summary of Estimated Costs[1] for Disposal Options. Costs in Millions of Dollars

		Alt 1				Alt 2				Alt 3				Alt 4				Alt 5				Alt 5 with Phasing [2]			
		Area A	Area B	Area C	Total	Area A	Area B	Area C	Total	Area A	Area B	Area C	Total	Area A	Area B	Area C	Total	Area A	Area B	Area C	Total	Phase 1	Phase 2	Phase 3	Total [2]

Notes

1 - Estimated construction costs include a 35% contingency

2 - The cost estimate for phasing Alternative 5 is higher due to the construction of a temporary levee

3 - Estimate not included for Beneficial Use - Landfill Cover, contamintant report pending

Table D-4. Summary of Unit Costs and Cost Estimate Assuptions

Item	Description	Unit	Unit Cost	Notes
	Unit Costs			
	Mobilization			
1	Mobilization	LS		8% of subtotal used as a typical value. This value may be high.
	Demolition			
2	Demo culvert, daylight channel	LF	$1,000	
	Excavation	CY		Excavation of material only. Transportation included in Item 9.
3	Excavate to Marshplain	CY	$15	Excavate material from existing grade to marshplain elevation.
4	New Ballona Creek	CY	$15	Excavate material to create new Ballona Creek channel.
5	Channels Order 5	CY	$15	Excavate material to create large channels
6	Channels Order 4	CY	$15	Excavate material to create medium channels
7	Channels Order 3	CY	$15	Excavate material to create small channels
8	Breach	CY	$15	Excavate material to create breach
	Transportation	CY		Transportation of excavated material only. Placement of material in stockpile included in Item 12.
9	Onsite trucking	CY	$5	Truck transportation of excavated material to locations of fill and stockpile in each sub-area. Does not include transportation between sub-areas.
	New Levees	CY		
10	Levee Fill - no road	CY	$10	Levee construction using earth fill from material excavated onsite in each sub-area
11	Levee Fill - with road	CY	$17	Levee construction per above and paved roadway.
	Stockpile	CY		
12	Place material at stockpile	CY	$5	Placement of excavated material in excess of fill material in a stockpile in each sub-area. Excavation (Items 3-8) and transporation (Item 9) included separately.
	Levee Lowering and Ballona Creek Fill			
13	Levee Lowering	CY	$5	Excavation of earth material from existing levees along Ballona Creek. Removal and salvage of rip rap included in Item 15.
14	Ballona Creek Fill	CY	$5	Fill placement in existing Ballona Creek channel by sidecasting excavated material from levee lowering to fill Ballona Creek and using some excavated material (Items 2-8)
15	Salvage Rip Rap	CY	$10	Removal of rip-rap from existing levees
16	Buried rock protection	CY	$20	Assumes half the salvaged volume is used for protection and remainder is taken off-site for use by contractor
	Water Control Structures			
17	Culvert	SF	$2,010	New culvert
18	Tide Gate	LS	$100,000	New tide gate for culvert
	Subtotal			
	Contingency			35% contingency included for concept-level cost estimate.
	Total			

Disposal Options - Cost Estimates from POLA / Weston and SCC

Item	Description	Unit	Unit Cost	Notes
1 / 2	**Unload Dredged Material at POLA / Disposal at CDF at POLA**			
	Mobilization	LS		8% of subtotal used as a typical value. This value may be high.
	Sediment Removal	CY	$3	From POLA / Weston
	Barge Sediment (approx. 30 NM)	CY	$4.50	From POLA / Weston
	Unload Dredged Material (hydraulic unloader) or Disposal at CDF	CY	$3	From POLA / Weston
	Subtotal			
	Contingency			35% contingency included for concept-level cost estimate.
	Total for Option 1			
3	**Beneficial Use - Landfill Cover**			
	Mobilization	LS		8% of subtotal used as a typical value. This value may be high.
	Sediment Removal	CY	$3	From POLA / Weston
	Barge Sediment (approx. 30 NM)	CY	$5	From POLA / Weston
	Stockpiling & Staging Material at POLA	CY	$1	From POLA / Weston
	Truck Material to Site (100 mi at $0.20/cy)	CY	$20	From POLA / Weston
	Placement, grading, compaction at Site	CY	$4.25	From POLA / Weston
	Subtotal			
	Contingency			35% contingency included for concept-level cost estimate.
	Total for Option 2			
4	**Disposal at Hazardous Waste Landfill - estimate not included, contamintant report pending**			
5	**Offshore Disposal [1]**			
	Mobilization	LS		8% of subtotal used as a typical value. This value may be high.
	Sediment Removal and Offshore Disposal (approx. 3 mi offshore)	CY	$28	Based on $28 per cubic meter cost from Upper Newport Bay project for dredging and disposal about three miles offshore provide by SCC
	Subtotal			
	Contingency			35% contingency included for concept-level cost estimate.
	Total for Option 3			
6	**Beach Disposal [1]**			
	Mobilization	LS		
	Sediment Removal and Beach Disposal	CY	$21	Based on cost for Option 1 / 2 with additional $10/CY premium for beach disposal
	Subtotal			
	Contingency			
	Total for Option 4			

Notes

1 - For Options 5 and 6, costs may range from the cost for Option 1 / 2 (lower end) up to the costs listed for Options 5 and 6 (upper end)

Alternative 1 Area A

Item	Description	Quantity	Unit	Unit Cost	Total Cost
	Mobilization				**$240,000**
1	Mobilization	1	LS	$240,000	$240,000
	Demolition				**$0**
2	Demo culvert, daylight chan	0	LF	$1,000	$0
	Excavation	**109,500**	CY		**$1,642,500**

MEMO

Date: October 15, 2008
From: Ballona Wetlands Science Advisory Committee
To: Ballona Project Management Team

Background and Overview

The purpose of this memo is to summarize the Ballona Wetlands Science Advisory Committee (SAC) technical review of the Ballona Wetlands Restoration Feasibility Report and to make recommendations to the Project Management Team for the development of more refined alternatives prior to the CEQA/NEPA environmental review.

One of the primary purposes of the SAC is to provide advice on science-based objectives for restoration and on the evaluation of restoration alternatives. Over a series of meetings, the SAC provided substantial input on the project's ecosystem restoration goals and subgoals. The overall goal of the project is to restore, enhance, and create estuarine habitat and processes in the Ballona Ecosystem to support a natural range of habitat and functions, especially as related to estuarine dependent plants and animals.

After input from the public, environmental organizations, and agencies, five conceptual project alternatives were developed by the project's consultant team which reflects possible restoration actions. The alternatives represent a continuum that ranges from preservation and enhancement of existing upland and wetland habitats to restoration and creation of a tidally influenced wetland system, including partial realignment and restoration of the lower portions of Ballona Creek/Flood Control Channel. It is also recognized that variations of these alternatives are possible.

To assist the project team in evaluating how the five alternatives meet the project goals and sub-goals, the SAC developed more specific "measures of change". The purpose of these measures was to identify a common means of comparison, quantified when possible, for the alternatives. The Restoration Feasibility Report applied the measures of change to each of the five project alternatives to compare how each alternative would be expected to meet the project goals. The Restoration Feasibility Report was reviewed by the SAC members and extensive comments were incorporated into the final version to ensure the report was technically accurate. With the exception of the sections on public access and costing (which are beyond the scope of the SAC's review), t***he SAC endorses the analysis provided in the Restoration Feasibility Report for use in subsequent stages of alternatives development and review***.

Although the Restoration Feasibility Report includes preliminary cost estimates, alternatives were compared only in relation to the project goals and subgoals, without regard to cost. In addition, the alternatives were only evaluated for conceptual feasibility; additional work is needed to determine if there are barriers (such as easements, public health and safety, or environmental constraints) that affect the logistical, legal, or practical feasibility of a given approach. In developing more refined project alternatives for the environmental review process, the SAC recognizes that the Project Management Team will need to balance factors such as cost and practical feasibility to develop alternatives that best achieve the project goals.

The conclusions and recommendations below address only the ecosystem restoration goals of the proposed project. They focus on critical restoration choices that will affect the function of the habitat ultimately restored at the site. The purpose of these recommendations is to help the Project Management Team to develop more refined project alternatives that achieve the project's ecosystem restoration goal. Refined alternatives could include incorporating elements from several alternatives to produce a "hybrid" alternative that best achieves the project goals.

Relationship Between Alternatives and Project Goals

The Restoration Feasibility Report summarizes a number of trade-offs between different restoration approaches. Although the project area is 600 acres, making it the largest wetland restoration project in Los Angeles County, it is much smaller than its historical extent and is now surrounded by development. Consequently, restoration of one type of habitat may limit the area available for another habitat type. There are also a number of choices with regard to the hydrology of the restoration project that will affect the habitat function and its long-term sustainability.

The Science Advisory Committee agreed upon the following subgoals in support of the overall ecosystem restoration goal for the project:

1. *Habitat*: Preserve, restore, enhance, and create a variety of functional wetland and estuarine habitats representative of the Ballona Ecosystem.

2. *Biodiversity*: Preserve and increase the native biodiversity of the Ballona Ecosystem. Identify and protect multiple levels of diversity (e.g. species, habitats, biogeographic provinces and trophic structure).

3. *Physical/Chemical Processes*: Maintain and establish physical and chemical processes consistent with the restoration goals.

4. *Sustainability*: Facilitate the conservation and restoration of natural resources in a manner that maintains and improves the ecological integrity, function, diversity and productivity for future generations.

The SAC developed a number of measures of change to evaluate how the restoration would address the subgoals and objectives for the project. The SAC determined that the goals and objectives could best be met based on the following criteria.

1. Maximize area of estuarine habitat.

The SAC believes that the best way to achieve the habitat goals is to through the restoration of a functional estuarine habitat that includes shallow subtidal, mudflats, fully tidal wetlands, salt pan and transitional habitats. Tidal estuarine habitats would benefit vascular and non-vascular plants, small mammals, and a diverse community of aquatic invertebrates, fish, and many bird species known to utilize other southern California wetlands. Enhancement of muted tidal wetlands or upland habitat, such as coastal sage scrub, grassland and saline seasonal marsh, does have benefits to fish and wildlife, but not to the extent that can be achieved with full tidal restoration. The SAC recognizes that upland habitat is important for functioning estuarine habitat and may be necessary to accommodate potential sea level rise in the future, and has given consideration to including such areas within the alternatives.

Alternatives 3, 4 and 5 create the largest areas of tidal estuarine habitat while Alternatives 1 and 2 have larger areas of upland and artificially muted tidal habitat (controlled by tide gates). Alternatives 4 and 5 create large areas of shallow subtidal habitat adjacent to mudflat. This would provide spawning and nursery habitat for pelagic and demersal fish species; these may disperse to the adjacent nearshore habitat and to other regional wetlands

2. Restore large, contiguous and diverse estuarine wetlands with subtidal habitat adjacent to mudflat and wide transitional habitat areas. Refined alternatives should include preservation and enhancement of some upland and freshwater wetland habitat but should emphasize contiguous estuarine wetland habitat. Opportunities to create regionally significant habitat including vernal pools and native grasslands should be pursued, but not at the expense of the restoration of estuarine habitat.

Alternatives with larger, contiguous, areas of diverse estuarine wetland habitat are more likely to sustain populations of associated species. Alternatives with fewer roads, wider transitions and more channels would have a higher quality of wetland habitat because they would be more remote from noise, lights, cars, and other human impacts. Alternatives with larger areas of contiguous wetland would also have fewer impacts from, and require less active management for, invasive plant and animal species.

Generally, the alternatives that restore more estuarine habitat have less area available for adjacent upland habitats or other regionally significant habitats. While upland habitats provide support to functioning estuarine habitat, there are opportunities for restoration of coastal sage scrub and bluff habitats in nearby offsite areas. Nevertheless, inclusion of some native upland habitat within the restoration project would be desirable.

Alternatives 3, 4 and 5 allow for the greatest range of elevation gradients and variation in topography. As such, these alternatives would allow for restoration of shallow subtidal habitat, intertidal channel, mudflats, low to high marsh, salt pans and transition zones. Alternative 4 would provide for the most extensive subtidal habitat and associated adjacent mudflats. The gradients associated with these habitats would be particularly beneficial for numerous fish and bird species.

3. Restore fully tidal wetlands by removing or breaching levees to the extent possible.

The form of the tidal connection would affect the connectivity and function of habitat by influencing the movement of sediment, seeds, gases, nutrients, fish and fish larvae. Muted tidal systems, as in Alternatives 1 and 2, will have a reduced tidal range and therefore a compressed vertical range of habitats, limiting the area of transitional habitat that can be created. Fully tidal systems allow for greater tidal circulation and reduced residence time which will lead to a more rapid exchange of water with the ocean, and positive effects on exchange of gases, nutrients, fish larvae, sedimentation and improved water quality.

Tide gates do allow for control of water surface elevations within the wetlands but would limit connectivity with Ballona Creek and Marina del Rey, likely reducing wetland species diversity. Gates can also control pollutant loading, especially during storm events, although the muted tidal systems would have a longer residence time allowing greater settling of pollutants in the wetland.

Levee breaches proposed as part of Alternatives 3 and 4 allow for full tidal range, movement of larger fish and greater seed dispersal. Open breaches would allow greater tidal circulation, reduced residence times and would be able to adapt to rising sea levels. Levee removal in Alternative 5 has the advantages of breaches and increases the interaction between the wetlands and the Creek - creating gradients of inundation and salinity across the site, letting the morphology evolve and allowing for periodic disturbance by flooding and scouring. However, this alternative would require reliance on upstream flood control and pollutant removal, and could necessitate periodic removal of accumulated pollutants from some portions of the restored wetlands. Furthermore, it is unknown how the flow and sediment yield from the upper watershed would affect the sustainability of the marsh in terms of scour or sediment deposition.

4. Maximize hydrologic connections within the subareas and minimize potential water quality effects associated with influent

The higher quality sources of tidal water are the ocean and portions of Marina del Rey. The ability to bring this water into the wetlands would depend on the location of the tidal connection and the tidal excursion length. Alternatives 2, 3 and 4 improve tidal connections between Area A and higher quality water in portions of Marina del Rey; this would also benefit habitat connectivity for fish species. All alternatives have some connection to Ballona Creek, which, at present, has poorer water quality. Longer excursion lengths increase the mixing of water on each tidal cycle, improving water quality. Alternatives 3, 4 and 5, with the largest tidal prism, have excursion lengths extending to the ocean. The large intertidal areas of Alternative 2, 3 and 5 would have the shortest residence times, completely draining on most tidal cycles. As stated above, Alternative 5 would rely on upstream pollutant control measures to ensure water and sediment quality within the restored wetland.

5. Adaptive management measures should be incorporated into any restoration alternative

Alternative 1 has little change from the present situation and the risk associated with failed implementation is low. The restoration of wetlands in Alternative 2, 3 and 4 could be undertaken in distinct hydrologic areas which would allow for adaptive management and experimentation. Alternative 5 restores a large, contiguous area of habitat connecting a number of existing hydrologic units with Ballona Creek. This alternative makes the greatest change to the site, would be the hardest to reverse and consequently has the most risk. This risk may be mitigated to an extent by incorporating an adaptive management approach through phased implementation.

Open breaches would allow greater tidal circulation, reduced residence times and would be able to adapt to changing sea levels. Gates would require regular maintenance and management as failure could impact habitat and cause flooding. Fixed structures, such as gates and culverts, will need to accommodate both scour and sea level rise in their design.

SAC Recommendations

The SAC evaluated the ability of each alternative to achieve the ecosystem restoration goals of the project. This evaluation was based primarily on the expected physical and biological processes and habitat enhancement that would occur as a result of each restoration concept. SAC evaluation was not based on other project considerations of cost, logistics, or feasibility. These are critical issues for project design and implementation and will be evaluated by the Project Management Team during later phases of the project. Relative rankings of alternatives based on the analysis in the feasibility report, and summarized above are provided in Table 1.

The SAC recommends that Alternatives 4 and 5 be carried forward to the next phase of the analysis. Alternative 5 would result in the greatest amount of contiguous wetland habitat and would have the least artificial structures or impediments. However, there are several unresolved issues associated with Alternative 5 that could affect its ability to provide sustainable, functioning wetland habitat. These issues would need to be addressed should it become a preferred alternative:

- Effect of erosive shear stress associated with high velocity storm flows on sustainability of the marsh plain
- Ability to manage potential adverse effects of pollutant input to the wetlands until such time as upstream management measures reduce watershed contaminant loading
- Ability to include additional upland habitat for both intrinsic value and as a buffer to the restored wetlands. For example, the Project Management Team could consider restoring Area C as primarily upland or transitional habitat.
- Lack of control structures to aid in accommodating sea level rise Refined analysis of potential flood elevations and associated implications for integrity of the restored wetland. This analysis

should include consideration of the need for new/additional flood protection measures if the Ballona Flood Channel levees are removed

- Ability to implement Alternative 5 in phases so that impacts to existing species and habitats can be minimized as restoration proceeds

- Although it would have lower internal connectivity and would retain more artificial structures, Alternative 4 would provide many of the same wetland functions as Alternative 5. Internal circulation and flushing would be lower than in Alternative 5, but Alternative 4 would provide more contiguous subtidal habitat and associated mudflats and transition zones. While Alternative 4 would reduce beneficial effects of flood inundation (e.g. temporary salinity reduction, nutrient influx), it would be less susceptible to the adverse effects of flooding, such as contaminant input. If Alternative 4 is carried forward as a preferred alternative, the subtidal area in Area A should be designed to be shallow enough to allow substantial turn over during a relatively few tidal cycles and should be reoriented to allow two tidal connections and gentle transition slopes.

The SAC also recommends that the following additional analyses be completed for both Alternatives 4 and 5:

- Potential effects of scour, sediment input, and deposition
- Potential effects of pollutant inputs (including trash and debris) and any necessary management measures
- Potential effects of sea level rise on long-term sustainability and/or adaptability of restored wetlands
- Potential ability of the restored wetland to support target species (to be defined in coordination with the SAC) as an additional measure of change in the final feasibility study. Each alternative should be evaluated for both the species that it would or would not be likely to support.
- Projected salinity and temperature regimes of Alternatives 4 and 5 to determine if defining estuarine transitions in these elements will be present (as opposed to primarily marine conditions). This analysis should also include the effect of potential salinity reduction and productivity-inducing effects of freshwater influxes.

Finally, whichever alternative is selected, it should be implemented in phases to allow mid-course corrections and re-evaluation of progress toward achieving project goals.

Table 1: Summary of Rankings of Alternatives Relative to Goals and Measures of Change

Subgoal	Measures of Change	Alt. Rankings Lowest	Alt. Rankings Highest	Rationale
Habitat				
	area of tidal habitat	1	3, 4 & 5	Alternatives 3, 4, and 5 would each provide most of the site with unrestricted tidal access
	quality of estuarine habitat	1	4 & 5	Alternatives 4 and 5 would provide for the greatest amount of estuarine habitat with complex edge habitat, diversity of habitat types, and transitions between areas with varying tidal regimes
	habitat connectivity	1	5	Only Alternative 5 would provide for full internal site connectivity
	lack of impact to existing habitats	5	1 & 2	Alternative 5 would results in severe impacts to existing habitats
Biodiversity				
	number of wetland/aquatic plant and animal functional groups	1	4	Alternative 1 would likely result in the highest upland species diversity; however, Alternative 4 would likely have the highest wetland species diversity, partially due to the opportunity for mudflats that are contiguous to transitional habitats
	capacity to support sustainable populations of wetland dependent species	1	4 or 5	Alternatives 4 and 5 each have advantages in terms of sustainability. Alternative 5 has fewer artificial features, so maintenance may involve removal of sediment or trash or restoring scoured marsh vs. repair of structures. Additional analysis is necessary to determine the likely ability of each alternative to support target species.
Phys/Chem Processes				
	tidal circulation	1	5	Alternatives 3, 4, and 5 would all provide for full tidal access; however, circulation and mixing in Alternative 5 would be most like a "natural" system
	quality and reliability of source water	1	4 or 5	Circulation and flushing patterns in Alternatives 4 and 5 are both high; however, Alternative 4 provides greater ability to control pollutant inputs from the upstream watershed

stormwater and freshwater inputs	1	5	Only Alternative 5 would allow for stormwater and freshwater inputs that simulate "natural" conditions and are least restricted by infrastructure
biogeochemical cycling	1	4 & 5	Alternatives 4 and 5 would both provide a variety of habitats of various moisture regimes. The somewhat natural flow and circulation in Alternative 5 may favor some processes, while the longer residence time in Alternative 4 may favor others
sediment supply and quality	1 & 2	3 & 4	Alternatives 3 and 4 would provide for wetlands that are less susceptible to scour and deposition patterns from the upper watershed than Alternative 5
flood management	5	1	Alternative 1 would involve the lowest risk to infrastructure

Sustainability

sensitivity to sea level rise	3 & 4	1 & 2 (short term) 5 (long term)	Alternatives that maintain existing infrastructure would be most stable to a changing climate until the point were increased sea level overwhelms infrastructure. The unrestricted features of Alternative 5 could allow for more natural migration patterns than Alternatives 3 or 4 over the long term
resilience to episodic events	5	1	Alternative 5 would be susceptible to scour, pollutant spills, etc. that accompany floods, due to the unrestricted access to Ballona Creek
risk of terrestrial invasion	1	5	Restoration of wetland processes would create conditions more conducive to native vegetation outcompeting invasive species. Full tidal flushing would likely prevent persistence of any non-halophytic plants that might occasional invade. However, all alternatives would require ongoing control of invasive species.
risk of aquatic invasion	4 & 5	1	Alternatives that result in more subtidal area would be more susceptible to aquatic invasion (e.g., Japanese yellowfin goby, Asian date mussel).
intensity of maintenance needs	1	5	Alternative 5 would have the least infrastructure that would require maintenance, but could require substantial maintenance if impacted by a large watershed event (e.g. flood, scour). Alternative 5 design

		and management features should allow for natural processes to compensate for periodic disturbance to the maximum extent possible.

<u>Defend Ballona Wetlands et al. v. California Department of Fish and Wildlife,</u>
21STCP00240

Decision on petition for writ of mandate: granted in part

Petitioners Defend Ballona Wetlands, Robert Jan Van De Hoek, and Molly Basler (collectively, "Defend") seek a writ of mandate compelling Respondent California Department of Fish and Wildlife ("CDFW") to set aside its certification of the Environmental Impact Report ("EIR") for the Ballona Wetlands Restoration Project ("Project").

The court has read and considered the joint moving papers and appendix, opposition, and replies, heard oral argument at the May 9, 2023 trial, and renders the following decision.

A. <u>Statement of the Case</u>

1. <u>Petition</u>

Petitioner Defend, an unincorporated association, commenced this proceeding on January 28, 2021, alleging a cause of action for mandamus pursuant to the California Environmental Quality Act ("CEQA"). The verified Petition alleges in pertinent part as follows.

CDFW owns the land rights to most of the Ballona Wetlands Ecological Reserve ("Reserve"), the California State Lands Commission owns 60 acres, and the Southern California Gas Company ("SoCalGas") owns or leases the mineral rights for the Reserve. The US Army Corps of Engineers ("Corps") and Los Angeles County Public Works/Flood Control District ("Public Works") manage the Ballona Creek that runs through the Reserve.

The California State Coastal Conservancy's executive director, who has a documented history of investing in the fossil fuel industry, financed front groups like the Santa Monica Bay Restoration Foundation (the "Bay Foundation") to plan the bulldozing Project that CDFW inaccurately touts as a "restoration." The Bay Foundation receives funding from SoCalGas and also had a SoCalGas executive on its board until recently. Other groups supporting the Project have also received funding from SoCalGas. Proponents of the Project falsely describe the Reserve as terribly degraded and needing intervention or the wetlands will die. The Reserve actually is thriving with wildlife, including seven endangered species and dozens of species of concern.

A total of $6.25 million dollars from the Prop 12 bond was allocated by the Coastal Conservancy for hydrological analysis and scenic trail design in the 600-acre Reserve. The State Coastal Conservancy has misused funds by flying staff to and from Oakland to stay at hotels in Playa del Rey and dining with Bay Foundation staff to discuss plans to destroy the Reserve.

At the same time as the scoping began for the Project's draft EIR ("DEIR"), the federal government undertook an environmental review process under the National Environmental Policy Act ("NEPA"), with the Corps as the federal lead agency. In September 2017, the Corps issued its draft NEPA environmental impact statement ("EIS") and CDFW issued its draft EIR ("DEIR"). CDFW circulated the DEIR from September 25, 2017 to February 5, 2018. On December 30, 2020, CDFW certified the final EIR ("FEIR"). The Corps does not expect to file the final EIS until 2.5 years after the EIR's certification.

The FEIR's project description is incomplete and misleading in describing it as a restoration. CDFW spent $15,000,000 of Proposition 12 bond funds on planning and engineering the Project, which cannot be called a restoration and rather is a destruction and creation of something different than that which has been in place for 3000 years. Prop 12 bond language required the Project to protect, acquire or restore these wetlands, but the Project instead destroys the habitat. Multiple groups noted that the Project seeks to remove currently existing wetlands and other habitats and replace them with a type of wetland never seen on the Reserve. In doing so, the Project would raze 640 acres of natural beauty and leave many animals without habitat.

The FEIR fails to evaluate the Project's significant impacts on grasslands and other upland habitats, as well as freshwater and brackish wetlands, the estuary in Ballona Creek, endangered species, and public access. The FEIR fails to adequately respond to comments and failed to adopt a statement of overriding considerations.

There is no substantial evidence that the plan as the "Environmentally Superior Alternative." CDFW denied that the Corps told it that the Project needed additional flood protection measures even though the Corps said it did.

The DEIR asserts that CDFW did not know about the illegal drains in the wetlands until 2013, but then asserts that the Coastal Commission should ignore the drains. The Coastal Commission did not agree that the drains were insignificant and ordered them sealed so that rainwater would not drain from the wetlands. CDFW then capped the drains but used the conditions with uncapped drains in the FEIR for baseline purposes. The capped drains were significant new information meriting FEIR recirculation.

The Project calls for increased public access. The FEIR provides no evidence why bicyclists should forego direct commuting paths for time-consuming detours on meandering routes.

The FEIR does not respond adequately to public comments that the Project would not provide a beneficial impact to carbon sequestration.

CDFW inadequately responded to comments about a longitudinal sandbar in the Reserve formed in the 1930s which is a habitat for several infauna and epifauna, including some fish essential to feeding the local bird species. Petitioners raised questions about the impact on this sandbar and CDFW's response indicated that it does not even know the habitat exists.

In response to comments about specific species, CDFW mischaracterized the Palmer's Goldenbush as a common species to justify not pursuing protection of its habitat. Its analysis also ignores four endangered species and several special status species like the peregrine falcon.

CDFW's duty is to protect rare species. Despite this, CDFW did not consult with botanist specialists or Petitioner Van Hoek -- who discovered the presence of the Palmers Goldenbush -- before issuing the FEIR. CDFW also chose not to recirculate the FEIR when the endangered Least Bell's Vireo was discovered to be nesting and breeding on either side of Ballona Creek. CDFW also ignored U.S. Fish and Wildlife Service ("USFWS") comments about the effect on the federally endangered California Least Tern which breeds on the Reserve.

USFWS also asked whether there will be appropriate habitat conditions within the site to support the species. CDFW only responded by referring to the DEIR's section on Monitoring and Adaptive Management. The response did not answer USFWS' question, which focused on assurance that appropriate habitat conditions are part of the Project plan, and they clearly are not.

CDFW admits that the wrong flood risk standards were used for modeling the Project but relies on them anyway. CDFW argued with the Corps for at least two years about the need for greater flood risk standards. The Coastal Conservancy even hired a lobbyist to persuade then U.S. Senator Kamala Harris to obtain Congress' approval for the old, less protective, standards.

Petitioners seek a writ of mandate compelling CDFW to (1) set aside certification of the Project's FEIR, (2) not develop or alter the site until it brings the Project into compliance with CEQA, and (3) prepare, circulate, and consider a legally adequate EIR. Petitioners also seek attorney's fees and costs.

2. Course of Proceedings

There is no proof of service on file. CDFW has generally appeared in this case.

On March 8, 2021, Department 54 (Hon. Maurice A. Leiter) related this case to: Protect Ballona Wetlands v. California Department of Fish and Wildlife, ("Protect") 21STCP00237; Ballona Wetlands Land Trust v. CDFW, ("Land Trust") 21STCP00242 and Grassroots Coalition et. al v. CDFW ("Grassroots") 21STCV03657 (collectively, "Ballona Cases").

On March 29, 2021, after a peremptory challenge in Land Trust, Department 1 reassigned the Ballona Cases to Department 93 (Hon. Joel L. Lofton).

On April 6, 2021, after a peremptory challenge in Grassroots, Department 1 reassigned the Ballona Cases to Department 15 (Hon. Richard L. Fruin).

On April 22, 2021, after a peremptory challenge in Protect, Department 1 reassigned the Ballona Cases to Department 20 (Hon. Kevin C. Brazile).

On May 3, 2021, after a peremptory challenge in Defend, Department 1 reassigned the Ballona Cases to this court (Dept. 85).

On July 15, 2021, the court consolidated the Ballona Cases for purpose of trial only.

On August 10, 2021, the court related Grassroots Coalition et. al v. California State Coastal Conservancy ("Grassroots v. Conservancy"), 21STCP02237 to the Ballona Cases.

On August 2, 2022, the parties stipulated to try Grassroots v. Conservancy separately from the Ballona Cases.

On September 28, 2022, CDFW filed Answers to each of the Ballona Cases.

On March 14, 2023, the court granted an *ex parte* application allowing Petitioners Protect and Land Trust and to file a joint reply brief separately from Petitioners Defend and Grassroots, which would file their own joint reply brief.

B. CEQA

The purpose of CEQA, (Public Resources ("Pub. Res.") Code §21000 *et seq.*), is to maintain a quality environment for the people of California both now and in the future. Pub. Res. Code § 21000(a). The Legislature chose to accomplish its environmental goals through public environmental review processes designed to assist agencies in identifying and disclosing both environmental effects and feasible alternatives and mitigations. Pub. Res. Code §21002. Public agencies must regulate both public and private projects so that "major consideration is given to preventing environmental damage, while providing a decent home and satisfying living environment for every Californian." Pub. Res. Code §21000(g).

"[T]he overriding purpose of CEQA is to ensure that agencies regulating activities that may affect the quality of the environment give primary consideration to preventing environmental damage." Save Our Peninsula Committee v. Monterey County Board of Supervisors, (2001) 87 Cal.App.4th 99, 117. CEQA must be interpreted "so as to afford the fullest, broadest protection to the environment within reasonable scope of the statutory language." Friends of Mammoth v. Board of Supervisors, (1972) 8 Cal.3d 247, 259.

The EIR is the "heart" of CEQA, providing agencies with in-depth review of projects with potentially significant environmental effects. Laurel Heights Improvement Assn. v. Regents o of University of California, ("Laurel Heights II") (1993) 6 Cal.4th 1112, 1123. An EIR describes the project and its environmental setting, identifies the potential environmental impacts of the project, and identifies and analyzes mitigation measures and alternatives that may reduce significant environmental impacts. Id. Using the EIR's objective analysis, agencies "shall mitigate or avoid the significant effects on the environment... whenever it is feasible to do so. Pub. Res. Code §21002.1. The EIR serves to "demonstrate to an apprehensive citizenry that the agency has in fact analyzed and considered the ecological implications of its actions." No Oil, Inc. v. City of Los Angeles, (1974) 13 Cal.3d 68, 86. It is not required to be perfect, merely that it be a good faith effort at full disclosure. Kings County Farm Bureau v. City of Hanford, ("Kings County") (1990) 221 Cal.App.3d 692, 711-12. A reviewing court passes only on the EIR's sufficiency as an informational document and not the correctness of its environmental conclusions. Laurel Heights Improvement Assn. v. Regents of University of California, ("Laurel Heights I") (1988) 47 Cal.3d 376, 392.

All EIRs must cover the same general content. Guidelines[1] §§ 15120-32. An EIR should be prepared with a sufficient degree of analysis to provide decision-makers with information which enables them to make a decision which intelligently takes account of environmental consequences. The environmental effects need not be exhaustively reviewed and the EIR's sufficiency is viewed in the light of what is reasonably feasible. Guidelines §15151. The level of specificity of an EIR is determined by the nature of the project and the "rule of reason." Al Larson Boat Shop, Inc. v. Board of Harbor Commissioners, (1993) 18 Cal.App.4th 729, 741-42. The degree of specificity "will correspond to the degree of specificity involved in the underlying activity which is described in the EIR." Guidelines §15146. The agency's decision whether to approve a project is a nullity if based upon an EIR that does not provide decision-makers, and the public, with the information about the project required by CEQA. Santiago County Water District v. County of Orange, (1981) 118 Cal.App.3d 818, 829.

C. Standard of Review

A party may seek to set aside an agency decision for failure to comply with CEQA by petitioning for either a writ of administrative mandamus (CCP §1094.5) or of traditional mandamus. CCP §1085. A petition for administrative mandamus is appropriate when the party seeks review of a "determination, finding, or decision of a public agency, made as a result of a proceeding in which by law a hearing is required to be given, evidence is required to be taken and discretion in the determination of facts is vested in a public agency, on the grounds of noncompliance with [CEQA]." Public Res. Code §21168. This is generally referred to as an "adjudicatory" or "quasi-judicial" decision. Western States Petroleum Assn. v. Superior Court, ("Western States") (1995) 9 Cal.4th 559, 566-67. A petition for traditional mandamus is appropriate in all other actions "to attack, review, set aside, void or annul a determination, finding, or decision of a public agency on the grounds of noncompliance with [CEQA]." Where an agency is exercising a quasi-legislative function, it is properly viewed as a petition for traditional mandamus. Id. at 567; Pub. Res. Code §21168.5.

At issue is Petitioners' CEQA challenge to CDFW's action to approve the Project and certify the FEIR. This procedural setting, in which CDFW acted in a quasi-legislative capacity in approving the Project, is governed by traditional mandamus. In determining whether to grant a petition for either traditional or administrative mandamus in a CEQA case, the court decides

[1]As an aid to carrying out the statute, the State Resources Agency has issued regulations called "Guidelines for the California Environmental Quality Act" ("Guidelines"), contained in Code of Regulations, Title 14, Division 6, Chapter 3, beginning at section 15000.

whether there was a prejudicial abuse of discretion. Public entities abuse their discretion if their actions or decisions do not substantially comply with the requirements of CEQA. Sierra Club v. West Side Irrigation District, (2005) 128 Cal.App.4th 690, 698. Abuse of discretion is established if the agency has not proceeded in a manner required by law or if the determination or decision is not supported by substantial evidence. Western States, *supra*, 9 Cal.4th at 568; Pub. Res. Code §21168.5.

The court must adjust its scrutiny to the nature of the alleged defect, depending on whether the claim is predominantly one of improper procedure or a dispute over the facts. Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova, ("Vineyard") (2007) 40 Cal.4th 412, 435. Challenges to an agency's failure to proceed in the manner required by CEQA, such as an EIR's failure to address a required subject or to disclose information about a project's environmental effects, are subject to a less deferential standard than challenges to an agency's substantive factual conclusions. Id. at 435. In reviewing these claims, the court must "determine *de novo* whether the agency has employed the correct procedures and "scrupulously enforced all legislatively mandated CEQA requirements." Id; Sierra Club v. County of Fresno, ("Friant Ranch") (2018) 6 Cal.5th 502, 512. Whether an issue is procedural or factual "is not always clear". Id. at 513. Clear-cut procedural issues—such as whether the agency provided sufficient notice and opportunity to comment and whether the agency omitted the required discussion of alternatives—are reviewed *de novo*. Id. at 512.

Greater deference is accorded to factual findings under the substantial evidence standard of review. Id. At 512. "Substantial evidence" is defined as "enough relevant information and reasonable inferences from this information that a fair argument can be made to support a conclusion, even though other conclusions might also be reached. Guidelines §15384(a). A court "'may not set aside an agency's approval of an EIR on the ground that an opposite conclusion would have been equally or more reasonable,' for, on factual questions, our task 'is not to weigh conflicting evidence and determine who has the better argument."' Sierra Club, *supra*, 6 Cal.5th at 512 (citing Laurel I, *supra*, 47 Cal.3d at 393). When reviewing factual determinations—such as the decision to use a particular methodology—substantial evidence review is appropriate. Id. at 514.

Whether substantial evidence exists is a question of law. *See* California School Employees Association v. Department of Motor Vehicles, (1988) 203 Cal.App.3d 634, 644. Argument, speculation, and unsubstantiated opinion or narrative will not suffice. Guidelines, 15384(a), (b). An EIR may not be overturned simply because the record reveals a disagreement among experts. Cadiz Land Co. v. Rail Cycle, (2000) 83 Cal.App.4th 74, 97. A petitioner must describe the evidence favorable to the agency and show why it is lacking. Mani Brothers Real Estate Group v. City of Los Angeles, (2007) 153 Cal.App.4th 1385, 1402. The failure to do so is fatal. Defend the Bay v. City of Irvine, (2004) 119 Cal.App.4th 1261, 1266. If the record contains any substantial evidence supporting the agency's decision, the decision must be upheld. Banning Ranch Conservancy v. City of Newport Beach, ("Banning Ranch") (2012) 211 Cal.App.4th 1209, 1230.

Deference to an agency's factual determinations is even more appropriate where the agency has been delegated regulatory authority in a particular field. CDFW is the state agency the missioni of which is to "manage California's diverse, fish, wildlife, and plant resources, and the habitats upon which they depend, for their ecological values and for their use and enjoyment of the public." Fish & Game Code §712.1(a). CDFW also is the state's trustee for fish and wildlife resources. Fish & Game Code §711.7(a). Under CEQA, state lead agencies are required to consult with CDFW before preparing environmental impact reports that evaluate impacts on these resources.

Pub. Res. Code §21104(a). CDFW has been recognized as possessing special expertise for matters concerning fish and wildlife conservation. Fish & Game Code §1802 (requiring CDFW to provide its biological expertise to lead and responsible agencies in their reviews of environmental impacts under CEQA); *see also* Environmental Council of Sacramento v. City of Sacramento, (2006) 142 Cal.App.4th 1018, 1042 ("The agencies entrusted with the statutory obligation of balancing the needs of human populations with those of endangered plants and animals are guided by the expertise of their scientific staffs"). For this reason, the courts defer to CDFW's fact findings, even when presented with conflicting opinions from other experts. *See* ibid. ("We will not arbitrate between scientists and we will not intrude on the public agencies' duties to make policy and protect the species"). *See* Opp. at 11.

The court also may have to determine "whether an EIR's discussion of environmental impacts is adequate, that is, whether the discussion sufficiently performs the function of facilitating 'informed agency decisionmaking and informed public participation.'" Sierra Club, *supra*, 6 Cal.5th at 513 (citation omitted). "[T]he adequacy of an EIR's discussion of environmental impacts is an issue distinct from the extent to which an agency is correct in its determination whether the impacts are significant." Id. at 514. Where the issue is the adequacy of an EIR's discussion of a potentially significant impact, "[t]he ultimate inquiry . . . is whether the EIR includes enough detail 'to enable those who did not participate in its preparation to understand and consider meaningfully the issues raised by the proposed project.'" Id. at 516 (citation omitted).

The inquiry on the adequacy of an EIR's discussion is generally a mixed question of law and fact. The court must engage in *de novo* review to determine "whether the EIR serves its purpose as an informational document." Id. at 516. This is an issue of law, and no deference is given to the agency's determination. Washoe Meadows Community v. Department of Parks and Recreation, ("Washoe") (2017) 17 Cal.App.5th 277, 286. However, "to the extent factual questions (such as the agency's decision which methodologies to employ for analyzing an environmental effect) predominate, a substantial evidence standard of review will apply." South of Market Community Action Network v. City and County of San Francisco, ("SoMa") (2019) 33 Cal.App.5th 321, 332. "[I]n reviewing an EIR's discussion, [courts] do not require technical perfection or scientific certainty." Sierra Club, *supra*, 6 Cal.5th at 515. The "overriding issue on review is thus whether the lead agency reasonably and in good faith discussed a project in detail sufficient to enable the public to discern from the EIR the analytic route the . . . agency traveled from evidence to action." SoMa, *supra*, 33 Cal.App.5th at 331 (citation omitted).

D. Statement of Facts[2]

---

[2] Petitioner Defend requests judicial notice of the Corps' Guidelines for Landscape Planting and Vegetation Management at Levees, Floodwalls, Embankment Dams, and Appurtenant Structures, published April 30, 2014 ("Corps Guidelines"). RJN Ex. A. Petitioners note that two superseded versions of the Corps Guidelines are in the record (AR 73597-618, 87015) and that CDFW agreed to allow the inclusion of documents that should have been in the record. CDFW responds only that RJN Ex. A does not prove that it failed to analyze potential impacts on flood control levee vegetation and has no objection to judicial notice of RJN Ex A. The request is granted. Evid. Code §452(c).

Petitioner Defend also requests judicial notice of the following facts: (1) the Project's Operations and Maintenance Plan ("Operations Plan") states that the levees will be maintained by applying the Corps Guidelines (AR 5438; RJN No. 2); (2) the Corps Guidelines state that

1. The Reserve

The Reserve is approximately 600 acres of open space located in the middle of the County's coast, approximately five miles north of the Los Angeles International Airport and close to Loyola Marymount University, bordered by the communities of Westchester, Marina del Rey, and Playa Vista. AR 103951.

CDFW manages and primarily owns the Reserve, with a smaller interest owned by the California State Lands Commission. AR 208. The County's Department of Public Works-Flood Control District ("Public Works" or "LACFCD") owns and operates the Ballona Creek channel and levee system, which are features of a federally authorized Los Angeles County Drainage Area ("LACDA"). AR 208.

The Corps is the federal agency with jurisdiction over the Ballona Creek channel and levee system within the Project site. AR 8300. As a result, authorization from the Corps under Section 404 of the Clean Water Act and Sections 10 and 15 of the Rivers and Harbor Act would be necessary to carry out the Project. AR 8300. Corps approval also would be required to modify the Operations Plan to reflect Project changes to existing LACDA infrastructure on the Project site. AR 8300. The Corps is the lead agency under NEPA for any such project. AR 8300.

The Reserve is a heavily impacted remnant of a much larger wetland complex that stretched from Venice to Baldwin Hills. AR 103951. The Ballona Wetlands once spanned more than 2,100 acres and supported a tremendous diversity of both freshwater and brackish wetlands. AR 275, 3246. A scoping report found that, after the Los Angeles River shifted to the south in 1825 with a resulting reduction of flow into the area, the Ballona Wetlands evolved into an expansive marshy system consisting mostly of brackish to salt marsh, which supported abundant wildlife. AR 3247. The scoping report found no evidence that the Ballona Lagoon remained perennially open to the Pacific Ocean. AR 3248. Rather, textual sources indicate that access to the ocean depended on hydraulic forces during any given year. AR 3248. In historical records, brackish, freshwater, and salt marsh predominated over perennially open tidal wetlands. AR 3249. Approximately half of the Ballona Lagoon consisted of freshwater and tidally affected saltmarsh and brackish habitats that transitioned to a more alkaline/freshwater system about 1.5 miles inland. AR 3248. As a result, the term "tidal" is too limiting for the Reserve because the tidal influence has been low or moderate and the predominant influence has been freshwater inputs from the watershed. AR 3247.

Ballona Creek runs through the center of the Reserve. AR 273. In the 1930s, the Corps built a concrete-sided flood risk management channel that confined the portion of Ballona Creek that flowed through the wetlands. AR 273. During Marina del Rey's construction in the 1950s,

---

vegetation must be controlled to limit those habitat characteristics that encourage the creation of animal burrows. (RJN No. 3); (3) the Corps Guidelines state that an operations and maintenance manual for levees must include an annual maintenance program to control animal burrows and vegetative growth (RJN No. 4); (4) the Corps Guidelines require repair of animal burrows (RJN No. 5); (5) this language is the same as in the Corps Guidelines in the administrative record (AR73609, 73617, 73618; RJN No. 6); (6) while a local sponsor may request a variance from the standard vegetation guidelines, such request process must follow specific procedures and meet certain requirements (Corps. Guidelines; RJN No. 7); and (7) based on the above facts, animal burrows are not allowed on levees unless a variance is requested and granted (RJN No. 8). The requested facts are merely Petitioners' interpretation of the Corps Guidelines and Operations Plan and are not subject to judicial notice. Requests Nos. 2-8 are denied.

2.8 to 3.5 million cubic yards of dirt was dumped on top of the Ballona Wetlands. AR 208, 210. This transformed the wetlands into an upland, degraded wetlands. AR 210.

The Reserve now consists of three areas. AR 273. Area A is approximately 156 acres in the northwestern portion of the Reserve north of Ballona Creek, west of Lincoln Boulevard, and south and east of Fiji Way. AR 273. Area A is undeveloped except for parking areas along the western boundary, a SoCalGas access road on the western end, and a drainage channel along the northern boundary. AR 273. Area B is approximately 335 acres in the southern portion of the Reserve, south of Ballona Channel and west of Lincoln Boulevard. AR 274. Area B is crossed by Culver Boulevard and Jefferson Boulevard. AR 274.

The state owns 60 acres in the southeast portion of Area B, as well as a freshwater marsh which is a treatment wetland and mitigation project that was part of the Playa Vista development and is not part of the Reserve. AR 274, 8327. Storm drainage in Playa Vista currently flows into the freshwater marsh and out to Ballona Creek through a culvert with a drainage flap. AR 392. The flap gate closes during periods of high flow in Ballona Creek, and stormwater drainage then collects in the freshwater marsh. AR 392. Storm flow greater than a one-year storm event overflows from the freshwater marsh into southeast Area B to prevent storm drainage from backing up into Playa Vista. AR 392.

Area C is approximately 69 acres located in the northeastern portion of the Reserve, north of Ballona Channel and east of Lincoln Boulevard. AR 274. It is bisected by Culver Boulevard. AR 274.

2. <u>The Corps Guidelines</u>

Per the Corps Guidelines' chapter on the treatment of levees and floodwalls, vegetation must be controlled to limit those habitat characteristics that encourage the creation of animal burrows. RJN Ex. A, p. 3-1.

Any project's operations and maintenance manual must include an annual maintenance program to control animal burrows and vegetative growth. RJN Ex. A p. 5-1. The repair of animal burrows is a separate requirement. RJN Ex. A p. 5-2 (citing a Federal Emergency Management Agency publication for more details).

In certain instances, to further enhance environmental values or to meet state or federal laws and/or regulations, the local sponsor may request a variance from the standard vegetation guidelines set forth in this ETL. RJN Ex. A, p. 1-1; AR 73603. The variance must be necessary and the only feasible means to preserve, protect, and enhance natural resources or to protect the rights of Native Americans. RJN Ex. A, p. 1-1. Any variance for flood damage reduction systems must retain (1) safety, structural integrity, and functionality, and (2) accessibility for maintenance, inspection, monitoring, and flood-fighting. RJN Ex. A, p. 1-1. The term "retain" assumes a pre-variance condition that is fully consistent with the requirements set forth in the Corps Guidelines and any other applicable criteria. RJN Ex. A p. 1-1.

3. <u>The Project</u>

The Project's purpose is to restore and reconnect Ballona Creek with its historical floodplain, include adaptation for sea-level rise, restore upland and non-tidal wetlands, construct public access improvements, establish new flood risk and stormwater management infrastructure, and provide for long-term maintenance activities. AR 1.

The Project includes restoration components of (1) an overall net increase of approximately 201 acres of wetlands, (2) removal and replacement of existing levees with transitional zones to accommodate sea-level rise and introduce a meandering shape, (3) restoring, enhancing, and establishing estuarine aquatic and associated uplands, (4) improving tidal circulation into the Reserve to support estuarine and associated habitats, (5) modifying existing infrastructure to implement restoration activities, including abandonment or relocation of SoCalGas wells and pipelines, and (6) implementing long-term post-restoration activities such as inspections, repairs, vegetation management, and related activities. AR 1.

Public access improvements include the removal and realignment of bicycle trails, installation of new pedestrian-only trails and boardwalks, construction of two bicycle and pedestrian bridges, construction of a bicycle trail connection under Lincoln Boulevard, and improvements to two parking lots. AR 1.

The Project FAQs sheet asserts that the Reserve is highly degraded after approximately three million cubic yards of marine sediment was dumped into the wetlands to build Marina del Rey's harbor and the Ballona Creek flood control channel. AR 103951. Invasive plants have become roughly half the vegetation of the Project site and will continue to outcompete native plant life if unchecked. AR 103955. Repairing the basic structure and function of the Reserve will provide additional habitat for native plants, birds, and other wildlife clinging to existence as their habitats shrink. AR 103951-52.

The Project FAQs sheet asserts that the tide gates could be closed permanently in the future with the rise of sea levels due to climate change. AR 103955. This would cut tidal wetland habitats off from the estuary and convert them into a mudflat or subtidal habitat. AR 103955. The Project attempts to respond to the rise in sea levels with gently sloping earthen levees that will allow the restored wetlands to migrate upslope as the sea level rises. AR 103955.

Currently, most of the Reserve is closed to the public due to its degraded state. AR 103956. The Project seeks to provide greater access for bike trails atop the newly built levees around the Reserve perimeter, new pedestrian-only trails, and approximately 2000 feet of new elevated boardwalks to allow visitors to walk adjacent to the wetlands and obtain closer habitat views. AR 103956.

4. <u>The Scoping Process and Interim Studies</u>

In July 2012, CDFW began the Project review process by issuing a NOP. AR 64907-09. In August 2012, CDFW held a public scoping meeting to receive agency and public comment for the DEIR preparation. AR 1430. CDFW received numerous comments, objections, proposed alternatives, and suggested environmental impacts. AR 1430-47.

The Corps also issued a Notice of Intent to prepare a joint draft EIS/EIR with CDFW for the Project. AR 25106. The Notice of Intent explained that the Project would require several permits including a 33 U.S.C. Section 408 permit ("Section 408 permit") from the Corps to LACDPW, the non-federal sponsor of the LACDA. AR 25106, 25109.

A January 2012 biology study found that, in contrast to hydrologic performance, biological structure in restored or created wetlands recovers to only an average of 77% of reference values, even 100 years after restoration. AR 66792.

On March 26, 2012, the United States Environmental Protection Agency ("EPA") released a report on total maximum daily loads for sediment and invasive exotic vegetation in the Ballona Wetlands. AR 66169. The report cited to data from a 1998 Marina Del Rey Shoaling and Disposal Feasibility Study that approximately 1,557,000 cubic yards of material was removed from Marina del Rey and placed in Area A of the Ballona Wetlands. AR 66240. Coupled with other historical sediment movement, the EPA estimated that 2.1 million cubic yards of sediment was placed in

Ballona Wetlands Area A between the 1870s and 2005. AR 66241. The EPA recognized the inherent assumptions and uncertainties with these estimates. AR 66241.

In October 2012, the University of Southern California's Spatial Sciences Institute advised that studies had found no evidence that the Ballona Lagoon remained perennially open. AR 1711. Rather, the Ballona wetlands were only open to the ocean periodically in response to winter rains. AR 1710. Textual sources indicated that access to the ocean depended on hydraulic forces during any given year. AR 1711. As a result, the site would not be restored by introducing permanent tidal flows and the creation of a meandering channel for Ballona Creek would not restore the Reserve. AR 1710-11.

On June 25, 2014, a study for the California State Coastal Conservancy ("State Coastal Conservancy"), which worked with DCFW for the Project, showed that Alternative 1 (which did not yet exist in a DEIR) would increase the Reserve's ability to sequester carbon dioxide by 13,100 to 40,300 tons by 2100 (minus emissions). AR 54408-09.

On February 1, 2017, the U.S. Fish and Wildlife Service ("USFWS") informed the Corps that it would no longer cooperate with the development of a joint EIS/EIR. AR 9313. USFWS previously suggested changes to Project design features that will restore and enhance natural estuarine functions, reduce habitat fragmentation, and minimize disturbance associated with recreational access and maintenance activities. AR 9313. Because of competing commitments, USFWS felt it could no longer provide the level of attention necessary to resolve the environmental issues. AR 9313.

5. <u>The Design Discharge Issue</u>

On August 22, 2012, the Corps referred CDFW to the Corps' Operations and Maintenance ("O&M") Manual for the required design discharges for the Project. AR 20009. The Corp representative stated that the design standard is based on the approved report for the original project, which he could not find because it dated back a lot of years. AR 20009. He attached the O&M Manual sheets and data tables and stated that the Project design should follow the discharges noted. AR 20009. The O&M Manual listed the design discharge as 46,000 cubic feet per second ("cfs"). AR 20014.

On February 28, 2017, the Corps asked CDFW what the "authorized discharge" is for the Project's channel. AR 19860. The Corps had learned that, after it (the Corps) designed and built the original project, LACFCD modified the project and appeared to have raised the levees. AR 19860. The Corps had not confirmed why this was done and whether it was intended to increase the design discharge. AR 19860.

On March 20, 2017, the Corps noted that it had found some additional documents regarding design discharge. AR 19859. According to these documents, any changes to the channel should be designed for a future Standard Project Flood ("SPF") of "unrestricted channel flow." AR 19859, 18829. The Corp had not found any documents to update the design discharge value for the Ballona Creek channel and stated that it should be 68,000 cfs. AR 19859.

On April 3, 2017, CDFW asked the Corps to clarify the design discharge for the Ballona Creek channel. AR 19859. LACFCD's design drawings from 1959 and 1963 for the levee modifications indicated a design discharge of 49,500 cfs. AR 19859. Based on the Corps' previous email referring to the O&M Manual, CDFW identified the design discharge for the Project as 46,000 cps. AR 19859. The hydrology report referenced in the Corps' email referred to a future, unrestricted SPF of 68,000 cfs but that did not match the Ballona Creek channel as constructed. AR 19859. CDFW also understood that the channel upstream of the Reserve could not contain a flow of 68,000 cfs. AR 19859.

On April 20, 2017, the Corps replied that the Ballona Creek channel was designed for SPF discharge, which changed over time as a result of development in the watershed. AR 19793. Based on a 1979 feasibility study, the SPF values were approved, and the table indicates a discharge of 68,000 cfs. AR 19793, 19596. Knowing that it was approved for an updated SPF of 68,000 cfs, the Corps would not go back and redesign the Project for the original design discharge of 46,000 cfs. AR 19793. To change the authorized level of protection for a flood risk, CDFW would have to have a new feasibility study that used risk-based probability methodology and procedures, and the study would have to be presented to Congress for reauthorization. AR 19793, Even in that circumstance, the Section 408 permit process follows almost the same methods of approval, and the outcome would still require a design discharge of 68,000 cfs. AR 19793.

On April 21, 2017, a CDFW employee wrote an internal email that the 68,000 cfs flow rate was presenting a real problem and he was trying to leave the issue to CDFW's engineers. AR 19596. The County believed (but would not say so in writing) that the 68,000 cfs is unreasonable because it is a hypothetical scenario that could not happen. AR 19596. That standard may require re-visiting a few chapters, raising the levee height, and performing all the calculations that go with it. AR 19596. He asked another CDFW employee what he still had up his sleeve to deal with this problem. AR 19596.

On April 24, 2017, CDFW's engineers informed a State Coastal Conservancy employee that they ran a hydraulic model based on a discharge of 68,000 cfs. AR 19580. The model showed that the south levee would be shallowly overtopped upstream of Lincoln Blvd, but that the rest of the channel conveys 68,000 cfs. AR 19580. The State Coastal Conservancy forwarded this information to the Corps. AR 19580.

In September 2017, the Corps sent CDFW a formal letter that the Project's Section 408 permit application was being withdrawn. AR 18321. While CDFW had provided preliminary engineering design information, it did not provide the detailed engineering information needed for a preliminary technical analysis for the application. AR 18321. CDFW did not anticipate providing the required information for approximately two years, and the Corps would reinitiate review of the previously submitted Section 408 permit application and restart the EIS process upon its receipt. AR 18321.

6. The DEIR

Also in September 2017, CDFW released the DEIR prepared by Environmental Science Associates. AR 183. The DEIR defines the Project as restoration of the Reserve and incidental work necessitated by the proposed restoration activities. AR 206.

The DEIR notes that, in 2012, the EPA determined that all wetland habitats within the Reserve are impaired. AR 208. Between 2012 and 2014, CDFW used a California Rapid Assessment Method estuarine module as a baseline to compare the Reserve's score with that of other wetlands in Southern California. AR 748. Most areas in the Reserve had the lowest scores in the state, and even the highest scoring parts of Area B fell below healthy reference scores. AR 748. Based on standardized wetland condition protocols, a portion of the Reserve is among the most degraded wetlands in California. AR 687. The most significant impact is a lack of hydrological connection to an estuarine water source. AR 687.

Because the Project's changes to the Ballona Creek channel would require the Corps' review and approval under NEPA, the Corps and CDFW prepared a joint DEIR/EIS. AR 207, 212. Under NEPA, the Project's purpose is to (a) restore ecological functions and services within the Reserve, in part by increasing tidal influence to achieve predominantly estuarine wetland conditions and (b) ensure that any alteration or modification to the LACDA project components maintain authorized levels of flood risk management. AR 213.

The DEIR acknowledges receiving comments and input from the public and various agencies during the scoping process. AR 222.

a. The Project

The Project site consists of approximately 566 acres, mostly in the Reserve. AR 273. The Ballona Creek channel bisects the Reserve. AR 273. Artificial fill from dredging is present in every area of the Project site and ranges from 0 to 20 feet in depth. AR 920. Areas A and C have the most extensive fill coverage, with depths exceeding 20 feet in most portions. AR 920-21.

The Project is a large-scale effort to restore, enhance, and establish native coastal wetland and upland habitats within the Reserve. AR 326. The Project's goals are, *inter alia*, to restore, enhance, and create estuarine and associated habitats, return the daily ebb and flow of tidal waters where practically feasible to achieve predominantly estuarine conditions, maintain freshwater conditions, and enhance physical and biological functions within the Reserve. AR 185, 214.

The Project objectives include establishing natural processes and functions within the Reserve that support estuarine and associated habitats. AR 271. Measures to accomplish this goal include improving tidal circulation into the wetlands, increasing tidal prism and excursion, lowering residence time of water, ensuring a more natural salinity gradient, and creating dynamic hydrologic interactions between the Ballona Creek channel, wetlands in the Reserve, and the Santa Monica Bay. AR 271-72.

The Project would restore and revitalize the Reserve by removing the dredged material from the 1950s Marina del Rey construction and clearing out the invasive plants. AR 323, 350-53.[3]

Under Alternative 1, the Project would remove the existing concrete levees on a portion of the Ballona Creek channel and realign the creek into a meandering shape as it flows through the Reserve. AR 216. This would reconnect Ballona Creek with its reestablished floodplain within the Reserve, which would improve tidal flow and circulation into and within the wetlands. AR 216, 103950. The Project would replace the removed levees with earthen, sloping levees to prevent flooding in the surrounding area. AR 216.

The construction would require CDFW to cut 2.4 million cubic yards of soil, up to 110,000 of which would be exported offsite, to build the levees in Area A. AR 426. The new levees would accommodate a flow rate of 46,000 cfs, which is the same as the channel's original design. AR 1112, 7475.

The 46,000 cfs flow rate was designed for a channel with five to seven feet of freeboard to the levee crest. AR 1112. The 46,000 cfs design flow was developed by the Corps from a 24-hour, 50-year rainfall event and is greater than the 44,690 cfs peak flow for a 100-year event on the Reserve because it considers canyon and mountainous wildfire debris in the runoff. AR 1112.

[3] As defined by the Corps' regulations (33 CFR §332.2), "restoration" means manipulation of a site to a former or degraded source. AR 323. A restoration may be a "re-establishment" or a "rehabilitation". A "re-establishment" 'returns natural/historic functions to a former aquatic resource and results in a gain in aquatic area and functions while a "rehabilitation" improves aquatic resource functions without a gain in aquatic resource area. AR 323. An "enhancement" intensifies or improves a specific resource function. AR 323.

The documentation for the original design capacity is limited, but the LACFCD project design and as-built drawings from 1959 and 1963 show a design discharge of 49,500 cfs. AR 213, n. 3. Documentation for subsequent projects refers to a SPF flow of 46,000 cfs, first computed by the Corps in the 1950s. AR 213. The SPF figure was later revised to identify a future, unrestricted flow of 68,000 cfs. AR 213, n. 3. The DEIR admits that the Corps could increase the required conveyance capacity up to the SPF of 68,000 cfs. AR 213, 270, 309. Nevertheless, all the data calculations, including for HEC-RAS Model Scenario and peek sheer stress, assume a flow rate of 46,000 cfs. AR 1134, 1144; *see also* AR 3700, 7476, 7631, 7481 ("based on preliminary direction from Corps staff, analyses of flood performance were based on the design flow rate of 46,000 cfs....")

The DEIR outlines and illustrates steps to improve public access to the Reserve and the wetlands through new visitor entrances, two pedestrian and bike bridges, elevated boardwalks, and bicycle paths. AR 217, 396-14. This includes 3.6 miles of bicycle paths over flood control levees (AR 406) and 29,000 feet of pedestrian-only trails (AR 412), 2,000 feet of which would be of elevated boardwalk adjacent to wetlands (AR 412). A map of proposed paths show that they would be deeper in the Reserve than existing paths. AR 407.

Based on a map of the proposed breakdown of habitats post-restoration, levees -- estimated to be up to 20 feet in elevation -- would be constructed along the edges of Area A, along the southern edge of Area C, and within Area B. AR 337, 406. The proposed habitats of this area would be upland or salt marsh. AR 337. A bike path of at least 12 feet wide, combined with a six-foot wide pedestrian path would be located on the top of the levees. AR 406.

The DEIR provides a breakdown of the infrastructure and utility modifications that will be required to complete the Project. AR 414-22. Of the wells on the Project site, Phase 1 would only decommission the wells needed to complete the work. AR 349. CDFW would decommission the rest of the wells in Phase 2. AR 349.

The DEIR provides a timeline for the different phases of Alternative 1. AR 422-442. Phase 1 of the Project consists of the restoration of Area A, North Area B and Area C, with realignment of the Ballona Creek channel. AR 349-50, 353-54. Within Area B, CDFW would build new perimeter flood protection levees and an interim levee along West Area B, berms around the wetlands, new culverts and tide gates, and new tidal channels. AR 353. Phase 1 also includes invasive vegetation removal and native vegetation restoration in south and southeast Area B. AR 353. Phase 2 would be full tidal restoration of west Area B and new west Area B perimeter flood protection levee. AR 349.

b. <u>The Alternatives</u>

The DEIR lists four alternatives, with Alternative 4 as the No Action Alternative. AR 216-21. Alternative 1 incorporates both freshwater and non-tidal elements. It routes freshwater into the southeast corner of Area B to create and maintain brackish marsh. AR 353. It also employs water control structures to limit tidal circulation, all to create habitats similar to historic wetland habitats at the Reserve. AR 363. This contrasts with current conditions whereby the freshwater marsh outflow discharges through the culvert to Ballona Creek. AR 363. The description of Alternative 1 includes a discussion of flood risk and stormwater management activities, including construction of levees along Fiji Way in Area A and Culver Boulevard in west Area B. AR 382-84. Maps illustrate the locations of various levees. AR 385-88.

Alternative 1 would provide the most comprehensive changes and is the Proposed Action proposed by CDFW in its Section 408 permit application to the Corps. AR 185, 216. The DEIR confirms that both Alternative 2 and Alternative 3 are reasonable, would meet the Project's overall purpose and basic objectives, and would be practicable to implement. AR 316-20.

All of Alternatives 1-3 would (1) enhance and create wetlands, aquatic resources and upland habitats within the Reserve, including through large-scale grading and revegetation, (2) improve flood and storm water management in the surrounding area, including by installing new levees and other water-control structures, (3) provide public access and visitor amenities, including by constructing new trails and bike paths, bridges, and gateway entrances, and (4) modify infrastructure and utilities within the Reserve to support the restoration efforts, including the abandonment of gas wells and removal of a sewer pipe. AR 185, 321.

The difference in the three restoration Alternatives is the size of the Project site. Alternative 1 would restore or enhance wetlands both north and south of the existing Ballona Creek channel in Areas A and B. AR 185, 211, 321, 323. Alternative 2 would only affect Area A and some of Area B, and Alternative 3 would not affect Area B at all. AR 185, 321. As a result, Alternative 1 would eliminate 17 more acres of habitat for the Belding's Savannah Sparrow than Alternative 2. AR 259. It is also the only alternative that would require construction of a flood control berm around a saltpan habitat, and the only one that would split the Project into two phases. AR 423, 485, 497. Alternative 2 is the only alternative that would require removal of Little League baseball fields. AR 1274, 1278.

The DEIR rejects Alternative 10, which attempts to increase the amount of freshwater introduced into the Reserve by pumping water from upstream, downstream, or groundwater to create fresh and brackish wetlands and seasonal wetlands habitats. AR 537. This alternative is designed to replace the historic freshwater and brackish marsh lost because the Ballona Creek channel was designed to have a permanent opening between the creek and the Pacific Ocean. AR 537.

Some elements of Alternative 10 could be adjusted to maintain the authorized LACDA project levels of flood risk management. AR 538. However, Alternative 10 would not maintain or improve flood protection. AR 538. Because it relies on mechanical means to pump freshwater into the system, it would introduce a new risk of flooding due to possible mechanical failures. AR 538. It also would not limit the need for significant modification to infrastructure because it called for the raising of roadways in the Reserve. AR 538. This makes Alternative 10 impracticable because raising Culver Boulevard and Jefferson Boulevard would almost double the restoration cost per acre, by a total between $143 and $200 million for a 20-foot raise and could create new significant environmental impacts. AR 538-39. The habitats would not be self-sustaining because the created habitats would rely on those pumps and other managed infrastructure. AR 538. Because Alternative 10 does not account for sea-level rise, additional construction costs could also accrue over time to address that issue. AR 538.

Although Alternative 10 is reasonable and would be practicable to implement and maintain, it would not meet the Project purpose of increasing tidal influence, would not be practicable in terms of cost, and would not avoid or lessen Alternative 1's significant impacts. AR 269-70, 538, 540.

c. <u>Environmental Impacts</u>

DEIR Section 3.4.6 discusses direct and indirect impacts of the restoration Project. AR 762. For greenhouse gas emissions ("GHG"), the DEIR acknowledged that soil disturbance can release sequestered carbon. AR 1032. While converting a salt marsh to a mudflat will not release carbon, draining a marsh can do so. AR 1032. Carbon dioxide emissions from the Project's restoration activities would total 25,252 megatons ("MT"). AR 1040. A 2014 study asserted that the wetlands' expansion under Alternative 1 would remove 13,100 to 40,300 MT by 2100. AR 1040.

The DEIR asserted that the Project would increase the wetland habitat suitable for native species by about 200 acres. AR 255. The area of tidal marsh would increase by about 137 acres. AR 895. This long-term conservation benefit mitigates to less than significant the short-term adverse impacts to special-status species and associated habitats that the Project fails to avoid. AR 896.

The DEIR identifies the vegetation contemplated for each of the habitats within the Reserve after the Project's completion. AR 337, 445, 448-50. A map shows the planned location of each habitat type. AR 337. Each habitat has its own set of performance criteria and timeframes for meeting them. AR 445-51. These criteria include comparisons of species before and during the Project for the following: tidal marsh birds (AR 445), tidal channel fish (AR 446), mudflat macroinvertebrates and birds (AR 447), saltpan birds (AR 449), and upland scrub birds AR 450-51. For example, the vegetation performance criteria for tidal marshes provides that there be a minimum of five native species, although one or two may predominate. AR 445.

The DEIR discusses the environmental impact of the Project on the essential habitats of rare and special status species inside the Reserve, including the El Segundo Blue Butterfly, Western S-Banded Tiger Beetle, Silvery Legless Lizard, Belding's Savannah Sparrow, California Gnatcatcher, Great Blue Heron, Least Bell's Vireo, and Burrowing Owl. AR 226–35.

For upland birds in general, the DEIR acknowledges that Alternative 1 would result in a substantial adverse impact without mitigation. AR 232. However, after restoration, Alternative 1 also would provide comparable amounts of habitat and may expand foraging and nesting habitat for these species. AR 232. As a result, it will create a long-term beneficial effect upon mitigation. AR 232.

The DEIR contains a map of the current potential Burrowing Owl habitats. AR 736. The DEIR compares the acreage on this map to the acreage on a projected post-Project map of Burrowing Owl habitats and finds that there will be a 7:1 increase in habitat. AR 337, 351, 794.

A table in the DEIR summarizes the Project's potential impacts on federal-listed and other special status species, including the El Segundo Blue Butterfly, California Least Tern, and Least Bell's Vireo. AR 258-75. This includes a breakdown of the permanent loss and net gain of each habitat. AR 258-60. Because of the increase in usable habitat, the DEIR concludes that the Silvery Legless Lizard, Belding's Savannah Sparrow, Least Bell's Vireo, special-status marsh birds, Southern California Salt Marsh Shrew, and South Coast Marsh Vole all would experience population net gains in the long-term. AR 228, 230, 232, 233.

The DEIR's Impact Summary for Alternative 1 lists multiple adverse direct and indirect impacts but considers them as either "less than significant with mitigation incorporation" or "less than significant impact." AR 784-85, 828-29. After mitigation, none of the three restoration alternatives have significant or unavoidable adverse impacts. AR 223.

d. <u>Mitigation</u>

The DEIR discusses required mitigation measures. AR 326, 230-31, 328-29. This includes preparation and implementation of a Habitat Restoration and Monitoring Plan ("HRMP") before commencement of any restoration activities that involve vegetation or land disturbance. AR 328-29. The HRMP shall identify (1) specific restoration activities and monitoring programs to implement during restoration and any long-term habitat management; (2) a timeline for the implementation of the monitoring program, with a work plan or schedule for long-term monitoring after the site has achieved applicable performance goals; and (3) specific protocols for monitoring. AR 328-29. A Conceptual Habitat Restoration and Adaptive Management Plan ("Conceptual Plan") attached as Appendix B3 provides further guidelines for HRMP preparation with the principle of adaptive management. AR 5265, 5273.

7. <u>The Continued Flood Standard Discussion</u>

On April 6, 2019, the Corps informed CDFW that a change in its internal Section 408 permit analysis and NEPA policies means that the Corps would not issue a final EIS until CDFW submitted additional design information for the Project and the Corps reviewed it. AR 18513. CDFW estimated that it could take 2.5 years to draft and provide that information. AR 103951.

CDFW decided to separate its EIR from the Corps' EIS to avoid an extended delay for the certification of the EIR. AR 99022, 103951.

On October 19, 2019, the State Coastal Conservancy requested then-Senator Kamala Harris to process a Water Resources Development Act ("WRDA") request to lower the authorized flood control standard to 46,000 cfs as that is "the documented design flow rate of the existing channel." AR 25082-84. The WRDA request triggered emails between the Corps and LACFCD indicating that the State Coastal Conservancy did not consult either entity prior to submitting the request. AR 24801-03. In one email, the Corps said that it could not support the lower number without an "H&H analysis" and a decision document to support the lower number. AR 24812. Another Corps employee noted that the proposed WRDA language would reinforce the existing authorized design discharge of 46,000 cfs but that any modification of the Ballona Creek channel would still be subject to the Section 408 permit requirement of no increased flood risk, which is independent of design discharge. AR 24811. Since the Project would reduce the existing capacity of the channel, it would increase the flood risk. AR 24811.

On October 22, 2019, after a conference call, Public Works informed the Corps that it had decided to support the higher discharge number as documented in the Corps' 1979 report. AR 24809. The project manager's notes explained that any change to the existing 68,000 cfs standard would require detailed analysis of changes in velocity, water surface profiles, flow distribution, scour analysis, sediment transport analysis, and upstream and downstream impacts of proposed alterations. AR 24809.

On December 10, 2019, in response to Petitioner Protect's inquiry, the Corps explained that, as part of the Section 408 permit process, the Corps would consider any information the applicant provides whether to change the flood standard for the Ballona Creek channel. AR 18196. The Corps has not taken a position on whether the channel's SPF should be changed, and it expected CDFW to provide the pertinent information in mid- to late-2020. AR 18196. When the Corps issues a final EIS, it would include a preliminary decision regarding the SPF as well as for the Section 408 permit application. AR 18196.

8. <u>The FEIR</u>

On December 1, 2019, CDFW issued the FEIR with 4,000 pages of responses to the comments. AR 8296, 8308. It published the FEIR to the State Clearinghouse on December 20. AR 36998.

The FEIR notes that the DEIR refers to the Project as any of the three Alternatives, all of which were similar. AR 8330. The FEIR concludes that the Project is Alternative 1. AR 8330.

The FEIR notes that a commenter stated that the term "restoration" is nuanced and complex. AR 8340. Another commenter accurately noted that the DEIR's use of the term "restoration" included elements of both habitat creation and restoration. AR 8340. The FEIR clarifies that it uses the word "restoration" for both reestablishment of natural processes and ecological functions and habitat creation or enhancement. AR 8341. The FEIR dismisses objections to the use of the word "restoration" as mere semantics. AR 8342. All three restoration alternatives would result in a greater quantity of estuarine and associated habitats at the Reserve than currently exist. AR 8342.

The FEIR responds to arguments that the Project should consider a predominantly freshwater restoration alternative. AR 8349. The Reserve has long been identified as a significant regional opportunity for estuarine wetlands restoration, which include vegetated tidal marsh, intertidal channels, mudflats, and saltpans, and are a regionally rare habitat that can only be restored in very specific locations. AR 8349. The Southern California Wetlands Recovery Project identifies tidal wetland restoration as a key priority for its regional strategy and restoration of the Reserve represents the only opportunity to restore a large tidal wetland in Santa Monica Bay. AR 8349.

The FEIR cites studies explaining that the Ballona Wetlands historically has experienced closed fresh water and intermittent tidal conditions resulting from breaching during high flows. AR 10664. Because the longshore drift of sand rapidly closed the berm connecting the Ballona Wetlands to the ocean after major storms, a large freshwater lake was the rule rather than the exception. AR 10670.

Some commenters asked how the Corps' 2005 feasibility study relates to the process. AR 8328. The purpose of the Corps' study was to evaluate alternatives for channel modification, habitat restoration, recreation, and related purposes along the lower reach of Ballona Creek. AR 8328. In July 2012, the Santa Monica Bay Restoration Commission requested that the Corps terminate the study, and it did so in September 2012. AR 8328. The FEIR explains that the Corps' 2005 study is separate and independent from the Project because the who, what, when, and where of the proposals differ. AR 8328. This Project is a restoration project, not a civil works cost-shared project, and it would maintain existing and authorized LACDA project levels of flood risk management. AR 8328.

For Mitigation Measure BIO-1b-ii's biological monitoring, the FEIR clarifies that the biologist shall salvage low-mobility wildlife "either by trapping or other appropriate means" if Project-related vegetation or ground disturbances could kill or injure the animal. AR 13113. Salvaged species should be relocated to adjacent suitable habitat not subject to site disturbances. AR 13114. Any relocation efforts would include assessment to determine areas within the Reserve that would be most appropriate to receive species. AR 13114.

The FEIR revises the DEIR's performance criteria tables by replacing language that that species abundance "may be" greater than pre-restoration levels with language that they are "expected to be" greater. AR 13133.

9. <u>Responses to Comments</u>

The public comment period for the DEIR began on September 25, 2017, and CDFW extended the deadline to February 5, 2018. AR 8304-05. During that period, CDFW received over 8,000 postcards, e-mails, and letters with almost 3,000 distinct comments. AR 103951.

The Project has support with some recommendations from Friends of Ballona Wetlands, Heal the Bay, Los Angeles Waterkeeper, the Trust for Public Land, and the Surfrider Foundation. AR 9647-48, 11494-95, 11497, 11633, 11768, 11789.

Some comments asserted that the DEIR did not firmly state a preferred alternative. AR 8721 (02-17), 11663 (021-2), 11518 (015-12). However, three Petitioners asserted that the DEIR presented Alternative 1 as the preferred alternative. AR 8784 (Alternative 1 is "being pushed" by CDFW), 8898 (Alternative 1 was "obviously preferred"), 8950 (preferred Alternative 1 was included in 2012 memorandum). In response, CDFW stated that the FEIR clarifies that Alternative 1 is the Proposed Project and the environmentally superior alternative. AR 8353, 11582. The FEIR also asserted that CEQA does not require it to identify a preferred alternative, which is a NEPA concept. AR 8353 (*citing* Washoe, *supra*, 17 Cal.App.5th at 289).

One comment asked about a DEIR footnote stating that its use of the term "Project" does not indicate or imply the Corps' endorsement. AR 8721 (02-17). CDFW explained that, while Alternative 1 is the "Proposed Action," the Corps will not decide whether to approve a permit for any alternative until it had an opportunity to consider all relevant evidence, including agency and public input. AR 8869. The Corps would make its own judgment about which of the three Alternatives is environmentally superior. AR 8869.

Land Trust asserted that the DEIR lacks a reasonable range of alternatives. AR 8944 (04-14), 8946. The three restoration alternatives reflected project goals and objectives were too narrowly defined in order to ensure a predetermined outcome. AR 8944. The restoration alternatives are all varying degrees of the same concept. AR 8944. Petitioner Grassroots also called the three alternatives limited and confusingly similar but narrow. AR 10268 (011-344).

10. Certification of the FEIR

On January 8, 2020, Petitioner Land Trust requested that CDFW add to the administrative record various government communications about flood control that Land Trust had received through a California Public Records Act ("CPRA") Request. AR 25080.

On January 29, 2020, the State Coastal Conservancy wrote to CDFW and the Corps that the reports with an SPF value of 68,000 cfs were created in 1978. AR 18070, 25092. If the Project modifies the flood control channel, it either should convey the SPF or the Corps and the County should make new models to update the SPF to reflect current conditions. AR 18070. The better option would be to update the model instead of relying on a figure from the 1970s. AR 18070.

In April 2020, a Land Trust representative asked CDFW to confirm that the Corps' EIS finalization process would not begin until after EIR certification. AR 13828. The Corps' website said that the EIS finalization could take two years. AR 13828.

On December 30, 2020, CDFW certified the FEIR. AR 141-42. The NOD filed with the Office of Planning and Research describes the Project as Alternative 1, except for construction of a three-story parking garage and an access road behind business on Culver Boulevard. AR 1.

E. The Motion to Augment Record

In conjunction with their reply, Petitioners Protect and Land Trust move to augment the record with five documents.

1. Applicable Law

For cases arising under CEQA, the contents of the administrative record is governed by Pub. Res. Code section 21167.6(e) ("section 21167.6"):

> (e) The record of proceedings shall include, but is not limited to, all of the following items:

(1) All project application materials.

(2) All staff reports and related documents prepared by the respondent public agency with respect to its compliance with the substantive and procedural requirements of this division and with respect to the action on the project.

(3) All staff reports and related documents prepared by the respondent public agency and written testimony or documents submitted by any person relevant to any findings or statement of overriding considerations adopted by the respondent agency pursuant to this division.

(4) Any transcript or minutes of the proceedings at which the decision-making body of the respondent public agency heard testimony on, or considered any environmental document on, the project, and any transcript or minutes of proceedings before any advisory body to the respondent public agency that were presented to the decision-making body prior to action on the environmental documents or on the project.

(5) All notices issued by the respondent public agency to comply with this division or with any other law governing the processing and approval of the project.

(6) All written comments received in response to, or in connection with, environmental documents prepared for the project, including responses to the notice of preparation.

(7) All written evidence or correspondence submitted to, or transferred from, the respondent public agency with respect to compliance with this division or with respect to the project.

(8) Any proposed decisions or findings submitted to the decision-making body of the respondent public agency by its staff, or the project proponent, project opponents, or other persons.

(9) The documentation of the final public agency decision, including the final environmental impact report, mitigated negative declaration, or negative declaration, and all documents, in addition to those referenced in paragraph (3), cited or relied on in the findings or in a statement of overriding considerations adopted pursuant to this division.

(10) Any other written materials relevant to the respondent public agency's compliance with this division or to its decision on the merits of the project, including the initial study, any drafts of any environmental document, or portions thereof, that have been released for public review, and copies of studies or other documents relied upon in any environmental document prepared for the project and either made available to the public during the public review period or included in the respondent public agency's files on the project, and all internal agency communications, including staff notes and memoranda related to the project or to compliance with this division.

(11) The full written record before any inferior administrative decision-making body whose decision was appealed to a superior administrative decision-making body prior to the filing of litigation.

Section 21167.6(e) "contemplates that the administrative record will include pretty much everything that ever came near a proposed development or to the agency's compliance with CEQA in responding to that document." County of Orange v. Superior Court, (2003) 113 Cal.App.4th 1,

8. The trial court makes determinations of the completeness of the administrative record. Madera Oversight Coalition, Inc. v. County of Madera, (2011) 199 Cal.App.4th 48, 63, *disapproved on other grnds.*, Neighbors for Smart Rail v. Exposition Metro Line Construction Authority, ("Neighbors for Smart Rail") (2013) 57 Cal.4th 439. Specifically, the trial court resolves disputes between the parties over what should be included in, or excluded from, the administrative record. Ibid.

2. Analysis

Petitioners Protect and Land Trust move to augment the record with five documents: (1) a November 30, 2021 Grant Agreement between the State Coastal Conservancy and CDFW (Ex. A); (2) a January 2023 email from Corp employee Aaaron Allen to Land Trust President Walter Lamb (Ex. B); (3) a January 2022 Preliminary Comments on Ballona Wetlands Concept Review by Public Works ("Ex. C"); (3) a December 2022 CDFW response to Ex. C (Ex. D); and a (4) Ballona Wetlands Restoration Project Frequently Asked Questions document published by CDFW (Ex. E).

As CDFW argues, Petitioners' motion to augment is untimely, having been filed and served on April 21, 2023, only 12 court days before the May 9, 2023 hearing, in lieu of the 16 days required by CCP section 1005. *See* Opp. at 2. Petitioners claim that the evidence is offered to rebut CDFW's opposition and that they could not have anticipated that CDFW would rely on a different set of facts. Mot. at 3. This may justify Petitioners' desire for late action, but it does not excuse making a noticed motion on less than 16 days' notice without seeking an order shortening time.

More important, this case concerns DFW's quasi-legislative decision to approve the Project and certify the EIR, and extrinsic evidence is generally not admissible for quasi-legislative administrative mandamus. Western States, *supra*, 9 Cal.4th at 573, 576. Evidence outside the record may be considered at trial only if it (1) existed before the agency made its decision, and (2) it was not possible to present it to the agency before the decision was made. Id. at 578. Even then, extra-record evidence may never be admitted to contradict the evidence relied upon by the administrative agency or question the wisdom of its decision. Id. at 579.

Petitioners admit that Exhibits A-D do not meet this test because four of the five documents were created after the FEIR was certified. Mot. at 3. They argue instead that the evidence is admissible to show CDFW's misconduct. *See* Barthelemy v. Chino Basin Municipal Water District, (1995) 38 Cal.App.4th 1609, 1621 (extra-record evidence may be admissible to show misconduct). They argue that CDFW committed misconduct by failing to admit that the Corps flow rate capacity is a firm Project requirement, and its supporting evidence in the record tries to mislead the public by obscuring the true facts around the size and configuration/design of levees that are part of the Project. Id.

As CDFW argues, Exs. A-D do not show its misconduct. Petitioners rely on these documents as evidence that the true flow rate required by the Corps is 68,000 cfs. Opp. at 3. As such, the exhibits are offered to contradict the evidence cited in CDFW's opposition, not to show agency misconduct. Petitioners' attempt to show CDFW's knowledge is not the type of misconduct that would permit extra-record evidence. Additionally, Ex. D, which was created before the EIR was certified, already is in the record. *See* AR 103951-56. The motion to augment is denied.

F. Analysis

Petitioners contend that the FEIR certification must be set aside because (1) it impossible to identify the preferred Project from the three restoration alternatives in the project description, (2) the project description's reference to "restoration" is misleading, (3) the project description fails to include the correct flood control design standard, (4) the Project's restoration performance criteria are indefinite and lack a binding framework, (5) the FEIR fails to include a vegetation map, (6) the FEIR fails to consider a reasonable range of alternatives by excluding a freshwater alternative, and (7) the FEIR's analysis of environmental impacts is inadequate.[45]

1. The Preferred Project

a. The Law Concerning the Project Description

An EIR "provide[s] public agencies and the public in general with detailed information about the effect which a proposed project is likely to have on the environment." Pub. Res. Code §21061. The ability of informed citizens to participate in environmental review is a key tenet of CEQA. Washoe, *supra*, 17 Cal.App.5th at 285. To adequately apprise the public of a project and its environmental impacts, an EIR must contain "an accurate, stable and finite" project description. Citizens for a Sustainable Treasure Island v. City and County of San Francisco, ("Treasure Island") (2014) 227 Cal.App.4th 1036, 1045; County of Inyo v. City of Los Angeles, ("Inyo") (1977) 71 Cal.App.3d at 185, 193.

"[A] project description that gives conflicting signals to decision makers and the public about the nature and scope of the project is fundamentally inadequate and misleading." Treasure Island, *supra*, 277 Cal.App.4th at 1052. An unstable and incomplete project description "stultifies" public participation. San Joaquin Raptor Rescue Center v. Cnty. of Merced, ("San Joaquin Raptor") (2007) 149 Cal.App.4th 645, 656. "Only through an accurate view of the project may affected outsiders and public decision makers balance the proposal's benefit against its environmental cost, consider mitigation measures, assess the advantage of terminating the proposal [] and weigh other alternatives in the balance." Inyo, *supra*, 71 Cal.App.3d at 192–193. A project description also cannot narrow the scope of environmental review or minimize the project's impacts on the environment. Laurel Heights I, *supra*, 47 Cal.3d at 405.

The failure to maintain an accurate and stable project description is a failure to proceed in the manner required by law subject to *de novo* review. Stopthemillenniumhollywood.com v. City of Los Angeles, ("Stothemillennium") (2019) 39 Cal.App.5th 1, 15; SoMa, *supra*, 33 Cal.App.5th at 332 ("Whether an EIR correctly describes a project is a question of law, subject to de novo review."). No deference is given to the agency's determination on this issue. Washoe, *supra,* 17 Cal.App.5th at 286. The court reviews a EIR "not for perfection but for adequacy, completeness, and a good faith effort at full disclosure." Guidelines §15151. However, an EIR's failure to provide a stable and finite project renders it deficient even if "the informative quality of the EIR environmental forecasts [were] not affected by the ill-conceived, initial project description". Inyo, *supra* 71 Cal.App.3d at 199. To conclude otherwise "would only countenance the practice of releasing a [DEIR] for public consumption that hedges on important environmental issues while

---

[4] CDFW does not contend that any of the four Petitions fails to allege the issues addressed in the joint opening brief. As a result, all issues raised in the joint opening brief have been considered for all Petitions.

[5] A FEIR includes the DEIR and the agency's responses to comments. For clarity, the court will refer to the document located at the citation, whether it is the DEIR, response to comment, or the FEIR.

deferring a more detailed analysis to the [FEIR] that is insulated from public review." *See* Mountain Lion Coalition v. Fish & Game Comm'n, (1989) 214 Cal.App.3d 1043, 1052 (declining to consider whether FEIR's cumulative impact analysis cleared up DEIR's deficiencies because it was never subject to public review and comment). Such error is necessarily prejudicial. Sierra Club, *supra*, 6 Cal.5th at 515; Washoe, *supra,* 17 Cal.App.5th at 290 (citation omitted). *See* Pub. Res. Code §§ 21005, 21168.5.

b. Inyo, Washoe, and SoMa

(i). Inyo

In Inyo, the court addressed whether an EIR project description for the extraction of subsurface water satisfied CEQA. 71 Cal.App.3d at 185. The EIR described the project as a 51-cfs increase in the water extraction rate. Id. at 189. The court noted that "the project concept expands and contracts from place to place within the EIR." Id. at 190. Even though not included in the project description, some sections of the EIR analyzed a "recommended project" with higher rates of groundwater extraction as well as the development of infrastructure to export water to Los Angeles. Id. The court explained: "The small-scale groundwater project described at the outset was dwarfed by the 'recommended project' ultimately endorsed by the FEIR and approved by the board of commissioners." Id. at 199.

As such, the city's approval of the FEIR was a failure to proceed in the manner required by law. Id. at 200. The court stated that, while the CEQA process is not designed to freeze the initial project as the project ultimately approved, and new and unforeseen insights may emerge that require project revision, the selection of a narrow project as the launching pad for a vastly wider proposal frustrated CEQA's public informational aims. Id. at 199-200. Although "the informative quality of the EIR environmental forecasts" was not affected by the initial project description, the court underscored that "[t]he defined project and not some other project must be the EIR's bona fide subject." Id. at 197, 199. The EIR's failure to properly describe the project, regardless of the adequacy of its environmental analysis, frustrated CEQA's public information aims. Id. at 199-200.

(ii). Washoe

In Washoe, the California Department of Parks and Recreation proposed an "Upper Truckee River Restoration and Golf Course Reconfiguration Project" because the existing golf course had altered the course and flow of the Upper Truckee River, causing deterioration in habitat and water quality. 17 Cal.App.5th at 282. The DEIR described five different project alternatives to reduce sediment discharge from the river into Lake Tahoe. Id. at 283. The DEIR did not identify a preferred alternative, and instead proposed that the department would identify the preferred alternative after public comment and the final decision would be included in the FEIR. Id. at 281, 283.

The FEIR identified "[a] refined version of Alternative 2" (river restoration with reconfigured 18-hole golf course) as the preferred alternative, stating that Alternative 2's acreages had been modified "to address public access issues" and the final design may reflect further modifications as a result of the "normal design refinement process". The FEIR stated that these minor modifications to Alternative 2 did not require recirculation because they did not change the DEIR's conclusions on the significance of impacts. Id. at 284.

The court affirmed the trial court's decision to set aside the project approval and FEIR certification because, *inter alia*, the DEIR did not contain an "accurate, final and stable" project description and this acted as "an obstacle to informed public participation." Id. at 285, 290. The court agreed with the trial court:

> "[F]or a project to be stable, the DEIR, the FEIR, and the final approval must describe substantially the same project. An EIR that states the eventual proposed project will be somewhere in 'a reasonable range of alternatives' is not describing a stable proposed project." Id. at 288.

The fact that the DEIR thoroughly analyzed Alternative 2's environmental impacts – a version of which was ultimately approved as the project -- did not alter the analysis. Id. at 288. The court held that "an agency's failure to propose a stable project is not confined to 'the informative quality of the EIR's environmental forecasts.'" Id. at 288 (quoting Inyo, *supra,* 71 Cal.App.3d at 197). The failure to identify and select any project at all impairs the public's right and ability to participate in the environmental review process. Ibid. "A description of a broad range of possible projects, rather than a preferred or actual project, presents the public with a moving target and requires a commenter to offer input on a wide range of alternatives that may not be in any way germane to the project ultimately approved." Ibid. While there may be situations in which the presentation of a small number of closely related alternatives would not present an undue burden on the public, the difference between the five projects was too vast because each created a different footprint on the land. Ibid.

The court found that the prejudice required by Pub. Res. Code section 21005 exists "'if the failure to include relevant information precludes informed decisionmaking and informed public participation, thereby thwarting the goals of the EIR process.'" Id. at 290 (citation omitted). "A deficiency in the EIR may be deemed prejudicial under this standard 'regardless of whether a different outcome would have resulted if the public agency had complied with those provisions.'" Id. Because the DEIR failed to designate a stable project, the court held that the lower court properly granted the writ petition challenging the project. Id.

(iii). SoMa

In SoMa, the city and county of San Francisco approved a mixed-use business and residential project. 33 Cal.App.5th at 327. The DEIR "described two 'options' for the [mixed-use] project, an 'Office Scheme' and a 'Residential Scheme.'" 33 Cal.App.5th at 328. The overall square footage was substantial the same in both project schemes, with varying mixes of office and residential use. Id. at 328. The DEIR discussed nine alternatives to the project, including a "Preservation Alternative" which was a similar mixed-use project that would avoid demolition of a nearby building and reduce certain environmental impacts. Id.

In upholding the approval of the revised project based on the DEIR's Preservation Alternative, the SoMa court found the petitioners' claim that the DEIR presented multiple possible projects to be specious. Id. at 332. The court explained that the office and residential schemes were two project options with the same overall square footage but a varying mix of residential and office uses." Id. at 333. Both involved construction of new floor space, similar massing and land use, and retention of some buildings and demolition of others. Id. at 333. The DEIR set forth in text and table format the square footage for both schemes. Id. at 333. The public was able to comment without confusion on the two schemes. Id. at 333. Thus, there was one project with two options for different allocations of residential and office uses. Id. at 333-34.

The SoMa court distinguished Inyo:

> "[In Inyo,] throughout the EIR process, the project description varied, with the result that the 'small-scale groundwater project described at the outset was dwarfed by the 'recommended project' ultimately endorsed' that dealt with 'important, large-scale phases of the city aqueduct management program.' The [Inyo] court concluded the agency's selection of a 'narrow project as the launching pad for a vastly wider proposal frustrated CEQA's public information aims.' Here, there were no similar fluctuations in the project description during the EIR process, nor is the initial project description a misleading fragment of the ultimately approved project." Id. at 335. (citations omitted).

The SoMa court also distinguished Washoe, stating that the SoMa project description clearly described a mixed-use project at a specific location with two options for allocations of office and residential use. Id. at 335. While the petitioners complained that the FEIR adopted a revised project that was a variant of the preservation alternative identified in the DEIR, the petitioners had not identified any component of the revised project that had not been "addressed in the DEIR or subject to public comment." Id. at 335 (emphasis added). Further, CEQA's reporting process is not intended to "handcuff decisionmakers" or "freeze the ultimate proposal in the precise mold of the initial project" since CEQA's purpose is to encourage adopting alternatives that reduce environmental impacts. Id. at 335-36. "The whole point of requiring evaluation of alternatives in the DEIR is to allow thoughtful consideration and public participation regarding other options that may be less harmful to the environment." Id. at 335-36. *See also* Treasure Island, *supra*, 227 Cal.App.4th at 1055 ("Many of the environmental impacts described in [Inyo's] EIR were related to the much broader project, rather than the smaller project described").

c. Analysis

Petitioners argue that the EIR fails to identify a preferred alternative or a stable project, thus confusing the public and reviewing agencies and rendering the EIR inadequate as an informational document. According to Petitioners, the EIR improperly identifies the Project as one of three restoration alternatives prejudices the public in two different ways.

First, it is impossible to determine what the Project is, thus rendering the EIR's project description defective. "[A] range of alternatives simply cannot be a stable proposed project." Washoe, *supra,* 17 Cal.App.5th at 288. The three alternatives proposed for the restoration are substantially different, with a different set of environmental impacts, mitigation measures, costs, duration, and other important considerations. For instance, Alternative 1 would eliminate 17 more acres of existing habitat for the endangered Belding's Savannah Sparrow than Alternative 2. AR 259. Alternative 3 leaves the Ballona Wetlands channel levees in place and would not affect any land south of the channel. AR 491. Alternative 1 envisions the construction of a new flood control berm around the saltpan habitat but this berm would not be necessary with Alternatives 2 and 3. AR 491, 467, 491. Alternatives 1 and 3 envision no change to the Little League baseball fields whereas Alternative 2 requires the removal of the fields. AR 1274, 1278. Alternative 1 is the only option with two phases of construction. AR 423, 485, 497. As such, the alternatives analysis was confusing and presented "an obstacle to informed public participation." Pet. Op. Br. at 22.

Second, it impossible to properly compare the preferred alternative to the other alternatives to determine if impacts could be lessened. Logically, an alternative is a choice to something else. CEQA requires an alternatives analysis that presents "a reasonable range of alternatives to the project…which…offer substantial advantages over the project proposal." Citizens of Goleta Valley v. Bd. of Supervisors, (1990) 52 Cal.3d 553, 566. This analysis cannot happen in the EIR because there is not a predictable way to measure alternatives against a proposed Project. Additionally, the EIR's treatment of alternatives placed too high a burden on the public commenters and reviewing agencies. As Washoe explained: "A description of a broad range of possible projects, rather than a preferred or actual project, presents the public with a moving target and requires a commenter to offer input on a wide range of alternatives that may not be in any way germane to the project ultimately approved." 17 Cal.App.5th at 288–89. Pet. Op. Br. at 22.

In making this argument, Petitioners fail to distinguish between the DEIR and the FEIR. The FEIR states that the DEIR used the term "Project" to refer to restoration via any of the three restoration alternatives…." AR 8330 (emphasis added). The FEIR then defines the term "Project" to mean "restoration of the Reserve and incidental work as presented in CDFW's application for authorization from the Corps (*i.e.*, Alternative 1)." AR 8330 (emphasis in original). Thus, the FEIR clearly identifies Alternative 1 as the Project.

The DEIR also identifies Alternative 1 as the Project, albeit less clearly, because it repeatedly refers to Alternative 1 as the "Proposed Action". AR 185, 216, 278, 336. The DEIR explains that Alternative 1 is the Project for which CDFW is seeking approval from the Corps. AR 276, n.13, 307, 311. The DEIR further explicitly states that Alternatives 2 and 3 are identified for the purpose of complying with the requirement under CEQA that an EIR discuss a reasonable range of alternatives to the proposed Project (Alternative 1). AR 301; *see also* 307, 314, 315. Hence, regardless of how they are labeled, the DEIR presents three alternatives as (a) the proposed Project (Alternative 1) and (b) two alternatives (Alternatives 2 and 3). The public was not misled by this approach. Indeed, three of the Petitioners indicated in their comments on the DEIR that they understood Alternative 1 is the preferred alternative. AR 8784, 8898, 8950.

Petitioners' reliance on Washoe is misplaced. Opp. at 14-15. Washoe did not hold that a DEIR must identify a preferred alternative. Instead, Washoe held that the DEIR in that case did not identify a proposed project because its range of alternatives was so broad, and the differences between them so vast, that the public effectively was required to "offer input on a wide range of alternatives that may not be germane to the project ultimately approved." 17 Cal.App.5th at 288-89. Unlike the DEIR in Washoe, the DEIR identifies Alternative 1 as the Proposed Action.

Even if the DEIR does not clearly state that Alternative 1 is the Project, Washoe does not support Petitioners' claim. The range of alternatives in Washoe was broad, their differences substantial, their objectives were fundamentally different (restoration versus stabilization), and they were to be accomplished in different ways (reconfiguration versus downsizing versus removal of the golf course). Washoe acknowledged that there could be cases in which the presentation of "a small number of closely-related alternatives would not present an undue burden on members of the public wishing to participate in the CEQA process." Ibid.

This is such a case. Unlike the dramatically different alternatives in Washoe, the three restoration alternatives in the DEIR are closely related and would accomplish similar objectives. As CDFW's opposition argues, each of the DEIR's three alternatives would (a) enhance and create wetlands, aquatic resources, and upland habitats within the Reserve, including through large-scale grading and revegetation, (b) improve flood and storm water management in the surrounding area, including by installing new levees and other water-control structures, (c) provide public access and visitor amenities, including by constructing new trails, bike paths, bridges, and gateway entrances, and (d) modify infrastructure and utilities within the Reserve to support the restoration efforts, including through the abandonment of gas wells and removal of a sewer pipe. AR 185, 321.

The only material differences between the three restoration alternatives are the location and extent of the planned restoration. Alternative 1 would restore or enhance wetlands both north of the existing Ballona Creek channel (Area A) and south of that channel (Area B), Alternative 2 similarly would restore wetlands in Area A but would restore or enhance wetlands only in a portion of Area B, and Alternative 3 would restore wetlands in Area A only. AR 185, 321. The three alternatives are not so different that the members of the public reviewing the DEIR were left to guess about the basic characteristics of the Project.

Finally, as in SoMa, Petitioners have not identified any component of the Project that was not "addressed in the DEIR or subject to public comment." 33 Cal.App.5th at 335. Indeed, Petitioner Land Trust acknowledged during in a public comment that the Alternatives discussed in the DEIR represented "varying degrees of the same concept." AR 8944.[6] Petitioner Grassroots also commented that the range of alternatives was too "narrow" and the individual alternatives too "similar." AR 10268.

By its repeated references to Alternative 1 as the Proposed Action and its identification of three closely related alternatives for restoring the Ballona Wetlands, the DEIR adequately identifies the Project and did not present the public with a moving target and require input on a wide range of alternatives that may not be in any way germane to the project ultimately approved. *See* Washoe, *supra,* 17 Cal.App.5th at 288–89. This identification carried over through the responses to comments and FEIR. AR 8353, 11582.

2. The Term "Restoration" in the Project Description

a. Pertinent Facts

The FEIR notes that a commenter stated that the term "restoration" is nuanced and complex and that a commenter accurately noted that the DEIR's use of the term "restoration" included elements of both habitat creation and restoration. AR 8340. The FEIR clarifies in Section 2.2.26 (The Definition of "Restoration") that the term "restoration" is defined to mean both reestablishment of natural processes and ecological functions and habitat creation or enhancement. AR 8341-42. The FEIR dismisses objections to the use of the word "restoration" as semantics. AR 8342. All Project alternatives would result in a greater quantity of estuarine and associated habitats at the Reserve than currently exist. AR 8342.

b. Analysis

A project description that gives conflicting signals to decisionmakers and the public about the nature of the project is fundamentally inadequate and misleading. SoMa, *supra,* 33 Cal.App.5th at 332. An EIR must be sufficiently detailed and accurate to allow "those who did not participate in its preparation to understand and to consider meaningfully the issues raised by the proposed project." Laurel Heights I, *supra,* 47 Cal.3d at 405.

Petitioners contend that the FEIR mischaracterizes the Project as a restoration instead of the creation of a full tidal estuary subject to the ebb and flow of daily tides. Restoring the daily ebb and flow of the ocean tide is not restoration when the Ballona Wetlands have been

---

[6] Petitioners reply that CDFW's opposition misleadingly quotes Land Trust because its comments in context underscore the materially different environmental impacts of the three alternatives. AR 8944. Protect Reply at 11. The context does not undermine CDFW's point that Land Trust admitted that the three alternatives, although modestly different, were similar.

predominantly closed to the Pacific Ocean for 2000 years. Contrary to CDFW's dismissal of this concern as semantics, there are material differences between restoring something that previously existed and creating something new to the site. Although hundreds of citizens decried the characterization of the Project as a restoration, and scientists submitted comments clarifying that their own studies were being misconstrued by CDFW, the FEIR only re-defines "restoration" to include "elements of both habitat restoration and habitat creation." AR 8341. Pet. Op. Br. at 30-31; Grassroots Reply at 5-6.

Petitioners note that San Joaquin Raptor struck down an EIR for a mining project because it both claimed that the project would not increase production and later indicated the potential to double production. 149 Cal.App.4th at 655. Because the reader could not determine whether the project would maintain or increase production, the court found the project description was fundamentally inadequate. Id. at 656. Similarly, in Communities for a Better Environment v. City of Richmond, ("Communities for a Better Environment") (2010) 184 Cal.App.4th 70, 83, uncertainty over whether the project would process heavy crude rendered the project description uncertain and misleading. Pet. Op. Br. at 31.

Petitioners argue that the starkest example of the ambiguity between restoration and creation is the DEIR's statement that the Project "is intended to return the daily ebb and flow of tidal waters where practically feasible to achieve predominantly estuarine conditions". AR 185, 216, 278 (emphasis added). The Dark et al. study cited by CDFW indicated that the Ballona Wetlands were historically a predominantly closed, fresh-water system not subject to the "daily ebb and flow of tidal waters." AR 3248. "We found no evidence that the [Ballona] lagoon remained perennially open, but rather textual sources indicate that access to the ocean depended on hydraulic forces during any given year." AR 3248. Other studies on the Ballona Wetlands similarly noted the episodic nature of tidal influence, explaining: "The longshore drift of sand rapidly closed the berm...a large freshwater lake was the rule, rather than the exception…" AR 10670. Pet. Op. Br. at 31-32.

CDFW responses to comments, including from experts, claimed that the Project restores the Ballona Wetlands to conditions that existed prior to 1825 when the Los Angeles River flowed through the wetlands to the ocean. AR 8343–44. CDFW cited to a portion of the Dark study mentioning the term "tidal." AR 8344 (quoting Dark study at AR 3248). CDFW failed to disclose that the study's authors found the use of the word "tidal" was too limiting to describe the habitat. AR 3247. Travis Longcore ("Longcore"), one of the co-authors of the Dark study, clarified that Ballona Lagoon periodically emptied into the Pacific Ocean but was always predominantly closed to the ocean. AR 11533. Pet. Op. Br. at 32.

Regardless, if CDFW believed the Ballona Wetlands were a predominantly tidal wetland prior to 1825, the FEIR should have set forth the disagreement between experts. Guidelines §15151. While the lead agency may ultimately disagree with the opinions of other lead agencies or experts, "[i]n order to serve the important purpose of providing other agencies and the public with an informed discussion of impacts, mitigation measures, and alternatives, an EIR must lay out any competing views put forward by the lead agency and other interested agencies." Banning Ranch, *supra*, 2 Cal.5th at 940. Yet, the FEIR contains no discussion that identifies the experts and controversy over the pre-1825 nature of the Ballona Wetlands. Pet. Op. Br. at 32; Grassroots Reply at 6.

Petitioners note that, instead of discussing the dispute, the FEIR broadened the definition of "restoration" to include both habitat restoration and creation. AR 8340–42 (citing 33 CFR §332.2). Petitioners admit that the DEIR states that the Project goals are to "restore, enhance and create estuarine and associated habitats". AR 214, 271. (Emphasis added.) However, 33 CFR section 332.2 separately defines "establishment (creation)". Even if CDFW may re-define federal regulatory terms, the DEIR is clear that Alternative 1 intends to restore tidal wetland in Area A and north Area B. AR 323. The FEIR fails to identify what portions of the Project constitute creation of tidal wetland in the amended FEIR Section 2.2.1.1 (The Definition of "Restoration"). *See* AR 8340. Pet. Op. Br. at 32-33.

Petitioners conclude that the practical implication of improperly defining "restoration" is that the public fails to appreciate that the Project will destroy rare alkali meadow and saltpan in favor of habitat that has not existed at the Ballona Wetlands for over 2,000 years. AR 10664, 11534, 11540, 11542. Responsible agencies not familiar with the Project may mistakenly believe that it constitutes restoration, not creation. This hazard is particularly acute for Coastal Commissioners who may only have time to review the FEIR's executive summary and must determine whether the Project fits within allowable activities in wetlands under the Coastal Act. Pub. Res. Code §30233(a)(6) (permitting diking and filling for "restoration purposes" in wetlands). As a result, the FEIR fails as an informational document. Pet. Op. Br. at 33.

The court does not agree. The FEIR clarifies that "restoration" means both reestablishment of natural processes and ecological functions and habitat creation or enhancement. AR 8341. That is sufficiently accurate, if not precise. "[I]n reviewing an EIR's discussion, [courts] do not require technical perfection or scientific certainty." Sierra Club, *supra*, 6 Cal.5th at 515. The "overriding issue on review is thus whether the lead agency reasonably and in good faith discussed a project in detail sufficient to enable the public to discern from the EIR the analytic route the . . . agency traveled from evidence to action." SoMa, *supra*, 33 Cal.App.5th at 331 (citation omitted).

Additionally, the EIR's reference to historic estuarine and tidal wetland is not entirely inaccurate. Petitioners do not assert that the Ballona Wetlands have always been closed to the Pacific Ocean, and the studies they cite acknowledge that there have been times during which the wetlands were open to the ocean, and thus open to tidal influence. AR 3247 (Ballona Lagoon system would be open to the ocean "during periods of significant rainfall"), 10664 ("The Ballona estuary/lagoon continued to experience...intermittent tidal conditions resulting from breaching during high flows"), 11533 ("access to the ocean depended on hydraulic forces during any given year"). To the extent that the FEIR's project description requires substantial evidence that the Ballona Wetlands have been subject to tidal ebbs and flows, it exists.

More important, as CDFW argues (Opp. at 28), the mere fact that the FEIR describes the Project as bringing about a return of tidal ebbs and flows is not an actionable violation of CEQA. An EIR's failure to meet CEQA's informational requirements is prejudicial only if it deprives the public and decision makers of "substantial relevant information" regarding the likely environmental impacts of the proposed project. Neighbors for Smart Rail, *supra,* 57 Cal.4th at 463. Information about whether the Ballona Wetlands historically was or was not subject to tidal influence is not relevant to an understanding of the Project's environmental impacts; the nature and extent of those impacts are determined based on environmental conditions at the Project site as they exist now. Guidelines §15125 (baseline for analyzing a project's environmental impacts generally should reflect existing conditions).

As CDFW argues, the public and decision makers might be interested in knowing that the Project is creating a new condition of tidal influence at the Ballona Wetlands as opposed to restoring a condition that was not there most of the time. But that distinction is meaningless for purposes of analyzing the Project's environmental impacts. Regardless of whether the wetlands historically were closed or open to tidal ebbs and flows, or whether the FEIR describes the Project as creating tidal influence or restoring it, the nature and extent of the Project's impacts on the present baseline environmental conditions at the Reserve are the same. *See* Opp. at 28.

The FEIR's reference to the Project as a restoration, and its definition of "restoration" to include both reestablishment and creation or enhancement, is not a misleading project description.

3. The Flood Control Design

The FEIR's failure to include the correct flood control design is the principal issue of this case. Petitioners argue that the FEIR fails to include in the project description the vastly larger flood control levee design required by the Corps. This prejudiced the public's review of the Project, particularly the true scope of the Project's habitat fragmentation. This failure also impermissibly deferred the required analysis of the larger flood control levees. Pet. Op. Br. at 14.

a. The Pertinent Facts

The Corps and CDFW initially prepared a joint DEIR/draft EIS. On August 22, 2012, the Corps referred CDFW to the Corps' O&M Manual for the required design discharges for the Project. AR 20009. The Corp representative stated that the design standard is based on the approved report for the original project, which he could not find because it dated back a lot of years. AR 20009. He attached the O&M Manual sheets and data tables and stated that the Project design should follow the discharges noted. AR 20009. The O&M Manual listed the design discharge as 46,000 cfs. AR 20014.

On February 28, 2017, the Corps asked CDFW what the "authorized discharge" is for the Project's channel. AR 19860. The Corps had learned that LACFCD[7] modified the original project that the Corps had designed and built and appeared to have raised the levees. AR 19860. The Corps had not confirmed why this was done and whether it was intended to increase the design discharge. AR 19860.

On March 20, 2017, the Corps noted that it had found some additional documents regarding design discharge. AR 19859. According to these documents, any changes to the channel should be designed for a future SPF of "unrestricted channel flow." AR 19859, 18829. The Corp had not found any documents to update the design discharge values, and they should be 68,000 cfs. AR 19859.

On April 3, 2017, CDFW informed the Corps that CDFW previously identified the design discharge as 46,000 based on the flow rate in the O&M Manual and the Corps' previous email. AR 19859. A review of the 1959 and 1963 LACFCD design drawings for the levee modifications indicated a design discharge of 49,500 cfs. AR 19859. The hydrology report referenced in the Corps' email referred to a future, unrestricted SPF of 68,000 cfs but that did not match the Ballona Creek channel as constructed. AR 19859. CDFW also understood that the channel upstream of the Reserve could not contain a flow of 68,000 cfs. AR 19859.

The Corps replied that the Ballona Creek channel was designed for the SPF discharge, which changed over time as a result of development in the watershed. AR 19793. Based on a 1979 feasibility study, the SPF values were approved, and the table indicates a discharge of 68,000 cfs. AR 19793, 19596. The Corps would not go back and redesign the Project for the original design discharge of 46,000 cfs. AR 19793. To change the authorized level of protection for a flood risk project, CDFW would have to have a new feasibility study that used risk-based

[7] LACFCD is the non-federal sponsor for LACDA and therefore any applications for a Section 408 permit must be submitted by LACFCD. AR 25109.

probabilistic methodology and procedures, and it would have to be presented to Congress for reauthorization. AR 19793. Even in that circumstance, the Section 408 permitting process follows almost the same methods of approval, and the outcome would still require a design discharge of 68,000 cfs. AR 19793.

On April 21, 2017, a CDFW employee sent an internal email to another CDFW employee that the 68,000 cfs flow rate was presenting a real problem. AR 19596. The County believed (but would not say in writing) that the 68,000 cfs is unreasonable because it is a hypothetical scenario that could not happen. AR 19596. The 68,000 cfs standard may require re-visiting a few chapters, raising the levee height, and all the calculations that go with it. AR 19596. He asked the other employee what he had remaining up his sleeve to deal with this problem. AR 19596.

Four days later, on April 24, 2017, CDFW's engineers informed a State Coastal Conservancy employee that they ran a hydraulic model based on a discharge of 68,000 cfs. AR 19580. The model showed that the south levee would be shallowly overtopped upstream of Lincoln Blvd, but that the rest of the channel would convey 68,000 cfs. AR 19580. The State Coastal Conservancy forwarded this information to the Corps. AR 19580.

In September 2017, the same month that the DEIR was issued, the Corps sent CDFW a formal letter that the Project's Section 408 permit application was being withdrawn. AR 18321. While CDFW had provided preliminary engineering design information, it did not provide the detailed engineering information needed for a preliminary technical analysis of the application. AR 18321. CDFW did not anticipate providing the required information for approximately two years, and the Corps would reinitiate review of the previously submitted Section 408 permit application and restart the EIS process upon its receipt. AR 18321.

On April 6, 2019, the Corps informed CDFW that it would not issue a final EIS until after CDFW submitted additional design information for the Project and the Corps had a chance to review it. AR 18513. CDFW estimated that it could take 2.5 years to draft and provide that information and decided to separate its EIR from the Corps' EIS to avoid an extended delay for the certification of the EIR. AR 99022, 103951.

On October 19, 2019, the State Coastal Conservancy requested then-Senator Kamala Harris to process a WRDA request to lower the authorized flood control standard to 46,000 cfs as that is "the documented design flow rate of the existing channel." AR 25082-84. The WRDA request triggered emails between the Corps and LACFCD indicating that the State Coastal Conservancy did not consult either entity prior to submitting the request. AR 24801-03. In one email, the Corps said that it could not support the lower number without an "H&H analysis" and a decision document to support the lower number. AR 24812. Another Corps employee noted that the proposed WRDA language would reinforce the existing authorized design discharge of 46,000 cfs but that any modification of the Ballona Creek channel would still be subject to the Section 408 permit requirement of no increased flood risk, a matter which is independent of design discharge. AR 24811. Since the Project would reduce the existing capacity of the Ballona Creek channel, it would increase the flood risk. AR 24811.

On October 22, 2019, after a conference call, Public Works (LACFCD) informed the Corps that it had decided to support the higher discharge number as documented in the Corps' 1979 report. AR 24809. The project manager's notes explained that any change to the existing 68,000 cfs standard would require detailed analysis of changes in velocity, water surface profiles, flow distribution, scour analysis, sediment transport analysis, and upstream and downstream impacts of proposed alterations. AR 24809.

On January 29, 2020, the State Coastal Conservancy wrote to CDFW and the Corps that the reports with an SPF value of 68,000 cfs were created in 1978. AR 18070, 25092. If the Project modifies the flood control channel, it either should convey the SPF or the Corps and the County should make new models to update the SPF to reflect current conditions. AR 18070.

In response to Petitioner Protect's subsequent inquiry, the Corps explained that it would consider any information a Section 408 permit applicant provides whether to change the flood standard for the Ballona Creek channel. AR 18196. The Corps has not taken a position on whether the channel's SPF should be changed, and it expected CDFW to provide this information in mid- to late-2020. AR 18196. When the Corps issues a final EIS, it would include a preliminary decision regarding the SPF as well as for the Section 408 permit application. AR 18196.

b. Analysis

Petitioners contend that the FEIR analyzes a 46,000 cfs flood control design that CDFW knew would be infeasible. Its omission of the 68,000 cfs design from the project description in favor of the lower design standard minimized environmental impacts in violation of CEQA. Pet. Op. Br. at 14-15.

When the DEIR was published, CDFW knew that the Corps would require the 68,000 cfs flood control design. CDFW also knew that its own hydraulic model based on a discharge of 68,000 cfs showed that the south levee would be shallowly overtopped upstream of Lincoln Blvd with the rest of the channel would convey 68,000 cfs. AR 19580. By the date of the FEIR, CDFW knew that Public Works had decided to support the 68,000 cfs number and that any change to the existing 68,000 cfs standard would require a detailed analysis of changes in velocity, water surface profiles, flow distribution, scour analysis, sediment transport analysis, and upstream and downstream impacts of proposed alterations. AR 24809. CDFW also knew that the Corps had rejected its preliminary engineering design information and was willing to look at CDFW's additional engineering on this issue, but it would not change its view absent clear evidence of no increased flood risk. Further, CDFW knew that the 68,000 cfs standard may require re-visiting a few chapters, raising the levee height, and all the calculations that go with it. AR 19596.

The DEIR makes it appear that the 46,000 cfs standard for the Project had been approved by the Corps: "Based on preliminary direction from Corps staff, analyses of flood performance were based on the design flow rate of 46,000 cfs..." AR 1133 (emphasis added). Petitioners correctly argue that, by repeating an outdated Corps standard instead of disclosing the Corps' actual position, the DEIR is not a good faith effort at disclosure.

The DEIR only mentions the 68,000 cfs requirement in a conclusory footnote:

> "The Ballona Creek channel was designed in the 1930s, and documentation for the original design capacity is limited. LACFCD design drawings (1959) and as-builts (1963) for later work on the segment of the Ballona Creek channel within the Ballona Reserve indicated a design discharge of 49,500 cfs. Documentation for other, subsequent projects refers to a Standard Project Flood (SPF) flow of 46,000 cfs, which was first computed by the Corps in the 1950s. The SPF figure was later revised to identify a future, unrestricted SPF of 68,000 cfs. The authorized discharge will be confirmed by the Corps during the permitting process for the Project, but would not be higher than 68,000 cfs." AR 213 (emphasis added).[8]

[8] Petitioners suggest that the last sentence of the footnote wrongly implies that the permit would authorize something less than 68,000 cfs but that CDFW knew that 68,000 cfs is the

An EIR must make a reasonable effort to explain the nature and magnitude of a project's impacts. Friant Ranch, *supra*, 6 Cal.5th at 519. Pursuant to the 68,000 cfs standard, the Project's levees must be able to handle water forces approximately 50% more powerful than those analyzed in the FEIR. AR 213, 309, 19793, 19859. The design standard required by the Corps is left out of the FEIR's analysis. Instead, every metric, table, chart, and measurement of flow is based on the 46,000 cfs standard. AR 1134 (Table 3.9–7), 1144 (Figure 3.9–9), 1163 (Figure 3.9–10), 1162 (Figure 3.9–12), 1112, 1128, 7476, 7481, 7631, 7663.

CDFW argues that the FEIR states that the Project, and specifically the levees that will be constructed to protect against flooding from Ballona Creek, are designed to accommodate a flow rate through the creek of up to 46,000 cubic feet per second (cfs). AR 1112. The FEIR further states that 46,000 cfs is the same flow rate that was used for the original design of the Ballona Creek channel (AR 7475), that 46,000 cfs would exceed the peak flow for a 100-year event at this location (AR 7476), and that CDFW used that flow rate based on a directive from Corps staff (AR 1133). CDFW contends that these statements are accurate. Opp. at 11-12.

These statements are accurate.[9] However, the FEIR leaves the false impression that the Corps' decision to pull out of the joint EIR/EIS process was mutual. AR 8301 ("Corps and CDFW have elected to prepare stand-alone final environmental analysis..."); AR 13828 (CDFW explained that "the Corps wanted more design information before they would complete the EIS. CDFW won't work on that additional design information until we've certified the EIR."). The FEIR also falsely assures that "implementation of [the Project] would maintain existing, <u>authorized</u> LACDA project levels of flood risk management". AR 8328. The existing <u>authorized</u> levels are 68,000 cfs.

More important, the FEIR's mere mention of the correct Corps design standard of 68,000 cfs is insufficient to alert the public to potential impacts. The DEIR and FEIR mention the 68,000 cfs flow standard but still analyze flood control using the 46,000 cfs standard. AR 213, 309, 1112, 1128, 1133, 1134, 1144, 1163, 7476, 7481, 7631, 7663. One of the main Project objectives is "[e]nsuring that structural changes to [the Ballona Creek channel and levee system] satisfy Corps and LACFCD criteria for functional, operational, and maintenance purposes." AR 210, 213. The DEIR refers to hydraulic modeling for 46,000 cps (AR 1112, 1130-34), and the FEIR does not even mention the hydraulic modeling based on a discharge of 68,000 cfs referred to in CDFW's April 24, 2017 email to a State Coastal Conservancy employee. *See* AR 7475-76, 7481, 7631, 7663, 19580.

This does not assure the public that the Project will meet flood standards. As a result of the DEIR's and FEIR's reliance on the 46,000 cfs standard, Petitioners correctly argue (Pet. Op. Br. at 16) that environmental consequences remained hidden from public view. Petitioners describe this as a fragmented presentation giving conflicting signals. *See* Banning Ranch, *supra,* 2 Cal.5th at 941 ("a fragmented presentation is inadequate"). Pet. Op. Br. at 18. Fragmented or not, the public is not supposed to guess at the increased impacts from the larger flood control

---

minimum standard required by the Corps. Pet. Op. Br. at 15-16.

[9] AR 1133 states that the 46,000 cps flow rate was based on "a preliminary direction from Corps staff". In an August 22, 2012 email, the Corps stated that "[t]he design should follow the discharges noted" in the O&M Manual. *See* AR 20009. The O&M Manual's discharge rate apparently was 46,000 cps. *See* AR 20014. Therefore, the statement of a preliminary direction from the Corps is accurate.

standard. A CDFW employee admitted that the 68,000 cfs standard may require re-visiting a few chapters, raising the levee height, and performing all the calculations that go with it. AR 19596. Yet, none of this was addressed in the FEIR. *See* Santiago County Water Dist. v. County of Orange, ("Santiago County") (1981) 118 Cal.App.3d 818, 829–30 (failure to include a required water pipeline in a mining project description was fatal to the informational purpose of CEQA as "some important ramifications of the proposed project remained hidden from view at the time the project was being discussed and approved").

Additionally, the levees crisscrossing both existing and proposed restored habitat consist of a 30-foot-wide vegetation free zone in which only grasses may be maintained and 15-foot-wide buffers allowing only limited small shrubs, all subject to invasive pest control for rodents and clearance for fire safety. AR 28443. These levees create potential wildlife impacts.

First, the levees limit the amount of habitat in the Reserve. Based on the 46,000 cfs design standard, the Project would require conversion to levees of over 36 acres of upland habitat around the saltpan or in the existing marsh in the southeastern portion of Area B. AR 28443. Because the proposed levee and berm systems (AR 348) permeate virtually every upland habitat area and much of the proposed salt marsh (AR 337), the amount of restored habitat is limited. *See* AR 826.

Second, there is a concern that the levees will exacerbate habitat fragmentation. AR 383, 8384, 9310. Coastal wetland habitats are typified by "a large expanse of low gradient open space that allows waterfowl and other wildlife to traverse unimpeded across the landscape and between habitats." AR 8384. The levees degrade habitat value for special-status bird species by fragmenting their foraging and breeding areas.

Third, because the levees are raised, activity on them could disturb prey species. AR 28461. Land Protection Partners ("LPP") noted: "Part of the reason that birds roost in open areas like salt pans is that they can see predators from a great distance. The berm and trail system would bring activity that would be perceived as dangerous closer to prey species, decreasing the value of the habitat for those species." Id.

Petitioners contend that the 68,000 cfs standard will require larger levees which would exacerbate all these impacts to wildlife habitat. As a result, the amount of soil that must be excavated to build the levees, the area that the levees must cover, the aesthetic impacts, and the impacts to flora and fauna are understated in the FEIR. Pet. Op. Br. at 16-17.

Whether or not this is true, the FEIR does not analyze the wildlife impacts of flood control under the 68,000 cfs standard, including whether larger levees will be required and whether they will impact habitat and impacts to prey, foraging, and nesting areas. The failure to do so thwarts public review of the full scope of both flood control and biological impacts, rendering the FEIR defective. *See* Santiago County, *supra*, 118 Cal.App.3d at 831.[10]

As Petitioners argue, the defects in the FEIR's project description surpass those in Stopthemillennium where the EIR provided "only conceptual drawings of a development that might not be built." 39 Cal.App.5th at 11 (emphasis added). Here, the FEIR is based on flood control design criteria that currently are infeasible under the Corps' requirements and cannot be built. The FEIR's inadequate depiction of the Project design underreports impacts, misleads the public, and thwarts the EIR process, rendering it inadequate as a matter of law. Pet. Op. Br. at 18-19.

CEQA requires an agency to evaluate the environmental effects of a project at the earliest

---

[10] The FEIR also does not explain the additional aesthetic impacts resulting from the additional height, armoring, vegetation free zones, and levee slopes.

possible stage in the planning process. City of Redlands v. County of Sn Bernardino, ("City of Redlands") (2002) 96 Cal.App.4th 398, 410. Guidelines §15151 (EIR's inclusion of information is judged by what is reasonably feasible to include). Key to deciding the correct time for CEQA compliance is whether the agency has taken any action that "gives impetus to a planned or foreseeable project in a manner that forecloses alternatives or mitigation measures that would ordinarily be part of the CEQA review". Guidelines §15004(b)(2)(B). Kings County, *supra,* (1990) 221 Cal.App.3d 692, 738 (review must occur early enough in the planning stage of project to enable environmental concerns to influence its design). "[T]he line must be drawn neither so early that the burden of environmental review impedes the exploration and formulation of potentially meritorious projects, nor so late that such review loses its power to influence key public decisions about those projects." Save Tara v. City of West Hollywood, (2008) 45 Cal.4th 116, 130-31.

Review of the 68,000 cfs flood standard would not be premature. Even if CDFW might develop engineering studies that would persuade the Corps that a lower 46,000 cfs is acceptable, such studies did not exist at the time of the DEIR or the FEIR. Thus, the 68,000 cfs design requirement and levee expansion is a reasonably foreseeable condition – indeed, the most foreseeable condition – of the Project's flood control design. *See* League to Save Lake Tahoe v. Cnty. of Placer, (2022) 75 Cal.App.5th 63, 104 (lead agency may not be justified in rejecting another agency's standards when the EIR "offers no other scientifically based information" for rejecting them). Guidelines §15144 ("While foreseeing the unforeseeable is not possible, an agency must use its best efforts to find out and disclose all that it reasonably can."). An EIR must include analysis of environmental effects of future expansion or other action if it will likely change scope of project or its existing effects. Laurel Heights I, *supra*, 47 Cal.3d at 396 A review of the 68,000 cfs standard is required to determine if environmental concerns will influence its flood control design. *See* Kings County, *supra*, 221 Cal.App.3d at 738.[11]

CDFW argues that the Corps has yet to finally determine the flow rate (SPF) that will be required for the Project. The Corps plans to make that decision as part of the Section 408 permit application process and has indicated that it will consider any information submitted by CDFW regarding the need to change the SPF and then provide a "preliminary decision regarding the Corps review of the standard project flood" when it issues its final EIS. AR 18196. Opp. at 12.

CDFW cannot defer analysis of the 68,000 cfs design until completion of the Corps' NEPA process. *See* AR 213, 13828. The FEIR is required to provide an impacts analysis based on the required standard of 68,000 cfs SPF and not defer the analysis to the Corps' NEPA process. Guidelines §15020; *see* Stopthemillennium, *supra*, 39 Cal.App.5th at 19; Citizens for Quality Growth v. City of Mt. Shasta, (1988) 198 Cal.App.3d 433, 442, n. 8 (city could not refuse to consider the project's impacts on wetlands simply because the Corps has federal authority over

[11] Petitioners correctly distinguish this case from Dry Creek Citizens Coal. v. Cnty. of Tulare, ("Dry Creek") (1999) 70 Cal.App.4th 20, which upheld an EIR that analyzed the technical and environmental characteristics of a flood control infrastructure and imposed well-established criteria as conditions of approval. Id. at 35. In Dry Creek, the bypass channel proposed and evaluated in the EIR was properly described as having "a 10-foot-wide bottom and 2:1 slopes and a depth of 10 feet." Id. The court found that the general description of the diversion structures coupled with approval of final designs after approval did not violate any CEQA mandate. Id. at 36. Here, the FEIR fails to set out and analyze the design criterion of 68,000 cfs, not detail specifications. Pet Op. Br. at 19-20.

wetlands protection). Such an approach "would permit lead agencies to perform truncated and siloed environmental review, leaving it to other responsible agencies to address related concerns seriatim," has been expressly rejected by the California Supreme Court. Banning Ranch, *supra*, 2 Cal. 5th at 918, 941.[12]

CDFW argues that it engaged in a good faith disclosure and truthfully informed the public of the design of the Project and the levees based on a flow rate of 46,000 cfs. The DEIR also truthfully alerted the public to the possibility that the Corps eventually might require the use of a flow rate as high as 68,000 cfs. AR 213, 270, 309. In the event the Corps decides to require a higher flow rate, and if CDFW needs to redesign the levees in a manner that potentially would change the environmental impacts of the Project, then it may become necessary for CDFW to conduct additional environmental review. Unless and until that happens, the current FEIR fully and accurately apprises the public of the anticipated design, size and potential environmental consequences of the levees and the Project as a whole. Opp. at 14.

CDFW is wrong. As Petitioners argue (Grassroots Reply at 4), CDFW bears the burden of demonstrating that the Corps' 1979 standard of 68,000 cfs should be changed. AR 19793. Changing the SPF requires a new feasibility study of the watershed and then re-authorization of the SPF by Congress. Id. Even then, the Corps has made plain that Section 408 requires no increased flood risk, which is independent of design discharge. AR 24811. Since the Project would reduce the existing capacity of the channel, it would increase the flood risk and the Corps still will require 68,000 cfs. AR 24811. Even LACFCD supports the higher discharge number as documented in the Corps' 1979 report. AR 24809. While the Corps stated that it would consider anything presented by CDFW as part of its Section 408 permit application (AR 18196), it appears unlikely to change. In any event, it is reasonably foreseeable that the 68,000 cfs flow rate will be required.

CDFW argues that, even if the Corps requires a 68,000 cfs flow rate, it remains to be seen whether and to what extent that decision might necessitate any modifications in the design of the levees. Petitioners cite no evidence that "much larger levees" would be needed to accommodate the 68,000 cfs flow rate. In fact, the evidence is that the levees as currently designed can contain a flow rate of 68,000 cfs with some "overtopping" of the narrow jetty that separates the channel from Marina Del Rey. AR 19580, 211 (map of Project site showing the jetty between the Ballona Creek channel and Marina Del Rey). Opp. at 13, n. 5.

At trial, CDFW's counsel pointed to AR 7483 and argued that it shows that the levees will be around the Reserve perimeter with considerable flood plain in between. Any overtopping of the jetty in the southwest portion of west Area B (AR 337) would not call into question the design of the levees, which would be situated elsewhere. Counsel noted that one cannot assume that the levees would be required to be larger even with the 68,000 cfs. Given that the proposed levees would be capable of containing that higher flow rate, it cannot be assumed that a 68,000 cfs flow rate would require any redesign of the Project, let alone much larger levees. Opp. at 12-13.

CDFW adds that the record does not support a conclusion that it is reasonably foreseeable that any levee redesign would change the scope or nature of the Project's environmental effects. Given that the levees as currently designed would be capable of containing a flow rate of 68,000 cfs, it is not reasonably foreseeable that the any redesign would be so substantial as to require a new analysis of the environmental impacts of those levees. CDFW is under no obligation to

---

[12] CDFW explained that it certified the FEIR prior to obtaining a Corps' EIS to avoid delay (AR 99022) but this is not a reason to certify an incomplete FEIR.

analyze the possible environmental impacts of a hypothetical levee redesign that may or may not become necessary. *See* Laurel Heights I, *supra*, 47 Cal.3d at 395 ("no purpose can be served by requiring an EIR to engage in sheer speculation as to future environmental consequences"). Opp. at 13-14.

CDFW's argument that the current levee design can handle 68,000 cfs is based on its own engineering analysis which the Corps found to be inadequate. AR 18321. CDFW's own employee stated that the 68,000 cfs flow rate presented a real problem that may require re-visiting a few chapters, raising the levee height, and all the calculations that go with it. AR 19596. Moreover, CDFW has the burden to show that the 68,000 cfs would not require higher levees and cannot overcome the FEIR's deficiencies by impermissibly placing the burden on Petitioners to prove a flood control design environmental impact that should have been addressed in the FEIR. CDFW, not Petitioners, was required to analyze in the FEIR the authorized 68,000 cfs flow rate and its impact on flooding, levee design, and wildlife and their habitats. Petitioners correctly add that the conclusion that the higher flow rate would spill over a jetty but that would not "call into question the design of the levees" is precisely the type of information that should be in the FEIR. *See* Protect Reply at 6.[13]

In sum, the FEIR fails to (1) state that the Corps currently intends to impose a 68,000 cps standard, (2) analyze the flood impacts of the Project under that flow standard, and (3) analyze the wildlife and habitat impacts of a levee design change under that standard. CDFW's failure to do so was a failure to proceed in the manner required by law. Protect the Historic Amador Waterways v. Amador Water Agency, ("Amador") (2004) 116 Cal.App.4th 1099, 1112.

4. The Project Description's Performance Criteria for Restoration

a. Pertinent Facts

(i). The HRMP Requirement

The DEIR explains that the Project incorporates certain design features intended to avoid or offset certain adverse impacts that could arise during project implementation, while also maximizing the anticipated beneficial environmental effects of the Project. AR 326. The DEIR expressly states that these Project design features are "not optional" and that its analysis of the Project's environmental impacts assumes that they will be implemented if the Project is approved. Ibid.

The DEIR's required mitigation measures (AR 326, 230-31, 328-29) include preparation and implementation of a HRMP, which shall be prepared before commencement of any restoration activities that involve vegetation or land disturbance. AR 328-29. Separate HRMPs may be required for different habitat types or species, and all restoration activities shall comply with an applicable HRMP. AR 328.

The purpose of an HRMP is to evaluate the progress made toward achieving the restoration goals for each of nine target habitat types, and to inform the need for adaptive management. AR 442-58. If progress toward performance criteria is not measurable or the habitat progresses toward

[13] CDFW's opposition's arguments concerning the flood control issue are not in the FEIR itself. "That a party's briefs to the court may explain or supplement matters that are obscure or incomplete in the EIR...is irrelevant, because the public and decision makers did not have the briefs available at the time the project was reviewed and approved." Vineyard, *supra*, 40 Cal.4th at 442-43; Friant Ranch, *supra*, 6 Cal.5th at 520 (explanations in a brief about the EIR are "directed at the wrong audience").

an alternative state, CDFW will evaluate the causes and whether performance criteria are being met to determine whether to intervene. AR 451.

The DEIR provides detailed instructions how an HRMP should be developed and what specific information should be included. AR 328-29. The HRMP shall identify (1) specific restoration activities and monitoring programs to implement during restoration and any long-term habitat management, (2) a timeline for the implementation of the monitoring program, with a work plan or schedule for long-term monitoring after the site has achieved applicable performance goals, and (3) specific protocols for monitoring. AR 328-29.

Performance criteria are first based on the primary ecological drivers of habitat development and function, the characteristic expression of such ecological drivers, and the primary values of the habitat. AR 444. A HRMP allows CDFW to revise performance criteria based on lessons learned in the Project's early stages. AR 442. The use of performance criteria relative to the conditions at reference sites should help overcome uncertainties related to habitat development and the regional impact of stochastic (random observation) events. AR 444. When the course of habitat development is relatively uncertain or when monitoring parameters are highly variable, CDFW may assess performance relative to conditions in suitable reference habitats in the region. AR 443.

The DEIR states that the purpose of a HRMP is to evaluate the progress made toward achieving the goals of the restoration and to inform the need for adaptive management, all as described in DEIR Section 2.2.2.6. AR 442-58. The DEIR further provides that a HRMP shall identify (a) specific restoration activities (*e.g.*, revegetation, removal of non-native plants, weeding, reseeding) and a monitoring program and any long-term habitat management as described in DEIR Section 2.2.2.6, (b) a timeline for the long-term monitoring after the site has achieved performance goals, and (c) specific protocols for monitoring. AR 329. The DEIR also identifies performance criteria that must be satisfied for the nine habitat types that are the focus of the Project, including through the restoration and monitoring activities identified in a HRMP. AR 444-51.

Special-status plant and wildlife species will be subject to focused monitoring efforts. AR 443. This would help identify trends in abundances and habitat use and inform the need for active management of the species or habitats in which they reside. AR 443. Separate habitats or species have separate criteria and may require separate HRMPs. AR 328, 445.

The DEIR's Stormwater Management Plan proposes that LACFCD would be responsible for the vegetation management in the levees and maintenance zones. AR 5437. In the event buried armoring is exposed after a storm, natural processes would be allowed to rebury or revegetate those areas. AR 5438-39.

(ii). <u>The Conceptual Plan</u>

The 148-page Conceptual Plan appendix in the DEIR provides further guidelines for HRMP preparation with the principle of adaptive management. AR 5265, 5273. "Adaptive management" is an iterative process whereby restoration practices are guided by best available technologies and hypothesis testing, with implementation and monitoring to evaluate results. AR 5279. An adaptive management plan will include triggers for remedial action to achieve the performance criteria for the various habitats. AR 5279.

Some aspects of the restoration plan involve restoration in the sense of recovering historical conditions. AR 5277. However, most aspects of the plan involve reestablishment of natural processes and either habitat creation where none existed or habitat enhancement (modification of existing conditions). For convenience, the Conceptual Plan's reference to "restoration" includes all of them. AR 5277.

The biological components of the Conceptual Plan, combined with hydrological and geomorphological design components, will inform the final design and implementation of the proposed restoration. AR 5273. Because there is not enough information to make a decision in some cases, the Conceptual Plan uses "should" rather than "shall" or "will" to show the uncertainty. AR 5273.

The Conceptual Plan outlines creation, restoration, an enhancement goals and objectives to both increase and improve tidal wetland plant, as well as flood control and water quality improvement. AR 5276. The public access objective includes preserving and increasing public access in a manner compatible with sensitive habitats and special-status species in the Reserve. AR 5278.

The Conceptual Plan explains that mitigation efforts often use rigid performance criteria to determine the success or failure of a project. AR 5323. To provide flexibility avoid a rigid framework to determine success, the plan uses the term "success criteria" instead of "performance goals." AR 5323. That said, regulatory agency permitting processes will refine the terms of the plan where regulatory agencies impose additional performance and monitoring requirements. AR 5318, 5323. The restoration plan's approach may also change based on funding constraints and regulatory requirements. AR 5316.

Triggers for adaptive management should be based on significant deviation from achieving performance goals. AR 5324. When CDFW's monitoring activities identify any deviations from the performance goals, an evaluation of the causes should be undertaken to determine if intervention is warranted. AR 5324. For instance, if saltpan or seasonal wetland habitats fail to meet hydrology performance goals, changes to the grade of the site may be necessary. AR 5325. If it is determined that a change will cause unacceptable disturbances to other habitats or animal populations in the Reserve, it may be necessary to reevaluate the performance goals. AR 5325. Any proposed modification to the performance goals or methods for achieving them should be subject to quantitative monitoring and analysis specifically designed to evaluate the effectiveness of such modifications. AR 5324. All decisions of adaptive management should be documented. AR 5325.

For upland habitat, reference habitats elsewhere in the region may provide a standard to assess project performance. AR 5320. If it is determined that trends in vegetation establishment or use by bird species are not on track to meet performance goals, an assessment will be conducted to determine if the deviations stem from circumstances unique to the Project site or on a regional scale. AR 5365. The Conceptual Plan describes the process to use to identify appropriate reference sites, potential candidates, and the factors to assess them. AR 5320-22. In general, any site with remnant or restored wetlands which demonstrates desirable qualities such as high diversity of native species or populations of rare plants or wildlife should be considered as a potential reference site. AR 5321. Because of the range of habitats in the Reserve, a range of potential reference sites may be necessary. AR 5327, 5338, 5345.

For tidal marshes, if marsh vegetation is not on track to meet long-term goals, corrective actions may include additional planting of tidal marsh species to increase the rate of vegetation establishment, the introduction of soil amendments to alter soil physical or chemical properties, or the addition of temporary irrigation or modifications to the tidal regime to improve plant growth or hinder the establishment of invasive species. AR 5332. For bird use of tidal marsh vegetation, corrective actions may include modifications to the management of vegetation, soil properties, or tidal regimes to create appropriate habitat structure for birds or to promote increased use of tidal marsh habitat by benthic (bottom of a lake) invertebrates or fish species. AR 5332.

b. The Project Description Incorporates Mitigation Requirements

Petitioners contend (Pet. Op. Br. at 24) that the incorporation of mitigation measures for potentially significant impacts in the FEIR project description (AR 828–29) distinguishes the FEIR from cases upholding an EIR against challenges to project components that were not relied upon to reduce impacts to less than significant levels. Because the FEIR's performance criteria and HRMP function to reduce the impacts of bulldozing hundreds of acres of habitat -- which the EIR admits are potentially significant without effective restoration -- they must be sufficiently definite and enforceable to ensure that the impacts remain less than significant. *See* Guidelines §15126.4(a)(1)(B).[14] CDFW does not disagree. *See* Opp. at 21.

CEQA requires an EIR to propose and describe mitigation measures to minimize a project's significant environmental impacts. Pub. Res. Code §§ 21002.1(a), 21100(b)(3); Guidelines §15126.4(a)(1). "Mitigation" is defined to mean avoidance of impacts, minimizing impacts, rectifying, reducing, or eliminating impacts, and compensating for impacts by replacing or providing substitute resources. Guidelines §15370; Mountain Lion Foundation v. Fish & Game, (1996) 16 Cal.4th 105, 119. Mitigation measures must be feasible—capable of being successfully accomplished in a reasonable amount of time, considering economic, environmental, social, and technological factors—and enforceable. Pub. Res. Code §21061.1; Guidelines §15126.4(a)(1)-(2).

Formulation of mitigation measures should not be deferred to a future date, but their specific details may be developed after project approval when it is impractical or infeasible to include those details during the project's environmental review, if the agency also (1) commits itself to the mitigation, (2) adopts specific performance standards the mitigation will achieve, and (3) identifies the type(s) of potential action(s) that can feasibly achieve that performance standard and that will considered, analyzed, and potentially incorporated in the mitigation measure. Guidelines §15126.4(a)(1)(B). Compliance with a regulatory permit or other similar process may be identified as mitigation if compliance would result in implementation of measures that would be reasonably expected, based on substantial evidence in the record, to reduce the significant impact to the specified performance standards. Guidelines §15126.4(a)(1)(B).

To take advantage of the exception to deferred mitigation in Guidelines section 15126.4(a)(1)(B), the agency must commit to specific performance criteria to measure efficacy of the mitigation. King & Gardiner Farms, LLC v. County of Kern, ("King & Gardiner") (2020) 45 Cal.App.5th 814, 856. A failure to set forth specific performance criteria constitutes a procedural violation of CEQA. *See* id. at 858. "Essentially, the rule prohibiting deferred mitigation prohibits open-ended performance criteria....If the measures are open-ended, such that they afford the applicant a means of avoiding mitigation during project implementation, it would be unreasonable to conclude that implementing the measures will reduce impacts to less than significant levels." Center for Biological Diversity v. Dept. of Fish & Wildlife, (2015) 234 Cal.App.4th 214, 240. Similarly, mitigation measures cannot be intentionally vague; the agency must explain details such as how the mitigation measure will be implemented. Gray v. County of Madera, (2008) 167

---

[14] At trial, Petitioners' counsel explained that their challenge to performance criteria may either be viewed as a challenge to the project description or to the mitigation "baked into" the FEIR.

Cal.App.4th 1099, 1118. Improper deferred mitigation is a failure to proceed in the manner required by law. Communities for a Better Environment, *supra,* 184 Cal.App.4th at 89-90.

For construction projects, as opposed to comprehensive zoning or general plan amendments, CEQA demands greater specificity "because the effects of construction can be predicted with greater accuracy." Guidelines §15146(a). Conceptual elements of a construction project may be permissible only in an unusual circumstance when precise details cannot feasibly be provided before approval and would "be likely subjects of supplemental review before a final design was approved." Stopthemillennium, *supra,* 39 Cal.App.5th at 13. Deferring the formulation of definite project features short circuits the informational purpose of CEQA. "When properly drafted, an EIR furnishes both the road map and the environmental price tag for the project so that the decision maker and the public both know how much they and the environment will have to give up in order to take that journey." Id. at 14. An indefinite description deferring formulation of project components "render[s] this 'price tag' unascertainable." Ibid. Pet. Op. Br. at 23.

c. Analysis

Petitioners contend that the FEIR lacks clear, enforceable guardrails limiting CDFW's discretion to scale back habitat restoration goals because the HRMP and the performance criteria are not binding commitments. Because species recovery hinges on effective restoration, the HRMP and performance criteria for various habitat types in Tables 2–12 through 2–20 do "all the heavy lifting" for reducing Project impacts. Without binding restoration objectives, the FEIR conceals the extent of impacts before mitigation, precludes comment on impacts, and obscures the need for additional mitigation. Pet. Op. Br. at 27.

The HRMP is merely conceptual, and the actual plan would be prepared only after Project approval. AR 326–28. In fact, the DEIR frankly states its intention to circumvent "the impression of a rigid framework for assessing the project's performance" that is required for mitigation measures. AR 5323–24. As a result, the HRMP admits that performance criteria are subject to change based on regulatory requirements without assuring the public that these changes will not reduce the performance criteria. Id. Given the Corps' insistence on larger flood control design, the failure to incorporate constraints against changing the restoration criteria alone is cause to invalidate the FEIR. *See* Stopthemillennium, *supra*, 39 Cal.App.5th at 23–24 ("[E]ven the limits imposed are vague and ambiguous."). Pet. Op. Br. at 25, 27.

The DEIR also admits that, even after a final HRMP is developed after Project approval, "it is likely that some aspects of the [HRMP] will be changed based on funding constraints[.]" AR 5316. The FEIR is distinguishable from cases upholding EIRs against allegations of uncertain funding because the project description claims that changes in funding could alter restoration goals. The FEIR cannot insist that habitat restoration is an integral Project objective while also reserving the ability to jettison those restoration goals based on funding. Once CDFW commits to the wholesale destruction of hundreds of acres of habitat, it must be legally bound to a restoration plan regardless of future penny-pinching. *See* King & Gardiner, *supra,* 45 Cal.App.5th at 860 ("Once the project reaches the point where activity will have a significant adverse effect on the environment, the mitigation measures must be in place."). Pet. Op. Br. at 25-26.

The DEIR further expands CDFW's authority to nullify the performance criteria by allowing changes based on unspecified "reference habitats" without establishing standards for the suitability of such reference habitats or ensuring such comparisons would not erode the initial criteria. AR 443. The DEIR grants CDFW discretion to choose the lowest-scoring, most degraded sites as reference habitats to lower the bar for performance criteria and gut Project restoration objectives. AR 443. The DEIR contemplates basing restoration goals on reference sites that are "either highly degraded or are the subject of on-going restoration efforts and may not function in the same way as undisturbed wetlands in the region." AR 5320. Moreover, the DEIR puts no limits on whether the lessons learned from reference sites would dilute or strengthen the initial performance criteria. AR 9576. If the lessons from cherry-picked reference habitats are that certain species cannot be easily re-established after their habitat has been bulldozed, this is a loophole for the HRMP to jettison the obligation to take corrective action for special-status species. AR 443-44. Pet. Op. Br. at 26; Protect Reply at 11-12.

Petitioners add that that the FEIR's indefinite project description infects its analysis of biological impacts. Without clear and binding standards and limits on CDFW's discretion to modify them, the FEIR's biological analysis is deficient. The DEIR recognizes potentially significant impacts to many species and habitats (AR 828–29) and numerous performance criteria are measured relative to pre-construction conditions. AR 445 (Tidal Marsh Birds), 446 (Tidal Channel Fish), 447 (Mudflat Macroinvertebrates and Birds), 449 (Salt Pan Birds), 450–51 (Upland Scrub Birds). After the Project destroys unique wetlands, the FEIR does not target species for restoration criteria, instead promising that biological impacts will be less than significant because the Project will expand habitat for all species (which is not possible since so many habitat types would be obliterated if the Project proceeds). Yet, even slight alterations to the initial performance criteria would allow CDFW to declare "mission accomplished" when habitats do not rebound to pre-restoration conditions. Pet. Op. Br. at 27-28.

Finally, Petitioners argue that the indefinite project description thwarts public comment. Several commenters protested the lack of clear, binding restoration objectives. USFWS commented that "[w]ithout clear restoration objectives, the overall intended benefits of the project for wildlife are difficult to evaluate" and recommended that specific restoration objectives be tied to specific performance criteria. AR 8386. Petitioner Land Trust commented that the DEIR employs the term "adaptive management" as a "euphemism for deferred planning." AR 9004. Performance objectives are subject to change without defined parameters and "there is no framework for stakeholders to understand what new information is expected and what decision-points will factor into the specific adaptive measures that will occur." Id. Land Trust recommended performance objectives for each species of special concern, including maps and tables of habitat acreage. AR 8952. Pet. Op. Br. at 28.

Although these commenters illustrated their argument by reference to different species or habitat types, their common theme was that the public had no basis to know (1) the ultimate performance criteria for habitat restoration and species monitoring, (2) the basis on which the performance criteria would be amended, and (3) the corrective actions that would be required if restoration falls short of the performance criteria. Informed public and agency input is "the strongest assurance of the adequacy of an EIR" (Sutter Sensible Planning, Inc. v. Bd. of Supervisors, (1981) 122 Cal.App.3d 813, 823), and the FEIR's indefinite project description evades informed public comment. Pet. Op. Br. at 29.

CDFW dismisses as unmeritorious Petitioners' contentions that (a) the FEIR fails to adequately describe the Project because it fails to provide details for the contents of each HRMP and instead defers the formulation of those details until after the Project is approved and (b) the FEIR improperly defers identification of necessary mitigation measures by failing to commit to specific performance criteria in a HRMP. Opp. at 19.

The court agrees with CDFW that the FEIR does not improperly defer the formulation of the details of each HRMP. The DEIR provides detailed instructions how a HRMP should be developed and information about the proper contents of a HRMP, including the specific performance criteria against which a HRMP must assess the progress of the restoration. While the DEIR does not state the precise terms and conditions of any individual HRMP, those details necessarily must account for the specific characteristics of the habitat or group of habitats to which the HRMP will apply, including the nature of the habitat (*e.g.*, tidal marsh, mudflat, salt pan, dune, grassland) and the wildlife or plant species that occupy it. Given that the design and implementation of the proposed restoration is subject to review and approval by other regulatory agencies (AR 5273), wildlife and plant habitats change and evolve over time, and the start date for the restoration activities is uncertain, it would have been speculative for CDWF to attempt to formulate a detailed HRMP for any species or habitat. CEQA does not require that a lead agency engage in such guesswork. *See* Treasure Island, *supra,* 227 Cal.App.4th at 1054 ("the EIR cannot be faulted for not providing detail that, due to the nature of the Project, simply does not now exist"). Opp. at 20-21.[15]

The court also agrees with CDFW that the FEIR does not improperly defer mitigation by failing to identify specific performance criteria for a HRMP. The DEIR identifies specific and detailed performance criteria for evaluating the effectiveness of the restoration process (AR 444-51), and expressly requires that a HRMP incorporate any applicable criteria (AR 328). Separate criteria are established for each relevant habitat type (*e.g.*, tidal marsh, mudflat, saltpan, dune, grassland), for different time frames, and for different species and habitat features such as morphology and water quality. For example, separate and distinct performance criteria for tidal marsh habitats are identified for vegetation, birds, and fish, and in each case separate criteria are stated for years 1 to 3, 4 to 7, and 8 to 10. AR 445.

The Conceptual Plan's description of the adaptive management process also identifies specific measures that can be implemented if the Project is not making sufficient progress towards performance criteria. For example, if vegetation development in a tidal marsh area is not on track to meet the applicable criteria, "[p]otential corrective actions may include additional planting of tidal marsh species..., the introduction of soil amendments to alter soil physical or chemical properties, or the addition of temporary irrigation or modifications to the tidal regime." AR 5332. Similarly, if the extent to which birds are using a tidal marsh area is not on track to meet the performance criteria, "[p]otential corrective actions may include modifications to the management of vegetation, soil properties, or tidal regimes to create appropriate habitat structure for birds," and

[15] Petitioners argue that Treasure Island bears little resemblance to this case. The indefinite aspects in Treasure Island of street configuration, building height, and landscape design (227 Cal.App.4th at 1053) were not impact-reducing features of the project in the way that restoring bulldozed coastal habitats are in this case. Additionally, there was a robust framework in Treasure Island that "maintain[ed] tight control" on development, including both fixed and conceptual elements, while imposing "quantitative standards" addressing location, height, mass and setbacks. Id. at 1053–54. The Treasure Island decision noted that future revisions "quite likely will be the subjects of supplemental review before the final Project design is implemented". Id. at 1054. Here, the FEIR authorizes CDFW to change the goals of the Project with no quantitative standards or framework for supplemental review. Finally, the Treasure Island court acknowledged that indefinite aspects of a project description must not interfere with public comment. Id. at 1048. Protect Reply at 14. The court agrees that Treasure Island is factually distinguishable and stands only for a general proposition that an EIR need not provide detail that does not exist.

further suggests actions to manage the presence of possible bird predators. Ibid.

CDFW is correct that Petitioners largely ignore these specific performance criteria and instead focus on CDFW's lack of commitment to them. Yet, the DEIR provides that a HRMP shall be prepared prior to the commencement of any restoration activities that will result in any vegetation or land disturbance, that such a HRMP shall include the performance criteria set forth in DEIR Section 2.2.2.6, and that all restoration activities shall comply with an approved HRMP. AR 328. By committing itself to having a concrete plan in place for meeting applicable performance criteria, and by expressly committing to conduct those activities in compliance with that plan, CDFW has demonstrated its commitment to meeting those criteria. *See* Sacramento Old City Assn. v. City Council, ("Sacramento Old City") (1991) 229 Cal.App.3d 1011, 1029 (agency adequately demonstrates its commitment to performance criteria for mitigation where "future action to carry a project forward is contingent on devising means to satisfy such criteria"). Opp. at 22-23.

The inclusion of these specific performance criteria distinguishes cases from cases where mitigation was improperly deferred because no specific performance criteria were imposed. *See* San Joaquin Raptor, *supra*, 149 Cal.App.4th at 670 (mitigation for special-status species improperly deferred because "no specific criteria or standard of performance is committed to in the EIR"; the fact that future management plans would be prepared after consultation with wildlife agencies did not cure the error since no adequate criteria or standards were set forth); King & Gardiner, *supra*, 45 Cal.App.5th at 859 (mitigation measure requiring oil companies to develop a plan to reduce municipal and industrial water use by a specified date was improperly deferred mitigation).

CDFW also correctly argues that there is no reason why any regulatory agencies with jurisdiction over natural resources affected by the Project -- *e.g.*, the Fish and Game Commission, State Water Resources Control Board, or California Coastal Commission -- might insist on weakening criteria designed to avoid harm to the very resources those agencies are committed to protecting. To the extent that these regulatory agencies might require changes in the performance criteria, the Conceptual Plan contemplates only that the agencies would require "additional performance and associated monitoring requirements". AR 5318. In other words, the DEIR contemplates that these other agencies may require more rigorous performance criteria. Moreover, Petitioners' concern that other regulatory agencies might require a weakening of the performance criteria does not suggest CDFW's lack of commitment to those criteria. An EIR's commitment to performance criteria cannot be rendered ineffective by the possibility that another agency may require something else. Opp. at 23-24.

Petitioners' claim that the DEIR provides for changes to a HRMP based on "funding constraints" is incorrect. The Conceptual Plan includes a reference to funding constraints, but not in the section relating to the HRMP and its performance criteria and adaptive management elements. The funding reference appears in a DEIR section discussing the general "restoration approach" for the restoration plan and the fact that "several alternatives are being considered". AR 5316. The court agrees with CDFW that this reference to funding for restoration has no bearing on mitigation once restoration occurs. Opp. at 23, n. 8

CDFW addresses Petitioners' argument that the FEIR's commitment to performance criteria is illusory because those criteria might be modified. CDFW argues that Petitioners' speculative concerns fail to provide any basis for disregarding CDFW's express commitment to meeting the performance criteria. Opp. at 23.

As for the possibility that CDFW might modify performance criteria based on an improved understanding of habitat development or species requirements, the Conceptual Plan's adaptive management process provides for modifications to the performance criteria only in limited circumstances and subject to strict guidelines. When CDFW's monitoring activities identify any deviations from the performance criteria, the Plan generally requires that appropriate corrective action be taken to ensure that the applicable criteria are met rather than allowing any modifications to those criteria. AR 5324-25. The Plan does provide for an exception where the Project is "on track to meet long-term goals" (*e.g.*, for years 8 to 10), where corrective action may not be necessary and modifications to interim goals (*e.g.*, for years 1 to 3) might be appropriate based on an improved understanding of habitat development. *See, e.g.*, AR 5355-56. But no changes to long-term performance criteria would be permitted under this exception; there would be no eroding or diluting of the Project's ultimate restoration goals. Opp. at 24.

The Conceptual Plan also allows for modifications to performance criteria where deviations from those criteria are attributed to circumstances unique to the Project site as opposed to on a regional scale. AR 5365. The Plan states that it may be useful to assess performance relative to suitable reference habitats elsewhere in the region. AR 5318, 5320. CDFW notes that Petitioners do not object in principle to the use of reference sites to evaluate habitat development and only contend that the FEIR fails to establish standards for identifying suitable reference habitats. However, the Conceptual Plan includes a detailed description of the process by which appropriate reference sites should be selected. AR 5320-22. The Plan states that "any site with remnant or restored wetlands which demonstrate desirable qualities such as high diversity of native species or populations of rare plans or wildlife should be considered as a potential reference site." AR 5321. The Plan lists potential reference sites in Los Angeles, San Diego, Orange, Ventura and Santa Barbara counties, and identifies specific factors that should be taken into account in evaluating the similarity of any potential reference sites to the Project site, including ecological functions, climate and hydrology, anthropogenic disturbances, vegetation types, soil and non-soil substrates and access by fish and wildlife. AR 5321. The Plan also notes that it may be necessary to use multiple reference sites given the range of habitat types planned for the Project site (AR 5322) and identifies potential reference sites for particular habitat types (AR 5327 (tidal marsh), 5338 (mudflat), 5345 (salt panne). Opp. at 24-25.

CDFW argues that, even in those limited situations where the Conceptual Plan allows for modifications to the performance criteria, CDFW would not have unfettered discretion. The Plan would allow for changes to the performance criteria only in cases where it would not be possible to correct a deviation from the criteria without causing "unacceptable disturbance to other habitats or animal populations" at the Reserve. AR 5324-25. The Plan further requires that any modification to the performance criteria will be subject to "quantitative monitoring and analysis specifically designed to evaluate the effectiveness of such modifications" (AR 5324), and that the rationale for any decision to modify the criteria will be "documented in a central location" (AR 5325). Any such modification also must be "supported by data collected at the [Reserve] or the reference sites or from advances in our understanding of coastal habitat restoration." AR 5369. Contrary to Petitioners' assertions, therefore, the FEIR appropriately limits CDFW's discretion to modify the performance criteria, both by allowing such changes only when there is no other viable course of action and by establishing procedural guardrails to ensure that any such changes are fully justified and documented. Opp. at 25.

The court agrees with CDFW in part. While the DEIR permits CDFW to modify performance criteria based on an improved understanding of habitat development or species requirements, the Conceptual Plan generally provides for modifications to the performance criteria only in limited circumstances and subject to strict guidelines. AR 5324-25. The court also agrees that the DEIR is entitled to permit modifications to performance criteria where deviations from those criteria are attributed to circumstances unique to the Project site, that the use of reference sites to evaluate habitat development at the Project site is appropriate, and that the Conceptual Plan includes a detailed description of the process by which appropriate reference sites should be selected.

Stopthemillenium, *supra*, 39 Cal.App.5th at 1, is a different factual circumstance. There, the EIR described the proposed project as a mixed-used development in Hollywood, California but did not provide such basic details as what buildings would be built or where they would be built. Instead, it provided only "conceptual drawings" of one "illustrative" development scenario. Id. at 9-11. The EIR also discussed two possible scenarios in addition to the "illustrative" scenario, but only for the stated purpose of establishing the "maximum environmental impacts" that could result from construction of the project. Ibid. Rather than describing the development that actually would be built, the EIR merely discussed different possible developments that might or might not be constructed. Id. at 18. The Stopthemillenium court held that these scenarios failed to describe a stable or finite proposed project. Ibid. Opp. at 19-20.

Unlike Stopthemillenium, the FEIR in this case includes detailed discussions of all aspects of the restoration Project. The DEIR provides an in-depth description of the restoration process which will include the removal of the existing levees of the Ballona Creek channel, realigning of the Ballona Creek to improve tidal circulation, and other actions to restore tidal wetlands and promote greater habitat diversity. AR 349-82. The DEIR provides maps, drawings, and other graphic representations of the completed Project. Id. The DEIR discusses the flood risk and stormwater management activities that are part of the Project, including the construction of levees along Fiji Way in Area A and Culver Boulevard in West Area B and various other water control structures. AR 382-96. It provides maps showing the locations and various characteristics of the levees. AR 382-96. The DEIR discusses the steps that will be taken to improve public access to the Reserve and the wetlands, including new visitor entrances, pedestrian trails, elevated boardwalks and bicycle paths. AR 396-414. Again, the DEIR provides maps, drawings and other depictions of these public access amenities. Id. Finally, the DEIR includes detailed discussions and drawings of the infrastructure and utility modifications that will be required, including the decommissioning of certain gas wells and relocation of a gas pipeline (AR 414-22), the timeline for the two phases of restoration (AR 422-42), and monitoring and adaptive management programs that will track the progress of the restoration toward specific performance criteria and determine whether any corrections might be warranted (AR 442-57). Opp. at 20.[16]

However, Petitioners are correct in one respect. The project description does not adequately commit CDFW to adopting and implementing specific performance criteria when it provides CDFW with authority to reduce restoration goals based on disturbance to other habitats without any supplemental environmental review. CDFW contends that its corrective actions to achieve the HRMP's performance criteria are constrained by the requirement that it find that achieving the adopted criteria would cause "unacceptable disturbances to other habitats or animal populations[.]" AR 5325. Yet, the cited language illustrates CDFW's authority to reduce performance criteria:

---

[16] Petitioners argue that Stopthemillennium remains informative because it affirmed the principle that CEQA requires analysis of the impacts of a defined project rather than a "set of environmental impacts". Protect Reply at 13-14. True, but that is not what the FEIR does.

> "However, some aspects of habitat or biotic community development may require more significant changes. For instance, if salt panne or seasonal wetland habitats fail to meet hydrology performance goals, changes to the grade of the site may be necessary. Similarly, if fish die-offs occur due to low dissolved oxygen levels, modification of tidal circulation patterns may be necessary. Any actions requiring grading or other major site alterations should receive increased scrutiny before implementation. <u>If it is determined that such changes will cause unacceptable disturbances to other habitats or animal populations at the BWER, it may be necessary to reevaluate the restoration goals.</u> All decisions related to adaptive management, including changes in management activities, alteration of the site, shifts in target habitats or performance goals, and the rationale for each decision, should be documented in a central location. . ." AR 5325 (emphasis added).

Thus, the Conceptual Plan authorizes "shifts in target habitats or performance goals" if CDFW determines that corrective action to meet those performance criteria would "cause unacceptable disturbance to other habitats or animal populations" (AR 5325) and it does so without a commitment to supplemental environmental review.

The Conceptual Plan also recognizes that, if saltpan or wetlands habitats fail to meet hydrology goals, or if fish die because of low dissolved oxygen levels, "some aspects of habitat or biotic community development may require more significant changes." AR 5325. The DEIR cautions that any additional grading or other major site alterations "should receive increased scrutiny before implementation." <u>Ibid</u>. As Petitioners conclude, this language permits CDFW unilaterally reduce the performance criteria to provide more attainable goals if hydrology or dissolved oxygen performance goals are not met and CDFW decides that it needs to perform grading/bulldozing.

Thus, the FEIR allows CDFW to bypass CEQA's procedures requiring public comment on modification of habitat restoration criteria. Guidelines §15162. Land Trust objected to this issue when it asserted that the DEIR uses the phrase "adaptive management" as a "euphemism for deferred planning", protesting that "there is no framework for stakeholders to understand what new information is expected and what decision-points will factor into the specific adaptive measures that will occur." AR 9004. Protect Reply at 13. The prejudice resulting from this deferred mitigation is that the public has no basis to know what corrective actions will be required if restoration falls short of the performance criteria. Whether analyzed as a defective project description or improperly deferred mitigation, this violates CEQA.

CDFW's argument that it would not arbitrarily change the HRMP to undermine its own restoration efforts and defeat the purpose of its own Project ignores the fact that the errors are in the FEIR, not in CDFW's intentions. Assuming CDFW will make its best efforts at habitat restoration, the FEIR violates CEQA by authorizing material changes to the HRMP without a framework for approval or future environmental review. This ability to change restoration goals renders the environmental cost of the Project unascertainable (<u>Stopthemillennium</u>, *supra*, 39 Cal.App.5th at 13) and stultifies public participation (<u>San Joaquin Raptor</u>, *supra*, 149 Cal.App.4th at 656).

In <u>Preserve Wild Santee v. City of Santee</u>, ("<u>Santee</u>") (2012) 210 Cal.App.4th 260, 281, mitigation for the endangered Quino Butterfly was found to be improperly deferred where "the timing and specific details for implementing other Quino management activities discussed in the draft habitat plan are subject to the discretion of the preserve manager based on prevailing environmental conditions" because these activities were not guaranteed to occur at any particular time or manner. Similarly, CDFW's ability to change performance criteria without committing to additional environmental review is improperly deferred mitigation.

At trial, CDFW's counsel argued that changes in performance criteria are narrowly tailored with "guardrails", it is impossible for CDFW to guess what the impacts will be if the performance criteria change, and any significant change will require additional review under CEQA. In response, although conceding that a commitment to supplemental review might suffice, Petitioners' counsel noted that the FEIR contains no assurance that CDFW will conduct additional review without being sued. The court agrees, and it also believes that this defect can be easily rectified by a commitment to additional environmental review.

5. <u>The Lack of a Vegetation Map</u>

a. <u>Pertinent Facts</u>

The FEIR proposes that LACFCD will maintain the levees, including vegetation free zones and maintenance zones. AR 5438-39. In addition, there will be certain areas where the levees will be armored with rock, which may or may not become exposed, but will be allowed to rebury itself naturally. AR 5439.

Per the Corps Guidelines' chapter on the treatment of levees and floodwalls, vegetation must be controlled to limit those habitat characteristics that encourage the creation of animal burrows. RJN Ex. A, p. 3-1. Any project's operations and maintenance manual must include an annual maintenance program to control animal burrows and vegetative growth. RJN Ex. A p. 5-1. The repair of animal burrows is a separate requirement. RJN Ex. A p. 5-2.

The DEIR identifies the vegetation contemplated for each of the habitats (*e.g.*, mudflat, tidal saltmarsh, lower marsh, and mid-marsh) after the Project's completion. AR 337, 445, 448-50. Each habitat has its own set of performance criteria and timeframes for meeting them. AR 445-51. For example, the vegetation performance criteria for tidal marshes provides that there be a minimum of five native species, although one or two may predominate. AR 445. The DEIR also lists the acreage of the basic habitats that will be created. AR 351.

Counsel for the Los Angeles Audubon Society ("Audubon Society") commented that the final distribution of vegetation types has not been established, which shows that the Project is about creating tidal wetlands and not uplands. AR 28417. The levees will have a vegetation free zone along the levee core in which only perennial upland grasses can be planted. AR 28443. This zone extends 15 feet beyond the toe of the levee core, after which a zone of limited vegetation should extend another 15 feet. AR 28443. As a result, the levee would have 30 feet of limited vegetation and 30 feet of grass. AR 28443. It appears that CDFW and the Corps have not agreed on the vegetation that will be allowed on the levees. AR 28443. CDFW should not have rushed to release the DEIR without a basic map of vegetation types to be created. AR 28443.

USFWS recommended that areas requiring frequent vegetation maintenance be mapped as "developed" or "invasive monoculture" based on the lower habitat value. AR 8385 (AF1-13). CDFW agreed to insert a footnote into Table ES-2 to clarify that areas mapped as upland habitat include both native upland habitat and invasive monoculture. AR 8393. The footnote was added to Table 2-3, not Table ES-2, but the actual acreage of maintained habitat was not disclosed and apparently will be quantified later. AR 351.

b. <u>Analysis</u>

Petitioners argue that, as pointed out by experts LPP, while the DEIR presents general categories of habitat, it does not provide final or proposed vegetation maps. AR 11520, 11540–41. Rather, the actual planting plan will be developed later. AR 328. The need for a specific planting plan is particularly acute because the levees have Corps maintenance requirements of mowing and rodent burrow control that are inconsistent with habitat restoration. AR 11560 (015-91).

Petitioners note that expert Longcore commented that the Corps' maintenance regulations for the levees would require at least 36 acres in which rodents are excluded and specific vegetation required. AR 11541. Petitioners argue that, since the Corps does not allow burrowing rodents or owls to inhabit flood control levees, there is a significant impact from the Project. Given the direct impacts of the Corps' maintenance requirements for levees, a specific planting plan is necessary. The FEIR must lay out an actual vegetation map as clearly as possible to allow experts to intelligently evaluate and opine about the impacts to endangered and protected species. Pet. Op. Br. at 29.

Petitioners add that CDFW cannot avoid preparing a vegetation map simply because it would be inconvenient; it can refuse to do so only when practical considerations prohibit devising such a measure in the planning process. Without such a map, the FEIR's claim that the Project will not have a significant impact on any endangered or protected species lacks substantial evidence and fails as an informational document for experts to properly evaluate and comment on the impacts. "An EIR is inadequate if '[t]he success or failure of mitigation efforts...may largely depend upon management plans that have not yet been formulated, and have not been subject to analysis and review within the EIR.'" Santee, *supra*, 210 Cal.App.4th at 281 (citation omitted). Pet. Op. Br. at 29; Grassroots Reply at 9-10.

Petitioners' contention that the FEIR must have a vegetation map is based on an argument that the failure to provide such a map is improperly deferred mitigation. CDFW is correct that this contention is undermined by Petitioners' failure to present the FEIR's evidence on the impacts of the Corps' prohibition of burrowing rodents on flood control levees and show why the FEIR's consideration of them is inadequate without a vegetation map. Opp. at 27.

CDFW also is correct that the FEIR does not defer the formulation of a planting plan. The performance criteria contain detailed information about the vegetation contemplated for each of the various habitats within the Project site. *See* AR 445 (tidal marsh), 448 (brackish marsh, seasonal wetland, salt pan), 449 (riparian), 450 (dune, upland scrub, and grassland). The DEIR also includes a map showing the planned locations of those habitat types. AR 337. Opp. at 26.

Petitioners acknowledge that there are specific habitat performance criteria but argue that the specific plant species targeted for restoration are not identified. For example, the performance criteria for tidal marsh are a minimum of five native species "although one or two may predominate." AR 445. These broad performance criteria fail to identify what species will be planted and appear to lump lower marsh, mid marsh, and upper marsh habitat together. Grassroots Reply at 9.

Petitioners fail to show that the FEIR is required to identify specific plants for specific habitat locations. Unlike Santee, this is not a matter where (a) "the timing and specific details for implementing" management activities are left to the discretion of an official, (b) there is no guarantee that these activities will occur, and (c) the success of mitigation will depend upon what the habitat plan will require for management of one or more species. *See* 210 Cal.App.4th at 281. Rather, Petitioners merely raise an issue whether CDFW's commitment to vegetation management should be in the form of specific performance requirements or a convenient map. The FEIR provides that categories of plant species will be required at specific habitats and Petitioners have not shown that specific vegetation must even be identified, let alone on a vegetation map.

Petitioners suggest that a vegetation map is required to evaluate the Project's impacts on the Borrowing Owl. *See* Pet. Op. Br. at 29-30. CDFW responds that there is substantial evidence that the Project will not have a significant impact on the Borrowing Owl, including (a) a map of the Burrowing Owl habitat that currently exists at the Project site (AR 736), (b) a map showing the locations of the types of habitat that will exist after the completion of the Project (AR 337), and (c) a chart showing the pre- and post-restoration acreages of each of those different types of habitats (AR 351). The DEIR finds that any temporarily impacted habitat for the Burrowing Owl would be replaced at a ratio of approximately 7:1, ensuring that the Project would not result in any net loss of foraging habitat for this species and in fact would have a net beneficial impact. AR 794. CDFW is entitled to rely on the opinions of its own staff on matters relating to wildlife conservation. *See* Browning-Ferris Industries v. City Council, (1986) 181 Cal.App.3d 852, 866 ("An agency may also rely upon the opinion of its staff in reaching decisions, and the opinion of staff has been recognized as constituting substantial evidence"). Opp. at 27.

In reply, Petitioners note that CDFW responded to a comment that the levees will comply with the Corps regulations but nevertheless "it is expected that some portions would provide foraging, prey base and other functions for Burrowing Owl." AR 11622 (015-107). Petitioners argue that the response fails to demonstrate that CDFW evaluated and mitigated the impact of the Corps' regulations on vegetation and animal burrowing on the levees. Grassroots Reply at 11. Petitioners add that the 7-1 replacement of Burrowing Owl burrows may mitigate nesting impacts but there is no explanation how the Project will mitigate the loss of rodents and other prey for the Borrowing Owl along the levees. AR 11568-69. Grassroots Reply at 10-11.

Aside from the fact that Petitioners cite a response to comment for which CDFW is not required to provide detail (*see post*), Petitioners' argument about how the impacts of the Corps regulations prohibiting borrowing rodents on levees were evaluated and mitigated strays afield from their contention that the FEIR must provide a vegetation map. Without a showing what evidence the FEIR has on these issues, and that they are significant matters, there is no requirement for a map, no matter how beneficial it would be for experts to review. Petitioners fail to show that a vegetation map is required.

6. The Range of Alternatives

a. Governing Law

An EIR shall describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project. Guidelines §15126.6(a). The EIR should briefly describe the rationale for selecting the alternatives to be discussed. The EIR should also identify any alternatives that were considered by the lead agency but were rejected as infeasible during the scoping process and briefly explain the reasons underlying the lead agency's determination. Guidelines §15126.6(c).

"[T]he mitigation and alternatives discussion forms the core of the EIR." In Re Bay-Delta, Etc., ("In Re Bay-Delta") (2008) 43 Cal.4th 1143, 1162. An EIR's alternatives analysis generally must analyze and weigh the costs and benefits of various alternatives. Failure to do so violates the informational requirements of CEQA. Preservation Action Council v. City of San Jose, (2006) 141 Cal.App.4th 1336, 1355. "An EIR must discuss project alternatives even when it concludes the project's significant environmental impacts will be avoided or substantially reduced by mitigation measures." Protect Our Water v. County of Merced, (2003) 110 Cal.App.4th 362, 371.

The rule of reason governs the nature or scope of the alternatives to be discussed. In Re Bay-Delta, *supra*, 43 Cal.4th at 1163. The "discussion of alternatives need not be exhaustive" and perfection is not required. Foundation for San Francisco's Architectural Heritage v. City and County of San Francisco, (1980) 106 Cal.App.3d 893, 910. A matrix displaying the major characteristics and significant environmental effects of each alternative may be used to summarize the comparison. Guidelines §15126.6(d). The project goals and objectives define the feasibility of alternatives; the more specific the goals are, the more limited are the alternatives. *See* Save San Francisco Bay Assn. v. San Francisco Bay Conservation, (1992) 10 Cal.App.4th 908, 922. The EIR is inadequate if it does not show "solid evidence of meaningful review" of the alternatives. Id; Pub. Res. Code §21080.5(d)(3)(A). A mere conclusion that there are no feasible alternatives without further explanation is inadequate; the reader has no opportunity to compare the project's problems with those for project alternatives. *See* People v County of Kern, (1974) 39 Cal.App.3d 830, 841-42. A petitioner challenging the agency's selected alternatives must show that the alternatives are manifestly unreasonable. Federation of Hillside & Canyon Assns. v. City of Los Angeles, (2000) 83 Cal.App.4th 1252, 1265.

b. The Rejection of Freshwater Alternatives

The DEIR sets forth a list of Project objectives. The objectives include establishing natural processes in the Reserve that support estuarine and associated habitats, such as through improving tidal circulation, lowering residence time of water, ensuring a more natural salinity gradient, and "creating dynamic hydrological interactions between the Ballona Creek Channel, wetlands within the Ballona Reserve, and the Santa Monica Bay." AR 271-72.

Petitioners argue that the DEIR's mischaracterization of the Ballona Wetlands as historically a predominantly tidal marsh improperly impacts the range of alternatives. Because the objectives expressly require tidal inundation and increasing tidal influence, all freshwater alternatives fail to meet them. Id. If the actual goal is restoration, then the FEIR was required to evaluate freshwater alternatives. Pet. Op. Br. at 33.

In We Advocate Thorough Environmental Review v. County of Siskiyou, ("WATER") 78 Cal.App.5th 683, the County of Siskiyou prepared an EIR for the reconstruction of a water-bottling plant that had not been running for a number of years. The EIR objectives included "1. operate a beverage bottling facility...to meet increasing market demand, 2. to site the proposed facility as the Plant previously operated by [Dannon]...etc.." Id. at 691–92. The court found that the EIR's objectives were "so narrow as to preclude any alternative other than the Project." Id. at 692. In taking this artificially narrow approach, the county transformed the EIR's alternatives into an empty formality, which produced a flawed EIR. Id. Pet. Op. Br. at 34.

Petitioners argue that, similar to WATER, the Project objectives are stated in a manner to foreclose any alternative that does not create interactions between the Ballona channel, wetlands within the Reserve, and the Santa Monica Bay. All freshwater alternatives for restoration were rejected in large part because the FEIR artificially narrowed the objectives based on the mischaracterization of the Ballona Wetlands as a tidal marsh. The FEIR failed to consider that freshwater alternatives -- which would not require the excavation of rare saltpan habitat or burying alkali meadow with flood control berms -- would avoid significant short and long-term environmental impacts. Guidelines §15126.6. Pet. Op. Br. at 34-35.

Specifically, the DEIR claims that Alternative 10 -- a freshwater alternative -- would be infeasible because it would necessitate a series of "pumps or other actively managed infrastructure" that would involve staff time and costs to operate on a frequent basis. AR 538. As such, it would not meet a major Project goal of self-sustaining habitats. AR 538. Yet, there is no requirement that an alternative fully accomplish all project objectives. California Native Plant Soc'y v. City of Santa Cruz, (2009) 177 Cal.App.4th 957, 991. Pet. Op. Br. at 35.

Petitioners argue that Alternative 10 is feasible despite the DEIR's claim to the contrary. Playa Vista, just to the east of Ballona Wetlands, pumps and treats a significant amount of groundwater to comply with a clean-up and abatement order of underlying pollution and to keep its methane mitigation systems operational. *See* AR 10157, 10175-79, 10181. Playa Vista is or was permitted to discharge 950,000 gallons per day to the freshwater marsh outside Area B. AR 10181. Groundwater diverted to the freshwater marsh discharges to the Ballona channel, and then to the Pacific Ocean, providing little or no benefit to the Reserve. AR 363. Simply closing the tidal flap gate and allowing the flows to spill into the Ballona Wetlands would greatly increase the amount of freshwater enjoyed by the Ballona Wetlands. *See* AR 362 (flap gate closes during storms). As for Areas A and C, the FEIR does not analyze what infrastructure is required to supply freshwater to those areas. No analysis supports a conclusion that building and maintaining such infrastructure would be more expensive than building massive levees and performing ten plus years of adaptive management and monitoring. Pet. Op. Br. at 35.

The DEIR states that Alternative 10 would not "maintain or improve flood protection" (AR 538) which is an unsupported conclusion that contradicts the previous paragraph that Alternative 10 would maintain the authorized LACDA flood risk management (id). The flap gate closes during periods of high flow in Ballona Creek, causing any storms greater than a one-year storm event to collect in the freshwater marsh. AR 392. As a result, Petitioners argue that the DEIR's bare conclusion appears to be contradicted by the evidence. Pet. Op. Br. at 35-36.

The DEIR also argues that a freshwater alternative would require the raising of Culver Boulevard and Jefferson Boulevard within the Reserve onto a causeway (elevated bridge), costing an "additional $200,000,000." AR 538–39, 5276. This estimate is based on the need for a causeway up to 20 feet high. AR 5726. Missing from the FEIR is an analysis of the current flooding potential of the existing Culver Boulevard and Jefferson Boulevard. It also is unclear why a causeway must be built for a freshwater alternative instead of just raising the road elevation as for other alternatives. *See* AR 5721. Pet. Op. Br. at 36; Grassroots Reply at 8.

Petitioners conclude that, even if a freshwater alternative would be more costly, that is not by itself a valid reason to deem it infeasible. *See* Watsonville Pilots Assn v. City of Watsonville, (2010) 183 Cal.App.4th 1059, 1087 (alternatives that would avoid or substantially lessen significant impacts must be considered even if they would be more costly). To reject an alternative as infeasibly expensive, the agency needs evidence that the additional costs of an alternative render it impracticable. Uphold Our Heritage v. Town of Woodside, ("Uphold Our Heritage") (2007) 147 Cal.App.4th 587, 599. The costs of a freshwater alternative and the financial savings of not constructing massive levees should have been compared against the costs of the Project. Pet. Op. Br. at 36.

The DEIR refers to Alternative 10 as the "Manipulated Wetlands Alternative" because it would create freshwater and brackish marsh by pumping water into the Ballona Wetlands from other locations and then rely on gates or other water structures to continuously manage the way water moves through the Wetlands. AR 537. The need to artificially manipulate the wetlands in this fashion stems from the fact that Ballona Creek flows through a concrete flood control channel with a permanent opening to the Pacific Ocean. AR 537. As a result, the historical conditions that once naturally supported large amounts of non-tidally influenced freshwater and brackish marsh at the Reserve no longer exist. AR 537.[17]

As CDFW explains (Opp. at 29-30), the Project objective of establishing natural processes in the Reserve that support estuarine habitats was not based on a characterization of the Ballona Wetlands as historically a predominantly tidal marsh. Rather, it was based on CDFW's objective of creating (or restoring) tidal wetlands habitats. This objective is grounded in the facts that tidal wetland restoration is a key priority in the Southern California Wetlands Recovery Project regional strategy, such habitats are rare in the region, the Reserve has long been identified as a significant regional opportunity for estuarine wetlands restoration, and the Project is the only opportunity to restore a large tidal wetland in Santa Monica Bay. AR 8349.

Framing Project objectives in this manner is not a violation of CEQA. "Although a lead agency may not give a project's purpose an artificially narrow definition, a lead agency may structure its EIR alternative analysis around a reasonable definition underlying purpose and need not study alternatives that cannot achieve that basic goal." In Re Bay-Delta, *supra*, 43 Cal.4th at 1166. Unlike WATER, *supra*, 78 Cal.App.5th at 683, CDFW did not define the Project objectives artificially narrowly to preclude any other alternative other than Alternative 1. In fact, the DEIR's two other restoration Alternatives (Alternatives 2 and 3) met enough of the Project objectives to warrant further consideration. AR 316-20. Opp. at 30.[18]

The DEIR states that CDFW decided not to consider Alternative 10 as feasible because it would not meet most of the basic Project objectives, including that it (a) would not maintain or improve flood protection and instead would rely on mechanical pumping of freshwater into the system, thus introducing a new risk of flood due to mechanical failure (AR 537-38),[19] (b) would require raising portions of Culver Boulevard and Jefferson Boulevard to allow the flow of water between different areas of the wetlands (AR 537-38), (c) would not create self-sustaining habitats and instead would depend on pumps to manage the wetlands (AR 538), and (d) would not account for sea-level rise and thus additional construction and reconfiguration potentially would be required to mitigate its impacts (AR 538). The impracticality of cost was an additional reason for rejecting Alternative 10 because raising Culver Boulevard and Jefferson Boulevard would substantially increase the restoration cost per acre compared to alternatives that did not require any raising of those roadways and potentially would create new significant environmental impacts. AR 538-39, 5721.

The court will defer to CDFW's choice of alternatives unless Petitioners show that Alternative 10 is both (a) feasible and (b) adequate (meaning that it is capable of attaining most of the basic project objectives). Save Our Access—San Gabriel Mountains v. Watershed Conservation Authority, (2021) 68 Cal.App.5th 8, 32. Even if a proposed alternative is both

---

[17] As CDFW's counsel argued at trial, the wetlands in Area A are gone and the Project is intended to bring back the salt marsh from the early 1800s.

[18] Petitioners argue that if the underlying goal is restoration, then stating the Project purpose in a way that precludes restoration of freshwater alternatives violates CEQA. Grassroots Reply at 6-7. As the court discussed with counsel at trial, this argument ties the freshwater alternative to the term "restoration", a matter which the court has resolved in CDFW's favor. *See ante.*

[19] This explains the apparent inconsistency between the DEIR's statement that Alternative 10 could maintain the authorized levels of flood risk management and the statement in the next paragraph that Alternative 10 "would not maintain or improve flood protection." AR 538. The court interprets the DEIR's language to mean that Alternative 10 would maintain the authorized flood protection but would run the risk of mechanical breakdown during a major storm.

feasible and capable of attaining most of the basic project objectives, the agency's exclusion of it will be upheld unless the chosen alternatives are not a reasonable range of alternatives. Id.[20]

Petitioners do not show that Alternative 10 meets these requirements. Petitioners do not explain why the introduction of pumps would not create a flood risk of mechanical failure, do not deny that the raising the boulevards would represent a significant modification to infrastructure, cite no evidence that the wetlands habitats would be self-sustaining, and have not demonstrated how Alternative 10 would accommodate sea-level rise. Petitioners also have not demonstrated that the FEIR's chosen range of alternatives is unreasonable. Opp. at 32-33.[21]

7. The FEIR's Analysis of Environmental Impacts

Petitioners argue that the EIR failed to quantify or analyze impacts to existing wildlife. The FEIR's justification for the Project is not tied to any specific metrics but rather a general promise that more net habitat will be created which will offset the destruction of habitat in the Reserve in the meantime. Pet. Op. Br. at 36-37.

> "Even when a project is intended and expected to improve conditions in the long term—20 or 30 years after an EIR is prepared—EIR must inform decision makers and the public about the short-term environmental costs of achieving that desirable improvement. These costs include not only the impacts involved in constructing the project, but also the environmental impacts that will result from the project's initial years of operation. Though we might rationally choose to endure short- or medium-term hardship for a long-term, permanent benefit, deciding to make that tradeoff requires some knowledge about the severity and duration of the near-term hardship. An EIR stating that in 20 or 30 years the project will improve the environment, but neglecting, without justification, to provide any evaluation of the project's impacts in the meantime, does not 'giv[e] due consideration to both the short-term and long-

---

[20] Petitioners reply that, if the purpose of the Project is limited to the creation of estuarine environment in Southern California, the FEIR must consider alternative locations in Southern California where the Project would have less significant impacts. *See* Guidelines §15126.6 (f)(2). *See* AR 11532. Grassroots Reply at 7. This would be true if Petitioners identified any such alternative location and showed that it was feasible and adequate.

[21] Petitioners argue that the FEIR fails to determine perform a cost comparison of Alternative 10 with the Project's Alternative 1 in determining that the former is financially infeasible. *See* Uphold Our Heritage, *supra,* 147 Cal.App.4th at 599. Neither the FEIR nor the appendices contain an estimate of the costs of Alternative 1's excavation of 2.4 million cubic yards of soil, constructing flood control levees up to 20 feet tall and occupying 36 acres, and the long-term habitat reconstruction and monitoring activities to provide a basis of comparison to the cost of Alternative 10. Grassroots Reply at 7-8.

The DEIR explains that Alternative 1 would cost between $1.5 and $1.8 million per restored acre for approximately seven acres of restored road whereas Alternative 10 would add between $143 and $200 million to the cost of restoration. AR 538-39. While this might seem dispositive, the DEIR does not address Alternative 1's cost of excavation and levee construction and compare it to Alternative 10's pumping costs. Without additional evidence, the cost comparison between Alternative 10 and Alternative 1 is incomplete and not by itself a reason to deem Alternative 10 infeasible.

term effects' of the project," (Guidelines §151262, subd.(a)), and does not serve CEQA's informational purpose well." Neighbors for Smart Rail, *supra*, 57 Cal.4th at 455 (emphasis added).

a. Procedural Failure

The purpose of an EIR is to identify the project's significant impacts, identify alternatives, and indicate the manner in which they may be mitigated or avoided. Pub. Res. Code §21002.1(a). An EIR must demonstrate that the significant environmental impacts were adequately investigated and discussed so the lead agency has sufficient information to make a decision that "intelligently takes account of environmental consequences." Guidelines §15125(c); San Francisco Ecology Center v. City and County of San Francisco, (1975) 48 Cal.App.3d 584, 594.

The amount of discussion for a particular environmental impact should be proportionate to its severity and probability of occurrence. Guidelines §15146. The EIR must consider every fair argument that can be made about the possible significant effects of a project and must also explain its reasons for deciding whether a project's impacts are significant. Amador, *supra*, 116 Cal.App.4th at 1107. The findings of the agency must indicate the analytic route that the agency took from the evidence to the findings and must be supported by substantial evidence in the record. *See* Pub. Res. Code §21081.5; Guidelines §15093(b). *See also* Whitman v. Board of Supervisors, (1979) 88 Cal.App.3d 397, 414 (EIR was deficient in failing to discuss environmental impacts of pipeline that would have to be built to transport oil if exploratory oil well was successful).

CEQA does not require a lead agency to conduct every test or perform all research, study or experimentation recommended or demanded by commentators (Guidelines §15204(a)), and extensive surveys are not always required. *See* Association of Irritated Residents v. County of Madera, (2003) 107 Cal.App.4th 1383 1396 (in light of field study showing no quality natural habitat or the presence of sensitive species on site, "protocol-level" biological survey using Fish and Game guidelines was not required). Disagreement among experts does not make an EIR inadequate, but the EIR should summarize the main points of disagreement among the experts. Guidelines §15151.

Whether the EIR includes sufficient detail of an environmental impact is a mixed question of law and fact generally subject to independent review. Friant Ranch, *supra*, 6 Cal.5th at 516. The underlying factual determinations in the agency's analysis are subject to a more deferential standard of substantial evidence. Id.

The law governing an EIR's response to comments differs from the law for its evaluation of environmental impacts. A lead agency must provide written responses to comments that "describe the disposition of each significant environmental issue" raised by commenters. Pub. Res. Code § 21091(d)(2)(B); Guidelines §15088(a). There must be good faith, reasoned analysis and major environmental issues raised in variance with the lead agency's position must be addressed in detail giving reasons why specific comments and suggestions were not accepted. Id. Although conclusory statements will not suffice, the level of detail contained in the response may correspond to the level of detail provided in the comment. Id. Thus, a response to a general comment may be equally general. Guidelines §15088(c). The agency's responses "need not be exhaustive," and it is enough that they demonstrate a "good faith, reasoned analysis." Los Angeles Conservancy v. City of West Hollywood, (2017) 18 Cal.App.5th 1031, 1040. In addition, the agency may appropriately respond to comments by referring to relevant parts of the EIR. Id. at 1040.

CDFW notes that Petitioners' opening brief makes claims about wildlife impacts based only of a series of arguments that CDFW failed to adequately respond to comments received during the public comment period. Opp. at 33-34.

Petitioners respond that their opening brief used CDFW's responses to comments to show that the FEIR lacks substantial evidence for its evaluation of biological impacts. The opening brief explains that the FEIR fails to quantify or analyze impacts to existing wildlife, fails to analyze or disclose impacts of habitat fragmentation, fails to analyze or disclose GHG emissions from soil excavation, and fails to mitigate impacts to specific species. Grass Reply at 13. The issue is not CDFW's inadequate responses to comments *per se* but rather that the EIR lacks substantial evidence to support the inadequate responses. Grass Reply at 13, 15.

In quoting and citing to CDFW's responses to comments, Petitioners fail to properly present an issue that the FEIR fails to adequately address biological impacts. Petitioners fail to discuss the FEIR's evidence or analysis of the issues addressed and show that it is inadequate or lacks substantial evidence. As a result, the court will analyze whether the responses to comments, which need not be exhaustive, are a "good faith, reasoned analysis" of any significant environmental issue raised by the commenter. *See* <u>Los Angeles Conservancy v. City of West Hollywood</u>, *supra*, (2017) 18 Cal.App.5th 1031, 1040.

b. <u>Impacts to Wildlife</u>

<u>USFWS Comments AF1-5 and AF1-6</u>

USFWS commented that the Project lacks clear objectives for the restoration. AR 8384 (AF1-5). CDFW responded that DEIR Section 1.1.2 defines the Project objectives and includes a detailed description of CEQA objectives. AR 8390.

USFWS also relayed its concern about the large extent of temporal impacts to vegetated areas (about 336 acres for 10 years) relative to the gain in aquatic/wetland habitats (about 61 acres). AR 8384 (AF1-6). CDFW responded: "As summarized in the Abstract and in Draft EIS/EIR Section ES.1, Background and Project Overview, all aquatic resources within the Project Site are degraded and the wetlands are among the most degraded wetlands in California. Without restoration, the degraded conditions would increase." AR 8391.

Petitioners describe CDFW's responses as evasive. In addition to not quantifying losses and gains, CDFW's reliance on Section ES.1 misrepresented the evidence. Section ES.1 states that "all wetland habitats within the Ballona Reserve are <u>impaired</u>...a <u>portion</u> of the Ballona Reserve has been identified as 'among the most degraded wetlands in California' using standardized wetland condition protocols." AR 208 (emphasis added). "Habitat" is not the same as "aquatic resources," "impaired" is not the same as "degraded," and "all" is not the same as "a portion." Pet. Op. Br. at 37; Grass Reply at 13.

DCFW's opposition contends that the responses were more than adequate given the non-specific nature of USFWS' comments. CDFW initially addressed comment AF1-5 by referencing the clearly defined objectives identified in Section 1.1.2 of the DEIR. AR 8390. CDFW then addressed comment AF1-6's suggestion that the gain in aquatic/wetland habitats was too small to justify the impacts to vegetated areas, noting the currently degraded nature of the aquatic resources and wetlands within the Project site and pointing out that the degraded conditions would get worse without restoration. AR 8391. CDFW also referred to DEIR Section 3.4.7.2, which describes the beneficial impacts of the Project for aquatic and wetland habitats, including the establishment of approximately 137 acres of tidal marsh in a region that has experienced severe loss of tidal marsh due to coastal development. AR 895. Opp. at 34-35.

Petitioners argue that the response still failed to explain how long it would take to establish such habitat and what the current impacts would be and how long they would last. AR 895. Simply stating that 137 acres of tidal marsh is expected to result at some point in the future does not allow for a proper cost/benefit analysis of temporal impacts. Grass Reply at 14.

The general response to AF1-5 was appropriate. As for AF1-6, Petitioners ignore the habitat performance criteria set forth in AR 445-51. Nonetheless, Petitioners are correct that DCFW's response did not address the commenter's point that the short-term impacts to vegetated areas appear to outweigh the gain in aquatic/wetland habitats.

USFWS Comments AF1-19 and AF1-20

USFWS commented that the performance criteria for the ten-year monitoring program "seem inconsistent" with the purpose of restoring ecological functions and services within the Project area. AR 8386 (AF1-20).

USFWS also commented: "Although the proposed project will restore about 154 acres of fully tidal salt marsh, the performance criteria set low expectations for wildlife within restored habitats. By the end of ten years, the abundance and diversity of wildlife (fish, birds, macroinvertebrates) is expected to meet pre-project levels. In addition, tidal marsh will support at least one breeding bird species. These criteria seem inconsistent with the purpose of the project to restore ecological functions and services within the project area." AR 8386 (AF1-20). Pet. Op. Br. at 37-38.

Finally, USFWS commented that the overall intended benefits of the Project for wildlife are difficult to evaluate because the Project lacks clear restoration objectives related this purpose. AR 8386 (AF1-19). "The project includes a 10-year monitoring program to 'document trends in habitat development and to assess progress toward meeting restoration objectives.' We were not able to locate specific restoration objectives related to the project purpose of restoring ecological functions and services in the project area. Without clear restoration objectives, the overall intended benefits of the project for wildlife are difficult to evaluate." AR 8386 (AF1-19). Pet. Op. Br. at 38.

CDFW responded that the adverse impacts and net gains in habitat area described in the DEIR provide comparable changes and ultimately net restoration. AR 8395. DEIR Section 2.2.2.6 and Tables 2-12 through 2-20 provide specific quantitative criteria to track restoration performance. AR 8395. As for overall wildlife benefit, the restoration would re-establish high value rare coastal habitat. AR 8396. Metrics such as species richness and abundance should also exceed pre-Project conditions after eight to ten years. AR 8396. "The habitat acreages at each time step have not been quantified due to the uncertainty of how certain habitats (e.g., brackish, willow, seasonal wetlands) may evolve," and "the Project would provide more salt marsh habitat compared to the No Project Alternative at each time step," without analyzing the actual impacts to wildlife. AR 8396.

Petitioners argue that CDFW's response about net gains in habitat area lack any specific criteria or timeframe. AR 8395. By relying solely on the amount of suitable <u>habitat</u> being created, CDFW claims all harm to <u>existing wildlife</u> will be offset. The public is entitled to know what that short-term harm will be and how long it will last. Pet. Op. Br. at 38.

CDFW's opposition points out that the response to comment AF1-19 refers to DFEIR Section 2.2.2.6, Tables 2-12 through 2-20, and CDFW's explanation how those tables show that the Project would result in net restoration. AR 8395. Those tables set forth specific performance criteria for each relevant habitat type, as well as the timeframes for meeting those criteria. AR 445-51. As for AF1-20, CDFW's response did not rely solely on "net gains in habitat area." It also noted that the performance criteria for wildlife call for "species richness and abundance" in the restored habitats to exceed pre-restoration levels by the end of the ten-year monitoring period. AR 8396. Opp. at 35.

Petitioners reply that DEIR Section 2.2.2.6 only vaguely refers to "some adverse impacts on habitats for special-status species due to the construction of levees, trail construction, and other earthwork," claiming that this will be offset by some unspecified amount at some unspecified time in the future "by the Project's immediate and long-term conservation benefits." AR 896.[22] Grass Reply at 14. Petitioners also reply that CDFW's claim that the Project would both create more habitat and result in greater "species richness and abundance" is a conclusion not supported by substantial evidence. Grass Reply at 15.

Again, Petitioners are ignoring the habitat performance criteria. AR 445-51. While the responses did not specifically address short-term wildlife impacts, they were sufficiently proportionate to the comments. In particular, the general conclusion about species richness corresponds to the general nature of the comment. *See* Guidelines §15088(a).[23]

<u>Comment I15-56</u>

A commenter noted: "So even if the bulldozing re-arrangement at Ballona appears to be working fairly well say in the year 2030 (which I highly doubt but for sake of argument), what will happen to the species who lose their habitat due to massive bulldozing and berm-building operations in the meantime?" AR 11914 (I15-56). Pet. Op. Br. at 38-39.

CDFW's response was: "As identified in Draft EIS/EIR Section 3.4, salvaged wildlife species will be relocated to adjacent or nearby suitable habitat that is not subject to site disturbances, or has been previously restored as planned under the Project. CFDW does not propose as part of the Project or any alternative to hold or retain any animals for any longer than it takes to relocate them within the Ballona Reserve." AR 11929 (I15-56).

Petitioners note that the FEIR proposed as a mitigation measure: "Attempts shall be made by the biologist to salvage (either by trapping or other appropriate means) all native wildlife species of low mobility that may be killed or injured prior to and during Project-related vegetation or ground disturbances" (AR 13113), and "Salvaged species should be relocated to adjacent suitable habitat not subject to site disturbances. Any relocation efforts would include assessment to determine areas with the Ballona Reserve that would be most appropriate to receive species. Any non-native flora or fauna can be abated by the biologist through any legal means available to CDFW." AR 13114. Pet. Op. Br. at 39.

Petitioners rely on the comment letter of Longcore and his colleague that "[s]imply 'moving' the wildlife out of the path of immediate harm is not a mitigation measure because any suitable destination site <u>would very likely already be occupied</u>." AR 11574 (emphasis added). Petitioners argue that CDFW's response demonstrates that it failed to analyze this displacement impact and simply claimed that trapping and relocating animals is better than doing nothing. AR 11629. If a mitigation measure identified in an EIR would itself cause significant environmental

---

[22] Petitioners' citation is incorrect. DEIR Section 2.2.2.6 is located at AR 442-58.

[23] USFWS further commented: "We are concerned that the extent of disturbance to wildlife from proposed operations and maintenance will be much greater than is currently represented in Figure 2–42." AR 8387 (AF1-21). CDFW correctly notes that Petitioners failed to present the substance of CDFW's response to this comment, which need not be considered further. *See* Opp. at 35, n. 12.

impacts, those impacts must be discussed in the EIR in less detail than the project's significant impacts. Guidelines §15126.4 (a)(1)(D). CDFW completely avoided analyzing the environmental impact the mitigation measure of trapping/relocating wildlife would have on wildlife occupying such habitat. CDFW also failed to analyze the impact of the displacement of animals that flee the habitat destruction without being trapped, and what effect such displacement will have on those animals and surrounding ecosystems to which they flee. Pet. Op. Br. at 39-40.

At trial, the court discussed with counsel the standard of the court's review if Petitioners contend that CDFW's response to a comment shows that the FEIR conducted no analysis of the environmental impact as opposed to whether the analysis was inadequate. The issue of an EIR's failure to address an environmental impact is a mixed question of law and fact generally subject to independent review, with the underlying factual determinations subject to a more deferential standard of substantial evidence. Friant Ranch, *supra*, 6 Cal.5th at 516. Comment I15-56 and CDFW's response do not show the FEIR's failure to address the issue of species relocation but rather only its sufficiency. Thus, the court's review is as a response to comment, not a failure to evaluate an environmental impact.

CDFW correctly points out that Petitioners offer no argument regarding the adequacy of the response to comment. Opp. at 36, n. 13. The response to the general comment was sufficient.[24]

Comment (F8-6)

A commenter stated that "we are concerned that once their habitat disappears, animals from Area C North will be driven into our neighborhood." AR 8669 (F8-6).

CDFW responded by acknowledging that redistribution of wildlife could occur "during the restoration period" and then stating that the presence and movement patterns of any wildlife that might occupy Area C are "likely already affected by the existing paved surfaces and areas of fill/dirt associated with existing parking lots and activities associated with the baseball fields and the SoCalGas well pads and staging areas." AR 8695. CDFW then stated that the various bird species that occasionally forage in Area C would be expected to redistribute "elsewhere within the Project site or within their range for the duration of restoration activities", and also pointed out that following the restoration, new native upland habitat would be available to support a return of wildlife to Area C. AR 8695.

Petitioners contend that CDFW's response admitted that it has not analyzed this impact, simply stating that "redistribution of wildlife...may occur." AR 8695. Pet. Op. Br. at 40.

CDFW's opposition notes it responded with as much detail as could reasonably be expected given the cursory nature of the comment. Because the comment did not state concerns about any specific types of wildlife possibly entering into residential areas, CDFW indicated that it could not respond in any greater detail. AR 8695. CDFW argues that Petitioners offer no explanation why

---

[24] CDFW's opposition notes that another commenter generally asserted that relocating wildlife could have adverse impacts on species that already occupy the destination site and cautioned that "[r]elocation should only be undertaken as a last resort and then must be properly planned." AR 11574 (015-112). CDFW's response agreed with the commenter that the relocation of wildlife should occur only as a last resort and noted that, as provided by Mitigation Measure BIO-1b-ii, any such relocation would occur only where ground or vegetation disturbance cannot practicably be avoided. AR 11628; *see* AR 13113 (describing MMBIO-1b-ii). Opp. at 35-36. It is unclear why CDFW's opposition refers to this comment and response because Petitioners do not mention it.

the response was inadequate. Opp. at 36-37. The court agrees.

USFWS Comment AF1-27

USFWS commented that there are "several additional species occurring within the project site" that were not listed in Table 3.4-4, including the federally threatened Snowy Plover. Please include these additional species in Table 3.4-4 or clarify why they are excluded." AR 8387 (AF1-27).

CDFW responded that, although the Western Snowy Plover is a regular migrant through the Reserve and only an overwintering visitor in a non-breeding capacity, it has been added to Table 3.4–4. AR 8399.

Petitioners contend that CDFW failed to respond to the comment about the additional missing species. Pet. Op. Br. at 40.

The only species USFWS identified as omitted from the list was the Western Snowy Plover. AR 8387. CDFW appropriately responded with the same level of specificity. The response was sufficient.

USFWS Comment AF1-29

USFWS commented: "The analysis of direct and indirect effects of the project lacks sufficient detail to determine if individual species will benefit or be impacted by the project over the long term." AR 8388 (AF1-29).

CDFW responded by referring to DEIR Section 4.4.6 which states that "the direct and indirect impacts are based on the content identifying aquatic and non-aquatic habitat and species presence or suitable habitat throughout the document." AR 8399 (emphasis added). Conversion of habitat types are tallied in great specificity. Id. Pre-construction species surveys will be required to reassess species presence and location. Id. The response also refers to Table ES-3 (Summary of Environmental Consequences), which contains a section on Biological Resources that provides a detailed summary of direct and indirect, and temporary and permanent, biological impacts. AR 8399, 258–61. CDFW also stated that there will be additional detail provided in consultation with the Corps. AR 8399. Finally, it was unclear what specific pages in the DEIR concern the commenter and CDFW was unable to provide a more detailed response. Id.

Petitioners contend that the response does not analyze impacts on individual species, only their habitats, and assumes without analyzing that if new habitat is created in the future after destruction of existing habitat, those species will return. Table ES-3 merely lists the "permanent loss" and "net gain" of habitat for each listed species, with no analysis of how long it will take to realize the net gain, nor how much wildlife will be destroyed by bulldozing. AR 258–61. Finally, CDFW stated that there will be additional detail provided in consultation with Corps, but no such detail is provided in the EIR. AR 8399. Pet. Op. Br. at 40-41.

CDFW's opposition describes the USFWS comment as conclusory. The substance of CDFW's response addressed the Project's impacts on individual species, citing DEIR Section 3.4.6's 130-page discussion of the Project's potential impacts both on habitats and individual species. AR 8399, 762-899. As an example, Section 3.4.6 states that there is a limited potential for El Segundo Blue Butterfly to collide with equipment used in restoration activities that could kill or injure adult butterflies, but the application of certain Project design features is expected to avoid any such impacts. AR 775-76. As another example, Section 3.4.6 observes that restoration-related ground disturbance could result in the direct mortality of Silvery Legless Lizards but explains how the application of certain design features and mitigation measures would reduce that impact to a less than significant level. AR 781-83. CDFW's response also referred to Table ES-3 that summarizes that the Project will have mitigable potential impacts on federally-listed and/or special status species. AR 8399, 258. Opp. at 37-38.

CDFW's opposition points out that it is no surprise that the Project potentially could have impacts on wildlife given the large ground and vegetation disturbance that will be involved in the restoration process. However, contrary to Petitioners' assertions, CDFW carefully analyzed the potential direct impacts on individual species and their habitats, and developed design features and mitigation measures that are expected to limit them to a less than significant level. Moreover, the FEIR's analysis demonstrates that the Project's net impact on many of those species will be beneficial given the new and improved habitat that will be available following restoration. For example, the DEIR concludes that the Project will result in net gains in the quality and quantity of habitat for such protected species as the Silvery Legless Lizard (AR 228), Belding's Savannah Sparrow (AR 228), Least Bell's Vireo (AR 230), special-status marsh birds (AR 232), and the Southern California Salt Marsh Shrew and South Coast Marsh Vole (AR 233). Opp. at 38-39.

The response to USFWS' general comment was sufficient.[25]

EPA Comment AF2-9

EPA recommended that CDFW "discuss the anticipated net improvement for each alternative, taking into consideration baseline conditions, known direct, indirect, and temporary impacts, and the performance goals," and "consider adding more robust performance goals for special status species and their associated habitats." AR 8405 (AF2-9).

CDFW responded: "Given the stated intention that restoration performance goals focus broadly on habitat development, species composition, and ecosystem functions rather than on specific acreages or specific species, CDFW has elected not to revise the Draft EIS/EIR in response to this comment." AR 8409.

Petitioners fail to make any argument about the adequacy of CDFW's response to this comment. Pet. Op. Br. at 41.

c. Habitat Fragmentation

Petitioners note that the Project includes approximately 3.6 miles of bicycle paths that loop on top of the levees. AR 406. In addition, the Project provides an additional 29,000 feet of pedestrian-only trails, including 2,000 linear feet of elevated boardwalk directly adjacent to the wetlands. AR 412. Based on such facts, both USFWS and LPP objected that the public access plan would significantly increase habitat fragmentation, resulting in significant adverse impacts. Pet. Op. Br. at 41.

USFWS Comment AF1-10 and LPP Comment O15-87

USFWS noted in an October 2015 letter to the Corps: "Construction of these levees and berms is not typical of a marsh plain and will introduce an elevation and visual barrier for wildlife where no such disruption exists." AR 46735.

USFWS later commented: "We remain concerned that the increased fragmentation will

---

[25] Petitioners also note that USFWS commented: "For many species there is little connection made between the mitigation measures and how they will reduce impacts to less than significant", and provided then specific examples. AR 8388 (AF1-29). Pet. Op. Br. at 41. Neither Petitioners nor CDFW's opposition set forth CDFW's response or whether it was adequate.

limit wildlife movement and subject a greater proportion of the remaining wildlife within Ballona Wetlands to noise and disruption associated with recreation and maintenance activities along the new berms, lowering the overall quality of remaining habitat from its current condition." AR 8384 (AF1-10).

In response to USFWS, CDFW cited the benefits of the Project and DEIR Section 2.2.23, which indicates that bike and pedestrian paths will no longer run along Ballona Creek but would be located farther up channel along the top of the elevated levees, minimizing the disruption to wildlife from recreational use. The pedestrian boardwalks also would be elevated by approximately five feet to avoid direct and indirect effects on wildlife. AR 8392.

LPP expressed concerns that "[t]he berm and trail system would bring activity that would be perceived as dangerous closer to prey species, decreasing the value of the habitat for those species." AR 11559 (O15-86). LPP recommended buffer areas of 50–250 meters to avoid disturbance of wetland species. AR 11599 (O15-87).

In response to LPP, CDFW cited other responses and stated that the DEIR analyzed potential impacts of the trail on habitat fragmentation, as well as the amount of area proposed for the trail system. AR 11608. The response also cited DEIR Fig. 2-1 showing the trails as "developed", with the exception of the boardwalks which would allow the presence and use of habitat beneath. AR 11608.

Petitioners contend that CDFW's response cites a list of potential direct and indirect impacts, not an analysis. AR 762. In addition, CDFW cites DEIR Figure 2–1 to claim that, with the exception of the boardwalks, the paths are identified as developed. AR 11608. Neither the responses nor the FEIR calculate the acreage of habitat in the buffer zone, failing to inform the public on how much habitat will be degraded by the presence of bicyclists and joggers. Pet. Op. Br. at 41.

In addition, USFWS pointed out that the proposed boardwalks are not even identified in Figure 2–1 and that the boardwalks "will result in a greater extent of permanent impacts." AR 8385. CDFW responded that it was not required to show the boardwalks as "developed areas...because the habitat would exist under the boardwalk trails." AR 8393. This again fails to analyze the impact on wildlife and habitat fragmentation caused by people standing a mere five feet above the habitat. AR 407. USFWS and LPP were not only concerned with the paths and boardwalks themselves, but degradation of habitat adjacent to the paths and boardwalks. AR 8384, 11559. Pet. Op. Br. at 42.

Petitioners ignore the fact that CDFW's responses to these comments discussed how the flat and gradually sloping design of the new levees would decrease habitat fragmentation, thereby reducing the "high degree" of fragmentation that currently exists at the Reserve. AR 8391-92. CDFW also noted that the new trails would run along the perimeter of the Reserve,[26] thus minimizing any disruption of wildlife or habitats within the Reserve. AR 8392; *see also* AR 348 (map showing proposed new trails).

In response to O15-86, CDFW explained that the DEIR analyzes fragmentation as a possible impact. AR 11608. DEIR Section 3.4.6 analyzed the potential impacts to wildlife due to increased human activity associated with reopening the Reserve for passive recreation and

---

[26] Petitioners note that, contrary to CDFW's contention, the trails will not be along the perimeter of the Reserve, but rather on the tops of the levees, which cut between Area A and Area C, and through Area B. AR 348, 374. Grass Reply at 12. True, but the trails still will run on top of the levees.

determined that indirect impacts could result from the increased human activity. AR 11583-84. That analysis concluded that such impacts could be reduced to a less than significant level through the application of certain design features and mitigation measures. AR 11584.

LPP's comment regarding the need for a buffer proposed only a general range of distances for a sufficient buffer (AR 11559), and CDFW's response appropriately responded with the same level of detail. CDFW acknowledged that a buffer is appropriate and referred the commenter to DEIR Section 3.4.6 which prescribes a distance of 250 feet for passerine birds and 500 feet for raptors. AR 11609. The responses were adequate.

USFWS Comment AF1-12

USFWS stated: "The location of boardwalks and pedestrian paths identified in Figure 2-23 do not correspond with the developed areas identified on Figure 2-1 and will result a [*sic.*] greater extent of permanent impacts." AR 8385 (AF1-12).

CDFW responded that the boardwalk trails and pedestrian paths are shown in DEIR Figure 2-23 as part of the public access plan. They are not shown in Figure 2-1, which shows the proposed habitats. AR 8393. The proposed boardwalks would be elevated above habitats by approximately five feet, thus avoiding any direct or indirect impacts on wildlife in the underlying habitat and allowing unimpeded movement of wildlife below those boardwalks. AR 8393. CDFW also noted that the boardwalks would cover only a small percentage of the Project site. AR 8392.

Petitioners contend that CDFW's response only addressed why the boardwalks are not identified on Figure 2-1 and ignored USFWS' concern about the possible impacts on surrounding wildlife. Pet. Op. Br. at 42.

CDFW rebuts this argument, noting that the response directly addressed that concern in discussing the elevation of the boardwalks and the ability of wildlife to move unimpeded below them, also noting that the boardwalks would cover only a small percentage of the Project site. Opp. at 40. The response fully addressed the issues raised by the commenter.

LPP Comment O15-87

LPP commented that trails depress the breeding density of sensitive open-land bird species and recommended a buffer. AR 11559 (O15-87).

CDFW responded that it will mitigate the impacts to nesting birds by providing a buffer zone around nesting, generally a distance of 250 feet for passerine birds and 500 for raptors. AR 11609.

Petitioners argue that, to the extent that CDFW disagrees with comments of USFWS and LPP, the FEIR must disclose and discuss the disagreement between experts in a manner that the public and decisionmakers can intelligently evaluate the issue. Guidelines §15151 (c); Banning Ranch, *supra*, 2 Cal.5th at 940–41. While the DEIR admits that habitat fragmentation is an area of known controversy, it fails to mention or summarize CDFW's disagreement with USFWS and other respected experts. AR 222. CDFW's conclusory statements in the response to comments fail to adequately explain the controversy, or rebut expert opinion with evidence, rendering the EIR inadequate as an informational document. Pub. Res. Code §21005. Pet. Op. Br. at 43.

Petitioners are attempting to argue that the FEIR's analysis of nesting bird impacts is insufficient when the only issue raised is whether the response to LPP's comment was adequate. It was.[27]

---

[27] Petitioners argue that CDFW's response to USFWS that the mitigation could, not would,

d. Greenhouse Gases Impacts

The DEIR acknowledged that carbon is sequestered into the plant and stored as carbon stock and some portion of the carbon removed from the atmosphere is returned to the atmosphere through several processes, including respiration, decay, and disturbance. AR 1032. CDFW also acknowledged: "When salt marsh converts to mudflat, aboveground biomass is lost and soil sequestration halts, but soil carbon stored prior to the conversion remains sequestered within the mudflat. In contrast, when wetlands are diked or drained, the belowground carbon stock can be released as CO_2." Id.

In asserting that there would be no significant GHG impact, the DEIR stated: "A recent assessment has indicated that under Alternative 1, the Ballona Wetlands would be expected to remove 13,100 to 40,300 MT of CO2 (minus emissions) from the atmosphere by the year 2100." AR 1040. "Although methane has a larger warming potential than CO2, the amount of brackish marsh assumed for Alternative 1 would be small enough that emissions would not outweigh the carbon sequestered in the salt marsh, even with conservative assumptions." Id.

One commenter raised concerns about whether Project-related bulldozing could release massive or dramatic amounts of sequestered carbon. AR 9600-601 (O6-11). The commenter added: "The soils, soil microbes and plants of the Ballona Wetlands are a key example of a vast carbon storage system...This proposed project has a major negative impact on the area's environment: it will release a dramatic carbon load, long sequestered in the soils, into the atmosphere. But the DEIR/DEIS fails to facilitate careful and informed decision-making on this issue." AR 9601(O6-12).

CDFW responded that land use practices offer an opportunity for carbon sequestration. AR 9619 (O6-12). However, the Project would not release a carbon load previously sequestrated in the soils. DEIR Section 3.7 assessed that the wetland restoration would increase the soil's ability to function as a carbon sink and the carbon sequestered after completion would more than compensate for any carbon released beforehand. AR 9619.

Another commenter stated: "Wetlands - with their plants and life-filled soils - provide some of the best ways to sequester carbon. But the project's proposed 'realignment' of creeks; lowering of land; bulldozing; excavating over two million cubic yards of soil (and removing plants and animals in the process) could completely destroy this fragile ecosystem." AR 12627 (I60-3).

According to Petitioners, CDFW's response to I60-3 referred to the same response as O6-12. AR 9619. Pet. Op. Br. at 44. This cite appears incorrect.

Petitioners argue that CDFW failed to analyze the amount of sequestered carbon and methane that would be released through the excavation of the Ballona Wetlands. CDFW failed to analyze "the severity and duration of the near-term hardship" from GHG impacts, merely claiming any such impacts will eventually be offset by more wetlands. *See* Neighbors for Smart Rail, *supra,* 57 Cal.4th 439, 455. Pet. Op. Br. at 44-45.

Petitioners note that "[e]ven when a project is intended and expected to improve conditions in the long term—20 or 30 years after an EIR is prepared— the EIR must inform decision-makers and the public about the short-term environmental costs of achieving that desirable improvement.

---

mitigate impacts constitutes an admission that CDFW's finding lacks substantial evidence. AR 8400. *See* Pub. Res. Code §21081(a)(1), (b); Guidelines §§ 15091, 15093. Pet. Op. Br. at 43. This argument is not tied to any USFWS comment (Petitioners do not cite AF1-30) and the existence of substantial evidence is not at issue for a response to comment.

These costs include not only the impacts involved in constructing the project, but also the environmental impacts that will result from the project's initial years of operation." Neighbors for Smart Rail, *supra*, 57 Cal.4th at 455 (emphasis added). *See* Grass Reply at 15.

Petitioners fail to cite any authority that short-term GHG impacts – which by definition affect climate change on a long-term basis -- must be addressed in an EIR. Additionally, as with the other environmental impacts, Petitioners are limited to contesting the adequacy of CDFW's response to comments about carbon sequestered in the soil because they have not presented the FEIR's evidence on carbon sequestration. CDFW's response clear that the soil at the Project site after restoration would be capable of sequestering and storing a greater amount of carbon than whatever amount might be released during the restoration process. Although Petitioners argue that CDFW's response was required to quantify the amount of carbon emissions that could result from Project-related soil disturbance, the general nature of the comments did not require it to do so. "CEQA does not require a lead agency to conduct every test, perform all research, or provide all information. Guidelines §15204(a); *see* Laurel Heights I, *supra*, 47 Cal.3d at 415. CDFW reasonably responded with the same level of detail.

c. Impacts on the Foraging Habitat of the White-Tailed Kite and Other Raptors

Petitioners argue that the FEIR was required to analyze the loss of White-Tailed Kite foraging habitat as a potentially significant impact. The White-Tailed Kite (a California protected species) has been observed at the Reserve. AR 11569; *see also* AR 11545, 47, 49. As noted in the CEQA Checklist, a project can have a significant impact on a listed species from either direct impacts or habitat modification. *See* Guidelines App. H, IV(a) (Biologic Resources Checklist). The Project will massively reduce the foraging habitat of the White-Tailed Kite and other raptor species that rely on upper marsh and grasslands for foraging. AR 11569. The Project not only will reduce foraging habitat on a short-term basis but will result in the permanent loss of 76 acres of upland habitat, not including the loss of habitat acreage for the bike and pedestrian trails and levees. AR 11570. The loss of the "exceedingly important foraging area" referred to in the DEIR may have a significant unmitigable impact on the White-Tailed Kite and other raptors. AR 743. Pet. Op. Br. at 45.

As with other environmental impacts, Petitioners fail to set forth the FEIR's evidence and analysis of the White-Tailed Kite. As a result, Petitioners are limited to contesting the adequacy of CDFW's response to comments about impacts to the White-Tailed Kite.

The Audubon Society commented that, because the Project will reduce upland habitats by 76 acres, the restoration of native vegetation at the Project site could cause a reduction in the population of rodents that are the preferred prey of White-Tailed Kites, and therefore no longer provide it with suitable foraging habit. AR 11569-70 (O15-108).

In response, CDFW stated that the replacement of hundreds of acres of invasive plants with annual and perennial grasslands will provide an important improvement to foraging habitat, despite a study noting a distinct reduction of raptor density in restored areas. AR 11569, 11623. Without conceding that there may be a significant impact, CDFW admitted that "the restoration effort may not benefit all raptors equally." AR 11623. As for the direct loss of 76 acres of upland habitats, CDFW claimed: "There would be no net loss of nesting or foraging habitat following restoration. Although a portion of suitable upland foraging habitat would be converted to tidal marsh, the marsh also would provide suitable foraging habitat for these species, and thus no net loss of foraging habitat is expected." AR 11623. CDFW concluded that "[u]nder CEQA, projects are not required to balance current and future raptor foraging capacity." AR 11623.

Petitioners argue that this response was an impermissibly conclusion. *See* People v. County of Kern, (1974) 39 Cal.App.3d 830, 841. Pet. Op. Br. at 45. CDFW's response was not conclusory. The response pointed out that the Project would provide an important improvement to foraging habitat for many raptor species because several hundred acres of invasive monoculture would be replaced with annual and perennial grasslands. AR 11623. The Audubon Society's own comment identified these grasslands as a habitat potentially "rich in rodent prey" for the White-Tailed Kite. AR 11569. CDFW's response also stated that, after restoration, the site would continue to support small mammals such as mice and voles, which are an important foraging species for raptors such as the White-Tailed Kite. AR 11623. For these reasons, CDFW concluded that the Project site would experience an "overall lift" in raptor foraging habitat quality when restored. AR 11623.[28] CDFW's response was a good faith, reasoned analysis that addressed the issue raised by the commenters.

The Audubon Society also commented that the Project would reduce by 76 acres the amount of upland foraging habitat for special-status upland birds. AR 11570-71 (O15-109). CDFW's response acknowledged that the Project would convert a portion of upland habitat to tidal marsh but pointed out that the newly created marsh would continue to provide suitable foraging habitat. AR 11623. CDFW also noted that the enhancement of existing non-native habitats would expand the available foraging habitat, citing DEIR Table ES-2 and Table 2-3 that showed the habitat acreages that would be created and enhanced by the Project. AR 11623-24, 255, 351. Table 2-3 shows that the Project would create 53.6 acres of new high marsh habitat, which the commenters themselves identified as an example of potentially suitable foraging habitat for the White-Tailed Kite. AR 11569. For these reasons, CDFW's response concluded that "no net loss of foraging habitat is expected." AR 11623.

Petitioners characterize CDFW's response as stating that (a) the lower marsh will continue to provide foraging habit and (b) the improvement to upland habitat will off-set the loss of foraging habitat. AR 11623. Petitioners argue that there is no evidence that upland species will use lower marsh for foraging. AR 11571. There also is no evidence that the density of small animals, such as voles, would increase to mitigate the loss of 24–28% of the available upland foraging habitat. Nevertheless, CDFW reaches the unsupported conclusion that there will be no net loss of nesting or foraging habitat. AR 11624. Pet. Op. Br. at 45; Grass Reply at 12.

The court disagrees. CDFW's response provided a good faith, reasoned analysis that fully addressed the issue raised by the Audubon Society, together with factual information supporting the conclusions.

Petitioners finally argue that, according to sea level rise maps, significant portions of Area

---

[28] The Audubon Society relied in part on a study which CDFW characterized as suggesting that the replacement of annual grassland with native perennial grassland generally could reduce native raptor populations. AR 11569. The Audubon Society suggested that CDFW undertake a separate study to evaluate how the Project might impact the abundance of prey for the White-Tailed Kite. AR 11569-70. CDFW's response described the study cited by the Audubon Society as "interesting" but rejected any duty to account for potential post-restoration changes in the rodent density of restored areas. AR 11623.

Petitioners argue that, if the response reflects a disagreement between experts, CDFW's opinion is unsupported by facts or studies. Grass Reply at 12. CDFW correctly notes that a lead agency is not required to conduct every study or analysis that commenters might recommend. Guidelines §15204(a). Opp. at 42-43. CDFW also can rely on its own expertise for evidence.

A and B will be converted from low marsh to mudflats by 2050, and to open water by 2100. AR 453-57. Mudflats and open water do not provide habitat for the White-Tailed Kite and many other terrestrial bird species. *See* AR 11569 (listing habitat for the White-Tailed Kite). Thus, even more "exceedingly important foraging" habitat will be lost. AR 743. As a result, CDFW's claim that the Project will not have significant near or long-term impacts for the White-Tailed Kite is not supported by substantial evidence. Pet. Op. Br. at 46.

The Audubon Society's comments did not raise any issue relating to sea-level rise, so CDFW was under no obligation to address that issue in its response to those comments. Moreover, "the purpose of an EIR is to identify the significant effects of a project on the environment, not the significant effects of the environment on the project." Ballona Wetlands Land Trust v. City of Los Angeles, (2011) 201 Cal.App.4th 455, 473. Any loss of foraging habitat at the Project site that might occur as a result of sea level rise would be an effect of the environment on the Project and is not a significant environmental issue that merited a response. Opp. at 44.[29]

f. Prejudice

"[T]he purpose of CEQA is to inform government decision makers and their constituency of the consequences of a given project, not to derail it in a sea of administrative hearings and paperwork." Long Beach Savings & Loan Assn. v. Long Beach Redevelopment Agency, (1986) 188 Cal.App.3d 249, 263. The petitioner must show that any defect in the responses to comments was prejudicial—*i.e.*, "it deprived the public and decision makers of substantial relevant information about the project's likely adverse impacts." Neighbors for Smart Rail, *supra*, 57 Cal.4th at 463. "[I]nsubstantial or merely technical" errors or omissions are not grounds for relief under CEQA. Ibid.

CDFW argues that it diligently and in good faith prepared more than 4,000 pages of responses to a deluge of comments consisting of over 8,000 separate postcards, e-mails, and letters. Petitioners and their representatives alone submitted over 2,500 pages of comments. If a handful of CDFW's responses were not as exhaustive or thorough as they could have been, Petitioners have not demonstrated that the 4,000+ pages of responses failed to adequately serve the disclosure purpose central to the EIR process. Opp. at 45.

The court agrees. Petitioners have failed to demonstrate that any of CDFW's responses to comments were prejudicial.

G. Conclusion

The Petition is granted in part. CDFW was required to disclose and analyze the proper flood control design parameters in the DEIR and FEIR and its failure to do so was a failure to proceed in the manner required by law. Additionally, the project description does not adequately commit CDFW to specific performance criteria when it provides CDFW with authority to reduce restoration goals based on disturbance to other habitats without any supplemental environmental review and when it permits performance criteria changes to provide more attainable goals if hydrology or dissolved oxygen performance goals are not met. In all other respects, the Petition

---

[29] At trial, CDFW's counsel explained that the maps at AR 453-57 show that the Project will slow sea-level rise. Petitioners' counsel argued that the appendix comparing the No Project Alternative with Alternative 1 (AR 7685) shows a vulnerability for impact to the lower portion of the Reserve that should have been addressed in the FEIR, but Petitioners cite no expert opinion on this issue.

is denied.

A writ shall issue directing CDFW to set aside the FEIR and any Project approvals, prepare and certify a legally adequate EIR for the Project if it chooses to proceed, and suspend any Project activity that could result in an adverse change or alteration to the physical environment until CDFW complies. An injunction shall also issue prohibiting CDFW from taking any action pursuant to the Project until it complies with CEQA.

Petitioner Defend's counsel is ordered to prepare a proposed judgment and writ of mandate, serve them on CDFW's counsel and other Petitioners' counsel for approval as to form, wait ten days after service for any objections, meet and confer if there are objections, and then submit the proposed judgment and writ along with a declaration stating the existence/non-existence of any unresolved objections. An OSC re: judgment is set for June 29, 2023 at 9:30 a.m.

WARNING: This message is from an external source. Verify the sender and exercise caution when clicking links or opening attachments.

Hi Brody,

As a Board Member of Culver Marina Little League for over 5 years, I can attest to the following:

Culver Maria Little League has been a fixture of our community since 1956. Youth sports including baseball and softball are important to the character and development of our children. Moreover, our League services the low-income residents, including the Mar Vista Housing Projects and the immediate surrounding area. Any disruption to the League's baseball season and fields could create a hardship and danger for many of our at-risk kids.

For over 6 decades. Culver Marina has provided full/part/payment plan scholarships and free equipment/uniforms for under privileged children of our area. Approximately 60-75% of our overall membership receive assistance in some capacity. The surrounding Little Leagues do not have the hardships as we do, but we strive to provide for our community.

We appreciate and respect the land managed by the Department of Fish and Wildlife.

Thankful,

Julie Valdez

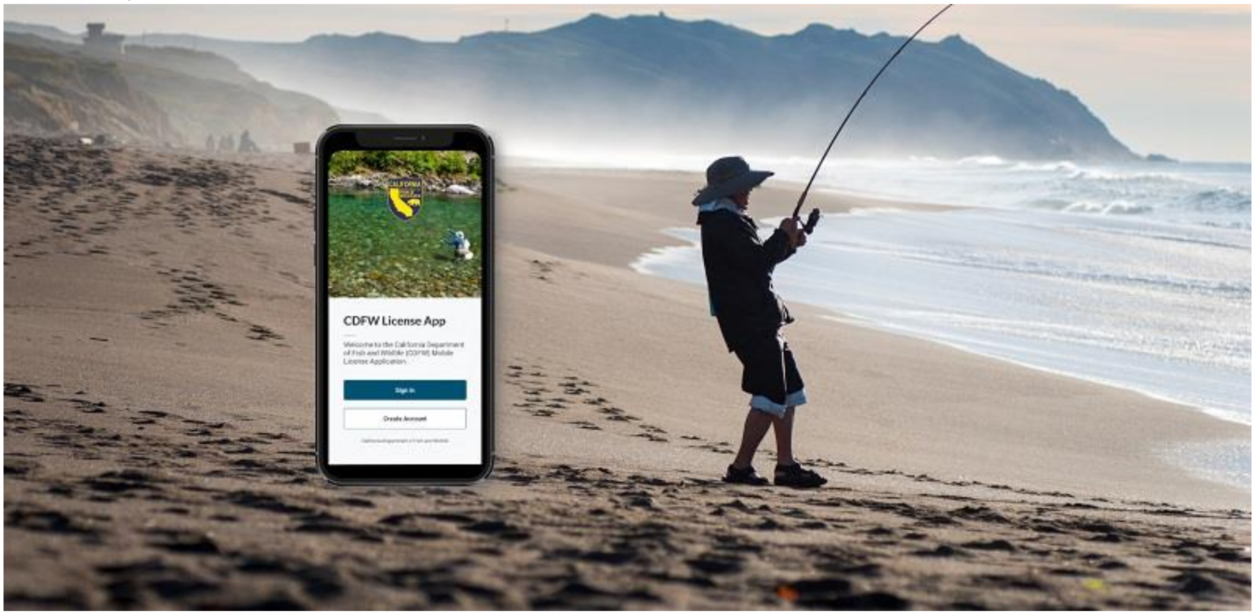
CDFW Introduces License Application for Mobile Devices

March 20, 2024



Media Note: A link to download fishing and mobile app **video** *is available at the bottom of the page.*

The California Department of Fish and Wildlife (CDFW) is pleased to announce the launch of the CDFW License App for mobile devices.

The new application allows residents and nonresidents to display California sport fishing licenses and validations on their mobile phones and other mobile devices in lieu of a physical license.

Users may also download and view various CDFW online resources, including hunting and fishing regulations booklets, the Fish Planting Schedule and access the Online License Sales and Services website.

Users can download the application on their mobile devices through the Apple App Store or Google Play Store or by accessing the direct download links from CDFW's License App web page.
Following the successful rollout of the CDFW License App, hunting licenses and related hunting validations will be added to the mobile display options as early as mid-2024.

"We sometimes think progress moves too slowly, but the Department of Fish and Wildlife has moved full-speed ahead in making fishing licenses valid for 365 days and has modernized the licensing process by going digital," said Assemblymember Jim Wood (D-Healdsburg), author of the original legislation, Assembly Bill (AB) 817, responsible for the change to a 365-day license and mobile licensing display. “I couldn’t ask for a better partner in implementing this new process. I look forward to CDFW’s goal of growing its digital footprint in other licensing areas.”

Wood’s AB 817, introduced in 2021, was widely embraced throughout the fishing community by national and statewide Recruit, Retain, Reactivate (R3) advocates, conservation organizations and CDFW.

The Coastal Conservation Association of California (CCA CAL), which works to protect the interests of recreational saltwater anglers and healthy marine habitats, also supported the legislation.

“The CDFW License App represents the culmination of efforts that will benefit license holders for many years,” said Wayne Kotow, executive director of CCA CAL.

Nathaniel Arnold, acting chief of CDFW’s Law Enforcement Division, said, “Wildlife officers expect the app will provide additional opportunities for the angling public to have their licenses conveniently in possession when checked.”

The rollout of the CDFW Licensing App aligns with the goals of CDFW’s R3 initiative to transform hunting and fishing barriers into opportunities. This app will allow California anglers to easily obtain, access and display their sport fishing licenses on their mobile devices, providing a convenient and paperless solution that promotes responsible fishing practices, ensures compliance with regulations, and enhances overall fishing experiences for individuals in both urban and remote areas.

More information about the app and Frequently Asked Questions can be found on the CDFW’s License App web page, which includes video tutorials covering the app’s various functionalities.

Mobile app and fishing video is available for download from the CDFW FTP site.

CDFW Seeks Artists to Enter Annual California Duck Stamp Art Contest

March 20, 2024

CDFW Photo by Travis VanZant: Mallard at Yolo Wildlife Area.

The California Department of Fish and Wildlife (CDFW) invites artists to submit their original artwork to the 2024-2025 California Duck Stamp Art Contest. Submissions will be accepted May 6 through June 14.

The artwork must depict the species selected by the California Fish and Game Commission, which for the 2024-2025 hunting season is the mallard. One of the most abundant ducks in the world, and the most abundant duck in North America, these familiar foragers can be seen in practically any environment with fresh water. The males are easily recognized by their iridescent green head and yellow bill, while both males and females have a patch of bright blue on their wings. They are swift and agile in the air, cruising at speeds of around 50 miles per hour and having the ability to take off almost vertically from water.

The winning artwork will be reproduced on the 2024-2025 California Duck Stamp. The top submissions are traditionally showcased at the Pacific Flyway Decoy Association's art show, which is scheduled to take place in July.

The contest is open to U.S. residents 18 years of age or older as of March 20, 2024. Entrants need not reside in California. Current and former CDFW employees are ineligible. All entries must be accompanied by a completed participation agreement and entry form. These forms and the official rules are available online at wildlife.ca.gov/duck-stamp/contest.
The design is to be in full color and in the medium (or combination of mediums) of the artist's choosing, except that no photographic process, digital art, metallic paints or fluorescent paints may be used in the finished design. Photographs, computer-generated art, art produced from a computer printer or other computer/mechanical output device (air brush method excepted) are not eligible for entry and will be disqualified. The design must be the contestant's original hand-drawn creation. The entry design may not be copied or duplicated from previously published art, including photographs, or from images in any format published on the Internet.

Entries will be judged in June. The judges' panel, which will consist of experts in the fields of ornithology, conservation, and art and printing, will choose first, second and third-place winners, as well as honorable mention.

Since 1971, CDFW's annual contest has attracted top wildlife artists from around the country. All proceeds generated from stamp sales go directly to waterfowl conservation projects throughout California. In past years, hunters were required to purchase and affix the stamp to their hunting license. Now California has moved to an automated licensing system and hunters are no longer required to carry the physical stamp in the field (proof of purchase prints directly onto the license). However, CDFW still produces the stamp, which can be requested by interested individuals at wildlife.ca.gov/licensing/collector-stamps.

Director

Subject: April 2024 Request for Changes to the Fish and Game Commission's Timetable for Anticipated Regulatory Actions

The Department of Fish and Wildlife (Department) requests the following schedule changes to the Fish and Game Commission's (Commission's) 2024 regulatory timetable for amendments to Title 14, California Code of Regulations (CCR):

1. Move the proposed rulemaking, "Possession of Wildlife and Wildlife Rehabilitation" from the TBD calendar to a June 2024 Notice. This proposal aims to strike and replace Section 679 with new subsections 679.1, 679.2, 679.3, 679.4, 679.5, 679.6, 679.7, 679.8, and 679.9, a manual, and associated forms. These proposed changes overhaul how the Department administers the wildlife rehabilitation program. The proposed rulemaking schedule following notice is discussion at the August 2024 meeting and adoption at the October 2024 meeting.

2. Add a new rulemaking, "White Sturgeon Harvest and Reporting" requesting to publish notice at the June 2024 meeting, amending sections and associated forms in sections 1.74, 5.79, 5.80, 27.90, 27.92, 701, and adding 701.1. These changes would provide options for Commission consideration for a revised management of the White Sturgeon Sport Fishery: with a catch and release only option, a limited entry harvest tag option. and a real-time quota option. The proposed rulemaking schedule following notice is discussion at the August 2024 meeting and adoption at the October 2024 meeting.

If you have any questions or need additional information, please contact Regulations Unit Manager, Ona Alminas, at (916) 902-9222 or Regulations@wildlife.ca.gov.

California Fish and Game Commission
Potential Agenda Items for the May and June 2024 Commission Meetings

April 11, 2024

The next Commission meetings are scheduled for May 15, 2024 via teleconference and June 19-20, 2024 in Mammoth Lakes and via webinar/phone. This document identifies potential agenda items for the meetings, including items to be received from staff and the California Department of Fish and Wildlife (Department).

As will be discussed under Agenda Item 27C (next meetings), the Commission will consider moving marine items to the second day of the June 2024 meeting and the wildlife and fisheries items to the first day; the potential change is reflected in the order of agenda items listed here.

Wednesday, May 15

1. Approve: Special hunt permit issuance and drawings continuation notice
2. Approve: Mitigating risks for cervid importation and movement continuation notice
3. Adoption: Central Valley sport fishing
4. Adoption: Klamath River Basin sport fishing
5. Adoption: Emergency closures of sport fishing in Klamath River Basin for spring-run Chinook salmon
6. General public comments for items not on the agenda

Wednesday, June 19: Wildlife- and inland fisheries-related

1. Commission executive director report
2. Department reports (Department director and Law Enforcement Division)
3. Notice: Possession of wildlife and wildlife rehabilitation (pending approval under Agenda Item 27B)
4. Notice: White sturgeon harvest and reporting beginning in 2025 (pending approval under Agenda Item 27B)
5. Adoption: Extension of white sturgeon emergency regulations
6. Discussion: White sturgeon regular rulemaking to continue emergency regulations
7. Discussion: Inland sport fishing
8. Determine whether listing white sturgeon (*Acipenser transmontanus*) as threatened under the California Endangered Species Act (CESA) may be warranted
9. Action on wildlife and inland fisheries petitions for regulation change
10. Action on wildlife and inland fisheries non-regulatory requests from previous meetings
11. Department presentation on bighorn sheep, deer and mountain lion
12. Department presentation on the Private Lands Wildlife Habitat Enhancement and Management Area Program

13. Commission Wildlife Resources Committee report
14. Department Wildlife and Fisheries Division, Department Ecosystem Conservation Division reports
15. General public comments for items not on the agenda

Thursday, June 20: Marine-related and administrative items

16. Justice, equity, diversity and inclusion plan update
17. Commission policies review
18. Discussion: California halibut and white seabass gillnet fisheries management measures
19. Discussion: Fisheries logbook forms and fishing block charts
20. Receive and consider a restricted species application to possess transgenic squid
21. Receive, consider and potentially act on experimental fishing permit application #2024-01 for testing on-demand fishing systems in box and king crab fisheries in northern California
22. Action on marine petitions for regulation change
23. Action on marine non-regulatory requests from previous meetings
24. Commission Marine Resources Committee report
25. Department Marine Region report
26. Administrative items (legislation, rulemaking timetable, next meeting)
27. General public comments for items not on the agenda (second day)
28. Executive (closed) session

BEFORE THE
FISH AND GAME COMMISSION
STATE OF CALIFORNIA

In the Matter of the Appeal of the Denial of the Restricted Species Exhibiting Permit Renewal Application of:

ATTILA MOLNAR,

Appellant.

Agency Case No. 21ALJ02-FGC

OAH No. 2023080229

PROPOSED DECISION

Thomas Heller, Administrative Law Judge (ALJ), Office of Administrative Hearings (OAH), State of California, took this matter under submission on December 18, 2023.

Patrick M. Ciocca, Esq., represented appellant Attila Molnar (Molnar).

David Kiene, Esq., represented the California Department of Fish and Wildlife (Department).

SUMMARY

Molnar appeals the Department's denial of his July 2019 application to renew his Restricted Species Exhibiting Permit. The permit authorized Molnar to possess and exhibit a variety of venomous snakes, exotic mammals, and other animals regulated by the Department as restricted species. The Department denied Molnar's renewal application in December 2020 after finding he committed multiple violations of the regulations regarding restricted species. Molnar contends the violations were technical and justified and do not warrant the denial of his renewal application under the totality of the circumstances.

The evidence supports the Department's action. Molnar possessed and exhibited a monkey for at least one year without assigning a unique identifier to the animal, possessed four species of venomous snakes not authorized by the permit, and imported and possessed four endangered snakes after his permit expired. The violations are grounds for denial of the renewal application, and the totality of the circumstances warrants that result. Therefore, the Department's denial of the renewal application is affirmed.

FACTUAL FINDINGS

Background and Procedural History

1. Molnar is a veterinarian who owns and operates All Animals Veterinary Hospital (All Animals) in Calabasas, California. He also collects exotic animals. In or about 2014, the Department first issued Molnar a Restricted Species Exhibiting Permit (Permit No. 3194) authorizing him to possess and exhibit a variety of venomous

snakes, exotic mammals, and other "restricted species" listed in California Code of Regulations, title 14, section 671 (Section 671). Molnar exhibited some of these animals at All Animals, at schools and in other educational settings, and at private homes.

2. The Department renewed Molnar's permit annually for several years. In the last such renewal on July 23, 2018, the Department authorized Molnar to possess and exhibit 26 species of venomous snakes, an American alligator, a dwarf caiman, and several exotic mammal species through July 23, 2019. The permit included conditions that Molnar "may import, export, transport, or possess only those species listed . . . for commercial and/or educational exhibition purposes," and he "may add new species to the inventory only with the prior written approval of the Department or as specified in the permit." (Department's Response to Appeal, Exhibit B (March 25, 2021) (Response).)

3. On July 23, 2019, the Department received Molnar's application to renew the permit for another year. The application included an edited list of species showing several changes to Molnar's animal collection, and a list of additional animals Molnar intended to acquire in the next 12 months. Between August and October 2019, Department investigators inspected All Animals several times and identified alleged violations related to Molnar's collection. In September 2019, the Department also asked Molnar to submit a résumé and letter of recommendation describing his qualifying experience for the permit. Molnar submitted several letters of recommendation to the Department that described his qualifying experience.

4. On December 18, 2020, the Department sent Molnar a notice of denial of the renewal application. The denial letter stated the Department's decision was based on findings that Molnar committed multiple violations of the regulations regarding

restricted species. On January 11, 2021, Molnar timely appealed the denial to the Fish and Game Commission (Commission) and filed a written statement in support of the appeal. On March 25, 2021, the Department filed a response with the Commission arguing that the denial should be affirmed. One of the Department's arguments for affirming the denial was that Molnar's statement in support of the appeal was not signed under penalty of perjury. On March 31, 2021, Molnar filed a copy of the same statement correcting that error.

5. On August 8, 2023, the Commission submitted a request to OAH to schedule a hearing on Molnar's appeal. After OAH granted the request, the Department moved to vacate the hearing, arguing that a hearing was not authorized under California Code of Regulations, title 14, section 671.1 (Section 671.1). Molnar's counsel did not oppose the motion but requested time to file a supplemental brief. An OAH staff member directed Molnar's counsel to file any such brief by September 15, 2023, and Molnar's counsel complied.

6. On September 27, 2023, Presiding Administrative Law Judge (PALJ) Matthew Goldsby vacated the hearing date and ordered the Department to file any response to Molnar's supplemental brief by October 4, 2023. The Department filed a response requesting reconsideration of the order authorizing Molnar's supplemental brief. In an order dated October 9, 2023, PALJ Goldsby denied the Department's request for reconsideration and deemed the matter submitted.

7. Thereafter, on December 4, 2023, the ALJ ordered the filing of exhibits to Molnar's written statement in support of the appeal that were missing from the submissions to OAH. Molnar's counsel filed the missing exhibits on December 18, 2023, and the matter was deemed resubmitted on that date.

Department's Contentions

8. In its Response to Molnar's appeal, the Department contends the Commission should affirm the denial of the renewal application because Molnar: (a) did not sign the statement in support of his appeal under penalty of perjury; (b) failed to microchip or otherwise uniquely identify a monkey and provide documentation of the identifier to the Department within 10 business days of receiving the animal; (c) imported and possessed four venomous snake species not authorized under his permit; and (d) imported and possessed four endangered snakes after his permit expired. The Department's original denial letter to Molnar also cited other alleged violations, but the Department's briefing in response to Molnar's appeal does not analyze those other alleged violations.

9. Regarding the statement in support of the appeal, Molnar initially did not sign it under penalty of perjury as required. (See § 671.1, subd. (c)(7)(B).) Molnar corrected the error on March 31, 2021, but only after the Department argued the appeal should be dismissed due to error. The Department contends the error justifies the Commission dismissing Molnar's appeal without reaching the merits.

10. Regarding the monkey, Lieutenant Kory Collins and Captain John Laughlin of the Department's Law Enforcement Division inspected All Animals on August 30, 2019. The Department's Response to Molnar's appeal attaches a report of Collins stating Molnar showed Collins and Laughlin a squirrel monkey (*Saimira sciureus*) during the inspection. (Response, Exhibit E.) According to the report, Molnar stated he acquired the squirrel monkey in October 2018, but he had not implanted a microchip in the animal or otherwise uniquely identified it (e.g., with an identifying tattoo).

11. According to Department records, the first indication that Molnar microchipped the squirrel monkey was in a revised inventory of animals that Molnar submitted on October 7, 2019, while his renewal application was pending. The revised inventory included the number and a bar code for the microchip that Molnar implanted in the animal. (Response, Exhibit G.)

12. Regarding the four unpermitted snake species, Collins inspected All Animals again on September 6, 2019. Collins reported he found Molnar to be in possession of four venomous snake species that were not listed on Molnar's permit. Specifically, Molnar had two Malabarian pit vipers (*Trimeresurus malabaricus*), one red adder (*Bitis rubidda*), two Ethiopian mountain adders (*Bitis parviocula*), and one Schulze's pit viper (*Parias schultzei*). Molnar's permit did not authorize him to possess these six animals.

13. Regarding the four endangered snakes, Collins and Laughlin inspected All Animals again on October 23, 2019, and they observed a wooden shipping container labeled "Live Animals" and "Live Reptiles, Venomous." According to Collins's report, Molnar stated he received a shipment of four Mangshan vipers (*Protobothrops mangshanens*) from overseas on October 19, 2019, several months after Molnar's permit expired. Collins asked Molnar why he had acquired the additional snakes, and Molnar replied he purchased them from someone in Germany approximately two years earlier and had just received them. Molnar stated the snakes are very difficult to acquire, and it takes a long time to obtain the required shipping paperwork. Mangshan vipers require Convention on International Trade in Endangered Species (CITES) paperwork because their wild populations are endangered. Before Molnar's permit expired, it authorized him to possess just one Mangshan viper. Molnar showed Collins and Laughlin the four new snakes, which were in individual containers.

14. According to the Department, Molnar's alleged violations evidence "a complete disregard for permitting laws intended 'to reduce the depletion of wildlife populations.'" (Response, p. 10 [quoting Fish & Game Code, § 2116.5].) Therefore, if the Commission does not dismiss the appeal, it should sustain the Department's denial of the renewal application on the merits.

Molnar's Contentions

15. Molnar contends he has worked with the Department for years assisting in seizures of illegal reptiles, mammals, and birds; identifying reptile species; treating confiscated exotic animals for free; and housing exotic and native wildlife as evidence for the Department. But starting in August 2019, Molnar became the subject of "a campaign of harassment" by Laughlin that led to the denial of his renewal application. (Molnar Appeal and Statement, p. 1 (Jan. 11, 2021) (Appeal).) Molnar never had a complaint against his permit, and Laughlin and Collins did not note any animal husbandry or safety problems at All Animals. Nonetheless, they demonstrated "dishonest, aggressive behavior" in front of Molnar's clients and staff. (*Id.* at p. 2.) Molnar contends he always provided up-to-date information to the Department, and he adhered to the regulations regarding reporting. But the entire process has been confusing, difficult, and "made worse by the behavior of officers who were supposed to guide me." (*Id.* at p. 5.)

16. Regarding the written statement accompanying his appeal, Molnar contends the initial lack of a signature under penalty of perjury was a technical error that does not justify denying his appeal. He remedied the error immediately upon learning of it.

///

17. Regarding the squirrel monkey, Molnar contends the animal was "technically on loan" from another animal handler when Collins and Lauglin inspected All Animals on August 30, 2019. (Molnar's Supplementary Brief, p. 4 (Sept. 15, 2023) (Supplementary Br.).) Molnar "had never taken official possession of the monkey," and when the animal was given to Molnar, it was "hypoglycemic and extremely weak." (*Ibid.*) According to Molnar, the monkey needed treatment in Molnar's capacity as a veterinarian before Molnar could or would consider taking it on as a personal animal. Molnar was not going to take on the monkey as his own before he knew it was fit for his individual possession. Putting a microchip in the monkey "was out of the question, due to its weakened state." (*Ibid.*)

18. According to Molnar, there were times that the monkey's health improved, and Molnar was able to show the animal in schools and other educational settings. At Laughlin's insistence and against Molnar's professional judgment, Molnar microchipped the animal and submitted the microchip information to the Department in October 2019. The monkey died in May 2020 due to metabolic disease.

19. Regarding the four species of snakes not listed in the permit, Molnar was awaiting approval of his renewal application at the time of the inspection on September 6, 2019. The list of species Molnar intended to acquire in the next 12 months that was part of the application included all four species of snakes (see Supplementary Br., Attachment A), and Molnar was qualified for approval of that request. Moreover, Molnar was under the mistaken belief that possession of these species, which were similar to vipers he was permitted to possess, was "essentially allowed under the Department's rules." (*Id.* at p. 6.) Therefore, possession of the four species of snakes is a "technical violation" that should be judged in light of the totality of Molnar's actions with regard to his restricted species permit. (*Ibid.*)

20. Regarding the Mangshan vipers, Molnar contends he ordered the snakes from a captive breeder in the Czech Republic long before the permit expired. The vipers should have arrived in 2018 when Molnar was properly permitted, but they were "waylaid by European regulations." (Supplementary Br., p. 7.) When the vipers arrived, Molnar had already applied to the Department to renew his permit. Although the pending application admittedly did not authorize Molnar to possess the snakes, Molnar was concerned for the animals' safety and well-being. Therefore, Molnar retrieved the vipers from Los Angeles Airport and took them "immediately" to another Department permittee who was authorized to possess these species. (*Ibid.*) According to Molnar, he acted as "little more than courier of these snakes to a properly permitted holder," and doing anything less would have put the snakes at risk. (*Ibid.*) While this may be a "technical violation," Molnar asserts his action was understandable and "even commendable." (*Id.* at p. 8.)

21. Overall, Molnar contends the Department is disregarding his good record as a permittee and his long record of service to the Department. He describes himself as a devoted veterinarian who has given completely of himself for the betterment of the animals that come to his facility for treatment. In Molnar's view, the violations do not justify denial of the renewal application.

Analysis of Contentions

22. The record supports Molnar's contention that his initial failure to sign the statement supporting his appeal under penalty of perjury was an oversight. Molnar corrected the error immediately after perceiving it, and he did not change the statement when he signed it on March 31, 2021. The Department also presented no evidence or argument that the error prejudiced the Department. These facts weigh

against the Department's contention that Molnar's appeal should be dismissed without reaching the merits.

23. The record does not support Molnar's contention that he only possessed the squirrel monkey in his capacity as a veterinarian. According to the letters of recommendation he submitted to the Department in late 2019, Molnar regularly exhibited the squirrel monkey to others in a variety of settings during the preceding two years. One letter states, "[f]or the last two years [Molnar] has . . . enchanted us with his baby squirrel monkey, that accompanied him almost at all times." (Appeal, Exhibit 4 [letter from Matt Kiosea, DVM].) Other letters similarly state Molnar acquired or started exhibiting the monkey about two years earlier, i.e., in late 2017. (*Id.* [letters from Nicole Yorkin, George Hees, Kimberly Ward, Michael Budnitsky, and Julian Sylvester].) In contrast, Molnar reportedly told Laughlin and Collins he acquired the monkey in October 2018. According to the letters, Molnar exhibited the squirrel monkey at All Animals, in school classrooms, at a wildlife learning center, and at private houses for children and adults. The monkey also appeared "several times in various promo shoots" in the entertainment industry. (*Id.* [letter from Julian Sylvester].)

24. Molnar would not be expected to exhibit what he contends was an "extremely weak" and "technically on loan" animal under veterinary care so widely, especially at locations other than his veterinary hospital. Considering the evidence, it is unlikely Molnar was acting only as the squirrel monkey's veterinarian from when he received the animal in October 2018 (as Molnar told Collins and Laughlin) or in late 2017 (as stated in the letters) until the inspection in late August 2019. This weighs against Molnar's contention that he was justified in not assigning a unique identifier to the monkey during that period.

///

25. There is no material factual dispute that Molnar possessed four species of venomous snakes not listed in his permit. Molnar told the Department he intended to acquire these species of snakes in his July 2019 renewal application, but he acquired and possessed a total of six specimens of these four species before obtaining Department approval, which the Department never gave. Molnar downplays the violation as technical and based on a mistaken understanding of the regulations, but he does not dispute the violation itself.

26. Regarding the Mangshan vipers, the record does not support Molnar's contentions that he gave the vipers to another permittee "immediately" and acted as "little more than a courier" for them. Molnar himself told Collins and Laughlin he picked up the vipers from the airport on October 19, 2019, and the vipers were still at All Animals when Collins and Laughlin inspected the facility four days later on October 23, 2019. There was no "immediate" transfer to another permittee, and no evidence suggests Molnar would have transferred the snakes to another permittee at all absent the inspection.

27. The record also does not support a finding that Laughlin conducted a "campaign of harassment" against Molnar as alleged. Laughlin and Collins inspected All Animals several times over a two-month period and found violations related to Molnar's animal collection. The number of inspections was reasonable in light of the nature and gravity of the violations found. Molnar's submissions on this appeal do not prove his claims of Department harassment, dishonesty, or other misconduct.

LEGAL CONCLUSIONS

Legal Standards

1. "The Fish and Game Code authorizes the Department to issue written permits to possess any wild animal designated as a restricted species, upon a determination that no detriment will be caused to agriculture, native wildlife, the public health and safety, or the welfare of the animal. (Fish and Game Code, § 2150, subd. (a)(1)." (*Young v. California Fish and Game Commission* (2018) 24 Cal.App.5th 1178, 1193.) Under Section 671.1, "[i]t is unlawful for any person to import, export, transport, maintain, sell, dispose of, or use for any purpose any animal restricted by Section 671 except as authorized in a permit issued by the department." (§ 671.1, subd. (a).) The animals restricted by Section 671 "are not normally domesticated in this state," and they are listed as restricted species "to prevent the depletion of wild populations and to provide for animal welfare," or "because they pose a threat to native wildlife, the agriculture interests of the state or to public health or safety." (§ 671, subd. (b).) The restricted species include all non-human primates, all species of vipers, and each of the other species identified in Molnar's permit and renewal application. (*Id.*, subd. (c).)

2. A restricted species exhibiting permit, such as the permit issued to Molnar, may be "[i]ssued to any person who is a resident or nonresident who is in the business of exhibiting animals at least half-time, for commercial and/or educational purposes, and who possesses the qualifications listed in subsection 671.1(c)(1)." (§ 671.1, subd. (b)(6).) For such a permit, "[t]he permittee may import, transport, and possess only those species specified on the department approved permit." (§ 671.1, subd. (c)(5)(A)(1).)

3. "The department may deny the issuance of a permit or amendment of an existing permit if: [¶] 1. the applicant or permittee has failed to comply with terms and conditions of a permit or any provision of the Fish and Game Code or regulations adopted pursuant thereto . . . ." (§ 671.1, subd. (c)(5)(A)(1).) "Any applicant or permittee who is denied a permit . . . may appeal that denial . . . by filing a written request for an appeal with the commission." (*Id.*, subd. (c)(7).) "The commission's president may appoint a commissioner, a current or former executive director of the commission, a current employee of the commission, or a member of the state bar of California in the active practice of law to serve as a hearing officer." (*Id.*, subd. (c)(7)(A).)

4. "[A] person requesting an appeal (appellant) shall submit a written statement to the commission that specifically identifies the legal and factual grounds for challenging the department's action." (§ 671.1, subd. (c)(7)(B).) The appellant's written statement "shall be signed by the appellant under penalty of perjury." (*Ibid.*) "[T]he department may submit a response to the commission, with a copy sent to the appellant, along with any supporting documentary evidence and/or declarations under penalty of perjury." (*Id.*, subd. (c)(7)(C).) If the Department submits a response, "the appellant may submit a reply to the commission signed by the appellant under penalty of perjury . . . that addresses arguments and evidence raised in the department's response." (*Id.*, subd. (c)(7)(D).) Thereafter, "the hearing officer may request additional information, including testimony under oath, from either party, and may permit either party to present additional information or rebuttal if the hearing officer determines such to be helpful in reaching a correct decision." (*Id.*, subd. (c)(7)(E).)

///

///

5. “No later than 60 days after receipt of all submittals and any additional information or rebuttal permitted by the hearing officer . . ., the hearing officer shall prepare and submit a proposed decision to the executive director of the commission. The decision shall contain proposed findings and reasons for the commission’s action.” (§ 671.1, subd. (c)(7)(G).)

Analysis

6. The Department’s contention that Molnar’s appeal should be dismissed without reaching the merits is unpersuasive. Molnar’s initial failure to sign the statement supporting his appeal under penalty of perjury does not justify dismissing the appeal. The error was inadvertent, Molnar corrected it immediately, and the Department presented no evidence of prejudice from the error. (Factual Finding 22.)

7. The Department’s contentions on the merits are more persuasive. The preponderance of the evidence proves the violations analyzed in the Department’s Response. (See Evid. Code, § 115 [“Except as otherwise provided by law, the burden of proof requires proof by a preponderance of the evidence.”].) First, Molnar failed to microchip or otherwise uniquely identify the squirrel monkey and provide documentation of the identifier to the Department as required. Under Section 671.1, “[e]very . . . non-human primate . . . that is possessed under a restricted species permit shall be identifiable by an approved unique identifying method and reported to the department for inclusion in a registry.” (§ 671.1, subd. (c)(3)(J).) “Approved methods include microchips, tattoos or any other alternative method that is approved by the department. . . . [¶] . . . Each permittee must provide an animal’s unique identification to the department within 10 business days of receipt or transfer of an animal, the birth or death of an animal, or change in unique identification for an animal.” (*Ibid.*)

8. Molnar violated these requirements by possessing the squirrel monkey for at least one year (according to Molnar) and up to two years (according to the letters of recommendation) before implanting a microchip in the animal and informing the Department of the microchip in October 2019. Furthermore, Molnar's contention that he possessed the animal solely in his capacity as a veterinarian during that entire period is unpersuasive. Molnar exhibited the squirrel monkey in a manner consistent with possession of the animal in Molnar's personal capacity. (Factual Findings 23-24.) Molnar's contention that the squirrel monkey was too fragile to microchip also does not justify the violation. Molnar could have used a different unique identifier (e.g., a tattoo) even if that were true.

9. Second, Molnar violated his permit and Sections 671 and 671.1 by possessing four species of venomous snakes (totaling six animals) not listed in his permit. Molnar's permit states he may "possess only those species listed" in the permit. (Response, Exhibit B.) Sections 671 and 671.1 include the same limitation. (§§ 671, subd. (a); 671.1, subd. (b)(6).) In his renewal application, Molnar identified the four species of snakes as species he intended to acquire within the next 12 months, but Molnar acquired the snakes without waiting for Department approval, which never came.

///

///

///

///

///

10. Third, Molnar violated Section 671, subdivision (a), by importing and possessing four Mangshan vipers after his permit expired. Molnar picked up the endangered snakes from the airport on October 19, 2019, about three months after the expiration of his permit. Molnar contends he ordered the snakes two years earlier, but that does not justify the violation. Molnar could have cancelled the shipment after his permit expired or informed Department staff of the snakes' impending arrival and arranged for another permitted facility to take them. Molnar also did not transfer the snakes to another permittee "immediately" as he contends; he only did so after Collins and Laughlin identified the violation. (Factual Finding 26.)

11. The violations described above authorized the Department to deny Molnar's renewal application. (§ 671.1, subd. (c)(5)(A)(1).) Considering the violations and the totality of the circumstances, denial is the correct result. Molnar committed multiple violations of the regulations related to restricted species. The violations were neither justified nor merely technical as Molnar contends. They resulted in Molnar possessing more restricted species than he was allowed to possess under his permit, and in the Department having incomplete information about Molnar's animal collection. Molnar's submissions on appeal also demonstrate limited acceptance of responsibility for the violations.

12. Molnar's lack of prior disciplinary history is a mitigating factor, as is his apparent assistance to the Department in other matters involving exotic animals. But those mitigating factors are not enough to justify granting the renewal application. Molnar was only a permittee for a few years before committing the violations, and the nature and gravity of the violations do not support renewal of the permit. Molnar contends his abilities and contributions as an exotic animal veterinarian weigh in favor of renewal, but his veterinary skills and practice are not at issue in this appeal. In

addition, there is no provision in Section 671.1 for the issuance of a restricted species exhibiting permit on a probationary basis. The Commission is presented with the binary choice of either affirming or reversing the Department's denial of Molnar's renewal application. Considering the entire record on appeal, affirming the Department's action is the correct result.

ORDER

The Department's denial of Attila Molnar's Restricted Species Exhibiting Permit Renewal Application is affirmed.
