## Foreward

This is the twenty-first annual report to the United States Bureau of Reclamation (USBOR). This year's activities were conducted under terms of Cooperative Agreement Number R11AC20520, and cover the period of January 1, 2009 through December 31, 2009. The field work was conducted by personnel of the California Department of Fish and Game's (CDFG) Klamath-Trinity Program. Cooperators of CDFG field studies include the Hoopa Valley Tribal Fisheries (HVTF), Yurok Tribal Fisheries Program (YTFP), U.S. Fish and Wildlife Service (USFWS) and U.S. Forest Service (USFS). The HVTF, YTFP, and USFWS were contracted separately by the USBOR for cooperative and singular work performed during FFY 2009. Please refer to those respective agency/tribal fisheries departments or USBOR for information regarding other projects/studies.

This year's CDFG work was comprised of six separate projects (Tasks) performed on the lower Klamath River, main stem Trinity River, and at Trinity River Hatchery. The necessity for performing our Klamath-Trinity basin monitoring activities have been outlined in several Acts of Congress including Public Law 386 (69 Stat. 719), August 12, 1955; Public Law 98-541, October 24, 1984; "Trinity River Basin Fish and Wildlife Management Reauthorization Act" of 1995; and Trinity River "Record of Decision", 2000.

## Acknowledgements

Thank you to the CDFG technicians who made possible our field seasons: Carmen Arey, Nancy Barnes, Linda Battin, Jason Coburn, Daniel Dempsey, Becky Dutra, Melissa Gordon, Mark Kerr, Carl Meredith, Todd Newhouse, Justin Pabich, Roddy Park, Warren Peterson, Vanessa Rosenthal, Daniel Santsche, Jane Sartori, Guy Smith, Ron Smith, Cadella Thomas, Cindy Walker and Eileen Williams. Thanks too to Brenda Tuel for the office support. A special thanks to Linda Allan who, after coming to the Trinity River Project in 1984 (after a year on the Smith River) has been there, steadfastly assisting the biologists of CDFG Weaverville, ever since. Linda retired in 2010

We are grateful for the help of the many biologists, technicians, crew, staff, and volunteers from HVTF, YTFP, USFWS, USFS, and other CDFG projects who worked cooperatively with us on our field projects.

We also greatly appreciate the cooperation of the CDFG Trinity River Hatchery staff during salmonid recovery, and the following landowners: Doris Chase, Tom O'Gorman, Pierre LeFuel, the Bureau of Land Management and the U.S. Forest Service.

The CDFG monitoring program was approved by the Trinity Management Council (TMC) and funded through the Trinity River Restoration Program (TRRP) office in Weaverville, CA. We thank Mike Hamman and the TRRP staff for their input and effort administering our projects and contracts.

#### Abstract

The California Department of Fish and Game's Trinity River Project (TRP) conducted tagging and recapture operations from June 2009 through March 2010 to obtain adult spring-run (spring Chinook) and fall-run (fall Chinook) Chinook salmon (Oncorhynchus tshawytscha), coho salmon (O. kisutch), and fall steelhead (O. mykiss) run-size, angler harvest, and spawner escapement estimates in the Trinity River basin. The project is conducted by the California Department of Fish and Game (CDFG) in cooperation with the Hoopa Valley Tribal Fisheries Department (HVTF). Two main stem weirs were placed in the Trinity River near the towns of Junction City and Willow Creek, and trapped 1,469 Chinook salmon, 202 coho salmon, 1,730 fall steelhead and 171 brown trout (Salmo trutta).

Based on Project-tagged fish recovered at Trinity River Hatchery (TRH) and on the return of reward tags by anglers, an estimated 7,426 spring Chinook migrated into the Trinity River basin upstream of Junction City weir (JCW). An estimated 442 spring Chinook were caught by anglers, leaving 6,984 fish as potential spawners. An estimated 29,593 fall Chinook migrated past Willow Creek weir (WCW), of which an estimated 704 were caught by anglers, leaving 28,889 potential spawners.

The coho salmon (coho) run in the Trinity River basin upstream of WCW was estimated at 6,396 fish. Zero coho were estimated as harvested by anglers, leaving all 6,396 as potential spawners.

An estimated 18,361 (5,047 naturally produced and 13,314 hatchery produced) adult fall steelhead returned to the Trinity River basin upstream of WCW. Anglers harvested an estimated 1,530 adult fall steelhead above the WCW, leaving 16,831 fish as potential spawners.

## TASK OBJECTIVES

1. To determine the size, composition, distribution, and timing of adult Chinook salmon, coho salmon, and steelhead runs in the Trinity River basin.
2. To determine the in-river angler harvest and spawner escapements of Trinity River Chinook salmon and coho salmon, and steelhead.

## INTRODUCTION

The California Department of Fish and Game's TRP, in cooperation with the HVTF, conducts annual tagging and recapture operations of adult Chinook and coho salmon, and fall steelhead in the main stem Trinity River. This effort determines the composition (race and proportion of hatchery-marked ${ }^{1 /}$ or Project-tagged ${ }^{2 / 1}$ fish), distribution, and timing of Chinook salmon, coho salmon, and fall steelhead runs in the Trinity River basin. Recaptures of hatchery-marked or Project-tagged fish are used to develop runsize, angler harvest, and spawner escapement estimates for Chinook and coho salmon, and steelhead runs. Additionally, tagging of brown trout continued to determine angler harvest and growth rates.

This is a continuation of studies that began in 1977 with the trapping, tagging, and recapture of fall-run Chinook salmon (fall Chinook), coho salmon (coho), and fall-run steelhead (steelhead). In 1978, similar studies were added to include spring-run Chinook salmon (spring Chinook). Steelhead were dropped from the program in 1985 through 1989 and reinstated in 1990. Results of these studies are available from California Department of Fish and Game (Heubach and Hubbell (1980); Heubach (1984a, 1984b); Heubach et al. (1992a, 1992b); Lau et al. (1994, 1998, 2000); Zuspan et al. (1985, 1995); Zuspan and Sinnen (1995); Sinnen and Hanson (1996); Zuspan (1996, 1997); Sinnen et al. (2001); Sinnen and Reese (2002, 2004); Reese (2004); Reese and Sinnen (2004); Sinnen and Knechtle (2005); Knechtle and Sinnen (2006, 2007, 2009), Sinnen and Kier (2009), and Kier and Sinnen (2010)).

Earlier studies were funded by the U.S. Bureau of Reclamation (USBR), and with Anadromous Fish Act funds administered by the U.S. Fish and Wildlife Service and National Marine Fisheries Service. The USBR has funded the program from October 1, 1989 through the present.

Prior to the current program, all efforts to measure salmon and steelhead populations in the Trinity River basin had been restricted to portions of the upper main stem Trinity River and several of its tributaries, including the South Fork Trinity River and some of its

[^0]tributaries (Moffett and Smith (1950); Gibbs (1956); LaFaunce (1965a, 1965b, 1967); Weber (1965); Rogers (1970, 1972, 1973a, 1973b, 1982); Miller (1975); and Smith (1975). Earlier efforts did not include fish which used the main stem and tributaries of the lower Trinity River nor attempt to determine the proportion of hatchery fish in the runs and the rates at which various runs contributed to the fisheries. To develop a comprehensive management plan for the Trinity River basin, it was decided all salmon stocks utilizing the basin must be considered, though the majority of the monitoring funding is now main stem Trinity River specific.

## METHODS

## Trapping and Tagging

## Trapping Locations and Periods

Trapping and tagging operations were conducted by TRP and HVTF personnel from June through late November 2009 at temporary weir sites near the towns of Willow Creek and Junction City on the main stem Trinity River. The downstream site, WCW, was located 36.5 km upstream from the Trinity River's confluence with the Klamath River ( $40^{\circ} 58^{\prime} 29.85^{\prime \prime} \mathrm{N}, 123^{\circ} 38^{\prime} 8.61^{\prime \prime} \mathrm{W}$ ). The upstream site, JCW, was located 132.7 km upstream from the Klamath River confluence ( $40^{\circ} 41^{\prime} 5.51^{\prime \prime} \mathrm{N}, 123^{\circ} 01^{\prime} 35.55^{\prime \prime} \mathrm{W}$ ) (Figure 1). In general, prior to 1995, JCW was operated from May through November. Since a court-mandated flow regime change was instituted in 1995, JCW has operated from late-June or mid-July (the earliest the weir can be effectively installed with the higher regulated flows) through September, with the exception of 2005 when an attempt was made to obtain additional estimates and JCW was operated from mid-July through the end of November. WCW is typically operated from mid-August through November. Most fall Chinook spawning occurs upstream of WCW, while the majority of spring Chinook spawning occurs upstream of JCW.

The JCW was operated July 17 through September 30, 2009, and the WCW was operated August 31 through November 19, 2009. At both weir sites, trapping was scheduled five nights a week, beginning around dusk of each trapping night, and continuing until mid-day the next day. Each trapping day the weir was opened for at least five hours to allow fish to pass unimpeded through the weir, and it was generally opened over the weekend as well. Occasionally, trapping schedules were modified to allow for holidays or high flows which prevented trapping in a safe manner. Trapping and tagging were not conducted if stream temperatures exceeded $22^{\circ}$ Celsius.

## Weir and Trap Design

Since 1989, a Bertoni (Alaskan) weir design has been used at both sites (Figures 2-4). The weir is supported by wooden tripods set 2.5 m apart. Weir panels consisted of 3.0 $\mathrm{m} \times 1.9 \mathrm{~cm}$ ( $10 \mathrm{ft} \times 3 / 4 \mathrm{in}$ ) electrical conduit spaced 5.1 cm apart on center, leaving a gap of 3.2 cm between conduits. Conduit pieces are supported by three sections of aluminum channel arranged 0.92 m apart, which are connected to the supporting
tripods. The tripods are anchored with cable to 1.8 m stakes driven into the stream bottom. The weir panels are angled at roughly a $45^{\circ}$ angle, with the top of the weir standing 1.8 m above the river bottom.

Figure 1. Location of trapping/tagging weirs for anadromous salmonids near Willow Creek and Junction City in the main stem Trinity River, 2009 season.

Figure 2. Photograph of Alaskan-style weir tripods, support channels and conduit (looking upstream).

Figure 3. Photo (looking downstream) of 2009 Willow Creek weir. Note the boat gate (left side of picture) and two trap boxes.

Figure 4. Typical Junction City weir configuration (looking downstream). Note the single trap box (on left) and boat gate (on right).

The traps are made of 1.9 cm electrical conduit spaced 2.5 cm apart and welded into panels. The panels are wired together at the corners to produce a 2.4 m square box which is bolted to a plywood floor and covered with a plywood lid to prevent fish from jumping out. A fyke, also made of conduit panels, is installed in the trap to guide fish into the trap box and prevent their escape. The trap is placed on the upstream side of the weir, directly in front of 12 raised conduit pieces creating an opening approximately 60 cm . This opening allows fish to pass through the weir, through the fyke, then into the trap. To allow boat passage, gates approximately 5.3 m wide were inserted between two weir panels. The gate at JCW was constructed of welded conduit panels with 2.5 cm spacing between pieces of conduit and was perpendicular to the stream substrate. The gate at WCW was constructed of 4.0 cm mesh chain-link fencing supported by a livestock gate and was sloped downstream, even with the weir.

## Processing of Fish

At both weirs, all trapped salmonids were identified to species, measured to the nearest cm fork length (FL), and examined for hook, predator, or gill-net wounds or scars, fin clips, and tags. Each untagged, un-spawned salmonid judged in good condition is tagged with a serially numbered Floy Tag and Manufacturing, Inc. FT-4 ${ }^{3 / 3}$ spaghetti tag (Project-tagged). Tags were inserted using an applicator needle through the fish's back approximately two cm below the base of the dorsal fin and $1 / 4$ the length of the dorsal fin, anterior of the posterior edge of the dorsal fin. At both weirs one-third of the Chinook received $\$ 10$-reward tags, while the remaining two-thirds received non-reward tags. At

[^1]WCW one-half of the adult steelhead received reward tags while the remaining fish received non-reward tags, while all the steelhead tagged at JCW were tagged with nonreward tags. Juvenile, or "half-pounder", steelhead were not tagged at either weir. Coho were tagged with non-reward tags at WCW, though none were tagged (nor trapped) at JCW. At JCW, brown trout were tagged with serially numbered (Floy) FD-94 anchor tags, while any brown trout tagged at WCW were done so with FT-4 spaghetti non-reward tags.

## Determining the Separation between Spring and Fall Chinook Runs at the Weirs

Each year there is a temporal overlap in the spring and fall Chinook runs in the Trinity River. Run timing varies between years, and each season dates are assigned that separate the spring and fall Chinook runs. This separation is determined by comparing proportions of known and estimated spring and fall Chinook trapped at the weirs each week. The week in which the proportion of fall Chinook exceeds spring Chinook is designated as the first week of the fall Chinook run at that weir. If there are two consecutive weeks with nearly identical proportions, then the first week is designated as spring run and the following as fall run.

A recovered Project-tagged Chinook is identified as either a spring or a fall Chinook based on two separate criteria. First, some Chinook tagged at the weirs have codedwire tags (CWTs) which were placed in their snouts as juveniles at TRH. These fish are identifiable by the absence of their adipose fin, which is clipped off (ad-clipped) during the CWT tagging process. If these fish are recovered at the hatchery or during spawner surveys, the CWT code (which is determined after the CWT is removed from the snout of the fish and read using a microscope) indicates whether they were spring or fall fish. Second, non-CWTed Chinook (Project-tagged at the weir then recovered at the hatchery) are classified as either spring or fall fish based on the date they entered the hatchery. If they entered the hatchery during the period associated with the spring run (based on CWT recoveries at the hatchery) they were considered spring Chinook. The Chinook entering the hatchery during the period associated with the fall run (based on CWT recoveries) were considered fall Chinook.

Determining the Separation between Summer, Fall, and Winter Steelhead Runs at the Weirs

Throughout this report we refer to fall-run adult steelhead, when in actuality we are reporting on a mix of runs. Most of the steelhead we encounter at the WCW are undoubtedly fall-run steelhead, but there is temporal over-lap in the run-timing of the summer, fall, and winter runs, as evidenced by a higher proportion of fish caught without adipose clips early in our sampling season (ie mid-August), and again toward the end of the season (November). The TRH endeavors to produce fall-run steelhead (100 \% of which are marked with an ad-clip). Until such time as we can distinguish the runs from each other we will continue to refer to all the steelhead we catch at Willow Creek weir as fall-run steelhead.

Estimating Numbers of Spring and Fall Chinook at Trinity River Hatchery
As at the weirs, there is an overlap in the return timing of spring and fall Chinook into TRH. To estimate the respective numbers of spring and fall Chinook without CWTs that entered TRH, the numbers of tags recovered from each returning CWT group were expanded by the CWT production multiplier (the ratio of tagged to total Chinook released by same strain, brood year [BY], release site, release group and date). For example, 126,729 fall Chinook of CWT group 06-52-99 plus 382,157 unmarked fall Chinook were released from TRH in June of 2003. The expanded estimate for each return from this group is $4.015(126,729+382,157 / 126,729)$. Each CWT return was expanded by its production multiplier to estimate the total number of spring and fall Chinook that entered the hatchery.

If more Chinook entered the hatchery on a particular sorting day than could be accounted for by the expansion of all CWT groups, the additional fish were considered to be naturally produced. These fish were designated as either spring run or fall run in the same proportions that were determined by the expansion of the CWT groups on that day.

To estimate spring and fall Chinook run-sizes, a separation date at the hatchery was assigned between the two runs. The separation date was the week in which fall Chinook out-numbered spring Chinook based on the expansion of CWTs.

## Size Discrimination Between Adult and Grilse Chinook and Coho Salmon

The size separating adult and grilse spring and fall Chinook was based on two criteria; length frequency data obtained at the two trapping sites and TRH, and length data obtained from groups of CWTed fish that entered TRH whose exact age was known. Fork length data from TRH Chinook was only used from weeks in which $\geq 90 \%$ of the Chinook could be designated as either spring run or fall run as explained by the expansion of CWTs.

Coho salmon do not receive CWTs, therefore exact ages are unknown. The separation of grilse and adult coho salmon was based entirely on length-frequency analysis.

Chinook and coho salmon length-frequency data collected at the weirs and TRH were smoothed with a moving average of five 1-cm increments to determine the nadir separating grilse and adults.

## Size Discrimination Between Adult and Immature Steelhead

All steelhead $>41 \mathrm{~cm}$ FL were considered adults, and steelhead $\leq 41 \mathrm{~cm}$ FL captured at the weirs were assumed to be half-pounders (assumed to have migrated to, and back from, the ocean). Steelhead $\leq 41 \mathrm{~cm}$ FL that entered TRH were not counted and were classified as sub-adults.

## Recovery of Tagged Fish

## Weir Recovery

All salmonid carcasses recovered at the weir were measured to the nearest cm FL and examined for wounds, tags, fin clips, and spawning condition. All heads from ad-clipped fish were removed for the potential recovery and decoding of the CWT. After processing, all carcasses were cut in half to prevent recounting and returned to the river downstream of the weir.

## Tagging Mortalities

Tagged salmonids recovered dead at the weir, in spawning surveys, or reported dead by anglers were considered tagging mortalities if there was no evidence they had spawned and they were recovered dead $\leq 21$ days after tagging. Tagged fish recovered dead more than 21 days after tagging, or those that had spawned, regardless of the number of days after tagging, were not considered tagging mortalities.

## Angler Tag Returns

All the tags placed on fish at the weirs were inscribed with the TRP Arcata field office address and the word RETURN. The information from returned Project-tags by anglers and river enthusiasts allowed for estimation of angler harvest and catch and release rates for all species marked. All anglers that returned tags were sent questionnaires asking the date and location of their catch and whether they harvested (kept) or released their catch. The questionnaire informed them of the fish's tagging date and location.

Tags returned to the TRP Arcata field office through May 31, 2010 were included in assessing harvest and catch and release rates. Tags returned after that date were processed for payment but not used for analysis.

## Trinity River Hatchery Returns

The TRH fish ladder was open September 08 through March 10, 2010. TRH closed the fish ladder between October 13 and October 24 (Julian week (JW) 42 plus a couple of days on each side of JW 42) as a means of separation of the spring and fall Chinook races, based on CWT analysis of recovered Chinook. Hatchery personnel typically conducted fish spawning operations two days per week during the Chinook and coho spawn. Additional spawn days occurred during the peak of the runs in November. Steelhead spawning operations ensued one day per week from January into March.

All salmon and steelhead entering TRH were identified to species, sexed, examined for tags and clips, and measured to the nearest cm FL. Each salmon and steelhead that enters the TRH spawning house is measured to the nearest cm FL only once.

Since fish are measured and counted only once, individual fish are marked at the time of first TRH entry. Coho and adult steelhead that come through the hatchery prior to the start of the TRH spawning of those species get upper caudal fin clips prior to live release to the river. Both coho and steelhead are known to make multiple returns to the
hatchery trap within the same spawning season. We refer to these marked returns as "re-runs". The purpose of the upper caudal clip is to prevent double counting of fish that have been released live to the river but return on subsequent days.

For spawning purposes, TRH staff initially sort fish as either ripe or unripe. Ripe salmon are either spawned or excised, and ripe steelhead either spawned or returned to the river. Unripe salmon are either moved to holding tanks for further ripening (up to 14 days) or are excised, and unripe steelhead either held for further ripening or returned to the river. Prior to transferring to the holding tanks, unripe fish with ad-clips or Project tags are given a week-specific fin clip to indicate which week they entered TRH. Unripe fish without an ad-clip or a Project tag were tallied prior to being transferred to the holding pond. Held fish are then processed on a later spawning day, after the "fresh" fish are sorted and processed. Entry week fin clips were recorded from all holdover fish when processed.

TRH routinely holds over unripe fish at the beginning of the spawning of each of the races of Chinook, coho and steelhead. Once the TRH egg-take quota is reached they cease to hold fish over.

In the database the Project-tagged salmon and steelhead recovered at TRH were generally assigned the FL recorded for them at the weir. The heads of all ad-clipped salmon were removed and placed individually in plastic bags with serially-numbered head tags noting the date, location of recovery, species, sex, and FL. Project personnel later performed extraction and decoding of those CWTs.

## Spawner Surveys

With crews from U.S. Fish and Wildlife Service, U.S. Forest Service, the Yurok Tribe, and Hoopa Valley Tribal Fisheries Program, TRP staff conducted spawner surveys in the upper Trinity River from Cedar Flat (rkm 78) upstream to Lewiston Dam (rkm 180) and from Hawkins Bar (rkm 64) to Weitchpec (rkm 0). Fish recovered in these surveys were examined for spawning success and Project tags. Results of these surveys are presented in Task 4 of this report.

## Statistical Analyses

## Effectively Tagged Fish

The number of effectively tagged fish was estimated by subtracting from the total tagged those fish that were classified as tagging mortalities, tagged fish recovered downstream of the tagging site, and angler caught and released fish.

## Run-size Estimates

Run-size estimates were calculated using Chapman's version¹ ${ }^{4}$ of the Petersen Single Census Method (Ricker 1975):

[^2]$$
N=\frac{(\mathrm{M}+1)(\mathrm{C}+1)}{(\mathrm{R}+1)} \text {, where }
$$
$N=$ estimated run-size
$M=$ the number of effectively tagged fish
$\mathrm{C}=$ the number of fish examined at TRH
$R=$ the number of Project-marked fish recovered in the hatchery sample.

Annually, TRP staff attempt to tag and recover enough fish to obtain $95 \%$ confidence within $\pm 10 \%$ of the run-size estimate. The confidence interval estimator is selected using criteria established by Chapman (1948). This year there were not enough spring Chinook, fall Chinook, or coho salmon caught to stratify grilse and adult salmon and obtain the $95 \%$ confidence interval on each of the stratified portions of the run, therefore the estimate we used in each case was for the run size as a whole. We then used the proportion of grilse/adults observed (at the JC weir and TRH combined for spring Chinook, at the WC weir and TRH combined for coho, and at WCW only for fall Chinook) and applied those proportions to the run-size estimate to break it into grilse/adult numbers.

All steelhead run-size estimates were for adults only. All TRH-produced steelhead since the 1997 brood year have received adipose-fin clips. The proportion of the run that was hatchery-produced is based upon the percentage of adipose fin-clipped steelhead observed at WCW.

Assumptions of run size estimates are: 1) Fish trapped and released from the weir were a random sample representative of the population; 2) Tagged and untagged fish were equally vulnerable to recapture at TRH; 3) All Project tags were recognized upon recovery; 4) Tagged and untagged fish were randomly mixed throughout the population and among the fish recovered at TRH; and 5) All tag loss was accounted for.

## Angler Harvest and Catch and Release Rates and Harvest Estimates

When reward tags are returned at a higher rate than non-reward tags, only returns from reward tags are used to determine harvest rates. When non-reward tags are returned at higher rates than reward tags, harvest rates are determined by combining the returns of both reward and non-reward tags.

Harvest rates were calculated for each species (and run of Chinook) by dividing the number of angler-returned tags from harvested fish by the number of fish that were effectively tagged. Independent harvest rates were calculated for grilse and adult salmon. Catch and release rate for each species (and run of Chinook) were calculated by dividing the number of angler-returned tags from caught and released fish by the number of fish effectively tagged plus the number of fish reported as released.

The numbers of fish harvested upstream of each weir were estimated by multiplying the harvest rates (for each species/race) by their respective run-sizes upstream of each weir.

## Use of Standard Julian Week

Weekly sampling data collected by Project personnel at the weirs are presented in Julian week (JW) format. Each JW is defined as one of a consecutive set of 52 weekly periods, beginning January 1, regardless of the day of the week on which January 1 falls (Appendix 1). The extra day in leap years is included in the ninth week. This procedure allows inter-annual comparisons of identical weekly periods.

## RESULTS

## Trapping and Tagging

## Chinook Salmon

Spring/Fall Chinook Separation and Run Timing
Chinook were designated as either spring-run (spring) or fall-run (fall) based on recovery of coded-wire tags or entry-timing into Trinity River Hatchery. For purpose of analysis, the spring/fall separation point is a hard date, but in reality the timing of the two runs of Chinook frequently overlaps.

Both spring and fall Chinook were trapped at JCW (Figure 5) in 2009. Spring Chinook trapping peaked during JW 28 at 11.5 fish per night decreasing in a patternless manner, eventually yielding to fall Chinook in JW 39 (Table 1, Figure 6).

At WCW in 2009, we were unable to install the weir until 30 August (JW 35) due to flow releases from Lewiston Dam to facilitate the Hoopa Valley Tribal Boat Dance.
Because of the relatively late start we did not trap any spring Chinook. Julian week 38 was our peak catch of fall Chinook with 61.8 fish trapped per night. The catch dropped off fairly dramatically after that, averaging fewer than 10 Chinook per night through the remainder of the season (Table 2, Figure 7). We removed the weir from the river, for the season, on 19 November (JW 47).

## Size of Trapped Fish

Spring Chinook trapped at JCW and TRH averaged 66.8 and 68.1 cm FL, respectively, with a combined average 68.0 cm FL (Figure 8, Appendix 4). The nadir between grilse and adult spring Chinook indicated a maximum grilse size of 49 cm FL. Data from known age, hatchery-marked spring Chinook that entered TRH reinforced a minimum adult fork length of 50 cm . There was no overlap between sizes of age 2 and age 3 fish (Appendix 2), though quite a bit of overlap was seen between the age 3, 4 and 5 fish. Applying the minimum adult size of 50 cm FL to observed populations of Chinook, an estimated $2.2 \%$ of the spring Chinook observed were grilse at JCW, and $3.5 \%$ at TRH. Historically, the maximum spring Chinook grilse FL averages 52 cm , and has only been greater than 56 cm once, since 1977.

Fall Chinook trapped at WCW and TRH averaged 64.8 and 69.3 cm FL, respectively, with a combined average FL of 68.7 cm . (Figure 9). The nadir between grilse and adult fall Chinook indicated a maximum grilse size of 54 cm FL. Data from known age, hatchery marked fall Chinook entering TRH supported this separation between grilse and adults; there was very little overlap between sizes of age 2 and age 3 fish (Appendix 3).

Using the maximum grilse size of 54 cm , fall Chinook grilse comprised $20.3 \%$ and $1.8 \%$ of the run observed at WCW and TRH respectively. The maximum grilse FL averages 54 cm over the 33 year period of record.

Figure 8. Spring Chinook fork lengths (cm) observed at Junction City weir, Trinity River Hatchery, and both sites combined during the 2009-10 season. The number of fish at each fork length is shown as a moving average of five, $1-\mathrm{cm}$ increments. The arrow denotes the size used to separate grilse and adults for analysis.

Figure 9. Fall Chinook fork lengths (cm) observed at Willow Creek weir and Trinity River Hatchery and both sites combined during the 2009-10 season. The number of fish at each fork length is shown as a moving average of five, $1-\mathrm{cm}$ increments. The arrow denotes the size used to separate grilse and adults for analysis.

## Effectively Tagged Fish

A total of 257 spring Chinook were trapped at JCW, of which 253 (9 grilse and 244 adults) were effectively tagged (Appendix 4). There were three tagging mortalities detected and one caught and released spring Chinook from which anglers reported removing tags (Appendix 8). A total of 81 (32.0\%) spring Chinook were tagged with reward tags ( 1 grilse and 80 adults); the remaining fish received non-reward tags. There were 22 (3 grilse and 19 adult) fall Chinook trapped at JCW in 2009, all of which were effectively tagged.

There were no spring Chinook trapped at WCW in 2009. A total of 1,190 fall Chinook were trapped at WCW, of which 1,166 were tagged. Of those 1,166 tagged fish (238 grilse and 924 adults), 1,148 of them ( 230 grilse and 918 adults) were effectively tagged (the number of effectively tagged fish excludes fish that were not tagged, tagging mortalities, and fish that had their tags removed by anglers (Appendix 5). There were one adult tagging mortality detected and 17 (eight grilse, nine adults) caught and released fall Chinook from which anglers reported removing tags (Appendix 9). Reward tags were placed on 377 ( 83 grilse and 294 adults), or $32.8 \%$, of the fall Chinook trapped at WCW; non-reward tags on the remaining fish ( 147 grilse and 624 adults).

## Incidence of Tags and Fin Clips

Ad-clipped fish comprised 13.2\% of the spring Chinook captured (34 of 257) at JCW, and $18.2 \%$ (4 of 22) of the fall Chinook (Appendix 4 and 5). Twenty one of the 34 adclipped spring Chinook ( $61.8 \%$ ) tagged at JCW were subsequently recovered at TRH (Table 3); 16 of those were released from the hatchery as yearlings in October 2007.

Of the 1,190 fall Chinook trapped at WCW, $8.8 \%$ (105) were ad-clipped (Appendix 5), and 293 ( $24.6 \%$ ) were later recovered at TRH (Table 3), 62 of which had ad-clips. Of the 62 TRH returnees, 60 were three year old fall Chinook, 38 of which were released in October of 2007, and 2 were four year olds released as yearlings in October 2006.

Incidence of Gill-net Wounds, Hook Scars, and Predator Wounds
Sixty-five (25.3\%) of the 257 spring Chinook trapped at JCW had gill net wounds, as did six ( $27.3 \%$ ) of falls. Crews also noted one old hooking scar, seven wounds of unknown origin and three predator wounds on spring Chinook at JCW, and three wounds of unknown origin on the JCW fall Chinook.

Of the 1,190 fall Chinook trapped at WCW 247 (20.7\%) had gill net wounds. Also observed were seven fish with new hooking wounds; 29 with unknown wounds; 50 with predator wounds; 12 with fungus; and nine with apparent disease.

Table 3. Release data and recoveries of coded-wire tagged (CWT) and maxillary-clipped salmon trapped in the Trinity River at Willow Creek weir (WCW) and Junction City weir (JCW), and subsequently recovered at Trinity River Hatchery (TRH) during the 2009-10 season.

a/ $f=$ fingerling; $y=$ yearling
b/ Fish with shed CWTs were designated as either spring or fall Chinook based on the date they were trapped at the weirs.
c/ Since 1996, all coho produced at TRH have received a right maxillary clip (RM). Coho < 54 cm FL were classified as brood year 2007 and coho >53 cm FL were classified as brood year 2006. Age cutoff based on fork length distribution.

## Coho Salmon

Run timing
No coho salmon were trapped at JCW in 2009. At WCW we trapped our first coho of the season during JW 37. The largest component of the coho run passed through the weir during JW 39, with a mean of 14.8 per night trapped, decreasing through the rest of the season (Table 4, Figure 10), with a sampling season mean of 3.5 fish trapped per night. A total of 202 coho salmon were trapped ( 105 grilse and 97 adults) at WCW during the 2009 season.

## Size of Trapped Fish

The average FL of coho trapped at WCW and TRH was 52.5 and 59.7 cm , respectively (Figure 11, Appendix 6). The size separating grilse from adult was based on the combined fork length data from coho salmon trapped at WCW and those that entered TRH. This year all coho salmon <54 cm FL were considered grilse. Grilse comprised $52.0 \%$ and $26.1 \%$ of the coho salmon trapped at WCW and TRH respectively.

## Effectively Tagged Fish

Of the 202 coho trapped at WCW, 186 ( 93 grilse and 93 adults) were effectively tagged (Appendix 6). Due to poor condition (wounds or other stressors) 14 coho trapped at WCW were not tagged. There is no legal recreational coho fishery, though two coho were caught and released by anglers (Appendix 10). To discourage anglers from targeting coho, all coho were tagged with non-reward tags.

## Incidence of Tags and Fin Clips

One hundred eighty four of the 202 (91.1\%) coho trapped at WCW (98 grilse and 86 adults) bore right maxillary (RM) clips (Appendix 6). Ninety seven of the WCW-tagged coho were recovered at TRH (Table 3).

## Incidence of Gill-net Wounds, Hook Scars and Predator Wounds

Gill net wounds were found on 12 of the coho trapped at WCW; 11 had unknown wounds; 20 had predator wounds; one had fungus, and two looked diseased.

a/ Trapping at Willow Creek weir took place from August 31 - November 19, 2009 (Julian weeks 35-47). b/ Coho < 54 cm FL were considered grilse.
c/ The right maxillary clipped fish are presented as a subset of the total grilse or adult coho caught.

Figure 10. Mean catch of coho trapped at Willow Creek weir during 2009.

Figure 11. Coho salmon fork lengths (cm) observed at Willow Creek Weir and Trinity River Hatchery and both sites combined during the 2009-10 season. The number of fish shown at each fork length is shown as a moving average of five, $1-\mathrm{cm}$ increments. The arrow denotes the size used to separate grilse and adults for analysis.

## Fall Steelhead

## Run Timing

At JCW, 56 ( 55 adult and one half-pounder) steelhead were trapped all season, of which 28 adults, and the one half-pounder, had ad-clips. Julian week 27 yielded the highest number of fish trapped (14), averaging 2.8 per night (Table 5, Figure 12). Adipose fin-clipped steelhead were again tagged at JCW in 2009; the results of this particular tagging are purely qualitative in nature. Of the 30 tagged fish, six were later recovered at TRH.

Sixteen hundred seventy four fall-run steelhead were trapped at WCW in 2009 (Table 6, Figure 13); 37 half-pounders ( $<42 \mathrm{~cm} \mathrm{FL}$ ) and 1,637 adults. The peak of the run was during JW 39 with an average of 66.8 fish per night trapped. The biggest week for halfpounders was JW 42, when 25 were caught; it was also the only Julian week in which more than four were caught.

## Size of Fish Trapped

Steelhead caught at JCW, WCW, and TRH averaged 58.6, 60.1 and 61.2 cm FL, respectively (Figure 14), with a mean combined FL for the three sites combined of 60.9 cm . Adult steelhead ( $>41 \mathrm{~cm} \mathrm{FL}$ ) made up $98.2 \%$ and $97.8 \%$ of the steelhead trapped at JCW, and WCW, respectively.

## Effectively Tagged Fish

Of the 1,637 adult steelhead trapped at WCW in 2009, 1,619 were tagged. Only adult fish were tagged. Twelve were not tagged due to poor condition and six were declared tagging mortalities (anytime a fish is found on the weir within 30 days of tagging and has not spawned it is considered a tagging mortality). Four of the six tagging mortalities, in addition to a DFG Project tag, received a radio tag in a cooperative study being performed by the Yurok Tribal Fisheries Department. Anglers reported removing tags from 182 caught and released fish, leaving 1,437 effectively tagged adult steelhead. One of the adult steelhead trapped wore a Project tags from the previous year. Of the 1,625 tagged fish, reward-tags were attached to 810 while the remainder (815) received non-reward tags.

## Incidence of Tags and Fin Clips

Ad-clips were found on 29 ( $51.8 \%$ ) of the steelhead at JCW, 1,204 (71.9\%) at WCW and $4,268(99.6 \%)$ at TRH (Appendix 7). Steelhead trapped at WCW were also noted as having other clips as well: 6 -left maxillary plus ad-clip; and 2 -right maxillary plus adclip. All steelhead released from TRH have been ad-clipped prior to release since brood year 1997.

Incidence of Gill-net Wounds, Hook Scars and Predator Wounds
At JCW one gill-net wound and two predator wounds were noted on steelhead in 2009. On the steelhead trapped at WCW we noted the following: 81 gill-net wounds; two old hooking scars; 19 fresh hooking wounds; 28 unknown wounds or scars; 161 predator wounds, one fish with fungus and one with disease.

## Brown Trout

## Capture Timing

During the 2009 sampling season, 169 brown trout were captured during 61 nights of trapping at JCW (Table 7, Figure 15). The highest catch occurred during Julian week 26 with a mean fish/night rate of 9.0. Only two brown trout were trapped at WCW during 2009.

## Size of Trapped Fish

Brown trout captured this season ranged in size from 31 to 70 cm FL (Table 8, Figure 16). Three brown trout tagged in previous years were recaptured at JCW in 2009, one tagged in 2005 (tagged at 43cm FL, recaptured at 56 cm FL) and two browns tagged in 2007 (each with about $6 \mathrm{~cm} /$ year increase in growth from the previous year).

## Effectively Tagged Fish

Of the 169 brown trout tagged at JCW in 2009, three were reported as caught/released by anglers, leaving 166 effective tags. One Project-tagged brown trout was reported as harvested. All of the brown trout at JCW were tagged with non-reward tags.

Incidence of Gill-net Wounds, Hook Scars and Predator Wounds
There were no gill-net wounds detected on brown trout at JCW in 2009, but nine of the fish had readily discernable lamprey wounds on them. One other wound of unknown origin was noted. Neither of the two browns trapped at WCW had distinguishing marks.

a/ Trapping at Junction City weir took place June 16 - September 30, 2009 (Julian weeks 24-39).

Figure 16. Fork length distribution of brown trout trapped at Junction City weir during 2009.

## Recovery of Tagged Fish

## Total Recoveries

Fish tagged at JCW and WCW were recovered from four different sources: Angler returns; upper Trinity River spawner surveys, Trinity River Hatchery, and tagging mortalities found on or near the tagging weirs. Length frequencies of spring and fall Chinook, coho, and steelhead tagged at the weirs and subsequently recovered are presented in Appendices 8-11.

Of the 279 tagged Chinook at JCW 47.7\% were recovered, whereas $34.0 \%$ of the 1,166 tagged WCW fall Chinook were recovered. Of the 188 coho tagged at WCW, 53.2\% were recovered, as were $37.0 \%$ of the 1,625 adult fall steelhead recovered throughout the Trinity basin. Most of the recoveries, for all species, occurred at TRH.

## Tag Returns by Anglers

Department of Fish and Game fishing regulations limit harvest each year, thereby affecting the return of tags. The adult fall Chinook sport quota for the Klamath River basin during the 2009-10 season was 30,800, split evenly between the lower (below the Highway 96 Bridge in Weitchpec) and upper basins. Thirty three percent of that 30,800 $(10,164)$ is the Trinity River sport allocation, which is split $50 / 50$ between two areas: Old Lewiston Bridge to Cedar Flat and Cedar Flat to the confluence of the Trinity and Klamath rivers. Anglers were allowed to retain two ad-clipped steelhead on the Trinity, only one on the Klamath. The take of coho was prohibited.

## Spring Chinook

Anglers returned five reward (zero grilse and five adult) and two ( zero grilse and two adult) non-reward tags from harvested spring Chinook tagged at JCW. Based on those tag returns, the estimated total harvest rate of Project-tagged spring Chinook upstream of JCW was 0\% for grilse, 2.9\% for adults. Anglers reported the catch and release of zero grilse and one tagged adult, and one found tag (with no fish still attached) (Appendix 8). The catch and release rate, therefore, for tagged adult spring Chinook was estimated at $1.2 \%$.

## Fall Chinook

Anglers returned nine reward (two grilse and seven adult) and seven (three grilse and four adult) non-reward tags from harvested fall Chinook tagged at WCW. Based on those tag returns, the estimated harvest rate of Project-tagged fall Chinook upstream of WCW was $2.2 \%$ for grilse and $1.2 \%$ for adults. Anglers reported the catch and release of three grilse and six adult reward-tagged fall Chinook from WCW, and five grilse and three adult non-reward tagged fish (Appendix 9). Using those numbers, the catch/release rates for fall Chinook upstream of the WCW were estimated at $3.4 \%$ of the tagged grilse and $1.0 \%$ of the tagged adults.

## Coho Salmon

To discourage the harvest of threatened coho salmon, all coho salmon tagged at WCW and JCW received non-reward tags. No tags were returned from any harvested grilse or adult coho salmon tagged at WCW, though we did receive two tags, one each from caught and released grilse and adult coho (Appendix 10). Catch and release rates for coho salmon above the WCW were estimated at $1.1 \%$ for both grilse and adults based on that return.

## Fall Steelhead

Anglers returned 264 tags from steelhead tagged at WCW. Of those 264 tags, 180 tags were from steelhead reported as caught/released, 81 from harvested fish, and 3 were tags found loose (not attached to a steelhead when found) (Appendix 11). Based on tag return, an estimated $11.2 \%$ of the tagged steelhead migrating upstream of WCW were caught and released, and an estimated $8.3 \%$ ( $10.3 \%$ of ad-clipped, $3.0 \%$ non-adclipped) of the (reward-tagged) steelhead were harvested.

## Brown Trout

All brown trout tagged at JCW received non-reward tags during 2009. Anglers returned one tag from a caught and released brown trout tagged during the season, one from a harvested fish, one tag found loose, and one tag was recovered in the upper main stem spawner surveys.

## Spawner Surveys

Main stem Trinity spawner surveys were conducted from September 14, 2009 to December 22, 2009 from TRH to Weitchpec. During the spawner surveys 11 spring and two fall Chinook tagged at JCW (Appendix 8), 69 fall Chinook tagged at WCW (Appendix 9), and 2 coho (Appendix 10) were recovered. There were no steelhead recovered in the spawner survey in 2009 (Appendix 11). For additional information on the 2009 spawner survey refer to Task 4 of this report.

## Trinity River Hatchery

## Operation Dates

The fish ladder and trapping facility at TRH were operated from September 08, 2009 (JW 36) through March 10, 2010 (JW 10). The ladder and trap were closed during parts or all of Julian weeks 41-43 to separate the spring and fall runs of Chinook. The ladder was also occasionally closed at the discretion of the hatchery manager for fish health concerns or labor constraints.

## Spring Chinook

Based on CWT recoveries, spring Chinook began entering TRH during JW 36 and continued through JW 42 (Figure 17, Table 9). Recovery of spring Chinook was at it's highest the first week TRH was open (JW 36) when 226 CWTed fish entered the facility and decreased thereafter with only six CWTs recovered in JW 41. Based upon CWT expansion, an estimated 3,033 spring Chinook entered TRH (Figure 17).

Of the 257 spring Chinook tagged at JCW, 105 (40.9\%) were recovered at TRH. The mean FL for effectively tagged JCW spring Chinook was 66.8 cm , whereas the spring Chinook recovered at TRH averaged 68.1 cm FL (Figure 8, Appendix 4). There were no spring Chinook tagged at WCW in 2009.

A total of 3,033 spring Chinook were recovered at TRH, from which 652 CWTs were recovered (Table 9). Spring Chinook age composition at TRH based on CWT analysis was $1.8 \%, 76.1 \%, 16.1 \%$, and $6.0 \%$ age $2,3,4$ and 5 year old fish, respectively (See Task 2 of this report).

## Fall Chinook

Based on the recovery of CWTs, the first fall Chinook entered TRH during JW 38 of 2009 (Figure 17, Table 11). The fall run peaked during JW 45 when an estimated 2,120 Chinook entered the facility, decreasing thereafter until the last Chinook entered during JW 2 of 2010. Using CWT expansions, an estimated 7,530 fall Chinook entered TRH.

There were 22 fall Chinook tagged at JCW in 2009. Two of those 22 (9.1\%) were recovered at TRH. Of the 1,166 tagged fall Chinook at WCW, 289 ( $24.8 \%$ ) were recovered at TRH. The mean FL for effectively tagged WCW fall Chinook was 64.8 cm while the mean FL for fall Chinook trapped at TRH was 69.3 cm (Figure 9). A total of 7,530 fall Chinook entered TRH, from which 1,613 CWTs were recovered (Table 11). Fall Chinook age composition at TRH based on CWT analysis was $2.3 \%, 90.8 \%, 6.4 \%$, and $0.5 \%$ age $2,3,4$, and 5 year old fish, respectively.

Figure 17. Estimated numbers of spring and fall Chinook that entered Trinity River Hatchery during the 2009-10 season, based on expansion of coded-wire tagged fish.

Table 9. Recoveries at Trinity River Hatchery of coded-wire tagged spring Chinook during the 2009-10 season

a/ The fish ladder was open September 08, 2009 through March 10, 2010 (JW s 36-10; closed parts or all of JW s 41-43).
b/ Entry week was the week that fish were initally sorted; they may have actually entered the hatchery during the previous sorting week.
c/ Release types are either fingerling (f) or yearling (y).
d/ The hatchery was closed to fish entry this week.
e/ No CW T's were recovered from these ad-clipped fish. Chinook with shed or lost tags recovered after October 14 , 2009 (JW 41 ) were considered fall run

a/ The fish ladder was open September 08, 2009 through March 10, 2010 (JWs 36-10; closed parts or all of JWs 41-43).
b/ Entry week was the week that fish were initally sorted, although they may have actually entered the hatchery during the previous sorting week.
c/ Release types are either fingerling (f) or yearling (y).
d/ The hatchery was closed to fish entry this week.
e/ No CWTs were recovered from these ad-clipped fish. Chinook with shed or lost tags recovered after October 21, 2009 (JW 42) were considered fall Chinook.

## Coho Salmon

The first coho entered TRH during JW 40 of 2009. The coho run peaked during JW 47 and the last coho entered TRH during JW 3 of 2010 (Table 12). A total of 3,351 coho ( 2,477 adults and 874 grilse) were recovered at TRH the season. Ninety seven of the 202 coho trapped at WCW were recovered at TRH (52.1 \% of those effectively tagged). The mean FL of coho trapped at WCW was 52.5 cm and the mean FL of all coho salmon recovered at TRH was 59.7 cm (Appendix 6).

Of the 3,351 coho entering TRH, 3,261 (97.3\%) were observed to have right maxillary (RM) clips, indicating they were of TRH origin, while 90 (2.7\%) had no clips. These unclipped fish are believed to be either naturally produced coho salmon which entered the hatchery or TRH-produced fish which received no or poor clips prior to release from the hatchery (Table 12).

Based on length frequency analysis, TRH-produced, RM-clipped coho salmon were apportioned into two brood years. Coho salmon $\leq 54 \mathrm{~cm}$ FL were considered grilse (age 2) from the 2007 brood year and accounted for $26.1 \%$ of the total, while the remaining 2,477 ( $73.9 \%$ ) were considered adults (age 3) from the 2006 brood year. The 90 non- RM clipped coho which entered the hatchery were also considered grilse or adults based on their length (Appendix 6).

## Fall Steelhead

Steelhead were recovered almost every week that the fish ladder and trap at TRH was open, though they did not arrive in sizeable numbers until the last week of October (JW 43) (Table 13). A total of 4,251 adult steelhead ( $>41 \mathrm{~cm}, \mathrm{FL}$ ) entered TRH during the season. Of the 1,437 adult fall steelhead effectively tagged at WCW, 332 were recovered at TRH (Table 13, Appendix 7). The mean FL of effectively tagged steelhead at WCW was 60.1 cm and the mean FL of all adult steelhead recovered at TRH was 61.2 cm

Ad-clipped adults composed 72.0\% of the steelhead trapped at WCW (1,204 of the $1,674)$ and $99.6 \%(4,268 / 4,287)$ of the steelhead that entered TRH this season (Appendix 7). Beginning with the 1997 brood year, all steelhead released from TRH have been ad-clipped prior to their release.

c/ Entry week was the week the fish were initially sorted, although they may have actually entered the hatchery during a previous sorting week.

## Run-size, Angler Harvest, and Spawner Escapement Estimates

## Spring Chinook Salmon

An estimated 7,426 (7,166 adults and 260 grilse) spring Chinook migrated into the Trinity River basin upstream of JCW. Based on the Poisson Approximation, the 95\% confidence interval for the spring Chinook run-size estimate was 6,166-9,054 (Table 14). Spawning escapement above JCW was estimated at 6,724 adult fish, including 3,000 spring Chinook that entered TRH (Table 15). This year's run-size estimate is $42.3 \%$ of the 30 year average spring Chinook run-size of 17,553. Estimated spring Chinook run-size has ranged from 2,381 fish in 1991 to 62,692 fish in 1988 (Appendix 12). Anglers were estimated to have caught and kept 442 adults and zero grilse from the spring run (Table 15).

## Fall Chinook Salmon

An estimated 29,593 (23,575 adults and 6,018 grilse) fall Chinook migrated into the Trinity River basin upstream of WCW. Based on the Poisson Approximation, the 95\% confidence interval for the fall Chinook run-size estimate upstream of WCW was 26,449-33,293 (Table 14). Trinity River fall Chinook spawner escapement, upstream of WCW, was estimated at 28,889 (5,873 grilse, 23,016 adult) fish, including 7,494 fall Chinook that entered TRH (Table 15). Harvest rates generated from tags applied at WCW were used to estimate 145 grilse and 559 adult fall Chinook harvested by anglers. The estimated total fall Chinook run-size, upstream of WCW, has ranged from 9,207 fish in 1991 to 147,888 fish in 1986 (Appendix 13). This year's fall Chinook estimated run-size of 29,593 fish is $70.4 \%$ of the 42,028 fish mean run-size for all the years since 1977.

## Coho Salmon

An estimated 6,396 (4,634 adults and 1,762 grilse) coho migrated into the Trinity River basin upstream of the WCW in 2009. Based on the Poisson Approximation, the 95\% confidence interval for the coho run-size estimate upstream of WCW was 5,271-7,846 fish (Table 14). Of those estimated 6,396 fish, 2,477 adults are estimated to have entered TRH (Table 15). Estimated coho salmonrun-size, upstream of WCW, has ranged from 852 fish in 1994 to 59,079 fish in 1987 (Appendix 14). This year's run-size estimate was $36.9 \%$ of the 17,316 fish 33 -year average. No tags were returned from harvested coho; therefore harvest rates generated from tags applied at WCW were estimated to be zero for both grilse and adults (Table 15).

## Adult Fall Steelhead

An estimated 18,361 adult fall steelhead migrated upstream of WCW this season. The 95\% confidence interval for the estimate, based on the Normal Approximation, was 16,519-20,306 adult steelhead (Table 14). The adult steelhead spawning escapement was estimated at 16,831 , of which 4,251 entered TRH. An estimated 154 naturallyproduced and 1,376 TRH produced steelhead were harvested by anglers above WCW (Table 15). In the 26 years for which we have data since 1980, run-size estimates have ranged from 2,972 in 1998 to 53,885 in 2007 (Appendix 15). The mean estimated run-
size for fall adult steelhead in the Trinity River above WCW across the period of record is 14,946 fish. This year's run was $122.8 \%$ of the average.

Table 14. Run-size estimates and $95 \%$ confidence limits for Trinity River basin spring and fall Chinook and coho salmon, and adult fall steelhead during the 2009-2010 season.

| Species/ <br> race | Area of Trinity River basin for run-size estimate | Stratum ${ }^{\text {a }}$ | Number effectively tagged ${ }^{\text {b }}$ | Trinity River Hatchery recoveries |  | Run-size estimate ${ }^{\text {d }}$ | Confidence limits$1-p=0.95$ | Confidence limit estimator |

|  |  | Total | 186 | 3,351 | 97 | 6,396 |  |  |
| Fall run steelhead | Upstream of Willow Creek weir | Adults | 1,437 | 4,251 | 332 | 18,361 | 16,519-20,306 | Normal Approx |

a/ Stratum: Grilse = two year old salmon; Adults = three years or older; Steelhead adults = fish greater than 41 cm FL.
b/ The number of effectively tagged fish was corrected for tagging mortalities, fish not tagged and fish which had their tags removed (caught and released).
c/ Numbers of spring and fall Chinook were estimated from expansion of coded wire tag recoveries at Trinity River Hatchery; coho and steelhead numbers were actual recoveries.
d/ Run-size estimates for coho were based on the proportion of grilse to adults observed at Willow Creek weir and Trinity River Hatchery combined; for spring Chinook on Junction City weir grilse/adult ratio only; and fall Chinook on the Willow Creek weir ratio.

Table 15. Estimates of Trinity River basin spring and fall Chinook and coho salmon, and adult fall-run steelhead run-size, angler harvest, and spawner escapement during the 2009-10 season.

|  | Willow Creek weir | Hatchery | 13,314 | 10.3\% | 1,376 | 7,704 | 4,234 | 11,938 |
|  |  | Total | 18,361 |  | 1,530 | 12,580 | 4,251 | 16,831 |

[^3]b/ Harvest rates were based on the return of reward tags for fall and spring Chinook and steelhead. There was no coho harvest.
c/ Calculated as the run-size times the harvest rate.
d/ Calculated as run-size minus angler harvest minus hatchery escapement. Natural area spawners includes both wild and hatchery fish that spawn in areas outside Trinity River Hatchery.

## DISCUSSION

The yearly water allocation (flow and schedule) adopted by the Bureau of Reclamation, after input from the Trinity Management Council, had the river at a level conducive to mid-June installation of the JCW, a month earlier than the previous year. The State of California Governor-mandated furloughs made sampling more than four days a week at Junction City problematic. We were able generally to maintain our standard five day a week sampling schedule at WCW, at least when storm-fed flows did not require that conduit be pulled.

The larger than normal (3000 cfs in 2009 v. 1860 cfs in 2007) late-August HVTF Ceremonial Boat Dance flows necessitated temporary removal of the weir at Junction City and the late installation of WCW, reducing the number of overall trap days. The rain storm (high water) event and conduit pull in mid-October may have resulted in missed fish, but both the Chinook and coho runs had peaked weeks prior to that time (and JCW was already out for the season) so we likely only missed a pulse of steelhead. With a wet storm looming on the horizon, and reduced catch of all target species, we pulled WCW for the season on November 19, 2009.

The extremely strong grilse component to both the spring and fall Chinook runs in 2008 did translate into a robust three year-old Chinook cohort in 2009 (76.1 \% of the springs and $90.8 \%$ of the falls), the size of the runs were not great, however, at $42.3 \%$ and $70.4 \%$ of average for the 33 year data set, spring and fall, respectively. The coho fared even less well at only $36.6 \%$ of the average run size, while the steelhead run was once again the strongest of the four runs at $123 \%$ of average (ranking $9^{\text {th }}$ of 23 years on record).

We again saw much larger numbers of grilse at WCW this year than at TRH (20.3\% of Chinook at WCW versus $1.9 \%$ at TRH), though nothing close to the nearly $52 \%$ observed at WCW in 2008. Until we have established, or re-established, monitoring on tributary streams we will have to continue to assume that those "excess" grilse are likely natural-produced fish headed into the South Fork Trinity, the New River and other tributaries. The fact that such a small percentage of them were ad-clipped (1.2\% grilse versus $10.8 \%$ of adults) supports that assumption. It is not surprising so few grilse enter TRH as there is a standing policy to spawn them only if no other milt is available, thereby effectively selecting against that life-history type.

Too few grilse spring or fall Chinook or coho salmon were tagged to generate independent estimates for adults and grilse, therefore we used numbers of adults and grilse combined to generate the total tagged, total recaptured and total recovered fish when calculating spawning escapement and run-size estimates for each species or race. For spring Chinook the total run-size estimate was stratified based on the ratio of adults and grilse observed at JCW and TRH combined, for fall Chinook the estimate was not stratified, but was based on the WCW grilse/adult ratio only. For coho the
division between grilse and adult was made purely by length frequency. The steelhead estimates above WCW are for adults only.

There were no coho caught at JCW in 2009. The WCW was installed prior to the arrival of the coho salmon run, which was concentrated in Julian weeks 38 through 43. We only caught five coho in the two final weeks of sampling. Slightly more than half of all WCW-tagged coho were eventually recovered at TRH, and all of those fish were RMclipped (hatchery-origin) fish. There were no WCW-tagged coho trapped at TRH after JW 51, and the last coho of the season was trapped at TRH JW 3.

Unaccounted tagging mortality creates a positive bias in all mark-recapture studies (Hankin 2001). We attempt to account for tagging mortalities through recovery of tagged fish found dead at the weirs and in carcass surveys, although we are sure that not all tagging mortalities are found. Most of our tagging mortalities from WCW are observed during the early part of the season when water temperatures are high (near $22^{\circ} \mathrm{C}$ ). We believe that tagging mortality is not a constant rate and is a function of water temperature. This postulation leads to difficulty in applying a potential tagging mortality rate for the season. Hankin (2001) concluded that tagging mortality could substantially positively bias our estimates. Using Hankin's example: If 90\% of untagged fish passing WCW survive to arrive at TRH (assuming that they are otherwise programmed to arrive at that destination), but only $75 \%$ of WCW tagged fish survive to arrive at TRH, then the approximate positive proportional bias would be almost $30 \%$. We have attempted to address this concern through our tagging protocol at the weirs. Fish are not tagged if deemed in poor condition or if they have already spawned, and trapping is suspended if water temperatures exceed $21^{\circ} \mathrm{C}$. We identified 10 total tagging mortalities ( $0.3 \%$ ) out of more than 3,323 fish handled at the two weirs; four of those mortalities were ad-clipped steelhead radio-tagged by Yurok Tribal Fisheries Department staff engaged in a straying study (for more information on that study contact Kyle DeJulio at YTF).

Before the 2000 Record of Decision, spring flow releases from Lewiston Dam were much lower than currently-mandated flows. JCW was historically installed in the beginning of May, trapping peak numbers of spring Chinook in late May and early June. Now, depending upon the water year classification and resulting flow regime, JCW is unable to be installed prior to mid-June or July, when Lewiston Dam releases allow the Trinity River main stem flows to recede below 800 cfs at Junction City. We hope to soon have a resistance board weir installed in lieu of the Alaskan-style JCW, a move we are anticipating will allow for a longer, more effective sampling season.

## RECOMMENDATIONS

1. Tagging and recapture operations for adult spring and fall Chinook and coho salmon, and adult fall steelhead in the Trinity River basin should be continued during the migration season, using the capture sites near Willow Creek and somewhere above the North Fork Trinity or Junction City.
2. Funding for re-instated monitoring of the South Fork Trinity River should be sought/identified/acquired. It is the largest tributary in the Trinity River Basin and has great production potential for fall Chinook and steelhead.

a/ Trapping at JCW took place June 16 - September 30, 2009 (Julian weeks 24 - 39). All Chinook trapped at JCW were considered spring Chinook. There were no spring Chinook trapped at WCW in 2009.
b/ Ad-clip = Adipose fin clipped fish.
c/ Number of effectively tagged fish excludes fish not tagged, tagging mortalities, and fish that had their tags removed (caught/released).
d/ Spring Chinook less than 50 cm FL were considered grilse.

${ }^{\text {a }}$ Trapping at WCW took place August 31 - November 19, 2009 (Julian weeks 35-47). The fish ladder was open September 08, 2009 - March 10, 2010 (closed all or parts of JW 41-43).
${ }^{\text {b }}$ Ad-clips= Adipose fin-clipped fish.
${ }^{\text {c }}$ Other clips included: 1-left maxillary, 1-left maxillary + ad-clip, and 1-right maxillary clip.
${ }^{d}$ Number of effectively tagged fish excludes those not tagged, tagging mortalities, and fish that had their tags removed (caught and released).
${ }^{e}$ Steelhead less than or equal to 41 cm FL were considered half-pounders. Only adult steelhead ( $>41 \mathrm{~cm}$ ) were tagged at WCW.

Appendix 8. Fork length (FL) distribution of Chinook salmon tagged at Junction City weir and subsequently recovered during the 2009-10 season. ${ }^{\text {a }}$

a/ Trapping at Willow Creek took place August 31 - November 19, 2009 (Julian weeks 35-47).
b/ Tagged fish found dead and unspawned within 30 days of tagging.
c/ Fish recovered in upper Trinity River carcass surveys. There were no steelhead recovered in the 2009 survey.
d/ The fish ladder was open September 08, 2009 - March 10, 2010 (closed all or parts of JW 41-43).
e/ Fish reported as caught and released by anglers.
$\mathrm{f} / \mathrm{Fish}$ reported as harvested by anglers.
$\mathrm{g} /$ Tags found on dead fish or found unattached.

Appendix 12. Spring Chinook run-size, spawner escapement, and angler harvest estimates for the Trinity River upstream of Junction City weir from 1977 through 2009.

Natural area spawners includes both wild and hatchery fish that spawn in areas outside Trinity River Hatchery.
b/ The 1978 sport harvest of spring Chinook was limited by a salmon fishing closure beginning August 25, 1978.
c/ The sport harvest of adult spring Chinook was subject to seasonal and size limit restrictions.

Appendix 12 (continued). Spring Chinook run-size, spawner escapement, and angler harvest estimates for the Trinity River upstream of Junction City weir from 1977 through 2009.

- 64 -

Appendix 13. Fall Chinook run-size, spawner escapement, and angler harvest estimates for the Trinity River upstream of Willow Creek weir from 1977 through 2009.

Natural area spawners includes both wild and hatchery fish that spawn in areas outside Trinity River Hatchery.
b/ The 1978 sport harvest of fall Chinook was restricted by a salmon fishing closure beginning August 25, 1978.
c/ The sport harvest of adult fall Chinook was subject to seasonal and size limit restrictions.
d/ The 1999-2008 sport harvest of Klamath Basin fall Chinook was managed with a quota system. The quota for adult fall Chinook was 957 in 1999; 693 in 2000; 9,834 in 2001; 6,926 in 2002; 10,800 in 2003; 4,700 in 2004 1,262 in 2005, zero in 2006, 10,600 in 2007, 20,500 in 2008, and 30,800 in 2009.

Appendix 13 (continued). Fall Chinook run-size, spawner escapement, and angler harvest estimates for the Trinity River upstream of Willow Creek weir from 1977 through 2009.

Appendix 14. Coho salmon run-size, spawner escapement, and angler harvest estimates for the Trinity River upstream of Willow Creek weir from 1977 through 2009.

#### Abstract

Recovery of marked spring-run (spring) and fall-run (fall) Chinook salmon (Oncorhynchus tshawytscha) at Trinity River Hatchery (TRH) was conducted between September 8, 2009 and March 10, 2010. Of the 10,564 Chinook salmon that entered TRH, we recovered 2,433 adipose fin-clipped (AD) Chinook salmon, 23.0 \% of the total. Of these, coded-wire tags (CWT) were recovered from 652 spring Chinook and 1,613 fall Chinook salmon.

We estimated that 979 marked (AD+CWT) spring Chinook returned to the Trinity River upstream of the Junction City weir (JCW) and 2,466 marked fall Chinook returned to the Trinity River upstream of the Willow Creek weir (WCW) during the 2009-10 season.

Estimated in-river run-size, angler harvest, and spawner escapements of marked TRH spring and fall Chinook salmon for the 2004 through 2007 brood years (BY's) are presented. Complete returns are only available for both runs of fish from the 2004 BY. These fish have reached age five and are considered to have completed their life cycle. Chinook in-river return rates (expressed as a percentage of release numbers) for the completed 2004 BY ranged from $0.685 \%$ to $0.968 \%$ for spring Chinook fingerling CWT groups and $0.432 \%$ to $0.91 \%$ for fall Chinook fingerlings. Returns of spring Chinook released as yearlings was estimated at $1.22 \%$, while fall Chinook yearlings returned at a rate of 1.79\%.

Total spring Chinook run-size, upstream of Junction City Weir, was estimated to be composed of 3,973 (53.5\%) Trinity River Hatchery produced fish and 3,453 naturally produced fish. Similar estimates for fall Chinook, upstream of Willow Creek Weir, were 10,072 (34.0\%) hatchery produced fish and 19,521 naturally produced fish.

## TASK OBJECTIVES

To determine relative return rates and the contribution to spawning escapement and inriver sport fisheries made by Chinook salmon produced at Trinity River Hatchery, and to evaluate experimental hatchery management practices aimed at increasing adult returns, while reducing competition among wild fish.

## INTRODUCTION

During the period of June 17, 2009 through March 10, 2010, the California Department of Fish and Game's (CDFG) Trinity River Project recaptured Chinook salmon returning to the Trinity River at two temporary main stem weir sites and Trinity River Hatchery (TRH) from previously marked brood years (BY's). Marked Chinook (AD+CWT) were identified by an adipose fin-clip (AD). These fish were implanted with a binary codedwire tag (CWT) prior to their release from TRH as either smolts or yearlings. Both spring-run (spring) and fall-run (fall) Chinook were representatively marked at a rate of approximately $25 \%$. Prior to 1995, the CDFG was responsible for the coded-wire tagging program at TRH. Beginning in 1995, the coded-wire tagging program at TRH has been conducted by the Hoopa Valley Tribal (HVT) Fisheries Department. Due to the change in responsibilities, the Department will no longer report on the juvenile tagging effort at TRH. Our efforts are directed at the recovery of these coded-wire tagged fish and analyzing the information derived from their recovery. This study is a continuation of previous studies conducted by the CDFG and is reliant on data presented in Sinnen 2000, 2002, 2004a, 2004b, 2005, 2006, 2008, 2009, 2010.

## METHODS

## Marking of Chinook Salmon at Trinity River Hatchery

As previously mentioned, the HVT representatively marks (AD+CWT) approximately $25 \%$ of all Chinook salmon at TRH. As such, the HVT is responsible for conducting quality control to ascertain the true number of marked individuals after subtracting for fish with shed tags, poor Ad-clips and mortalities. The estimated number of fish marked correctly is recorded on standard release forms and sent to the DFG tagging coordinator for dissemination. The release forms detail the number of fish marked, the corresponding CWT tag code used for individual lots of fish and the estimated number of un-marked fish that are part of the lot. The number of marked fish plus the number of un-marked fish are summed and then divided by the number of marked fish to produce an expansion multiplier. The multiplier is used to estimate the number of hatchery produced fish for each CWT recovery (i.e. approximately 4 for every recovery). TRP staff maintain a file of all CWT codes, the corresponding biological information (species,
brood year, race, size at release, date of release) and the expansion for each code. This information is then used to develop total hatchery contribution rates for escapement and harvest above weir sites in the Trinity Basin.

## Main Stem Weirs

We examined all salmon captured at two main stem Trinity River weirs (near the towns of Willow Creek and Junction City). The upper site, Junction City weir (JCW), was located approximately 47 KM downstream of Lewiston Dam, the uppermost point of anadromy. The lower site, Willow Creek weir (WCW), was located 143 KM downstream of Lewiston dam and approximately 36.5 KM upstream of the Trinity River and Klamath River confluence near Weitchpec.

Both weirs are operated to capture a sample of migrating salmon and steelhead for the purpose of estimating in-river run-size of spring and fall Chinook salmon, coho salmon and fall-run steelhead using mark-recapture methods (See Task 1 of this report for complete methods and results). The JCW is operated to estimate spring Chinook runs while WCW is utilized to estimate runs of fall Chinook, coho and fall-run steelhead runs. At both weir sites all Chinook captured are examined for the presence or absence of adipose fins, as well as other biological information such as length, scarring, predator wounds, etc. A missing adipose fin (AD-clip) indicates the fish is of hatchery origin and may contain a coded-wire tag (CWT), implanted as juveniles prior to their release from Trinity River Hatchery. The CWT code identifies the race, release type (fingerling or yearling) and brood year of each fish. Each Chinook that is deemed in good condition is tagged with a serially numbered floy tag (project tag) and immediately released. After the weirs are removed for the season the number and ratio of Ad-clipped to non-clipped Chinook salmon used to estimate the proportion of each run that is of hatchery origin. Cohort tables are maintained for in-river returns of hatchery produced Chinook salmon.

## Coded-Wire Tag Recovery

## Trinity River Hatchery (TRH)

All Chinook salmon which enter TRH are examined for Ad-clips and Project tags, as well as other biological information. All Chinook salmon with Ad-clips are given a unique head tag number and the head of that salmon is removed, placed into a bag with the head tag, and stored in a freezer for later dissection, CWT extraction and decoding in the laboratory.

## Chinook Salmon CWT Dissection

Heads from Chinook salmon recovered at TRH are processed in our office lab. The process for dissection is the following: 1. Heads and corresponding head tag numbers are removed from the storage bag one at a time. 2. Each head is run through a Northwest Marine Technologies FSD-I field metal detector. A beep from the machine indicates the presence of the tag or any other metal. 3. The head is cut into smaller pieces and passed through the detector until a small piece of head is left that contains the tag. The tag can then be visually detected and removed using a magnetized pencil.
4. The tag is placed into a $2 \times 3$ inch sealed baggie and is stapled to the corresponding head tag. If no tag is detected in the initial and subsequent passes through the metal detector, then it is assumed the fish had shed its tag prior to recovery at TRH. In this case, a code (100000) is assigned to the head tag. If the tag was initially detected but lost during the dissection process a separate code (300000) was assigned to the head tag to indicate such.

All CWTs recovered during the dissection were read using a Nikon SMZ-1 Stereozoom microscope equipped with a 10X widefield eyepiece. The microscope has a continuous magnification zoom range of 7 X to 30X. The code was identified and transferred to the head tag. All head tags and corresponding CWT codes were entered into a database and merged into the TRH recovery database based on the common "head tag" field. Thus, each CWT code, along with the corresponding release information and TRH recovery information was a single record in our database ready for pertinent analysis.

## Estimation Techniques

The information needed to estimate the numbers of salmon of a specific CWT group that returned to the Trinity River basin and contributed to the fisheries and spawner escapement are: 1) Grilse and adult total run-size, 2) Angler harvest rate of grilse and adults, 3) Proportion of the run comprised of marked fish, and 4) Proportion of CWT groups recovered at TRH. Independent estimates of spring and fall Chinook run-size and angler harvest rates for each race of Chinook are required. Methods to determine total run-size and angler harvest rate estimates were presented in Task 1 of this report.

To estimate the number of grilse and adult salmon above a specific weir site with a CWT, we used the equation:

$$
\mathrm{N}_{\mathrm{CWT}}=\frac{\mathrm{NW}_{\text {ADclip }}}{\mathrm{NW}} \times \frac{\mathrm{NH}_{\text {ADCWT }}}{N H_{\text {ADClip }}} \times \mathrm{N}_{\text {run-size estimate }}
$$

where, $\mathrm{N}_{\mathrm{CWT}}=$ estimated number of Chinook salmon above the weir with a CWT; $\mathrm{NW}_{\text {ADclip }}=$ number of salmon observed at the weir with an AD clip; NW = total number of salmon observed at the respective weir; $\mathrm{NH}_{\text {ADCwT }}=$ number of salmon observed at TRH with an AD clip and a CWT; $\mathrm{NH}_{\text {ADclip }}=$ total number of AD-clipped salmon observed at TRH; and $\mathrm{N}_{\text {run-size estimate }}=$ run-size estimate. Independent estimates were generated for grilse (2-year-old) and adult (ages 3-5) salmon.

Using the various CWT groups recovered at TRH, we estimated the fraction of the population upstream of the weir with a specific CWT with the equation:

$$
\mathrm{F}_{\mathrm{CWT} \text { group }}=\frac{\mathrm{NH}_{\mathrm{CWT} \text { group }}}{\mathrm{NH}_{\mathrm{ADCWT}}}
$$

where, $\mathrm{F}_{\mathrm{CWT} \text { group }}=$ fraction of the salmon population with a specific CWT code; and $\mathrm{NH}_{\mathrm{CWT}}$ group $=$ number of salmon observed at TRH with a specific CWT code; and $\mathrm{NH}_{\text {ADCWT }}=$ number of salmon observed at TRH with an AD clip and a CWT.

We estimated the total number of grilse and adult Chinook salmon upstream of the weir with a specific CWT code with the equation:

$$
N_{\text {CWT group }}=N_{\text {CWT }} \times X \quad F_{\text {CWT group }}
$$

where, $\mathrm{N}_{\mathrm{CWT} \text { group }}=$ estimated total number of salmon of a specific CWT group.
The estimated number of fish from each CWT group caught in the Trinity River sport fishery upstream of the weir was then estimated by the equation:

$$
\mathrm{SF}_{\mathrm{CWT} \text { group }}=\mathrm{N}_{\mathrm{CWT} \text { group }} \times \quad \mathrm{N} \text { harvest rate estimate }
$$

where, $\mathrm{SF}_{\mathrm{CWT} \text { group }}=$ number of salmon of a specific CWT group caught in the Trinity River sport fishery; and $\mathrm{N}_{\text {harvest rate estimate }}=$ harvest rate estimate.

We estimated the total number of fish of a specific CWT code group available to the spawner escapement by the equation:

$$
\mathrm{N}_{\mathrm{CWT} \text { escapement }}=\mathrm{N}_{\mathrm{CWT} \text { group }}-S \mathrm{~F}_{\mathrm{CWT} \text { group }}
$$

where, $\mathrm{N}_{\mathrm{CWT} \text { escapement }}=$ the total number of salmon of a specific CWT group available to the spawner escapement.

The estimated number of salmon of specific CWT code group available to natural spawner escapement was:
$\mathrm{N}_{\mathrm{CWT} \text { natural escapement }}=\mathrm{N}_{\mathrm{CWT} \text { escapement }}-\mathrm{NH}_{\mathrm{CWT} \text { group }}$
where, $\mathrm{N}_{\mathrm{CWT} \text { natural escapement }}=$ the estimated number of a specific CWT group contributing to natural spawning escapement.

As stated above, estimating the total return of individual CWT groups depends on a basin run-size estimate. In evaluating the return of CWT hatchery Chinook, we normally report on the individual year's return along with a summary of each CWT group throughout their five-year life cycle.

Total run-size and CWT return estimates for spring and fall Chinook are calculated for the Trinity River upstream of the JCW (river km [RKM] 137.1) and the WCW (RKM 36.4), respectively. Escapement and harvest and corresponding CWT estimates for natural escapement areas below the respective weirs and harvest in the ocean are not included in the estimates presented in this report.

In this report, we present estimated contribution rates of TRH-produced Chinook salmon to total spring and fall Chinook run-sizes. This is accomplished by expanding each of the individual CWT estimated run-sizes by its corresponding hatchery expansion factor (total releases represented by each CWT release group/CWTed fish released). In doing this, we assume that marked fish are representative of their unmarked counterparts.

## RESULTS

## Coded-Wire Tag Recovery

We recovered 10,564 Chinook salmon at TRH this season, of which 2,433 (23.0\%) bore AD-clips. We recovered CWTs from 652 known spring Chinook and 1,613 known fall Chinook (Table 1). The remaining 168 AD-clipped fish had either shed their CWT (134) or the CWT was lost or unreadable (34). Chinook with shed, lost, or unreadable CWTs were classified as either spring- or fall-run based on their date of entry into TRH.

Spring Chinook CWTs were represented by 23 release groups from the 2004 through 2007 BY's. Fall Chinook CWTs were composed of 18 groups representing the 2004 through 2007 BY's (Table 1).

## Run-size, Angler Harvest, and Escapement of Coded-wire Tagged Salmon

## Spring-run Chinook Salmon

Based on estimated total Chinook run-size above JCW, the AD-clip rate of spring Chinook at JCW, the estimated angler harvest rate, and recovery of spring-run CWT fish at TRH, we estimated that 979 ( 21 grilse and 959 adults) CWTed spring Chinook salmon returned to the Trinity River above JCW during the 2009 season (Table 2).

An estimated 59 adult and zero grilse CWTed fish were harvested by anglers during the season. Escapement of CWTed spring Chinook was divided between 652 fish recovered at TRH and 268 estimated to have spawned in natural areas (Table 2). The year's run of known aged CWTed spring Chinook was composed of the following: 21 (2.2\%) age 2; 742 (76.0\%) age 3; 155 (15.9\%) age 4; and 58 (5.9\%) age 5 fish (Table 2).

## 2004 Brood Year

Four spring Chinook CWT groups from the 2004 BY completed their life cycle this season, having reached the age of five. Cumulative age two through five in-river return rat estimates, expressed as a percentage of release numbers, ranged from $0.685 \%$ to $0.968 \%$ for fingerling release groups. The one yearling release group, 065326, experienced a return rate of $1.22 \%$ (Table 3). Thus, yearlings returned at a rate approximately twice If that of their fingerling released cohorts. All release types experienced their highest returns as age three fish, although similar returns were noted for age three and four-year old fish from the yearling release group.

## 2005 Brood Year

Spring Chinook from the 2005 brood year will complete their life cycle next year. To date, fish from this brood have returned through age four. Both fingerling and yearling release groups have experienced poor returns (less than $0.2 \%$ to date), which is approximately 3 times less than the completed 2004 BY returns (Table 3). It is not expected that return rates for this brood will increase much since the age five component is historically very small for Trinity River Hatchery Chinook stocks.

## 2006 Brood Year

Spring Chinook from the 2006 brood year have returned as age two and three thus far. Based on early returns ranging from $0.055 \%$ to $0.642 \%$, this brood is appears to be stronger than 2005 BY spring Chinook (Table 3), particularly the yearling group (065360).

## 2007 Brood Year

Three 2007 BY release groups (2 fingerling and 1 yearling) returned as two-year-olds this season. Thus far, the yearling CWT group, 068810, has experienced the highest return rate (Table 3). Spring Chinook from this BY are expected to return as three through five-year-olds during the next three years.

## Fall-run Chinook Salmon

Based on estimated total Chinook run-size above WCW, the ad-clip rate of fall Chinook at WCW, the estimated angler harvest rate, and recovery of fall-run CWTed fish at TRH, we estimated that 2,466 CWTed fall Chinook salmon returned to the Trinity River above WCW during the 2009-10 season. We estimated that anglers harvested 2 grilse and 57 adult CWTed fall Chinook. Escapement of CWTed fall Chinook was divided between 1,613 fish recovered at TRH and 795 estimated to have spawned in natural areas this season (Table 2).

The fall Chinook CWT run was composed of 70 (2.8\%) age 2 fish, 2,226 (90.5\%) age 3 fish, 158 ( $6.4 \%$ ) age 4 fish, and 14 ( $0.57 \%$ ) age five fish (Table 2).

## 2004 Brood Year

The 2004 BY releases were composed of six fingerling and one yearling release groups and have completed their life cycle this season, having reached the age of five. Return rates for fingerling releases ranged between $0.043 \%$ and $0.092 \%$. The lone yearling group, 065327 returned at a rate of $1.79 \%$, which is approximately two and half times that of the mean fingerling group return rates (Table 4). All Chinook from the 2004 BY experienced their highest returns as three-year-old fish (Table 4).

## 2005 Brood Year

The 2005 BY is represented by six CWT groups, of which five are fingerling groups and one a yearling group. In contrast to the good returns of the 2004 BY releases, fall Chinook from the 2005 BY are returning at a much lower rate. Through age four returns, all groups have returned at rates less than 0.3\% (Table 4). Age three returns have been the most numerous for all release types to date. Fish released from this BY are expected to return as five-year-olds during the 2010 season.

## 2006 Brood Year

Five release groups (four fingerlings and one yearling) have returned to date as twoand three-year-old fish (Table 4). The yearling group, 065361, has experienced the best returns to date, surpassing $0.75 \%$ through age 3 . Fish from both release types should return as four and five-year-olds in 2010 and 2011, respectively.

## 2007 Brood Year

Five CWT groups (four fingerlings and one yearling) from the 2007 BY returned as two-year-olds during the 2009 season (Table 4). Age two return rates have been low so far, surpassing 2005 BY returns for age two, but considerably less than 2006 BY returns through age two. Adult returns from these groups will occur over the next three years.

Table 4. Run-size, percent return, in-river sport catch, and spawner escapement estimates for Trinity River Hatcheryproduced, coded-wire-tagged fall-run chinook salmon returning to the Trinity River upstream of Willow Creek Weir during the period 2006 through 2009.

a/ CWT = coded-wire tag.
b/ Chinook salmon released during June were smolts, those released in October were yearlings.
c/ TRH = Trinity River Hatchery.
d/ Totals are presented only for brood year 2001. These fish have reached five years of age and are considered to have completed their life cycle.
e/ The term "adults" includes chinook aged three through five.

## Contribution of Hatchery Produced Chinook to Total Estimated Run-Size

The contribution of hatchery-produced spring and fall Chinook to the overall Trinity River basin run-size estimates for the two races of Chinook are presented in Table 5. We estimate that the 2009 run of spring Chinook was composed of 3,973 ( 85 grilse and 3,888 adult) fish of TRH origin. This represents 32.7\% (85/260) of the grilse, 54.3\% $(3,888 / 7,166)$ of the adult run, and $53.5 \%(3,973 / 7,426)$ of the total run estimated upstream of JCW.

The fall run, upstream of WCW, was estimated to be composed of 10,072 ( 285 grilse and 9,787 adults) TRH-produced Chinook, which represents $34.0 \%(10,072 / 29,593)$ of the total estimated run. Hatchery produced fall Chinook were estimated to contribute $4.7 \%(285 / 6,018)$ of the two-year-olds (grilse) and $41.5 \%(9,787 / 23,575)$ of the adult run this season.

Table 5. Estimated run-size, angler harvest, and spawner escapement estimates for Trinity River Hatchery-produced, spring and fall chinook salmon expanded for unmarked releases (hatchery multiplier) returning to the Trinity River during the 2009-10 season. a/

a/ Estimates are upstream of Junction City and Willow Creek weirs for spring and fall estimates respectively. b/ CWT=coded-wire tag code. Fish are of the same race and release type (smolt or yearling). c/ BY=brood year.
d/ Expansion factor used to account for untagged releases of the same BY and release type for each CWT group.
e/ Run-size times TRH expansion factor.
f/ TRH=Trinity River Hatchery.

## DISCUSSION

Since CWT estimates are based, in part, on the overall run-size estimates for each race of Chinook, CWT estimates are subject to the precision and potential biases associated with the mark-recapture estimates performed under Task 1 of this report. The potential impact of this would be most relevant in regard to the number of fish estimated to have spawned in "natural" areas. This is due to the fact that hatchery recoveries are actual counts, while CWTed fish estimated to have spawned naturally are the remaining estimated number of fish after hatchery CWTs and estimated angler harvest are subtracted from the overall CWT estimate. Return rates are also affected by ocean and in-river harvest and escapement below the weir sites, which is not included in our estimates. Harvest and stray rates in these sectors can greatly affect river returns upstream of respective weir sites in any given year.

Several other potential biases that could distort our CWT run-size estimates are vulnerability of capture, run-timing, and the assumption that CWT fish that enter the hatchery are representative of the entire CWT population. Assumptions of our CWT estimates include equal probability of capture for hatchery and wild fish and capture of Chinook throughout the entire run. The second assumption, due to trapping constraints at JCW which preclude operating our weir there until late June, may affect our springrun Chinook CWT estimates. If an age or release type of hatchery produced Chinook is more likely to stray than others the proportional CWT run estimate, based on fish recovered at TRH, will over or under estimate the true proportions of each CWT group. Recoveries of TRH-produced Chinook during 2009 carcass surveys (Task 4) were generally consistent with TRH recoveries with the exception of age 2 hatchery fish. No age 2 hatchery fish were recovered this year in main stem carcass surveys. Estimated in-river 2004 BY spring Chinook return rates of fingerling ( $0.825 \%$ ) and yearling (1.215\%) TRH releases surpassed the nineteen year average in our data set (Appendix 1). Compared to the previous BY (2003), spring Chinook fingerling and yearling releases from the 2004 BY returned at a rate 7 and 3 times that of fish from the 2003 BY for fingerling and yearlings, respectively.

Fall Chinook from the 2004 BY experienced similar patterns of return as their spring Chinook counterparts. Fall Chinook yearling releases returned at a rate just over twice ( $1.79 \%$ vs. $0.85 \%$ ) that of their fingerling released siblings (Appendix 2). Return rates for yearling releases were slightly above the long term average (Appendix 2). Fingerling release groups returned at a rate more than double the long term average.

The contribution of hatchery-produced spring Chinook to total run-size was an estimated $53.5 \%$ of the run upstream of Junction City weir (Appendix 3). This is slightly lower than the long term average of $58.5 \%$ and is the third best in the last 11 years. The contribution of hatchery-produced fall Chinook to total run-size, upstream of Willow Creek weir, was estimated at 34.0\% (Appendix 4), the third lowest estimated rate since 1991. The reason for the low rate of hatchery fish in both the spring and fall runs of Chinook this year is unknown, but may be due to hatchery fish performing poorly or wild
fish surviving reasonably well, compared to their hatchery counterparts. This metric, hatchery/wild ratio, has been proposed to the Trinity River Restoration Program as a performance indicator for naturally produced Trinity River Chinook stocks. Two of the premises behind the use of this metric are maintenance of the marking program at the hatchery and static release numbers of Chinook salmon.

Run-size estimates may have potential bias (see Task 1), which under most scenarios would tend to be positive. However, this bias should not affect hatchery contribution rates since total CWT grilse and adult run-sizes are based on AD clip rates observed at either JCW or WCW times the total estimated grilse and adult runs above these sites. Thus, even if total run-size was adjusted lower, the AD clip rate would remain the same, resulting in the same hatchery contribution rates. If, however, hatchery produced fish are more vulnerable to capture or their run-timing coincides with dates of weir operations (i.e. spring Chinook at JCW) more than their wild counterparts at the weirs, the estimated contribution of hatchery fish could be biased.

## RECOMMENDATIONS

1. Coded-wire tagging and release of smolt and yearling Chinook salmon, and the monitoring of adult salmon returns at Trinity River Hatchery, should be continued in 2010-11.
2. Monitor the annual TRH-produced Chinook salmon contribution rates to the overall runs to determine the relative status of naturally produced Chinook salmon in the Trinity basin.
3. Continue spawner carcass surveys (Task 4) in the upper Trinity River to evaluate straying of TRH produced fish.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2009-2010 SEASON 

TASK III
SURVIVAL AND SPAWNER ESCAPEMENTS MADE BY COHO SALMON PRODUCED AT TRINITY RIVER HATCHERY

by<br>Wade Sinnen and John Hileman

#### Abstract

Project personnel effectively marked 413,178 yearling coho salmon (Oncorhynchus kisutch) from the 2008 brood year (BY) with a right maxillary (RM) clip prior to their release from Trinity River Hatchery (TRH) in April of 2010. These fish are expected to return as two and three-year-old fish during the 2010-11 and 2011-12 seasons respectively.

An estimated 6,396 coho salmon returned to the Trinity River, upstream of the Willow Creek Weir (WCW), during the 2009-10 season. We estimated the TRH-produced component of this run to be 5,753 fish, approximately $90 \%$ of the total. Spawning escapement of TRH-produced coho was divided between 3,261 fish which entered TRH and 2,492 fish estimated to have spawned outside of the hatchery facility.

TRH-produced coho from the 2006 BY (age 3) are considered to have completed their life cycle this year. An estimated 6,398 grlise and adult coho from the 2006 BY returned to the Trinity River basin, upstream of Willow Creek weir, the past two seasons. This represents $1.4 \%$ of the 455,623 marked coho yearlings released from TRH in March of 2008. Estimated TRH-produced coho returns from the 2007 brood year are complete for age two returns only. An estimated 1,645 coho have returned thus far, representing $0.36 \%$ of the number released.

## TASK OBJECTIVES

To determine the relative return rates and contributions to spawning escapement and the fisheries made by naturally- and hatchery-produced coho in the Trinity River basin.

## INTRODUCTION

Coho salmon are propagated at Trinity River Hatchery (TRH) by the California Department of Fish and Game (CDFG) as mitigation for lost habitat/coho production upstream of Lewiston Dam. The Trinity River Project, an element of CDFG, is responsible for marking coho prior to their release from the hatchery facility and estimation of the naturally- and hatchery-produced components of coho salmon returning to the Trinity River basin upstream of Willow Creek Weir (WCW). Beginning with the 1994 brood year, all coho salmon reared at TRH have received a right maxillary (RM) clip prior to release. Prior to the 1994 brood year, a portion of the coho production was coded-wire tagged similar to the Chinook marking program at TRH. With the advent of coho becoming listed as a threatened species pursuant to the Federal Endangered Species Act (ESA) in 1994, the CDFG began a program to mark 100\% of the hatchery production so that a more thorough analysis of hatchery and natural stocks could be accomplished.

## METHODS

There are two phases involved in this task; marking all coho produced at TRH and estimating coho run-size, harvest, and escapement of TRH- and naturally-produced coho salmon returning to the Trinity basin. The latter phase is partially accomplished under Task 1 of this report. In this section we present release and recovery data that is used to estimate the hatchery- and naturally-produced component of the 2008-09 coho run above WCW. Data compilation and analysis is reliant upon previously reported data in Sinnen and Null, 2002; Sinnen and Moore, 2000; Sinnen, 2004a, 2004b, 2005, 2006, 2008; and Sinnen and Hileman, 2009, 2010a and 2010b.

## Marking at Trinity River Hatchery

Marking of coho is performed by CDFG personnel in marking shed which is placed parallel to the raceways at TRH. The shed is moved along raceways with a fork lift, utilizing slots in each shed for this purpose. Raceways are segregated with removable barriers to isolate clipped coho from un-marked fish.

Coho are anaesthetized with carbon dioxide and have their right maxillary (RM) bone removed with a pair of sharp surgical scissors. Marked fish are tallied with a manual
counter and returned to hatchery ponds. Observed mortalities of marked coho are counted and subtracted from the daily effectively tagged total.

To determine overall marking accuracy, we examine a sample of the marked coho just prior to their release into the river. These fish are anaesthetized with carbon dioxide, measured to the nearest millimeter (mm) fork length (FL), and checked for quality of the maxillary clip. If more than $3 / 4$ of the bone was excised it is considered a good clip; less than that is considered a poor clip. We estimate the total number of coho in each raceway by adding marked totals with the estimated unmarked totals minus mortalities. The number of unmarked fish is determined using quality control data collected just prior to the release date.

## TRH-produced coho run-size, escapement, and in-river harvest

To estimate the contribution of TRH-produced coho to run-size, escapement and in-river angler harvest above Willow Creek Weir (WCW), the following information is required:

1. Marking of coho production released from TRH.
2. Recovery totals of marked and unmarked coho returning to TRH.
3. Total coho run-size above WCW.
4. The percentage of marked coho salmon observed at WCW.
5. In-river angler harvest rates on coho above WCW.
6. Specific age class determinations.

The assumptions underlying the validity of run-size estimates are discussed under Task 1 of this report. Additionally, we assume that coho right-maxillary marks do not regenerate and that the mark is recognizable.

To estimate the TRH-produced component of the run above WCW, we used the equation:
$\mathrm{N}_{\mathrm{RM}}=\frac{\mathrm{NW} \text { RM }}{\mathrm{NW}} \times \mathrm{N}_{\text {cohorun }}$
where NRM = the estimated number of coho salmon above Willow Creek weir with a right maxillary clip;
NWRM = the number of coho salmon observed at Willow Creek weir that were rightmaxillary clipped;
NW = the total number of coho salmon observed at Willow Creek weir;
NCohorun = total estimated run of coho salmon above Willow Creek weir.
To estimate the number of un-marked coho salmon above the weir we used the equation:
$\mathrm{N}_{\mathrm{N}}=\mathrm{N}_{\text {Cohorun }}-\mathrm{N}_{\mathrm{RM}}$
where, $\mathrm{NN}=$ the estimated number of naturally produced coho above Willow Creek weir.

The size separating grilse and adult coho is determined by performing length frequency analysis using WCW and TRH data sets. The number of grilse and adults in the coho run was determined by multiplying the proportion of each observed at WCW times the total run-size estimate. The number of right maxillary-clipped coho for each age strata is estimated by multiplying the ratio of marked to unmarked coho observed at Willow Creek weir times the total age stratified run-size estimate. The remaining coho are considered naturally produced. Coho harvest rate estimates are developed using angler tag return data presented in Task 1. Harvest rates are applied to the age stratified coho run to produce a harvest estimate. The estimate is apportioned to either RM clipped or naturally produced coho based on tag returns. Coho escapement is determined by the following equation:

$$
\mathrm{N}_{\text {escapement }}=\mathrm{N}_{\text {Cohorun }}-\mathrm{H}_{\text {coho }}
$$

where, Hcoho = the estimated number of coho salmon harvested by anglers upstream of Willow Creek weir.

Escapement is divided into Trinity River Hatchery escapement and natural escapement. Hatchery escapement is a direct count of RM clipped and unmarked coho that entered TRH, while natural escapement is estimated by the following equation:
$\mathrm{N}_{\text {Naturalescapement }}=\mathrm{N}_{\text {escapement }}-\mathrm{N}_{\text {TRHescapement }}$
where NNaturalescapement = the estimated number of coho salmon above Willow Creek weir estimated to have spawned in natural areas; and
NTRHescapement = the number of coho salmon that entered TRH.
All estimates are stratified by grilse and adults and by RM - marked and unmarked coho salmon.

## RESULTS

## Marking at Trinity River Hatchery

Staff personnel marked (RM clips) approximately 436,427 2008 BY coho, representing $99.75 \%$ of the entire production at TRH. We began marking coho in late December, 2009 and finished in late March, 2010.

We performed a quality control check to determine our clipping effectiveness for coho in each raceway on March 22-24 2010. We measured and examined approximately $2 \%$ of the coho in each raceway. The percentage of coho with proper clips ranged from
99.5\% to $99.9 \%$ and averaged 99.75\% for the 8,694 fish examined. We also recorded 21,397 post-clip mortalities. Based on these data we estimate that 413,178 coho were effectively clipped and released (Table 1). These fish ranged in size from 81 to 334 mm , fork length (FL), with a range of mean lengths of 132 to 161 mm , FL. We estimate that 1,036 unmarked coho were released for a total release number of 414,214 fish. All BY 2008 coho were volitionally released from TRH April 4-6, 2010.

## Contribution of TRH-Produced Coho to Escapement and in-River Sport Fisheries

Total (natural and TRH-produced) coho run-size for the 2009-10 season, above WCW, was estimated at 6,396 fish (Task 1), of which 1,762 were grilse (age 2) and 4,634 were adults (age 3). Age classes were determined using length frequency analysis. The size separating grilse and adults was 54 cm FL (Task 1). Therefore all coho < 54 cm , FL were considered grilse and larger fish as adults.

The percentage of right maxillary-clipped (RM) coho observed at WCW was $93 \%$ (98/105) for grilse salmon and $89 \%$ (86/97) for adults. Based on this information the overall marked coho total observed at WCW for the 2009-10 season was $91 \%$ (184/202). Based on RM-clipped coho at WCW and recovery of Project-marked coho at TRH, we estimate that the 2009-10 coho run was composed of 643 naturally-produced fish and 5,753 TRH-produced fish (Table 2.).

Anglers did not return any tags from harvested coho salmon this year, therefore we estimated that no harvest occurred, upstream of WCW. The sport take of coho, a state and federally listed threatened species on the Trinity River, has been prohibited since 1995; however, some fish are occasionally harvested by unknowledgeable anglers due to mistaken identity or a lack of knowledge concerning the closure.

a/ BY=Brood year
b/ Age classes are determined using fork length frequency analysis.
c/ TRH=Trinity River Hatchery

Based on age three coho run-size estimates presented above (Table 2) and age two estimates provided last year, the percent return for BY 2006, TRH-produced coho was $1.40 \%$ (Table 3). Coho from the 2006 BY have reached three years of age and are considered to have completed their life cycle. Percent return of two- year-old 2007 BY coho was $0.36 \%$. These fish will return during the 2010-11 season as three-year-olds.

Spawning escapement of 2006 BY, TRH-produced coho consisted of 3,033 (47.4\%) fish that entered TRH and 3,365 (52.6\%) fish estimated to have spawned in natural areas (Table 3).

Estimated escapement in 2009-10 of TRH-produced, two-year-old coho from the 2007 BY was 871 (52.9\%) hatchery spawners and 774 (47.1\%) fish estimated to have spawned in natural areas (Table 3).

Table 3. Run-size, percent return, in-river angler harvest and spawner escapement estimates for Trinity River Hatchery-produced coho salmon returning to the Trinity River upstream of the Willow Creek weir during the period 2008 through 2009.

## DISCUSSION

Since estimation of TRH-produced contribution rates to overall coho run-size, escapement and harvest are directly related to the total coho run-size estimates produced under Task 1 of this report, it must be noted that the information presented under Task 3 is generally only moderately rigorous, statistically speaking, due to low numbers of coho marked at WCW. This season we only trapped 202 coho, of which we effectively tagged 186 coho. The total coho run-size estimate of 6,396 fish, produced under Task 1 of this report, had confidence intervals ( $1-\mathrm{p}=0.95$ ) within $18-23 \%$ of the point estimate. Confidence intervals can range up to $35 \%$ in some years. Another source of potential bias, not trapping through the entire run, did not appear to be a major factor this season. Trapping CPUE (Task 1. Table 4, Figure 10) at WCW indicated that the run of coho was declining, but not completely over, prior to its removal November 19th. Since our efforts represent the majority of work to quantify the hatchery vs. wild runs and survival and contribution rates of returning coho, we feel it is important to present the available information. It must be noted that any bias in coho run-size estimates would be reflected in natural areas since the number entering the hatchery are actual counts.

In-river returns of 2006 BY coho, estimated at $1.40 \%$, is the fourth lowest in-river return rate over the last thirteen coho cohort cycles (Appendix 1). Return rates have ranged from a low of $0.98 \%$ for BY 2004 coho to $6.61 \%$ for BY 2001 coho. Since coho are raised to slightly larger than yearling size (spawned in late November through early January and released in March of the following year) it would seem reasonable that survival rates could potentially be high. Return rates of coho to the Trinity basin, unlike

Chinook salmon, are in theory minimally affected by ocean and in-river commercial and sport harvest, since the take of coho has been prohibited in these fisheries since 1994. The Native American gill-net fisheries may harvest substantial numbers of coho, but it is doubtful that this harvest rate approaches historical harvest rates for all combined fisheries (ocean sport, commercial, in-river sport, and gill-net).

In all but four years, including this year, the estimated number of hatchery-produced coho that have spawned in natural areas has surpassed those that entered TRH (Appendix 1). This indicates that TRH-produced coho stray at substantial rates. Our main stem carcass surveys (Task 4) have demonstrated that, similar to TRH-produced Chinook, TRH-produced coho do spawn outside of the facility and that coho carcass recoveries are greatest in areas near TRH. This season we recovered 169 coho in the main stem Trinity River (Task 4). Of these, 106 (62.7\%) were RM clipped.

Despite potential run estimate biases, coho trends, based on trapping data at Willow Creek weir, indicate that coho runs returning to the upper Trinity basin are heavily supported by TRH production. Coho run estimates, upstream of WCW, (years in which all TRH-produced coho have been $100 \%$ marked) have consistently shown that the marked percentage of coho has been substantial, 77 to $94 \%$ of the estimated total (Appendix 2). This season we estimated that approximately $90 \%$ of the run was composed of TRH-produced coho.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2009 SEASON 

TASK IV<br>SALMON SPAWNER SURVEYS IN THE UPPER TRINITY RIVER

by

Andrew Hill

#### Abstract

A spawning survey monitoring the escapement of Chinook and coho salmon was conducted on the Trinity River from September 14, 2009 to December 22, 2009. This survey was a joint-agency effort including staff from California Department of Fish and Game (CDFG) Trinity River Project (TRP), Yurok Tribal Fisheries (YTF), Hoopa Valley Tribal Fisheries (HVTF), U.S. Fish and Wildlife Service (USFWS), and U.S. Forest Service (USFS). The survey focused on the main stem Trinity River from the Lewiston Dam to Cedar Flat (101.6 river kilometers) and from Hawkins Bar to Weitchpec (64.1 river kilometers). The section from Cedar Flat to Hawkins Bar is not surveyed due to safety concerns. The survey did not include any tributaries. During the survey, 3,419 Chinook (Oncorhynchus tshawytscha), 169 coho salmon (Oncorhynchus kisutch), 13 steelhead (Oncorhynchus mykiss), and 65 brown trout (Salmo trutta) were recovered.

This survey focused on Chinook carcasses recovered throughout the spawning season including both spring and fall Chinook. Coded wire tag (CWT) recoveries from adipose fin-clipped Chinook indicate spring Chinook carcasses outnumbered fall Chinook carcasses until after Julian week 43 (ending October 28, 2009). With this Julian week separation, 1,040 spring Chinook carcasses were recovered, and 2,379 fall Chinook carcasses were recovered. Coded wire tag recoveries also allow separation of 2 year old grilse from adults (greater than 2 years of age), so $93.4 \%$ spring Chinook and $94.6 \%$ fall Chinook were adults. The recovery of these adipose fin-clipped Chinook carcasses also indicated $8.34 \%$ of the spring and $11.14 \%$ of the fall carcasses observed in the main stem surveys were of hatchery origin. The Schaefer with Law's Adjustment markrecapture model estimates the lowest in-river escapement of 8,899 Chinook salmon ( 2,707 spring and 6,192 fall). The Weekly Peterson model provides the highest estimate of 13,372 Chinook salmon (4,068 spring and 9,304 fall).

All fresh Chinook carcasses (condition-1) were marked with numbered jaw tags and returned to the water for a mark-recapture estimate of in-river escapement. Over the course of the survey, 691 Chinook carcasses were marked, of which (235) $34.0 \%$ were subsequently recaptured. The Schaefer with Law's Adjustment mark-recapture model estimates the lowest in-river escapement of 8,899 Chinook salmon (2,707 spring and

6,192 fall). The Weekly Peterson model provides the highest estimate of 13,372 Chinook salmon ( 4,068 spring and 9,304 fall).

The recovery of hatchery clipped coho salmon and adipose-clipped steelhead carcasses indicate that $62.72 \%$ of coho salmon and $38.46 \%$ of steelhead carcasses are from hatchery origin. Adult coho salmon represented $92.6 \%$ of all coho salmon recovered.

## TASK OBJECTIVES

1. To determine the size, sex composition, and hatchery component of Chinook and coho salmon spawning populations in the main stem Trinity River.
2. To determine the incidence of pre-spawning mortality among naturally spawning Chinook and coho salmon in the main stem Trinity River.
3. To determine the temporal and spatial distribution of the naturally spawning populations of Chinook and coho salmon within the main stem Trinity River.
4. To estimate in-river escapement of spring and fall utilizing mark-recapture and multiple estimators.

## INTRODUCTION

The California Department of Fish \& Game's (CDFG) Trinity River Project (TRP) in cooperation with the Yurok Tribal Fisheries Program (YTFP), Hoopa Valley Tribal Fisheries (HVTF) and the U.S. Fish and Wildlife Service (USWFS) conducted a carcass and redd survey in the main stem Trinity River. The survey was funded through the Trinity River Restoration Program (TRRP). The U.S. Forest Service (USFS) also participated in the survey using internal funding. USFS participation was limited to enumerating redds in the uppermost reach from Lewiston Dam to Old Bridge (Reach 1).

Reporting responsibilities for the project were divided into two parts: 1) CDFG was responsible for reporting on the carcass survey portion of the study, and 2) the USFWS for the redd enumeration part of the study. Redd survey information included in this report was summarized by the USFWS.

Spawner surveys have been conducted intermittently on the Trinity River since 1955. Spawning surveys prior to 1964 included river sections located above river mile 111.9 (RKM 180.1), the site of present day Lewiston dam.

Results from spawner surveys can be utilized to improve our understanding of the preand post- treatment effectiveness of flow and habitat manipulations being implemented by the TRRP to improve salmon spawning conditions. Pertinent metrics to be analyzed over time include spawner density, spawner distribution, and prespawn mortality rates in
the upper main-stem Trinity River. Additionally, estimates produced from the markrecapture carcass survey can be used to validate and refine estimates produced in Task 1 of this report.

## METHODS

The study area included the main stem Trinity River from its upstream limit of anadromy at Lewiston Dam downstream to the Cedar Flat Recreational Area and from Hawkins Bar to Weitchpec. The stretch from Cedar Flat to Hawkins Bar is not surveyed due to hazardous conditions. The study area was divided into 14 reaches (Table 1, Figure 1). Reaches were surveyed between September 14, 2008 and December 22, 2009. Two rafting teams consisting of DFG and Yurok Tribal Fisheries crews attempted to survey reaches 1-5 weekly by starting at reaches one and working downstream through reach five. USFWS and HVTF crews also attempted to survey reaches six and seven weekly, while reaches 8-10 and 12-14 were surveyed on a bi-weekly basis. However, logistical constraints caused some reaches to be occasionally excluded (Table 2).

Figure 1. Survey reaches for 2009 Trinity River main stem spawner survey. Map courtesy of USFWS.

Surveys were conducted using $12-\mathrm{ft}$ NRS $^{\text {TM }}$ Otter inflatable rafts equipped with rowing frames. Each raft was staffed by two crew members, one rower-recorder and one technician responsible for recovering carcasses and enumerating redds. Each rafting crew covers one side of the river (right bank to middle and left bank to middle) as the crews proceeded down stream. Additionally, all side channels are walked by the crew covering the bank of origin. Carcasses were recovered from all accessible areas in the river and along the shoreline. Fish in deeper areas were recovered using telescoping poles with attached gigs.

## Spring/ Fall Chinook Separation

In the Trinity River, there is a temporal and spatial overlap in the spring and fall Chinook runs. Since there is annual variation in spring and fall Chinook run timing, a date separating the two races is determined. Most adipose fin-clipped Chinook carcasses recovered during the survey contained coded wire tags (CWTs), which are implanted in their snouts prior to release from Trinity River Hatchery (TRH). CWTs are race and brood year specific and are currently implanted in approximately $25 \%$ of all TRH

Chinook as juveniles. The week separating spring and fall Chinook runs was established when the percentage of fall Chinook recoveries (based on CWT analysis) was greater than spring Chinook.

Carcasses encountered in the survey were given a condition rating in order to describe their stage or degree of decomposition. During the survey, carcasses were separated into one of three categories: 1) condition-1 was a carcass with at least one clear eye, 2) condition-2 was a carcass with both eyes cloudy, and 3) condition-3 was skeletal remains. All condition-1 Chinook carcasses were marked with week specific jaw tags and returned to moving water. These carcasses were then available for recapture providing the means to estimate an in-river escapement using several mark-recapture estimators. Estimators used to calculate the estimate include a pooled Petersen (Chapman, 1951), a weekly stratified Petersen, the Schaefer (Ricker, 1975) and a modified Schaefer (Law, 1994).

Carcasses that were recovered during the survey were identified to species, gender, and examined for hatchery clips and any tags (Trinity River Project (Project), or other tags). Carcasses were measured to the nearest cm fork length (FL). Trinity River Hatchery (TRH) clips included adipose fin-clips (Ad) on Chinook and steelhead and right maxillary clips (RM) on coho salmon. Additionally, all TRH Ad-clipped Chinook salmon are implanted with a CWT. At TRH, approximately $25 \%$ of all juvenile Chinook and $100 \%$ of coho salmon and steelhead are clipped prior to release. Heads of all recovered Ad-clipped Chinook were removed and retained for later CWT tag recovery. The CWTs are extracted and read by the Department's Trinity River Project staff. All Project tags, applied at the two main stem weirs, were removed and recorded.

Field crews examined all condition-1 and condition-2 female salmon for spawning condition by direct observation of ovaries. Fish were classified as either spawned or unspawned based upon percent egg retention. Females retaining the majority of their eggs were classified as un-spawned; conversely females retaining very few eggs were determined to have spawned. Due to the difficulty in accurately determining if a male has successfully spawned, male spawning condition was not assessed. All condition-1 Chinook carcasses were marked with a week specific jaw tag and returned to moving water. All condition-2 and condition-3 Chinook, marked recaptures, coho salmon, steelhead, and brown trout carcasses encountered during the survey were cut in half with a machete to prevent recounting the same fish on later surveys.

To estimate in-river escapement in the main stem Trinity River, two generally accepted mark-recapture models were employed. The simplest of these models used is the Petersen mark-recapture estimator as described by Ricker (1975). The Petersen estimator calculates seasonal escapement by incorporating data from the entirety of the survey period. We also employed a weekly stratified Petersen to further analyze weekly population substructure. The second model used is the Schaefer estimator as described by Schaefer (1951). We also employed a modified Schaefer estimator as described by Law (1994). This model differs from the original Schaefer in that the number of tags applied after the first week is subtracted from the population estimate to account for
sampling with replacement. Schaefer's original model was based on sampling without replacement. However, sampling with replacement occurs during the salmon spawning season.

The Petersen model as described by Ricker (1975):
$N_{i j}=\left(\left(M_{i}\right)\left(C_{j}\right) / R_{i j}\right)$
Where: $\quad \mathrm{N}_{\mathrm{ij}}=$ population size in tagging period $i$ recovery period $j$, $M_{i}=$ number of carcasses tagged in the ith tagging period, $\mathrm{C}_{\mathrm{j}}=$ number of carcasses recovered in the jth recovery period, $\mathrm{R}_{\mathrm{ij}}=$ number of carcasses tagged in the $i$ th spawning period and recaptured in the $j$ th recovery period,

The Schaefer model as described by Schaefer (1951)
$N_{i j}=\sum\left(R_{i j}\left(\left(M_{i} / R_{i}\right)\left(C_{j} / R_{j}\right)\right)\right)$
Where: $\quad N_{\mathrm{ij}}=$ population size in tagging period $i$ and recovery period $j$, $\mathrm{R}_{\mathrm{ij}}=$ number of carcasses tagged in the ith spawning period and recaptured in the $j$ th recovery period,
$M_{i}=$ number of carcasses tagged in the $i$ th tagging period,
$\mathrm{C}_{\mathrm{j}}=$ number of carcasses recovered in the jth recovery period,
$\mathrm{R}_{\mathrm{i}}=$ total recapture of carcasses tagged in the ith tagging period, and
$\mathrm{R}_{\mathrm{j}}=$ total recapture of carcasses tagged in the jth tagging period.
The Schaefer model as modified by Law (1994):
$N_{i j}=\sum\left(R_{i j}\left(M_{i} C_{j} / R_{i} R_{j}\right)-M_{i}\right)$
Where: $\quad \mathrm{N}_{\mathrm{ij}}=$ population size in tagging period $i$ recovery period $j$,
$\mathrm{R}_{\mathrm{ij}}=$ number of carcasses tagged in the $i$ th spawning period and recaptured in the $j$ th recovery period,
$M_{i}=$ number of carcasses tagged in the $i$ th tagging period,
$\mathrm{C}_{\mathrm{j}}=$ number of carcasses recovered in the jth recovery period,
$\mathrm{R}_{\mathrm{i}}=$ total recapture of carcasses tagged in the ith tagging period, and
$\mathrm{R}_{\mathrm{j}}=$ total recapture of carcasses tagged in the jth tagging period.

## RESULTS

## Spring/ Fall Chinook Separation

From CWT extraction of adipose fin-clipped carcasses, the only overlap of spring and fall Chinook runs occurred during Julian week 44. Spring Chinook carcasss were predominant through Julian week 43 (October 22, 2009 to October 28, 2009), after which fall Chinook recoveries were most numerous. For the purpose of analysis, all Chinook recoveries prior to and during Julian week 43 are classified as spring Chinook and all subsequent carcass recoveries are classified as fall Chinook (Figure 2).

Figure 2. Weekly proportions of coded-wire tagged spring and fall Chinook observed in the 2009 main stem Trinity River spawner survey.

## Temporal Carcass Distribution

A total of 3,419 Chinook carcasses were encountered during the survey. Recovery of Chinook carcasses peaked during Julian week 48 (November 26, 2009 to December 2, 2009) when 521 carcasses were counted. The first coho salmon carcass was recovered during Julian week 39 (September 24, 2009 to September 30, 2009). A total of 169 coho salmon carcasses were recovered during the survey with peak recovery number of 39 during both Julian weeks 47 and 48 (November 19, 2009 to December 2, 2009) (Figure 3). It should be noted that temporal coverage of the coho run was incomplete because the survey efforts ended prior to the end of spawning activity. To fully enumerate coho salmon spawning activity in the main stem, survey efforts would need to continue at least through January.

Figure 3. Chinook and coho salmon carcasses collected by Julian week during the 2009 Trinity River main stem spawner survey.

## Carcass Distribution

A total of 3,419 Chinook carcasses were recovered during Julian weeks 37 to 51 (September 14, 2009 to December 22, 2009) in the 14 survey sections (Table 2). Of the 3,419 Chinook carcasses encountered, 1,739 (50.83\%) were recovered in reaches 1 and 2 , and $1,069(30.27 \%)$ of the carcasses were recovered in reach 1 alone. Reaches 8 and 14 had the fewest carcasses (12 in both reaches) and 20.09\% of encountered carcasses were downstream of reach 5 (Table 2).

## Redd Distribution

Similar to carcass recovery, Chinook redds were encountered most frequently in reach 1 with a total of 4,162 redds enumerated during the 2009 survey (Table 3). A total of 846 ( $20.33 \%$ ) redds were enumerated in reach 1, and the fewest redds (57) were observed in reach 8 . Peak redd enumeration occurred during Julian week 40 where 598 redds were counted.

## Spring Chinook Salmon

A total of 1,040 Chinook carcasses were classified as spring-run during the survey, of which 371 were classified as condition-one (Table 4). Spring Chinook carcass recovery by reach ranged from 235 in reach 3 to zero in reaches $8,10,12$, and 14. Spring Chinook carcass density was greatest in reach 1 at 41.52 fish/km.

Table 4. Number, density, incidence of ad-clips, project tags, and condition of spring Chinook recovered during the 2009 main stem Trinity River spawner survey 1/

## Fall Chinook Salmon

A total of 2,379 Chinook carcasses were classified as fall-run during the survey, of which 368 were classified as condition-one (Table 5). Fall Chinook carcass recovery by reach ranged from 925 in reach 1 to 12 in both reaches 8 and 14. Fall Chinook carcass density was greatest in reach 1 at 280.30 fish/km and dropped considerably to 77.04 fish/km in reach 2. Below reaches 1 and 2 carcass density was considerably less.

## Coho Salmon

A total of 169 coho salmon carcasses were recovered during the survey, of which 35 were classified as condition-one (Table 6). Coho carcass recovery by reach ranged from 81 ( $47.93 \%$ ) in reach 1 to zero in reaches $6,8,12$, and 13 . Coho salmon carcass density was greatest in reach 1 ( 24.55 fish/km) and dropped considerably to 7.32 fish/km in reach 2. Coho salmon carcass density downstream from reach 3 was less than 2 fish per kilometer.

## Steelhead and Brown Trout

A total of 13 steelhead carcasses and 65 brown trout carcasses were recovered during the survey (Table 7). Steelhead density with and without the adipose fin clip was highest in reach 1, which is closest to the hatchery. Brown trout density was highest in reach 3, and one Project tag turned up in reach 5. For the second year in a row a brown trout was observed in reach 1.

Table 7. Number, density, incidence of adipose clips, and project tags recovered during the 2009 main stem Trinity River spawner survey

1/ Adipose clipped steelhead presumably from Trinity River Hatchery with 100\% hatchery clip rate 2/ Spaghetti tags applied at Willow Creek and Junction City weirs

## Size Composition

Only condition-1 and condition-2 fish were measured and included in the size composition analysis. Condition-3 fish were assumed to have decomposed to a point where length measurements were no longer accurate. The size separating grilse and adults for spring-run and fall-run Chinook and coho salmon was determined using length frequency analysis of fish trapped at the Willow Creek weir, Junction City weir, and the Trinity River Hatchery. For additional information regarding grilse and adult fork length separation see Task 1 of this report.

Fork lengths of spring Chinook ( $\mathrm{n}=984$ averaged 70.6 cm . and ranged between 32-106 cm . (Figure 4). Grilse ( $\mathrm{FL}<50 \mathrm{~cm}$ ) accounted for $6.61 \%$ (65/984) of the measured spring Chinook.

Figure 4. Length frequency for all condition-1 and -2 spring Chinook measured during the 2009 main stem Trinity River spawner survey.

## Fall Chinook Salmon

Fork lengths obtained from fall Chinook ( $\mathrm{n}=2,164$ ) averaged 72.5 cm and ranged between $32-111 \mathrm{~cm}$. (Figure 5). Grilse (FL $<55 \mathrm{~cm}$ ) accounted for $5.36 \%(116 / 2,164)$ of measured fall Chinook.

Figure 5. Length frequency for all condition-1 and -2 fall Chinook measured during the 2009 main stem Trinity spawner survey.

Coho Salmon
Fork lengths of measured coho salmon ( $\mathrm{n}=162$ ) averaged 64.7 cm and ranged from $32-81 \mathrm{~cm}$. (Figure 6). Grilse (FL < 54 cm ) accounted for $7.41 \%$ (12/162) of measured coho salmon.

Figure 6. Length frequency for all condition-1 and -2 coho salmon measured during the 2009 main stem Trinity River spawner survey.

## Adult Sex Composition and Female Pre-Spawn Mortality

## Spring Chinook Salmon

Of the spring Chinook recovered that were sexed; 363 were sexed as males and 626 as females, a male to female ratio of 0.58:1 (Table 8). Gender was indiscernible on 51 fish due to advanced decomposition. Thirty four ( $5.43 \%$ ) of the 626 female spring Chinook carcasses evaluated were determined to be pre-spawn mortalities.

Table 8. Male to female ratio and prespawn mortality of spring Chinook during 2009 main stem Trinity River spawner survey

| Reach | Total <br> Chinook | Males | Females | Unspawned <br> Females | Unknown <br> Gender | Males per <br> Female | Prespawn Mortality <br> (Females) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Total | 1,040 | 363 | 626 | 34 | 51 | 0.58 | $5.43 \%$ |

## Fall Chinook Salmon

Of the fall Chinook recovered that were sexed; 796 were sexed as males and 1,343 were sexed as females, for a male: female ratio of 0.59:1 (Table 9). Gender was indiscernible on 229 fish due to advanced decomposition. Sixty six ( $4.91 \%$ ) of the 1,343 adult female fall Chinook carcasses examined were determined to be pre-spawn mortalities.

Table 9. Male to Female Ratio and Prespawn Mortality of fall Chinook during 2009 main stem Trinity River spawner survey by reach.

| Total | 2,379 | 796 | 1,343 | 66 | 229 | 0.59 | $4.91 \%$ |

## Coho Salmon

Of the 169 coho salmon recovered that were sexed; 67 were sexed as males and 95 were sexed as females, for a male: female ratio of 0.71: 1 (Table 10). Grisle have been included in number of males, and gender was indiscernible on 7 fish due to advanced decomposition. Fifteen (15.79\%) of 95 female coho salmon carcasses examined were determined to be pre-spawn mortalities.

Table 10. Male to female ratio and prespawn mortality of all coho salmon during 2009 main stem Trinity River spawner survey by reach.

## Incidence of Hatchery Produced Chinook and Coho Salmon

## Spring Chinook Salmon

During the spring-run period, $2.70 \%(n=10)$ of condition-one and $2.30 \%(n=24)$ of all spring Chinook bore Ad-clips. One hundred percent of all ad-clipped spring Chinook were recovered in reaches 1 and 2. CWTs were recovered from 23 Chinook encountered during the spring Chinook recovery period, all of which were spring-run fish. During the period associated with the spring-run, 1 ad-clipped Chinook was recovered in which no CWTs was found. The majority of CWTs were represented by the 2006 spring-run yearling release group ( $n=6,26.09 \%$ ) and 2005 spring-run fingerling release group ( $\mathrm{n}=6,26.09 \%$ ). All other CWTs were represented by 2004 brood year spring-run fingerling ( $n=4,17.39 \%$ ), 2004 spring-run yearling ( $n=3,13.04 \%$ ), and 2006 brood year fingerling release groups ( $n=1,4.35 \%$ ).

Based on expansion of all CWT codes recovered during the spring period, an estimated 87 (8.34\%) of the total 1,040 fish recovered were of TRH origin (Table 4). Based on expansions of all spring-run CWT groups, an estimated age structure of TRH spring Chinook recovered in the main stem Trinity River spawner survey was $34.46 \%$ age 5 , $28.45 \%$ age 4 , and $37.19 \%$ age 3 (Table 11).

[^6]
## Fall Chinook Salmon

During the fall-run period 8.15\% $(n=30)$ of the condition-1 and 3.49\% $(n=83)$ of all fall Chinook bore ad-clips (Table 5). Observed ad-clip rates in reach 1 and 2 for fall Chinook were $7.34 \%$ ( $n=27$; condition-1) and $3.49 \%$ ( $n=83$; all carcasses) respectively. In reach 3, fall Chinook ad-clip rates of $0.82 \%$ ( $n=3$; condition-1) and $0.39 \% ~(n=9$; all carcasses) were observed. No CWTs were found in reaches 4 through 14. CWTs were recovered from 83 of the total Chinook encountered during the fall Chinook recovery period; all but one of which were fall Chinook. During the period associated with the fallrun, 18 ad-clipped Chinook were recovered in which no CWTs were found. The majority of CWTs during the fall-run recovery period were represented by 2006 fall fingerling releases ( $\mathrm{n}=25 ; 30.48 \%$ ). All other CWTs were represented by the following brood year groups; 2004 fall brood year fingerlings ( $n=2,2.44 \%$ ), 2005 fall brood year fingerlings ( $n=9,11.0 \%$ ), 2005 fall brood year yearling ( $n=7,9.0 \%$ ), 2006 fall brood year fingerlings ( $n=21,24.61 \%$ ), and 2006 spring brood year yearling ( $n=1,1.22 \%$ ).

Based on expansion of all CWT codes recovered during the fall-run period, an estimated 265 (11.14\%) of the total 2,379 fish recovered were of TRH origin (Table 5). Based on expansions of all fall CWT groups, the estimated age structure of TRH fall Chinook recovered in the main stem Trinity River spawner survey was $3.13 \%$ age 5, $25.64 \%$ age 4 , and $71.22 \%$ age 3. (Table 11).

## Coho Salmon

During the course of the survey, $71.43 \%(n=25)$ of condition-1 and 62.72\% ( $n=106$ ) of all coho salmon recovered bore right maxillary (RM) clips (Table 6). Coho RM clip rates for condition-1 carcasses were highest in reach one. Based on a $100 \%$ clip rate of Trinity River Hatchery (TRH) produced juvenile coho salmon, an estimated $62.72 \%$ of adult coho salmon recovered during the survey were of TRH origin.

## Incidence of Project Marked Salmon

## Spring Chinook Salmon

A total of 17 Project tags applied at the Junction City and Willow Creek weirs were recovered in survey reaches 1 through 14 (Table 4). Nine of these were recovered on condition-1 carcasses. No spring Chinook Project tags were found on carcasses in reaches 8 through 14. During the course of the survey, 10 tags from the Junction City weir and 7 tags from the Willow Creek weir were recovered prior to Julian week 44. All spaghetti tags were found above reach 5 (Table 4).

## Fall Chinook Salmon

A total of 65 Project tags applied at Junction City and Willow Creek weirs were recovered during the survey (Table 5). Fifteen of these were recovered on condition-1
carcasses. During the course of the survey, 62 tags from the Willow Creek weir and 3 tags from the Junction City weir were recovered after Julian week 43. Spaghetti tags were found in all reaches except $8,9,12,13$, and 14 , and $56.92 \%$ were found in reaches 1 and 2 (Table 5).

## Coho salmon

A total of 4 Project tags applied at the Willow Creek weir were recovered during the survey (Table 6). All of these were recovered in reaches 2 and 3 during Julian weeks 45 through 49.

## Steelhead/Rainbow trout

No Project tags were found on steelhead carcasses during this survey.

## Brown Trout

One Project tag was found on a brown trout carcass during this survey in reach 5 during Julian week 49.

## In-river Escapement Estimates

This season, a mark-recapture methodology was employed on the upper Trinity River to estimate in-river escapement of Chinook (Tables 12, 13, \&14). Mark-recapture techniques were historically used on the Trinity, and were recently reintroduced during the carcass survey in 2005. During the 2009 survey, crews marked all condition-1 Chinook with week specific jaw tags. Fish are subsequently recaptured to produce weekly estimates. During the course of the survey, six hundred ninety one (20.21\%) of Chinook were marked, and two hundred thirty five (34.0\%) of those fish were subsequently recaptured (Appendix 6). The upper reaches (reaches 1-5) had a lower marking rate of $16.32 \%$ and a slightly higher recapture rate of $42.15 \%$ than the survey in its entirety (Appendices 5\&6). The lower reaches (reaches 6-10) had a marking rate of $35.66 \%$, and a recapture rate of $19.18 \%$ (Appendix 6). Estimates could not be made for spring-run in the lower reaches due to low numbers of recaptures ( 6 recaptures). All estimators used in this report require at least 25 recaptures to produce reliable results.

Table 12. In-river escapement estimates for Chinook collected during 2009 Trinity River spawner survey.

| Estimator | Reaches <br> $1-5$ | Reaches <br> $1-14$ | Reaches 1-5 <br> $(95 \% \mathrm{CI})$ |
| :--- | :---: | :---: | :---: |
| Peterson | 6,463 | 10,027 | 675 |
| Weekly Stratified Peterson | 8,754 | 13,372 | 1,115 |
| Schaefer | 8,389 | 9,590 | 697 |
| Schaefer with Law's adjustment | 7,797 | 8,899 | 697 |

The different estimators produced estimates which range from 8,899 to 13,372 Chinook for the entire survey, and from 6,463 to 8,754 for the upper reaches 1-5 (Table 13). Adding in the $95 \%$ Confidence interval, the estimates ranged from 8,026 to 15,075 for the entire survey, and from 5,788 to 9,869 for the upper reaches. These results indicate there is a $5 \%$ chance that the true estimate falls outside of the confidence intervals.

Table 13. In-river escapement estimates for spring and fall Chinook collected during 2009 Trinity River spawner survey above Junction City.

| Above J.C. (reach 1-5) | Spring | Fall | Ratio of spring to <br> fall Chinook |
| :--- | :---: | :---: | :--- |
| Petersen | 1,840 | 4,622 |  |
| Weekly stratified Petersen | 2,493 | 6,261 | $0.398: 1$ |
| Schaefer | 2,389 | 6,000 |  |
| Schaefer w/ Law's adjustment | 2,220 | 5,577 |  |

Estimates for the different runs in the entire survey ranged from 2,707 to 4,068 for spring Chinook and 6,192 to 9,304 for fall Chinook (Table 14). The estimates for the upper reaches ranged from 1,840 to 2,493 for spring Chinook and 4,622 to 6,261 for fall Chinook (Table 13). The results of the carcass survey indicate spring to fall Chinook ratios of $0.437: 1$ for the entire survey and $0.398: 1$ for the upper reaches (Tables $13 \&$ 14).

Table 14. In-river escapement estimates for spring and fall Chinook collected during 2009 Trinity River spawner survey in all reaches.

| Entire survey (reach 1-14) | Spring | Fall | Ratio of spring to <br> fall Chinook |
| :--- | :--- | :--- | :--- |
| Petersen | 3,050 | 6,977 | $0.437: 1$ |
| Weekly stratified Petersen | 4,068 | 9,304 |  |
| Schaefer | 2,917 | 6,673 |  |
| Schaefer w/Law's adjustment | 2,707 | 6,192 |  |

## DISCUSSION

When looking at the spring and fall runs as a whole, year to year variation in numbers of salmon carcasses recovered on the upper Trinity River is fairly minimal when examined as an order of magnitude (with the exception of the 2003 Chinook season) and normally tracks well with the number of fish recovered at Trinity River Hatchery (see Task 1). During the 2009 season, crews recovered slightly more total Chinook than during the 2008 field season (Appendix 1). Coho salmon carcass numbers were the lowest since they began being enumerated during the 2000 field season. When comparing yearly data, it is important to acknowledge differences in survey timing and periodicity, as well as climatic events and budgetary constraints that inhibit survey timing and periodicity.

In some years, surveys ran into January, therefore covering a greater proportion of the coho salmon run. Additionally, in some years weekly survey periodicity was far from perfect due to extreme weather and high flows.

Prior to 1996, CDFG conducted mark recapture carcass recovery surveys which allowed for estimation of the total numbers of spawners in each survey reach. Due to inclusion of redd data collection and other crew constraints during the 1996-2004 seasons, carcass totals were then solely based on total numbers of carcasses recovered. With the reintroduction of a mark recapture methodology in 2005 , we will continue to display the number of carcasses observed per reach, independent of mark recapture, for comparison with past years. Current mark recapture efforts do not produce reach escapement estimates, as weekly efficiencies by reach are sporadic and highly variable.

## Carcass Distribution

As in past years, Chinook and coho salmon carcass densities were highest in the uppermost reaches and were negatively associated with increased distance from Lewiston Dam and TRH (Appendices 1, 2, \& 3). Salmon imprint upon the waters in which they rear, and subsequently home on those waters when returning to spawn. If more spawners utilize upper reaches and their progeny rear in those reaches, then it is logical to speculate that the majority of returning salmon would then subsequently spawn in those same upper reaches. Other potential factors contributing to the observed high densities in the upper reaches include hatchery fish spawning in-river instead of returning to the hatchery, blockage of further upstream migration by Lewiston Dam, and availability of suitable spawning habitat.

This years' Chinook numbers as a whole show this same trend, but a deviation from this trend has occurred for the first time with spring Chinook and not for fall Chinook. This year, reach 3 has the greatest percentage of spring Chinook (235/1040; 22.60\%) than any other reach, and reach 9 produced the highest numbers of spring ( $n=48$ ) ever observed. This deviation may be due to decreased hatchery contribution to the spring run (Table 15). This decrease has resulted in more naturally spawning spring Chinook in the Trinity River which may be due to restoration activities.

Table 15. Hatchery contribution from previous years to spring Chinook spawning in the main stem Trinity River.

| Year | Hatchery Contribution (\%) |
| :---: | :---: |
| 2002 | $38.00 \%$ |
| 2003 | $25.20 \%$ |
| 2004 | $25.20 \%$ |
| 2005 | $32.50 \%$ |
| 2006 | $18.14 \%$ |
| 2007 | $19.28 \%$ |
| 2008 | $10.27 \%$ |
| 2009 | $8.37 \%$ |

## Adult Sex Composition and Female Pre-spawn Mortality

For all races and species of salmon carcasses recovered on the upper Trinity, female adults out numbered male adults when number of grilse is subtracted from the total number of males recovered. Previous studies on the Trinity River presented in Aguilar (1996), suggest this is common for Chinook salmon. If a portion of males return as grilse (two year olds), then adult females would then make up a higher percentage of adults. Another factor that could possibly skew male to female ratios is unequal capture probability by sex. Zhou (2002) modeled and analyzed 12 years of Salmon River, Oregon fall Chinook carcass data and found that male Chinook were underestimated by $8 \%$, while female Chinook were overestimated by $12 \%$. Assuming similar bias in Trinity River carcass composition results, male to female ratios including grilse have been estimated as follows: $0.58: 1$ for spring Chinook and 0.59:1 for fall Chinook.

Trinity River Chinook salmon pre-spawn mortalities for years when more than 100 females were examined have ranged from 0.0 to $62.8 \%$ for spring Chinook, and 0.7 to $43.7 \%$ for fall Chinook (Appendices 4). Pre-spawn mortality rates observed this year were 5.43 \% for spring Chinook and $4.91 \%$ for fall Chinook. For years in which more than 100 female coho salmon were examined, pre-spawn mortality rates have ranged from 8.5 to $15.9 \%$. The coho salmon pre-spawn mortality rate observed this season was $15.8 \%$. It is unclear how this rate is influenced by a truncated survey season, although if pre-spawn mortalities die sooner than successful spawners, this rate would most likely be overestimated. It has also been noted, most recently by Zuspan (1998), that pre-spawn mortality may be density dependent and is positively related to run-size in the Trinity River. As in the past, pre-spawn mortality numbers fluctuate similarly to fluctuating escapement numbers.

## Mark Recapture Estimators

Carcass mark recapture or capture recapture estimators are commonly used by the Department to estimate in-river escapement of salmon; these estimators have been used in Central Valley tributaries including the American and Sacramento since the early 1970's (Snider, Reavis and Hill, 1999). In the Klamath basin, the Department
currently utilizes both the Petersen and Schaefer estimators to produce in-river escapements from carcass survey data (S. Borok, pers comm, 2005). It is important to acknowledge the limitations and potential biases associated with these estimators. If basic assumptions are violated, or bias is excessively high, options should be pursued to refine these estimators or another estimator should be selected.

The Petersen estimator is the most popularly used mark recapture model in fisheries management. However, it is often portrayed as a crude application because it is a closed population model, and its assumptions concerning zero births or death (immigration and survival) are rarely met. With respect to salmon carcass surveys, the Petersen model has been found to consistently overestimate population estimates, sometimes exceeding $250 \%$ of the true population (Law, 1994). Stratifying Petersen estimates by week can minimize some of the bias created by births and deaths..

The Schaefer estimator is commonly used as an alternative to the simple pooled Petersen when the assumptions of equal mixing, homogenous capture, or homogenous recapture probabilities will not hold (Schwarz et al, 2002). When these assumptions are violated, stratifying capture and recaptures by time or location and using either a stratified Petersen or Schaefer estimator may be appropriate. Law (1994) found the Schaefer estimator to be less positively biased than the Petersen estimator, but cautioned that it also overestimates populations, especially at low survival and low catch rates. Law (1994) suggests the use of the Jolly-Seber open population mark recapture model for use in salmon carcass population estimates, but recognized that on larger rivers, the Jolly-Seber may produce estimates that are consistently low. It is also possible that the basic assumption of equal mixing of tagged carcasses with all carcasses may be violated, in which case, recaptured carcasses may constitute a different sub-population.

## Other Possible Sources of Bias

Problems or biases associated with salmon carcass surveys should be identified and subsequently minimized in order to produce more accurate and precise estimates. Some problems are inherent to survey design or human nature, while others are specific to situations or crews working on the Trinity River.

Inter-observer variation is a source of bias affecting all types of fish surveying methods. During this survey, we attempted to minimize this variation by maintaining the same rower/observer teams and rotating sides of the river by week. By rotating banks weekly, bias concerning memory of where marked carcasses were released was minimized. Maintaining the same crew throughout the season is also important to minimize variation in data collection methods and ensure data consistency between weeks and sections.

Carcass condition is a potential source of bias in the mark-recapture estimators due to the fact that fall Chinook carcass eyes appear to rot more quickly than spring Chinook carcasses. The decrease in marking rates is apparent as the season progresses. Only
condition-1 carcasses are marked, and that criterion is met when at least one of the carcass eyes is clear. Since fall Chinook carcasses rot quicker and both eyes are often cloudy even at the time of spawning, a lower percentage of fall Chinook carcasses ( $15.47 \%$ ) were classified as condition-1 than spring Chinook carcasses (35.67\%) (Tables 4 and 5). This accounts for the different marking rates between spring and fall Chinook. Therefore, due to the higher marking rates for spring Chinook, the estimates may be more efficient for spring Chinook than fall Chinook due to the higher marking rate.

Weather is an uncontrollable factor, which most likely has a great affect on consistency of survey methods. High flow events reduce carcass capture efficiency due to higher instream velocities and increased turbidity. Extreme high flow events may also cause exclusion of weekly surveying efforts on dropped reaches. Capture efficiency can also possibly be reduced by excessive cloud cover or glare associated with the azimuth of the sun.

Sufficient survey periodicity is necessary to ensure proper temporal coverage in recovery of salmon carcasses. Weekly survey periodicity is most convenient when surveying long sections, necessitating the use of four crews. In reaches 8 to 10 and 12 to 14 , bi-weekly surveys were conducted due to logistical constraints. Fresh carcasses were available for recapture for four to five weeks following initial capture, thus only fresh carcasses were tagged and used to calculate capture efficiency. An additional problem which may necessitate more frequent surveying is predation and removal of carcasses. No direct evidence of carcass removal by predation was observed during the 2009 season, but we assume that predation does exist. High carcass predation rates reduce the efficiency of carcass recovery. If predation rates are found to be inversely proportional to run size (ie predators remove a higher ratio of carcasses when less carcasses exist) then survey periodicity should be increased in lower run-size seasons. Conversely, there could be a density dependent relationship between run-size and attraction of predators, which would also necessitate increased survey periodicity.

Hatchery contribution estimates may be underestimated due to problems associated with identification of hatchery fish. Poor detection of fin clips or errors in recording those fin clips can negatively skew hatchery contribution rates. The right maxillary clip exhibited by TRH released coho salmon is very easy to miss if special attention is not paid to detecting that clip. Advanced decomposition of salmon carcasses may also inhibit the ability to detect hatchery clips. Poor detection or loss of adipose clipped salmon heads or CWTs extracted from those heads also could negatively skew hatchery contribution rates.

## RECOMMENDATIONS

1.) Annual spawner surveys incorporating a mark-recapture methodology should be continued for future seasons, facilitating future comparisons of mark recapture escapement estimates.
2.) Mark recapture estimators should be statistically evaluated for bias, and the JollySeber model should be considered if bias is found to be excessive, thus minimizing the potential of producing unacceptable estimates.
3.) In future years, the entire survey area should be surveyed on a consistent temporal basis (e.g. once each week) if possible.
4.) Redd survey protocols and datasheets should be simplified, in order to concentrate crew efforts on carcass and redd detection.
5.) If recovery of coho salmon becomes a high priority, the temporal coverage of the surveys will need to be extended into January. If surveys are extended into January, a mark-recapture methodology should be initiated for coho salmon.
6.) More research into carcass deterioration rate differences between spring-run and fall-run Chinook.

# ANNUAL REPORT <br> KLAMATH RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2009-10 SEASON 

# ANGLER CREEL SURVEYS IN THE LOWER KLAMATH RIVER 

By

Sara Borok

#### Abstract

During August 6, 2009 through November 4, 2009 a creel census was conducted in the lower (Ocean to Hwy 96 Bridge in Weitchpec) Klamath River to determine numbers of upstream migrating Chinook salmon (Oncorhynchus tshawytscha), coho salmon (Oncorhynchus kisutch) and steelhead trout (Oncorhynchus mykiss) harvested by sport anglers. A total of 5,133 (3,197 adults and 1,936 grilse) Chinook salmon and 200 (192 adults and 8 half-pounders) steelhead were harvested. Chinook salmon caught before August 15, 2009 were considered spring-run Chinook salmon. Forty-nine spring-run Chinook ( 38 adults and 11 grilse) salmon were harvested in 2009. A total of 5,084 fallrun Chinook ( 3,159 adult and 1,926 grilse) salmon were harvested by sport anglers. The 2009 in-river sport quota was 30,800 adult Chinook salmon. Seasonal summaries and comparisons of angler effort and catch, catch timing, length frequencies, species composition, hatchery fin clips and tag recoveries are presented.

## INTRODUCTION

The Klamath River basin is the second largest river system in California (the Sacramento system is the largest). It drains over $40,000 \mathrm{sq} \mathrm{km}$ in northern California and southern Oregon. The Trinity River is its largest tributary and empties into the Klamath River at Weitchpec (river kilometer (rkm) 68.8). Other major tributaries of the Klamath River are the Salmon River (rkm 105.6), the Scott River (rkm 228.8) and the Shasta River (rkm 283.2).

The upper limit of anadromy in the main Klamath River is Iron Gate Dam (rkm 304.2). Iron Gate Hatchery, at the base of the dam, mitigates for loss of historic anadromous fish habitat above the dam. The upper limit of anadromy in the Trinity River is at Lewiston Dam (rkm 177.8). Trinity River Hatchery is located at the base of Lewiston Dam and mitigates for loss of historic anadromous fish habitat above the dam. Both hatcheries are operated by California Department of Fish and Game (CDFG). The Klamath River system is one of the state's primary producers of Chinook salmon and steelhead trout. These two species support popular sport fisheries throughout the

Klamath River system with most of the concentrated effort and catch occurring in the lower 50 kilometers of the main stem Klamath River.

Although sport angling has been popular throughout the Klamath River for many decades, angler harvest data of anadromous salmonids within the Klamath River system prior to 1978 is limited. The earliest report found mentioning angling in the Klamath River is by Snyder (1931) where he briefly describes methods, mean length and sex of a two day creel sample at the mouth of the Klamath River in August of 1921. Coots (1952) reports on angler harvest of anadromous salmonids during a year long creel census from the mouth of Salmon River (rkm 105.6) to Copco Dam (rkm 314) during 1949 and 1950. Gibbs and Kimsey (1955) provide angler effort and harvest estimates for the boat fishery in the Klamath River estuary during 1951. Bailey (1952) reported on a creel census of the fishery in the lower Klamath River above the Highway 101 Bridge conducted during the fall 1951 adult steelhead and Chinook salmon immigration period.

Other earlier creel census reports on the main stem Klamath River conducted upstream of the Salmon River (rkm 105.6) deal with angler catches during the summer trout season. Some adult steelhead and juvenile coho salmon are reported in the catch reports (Coots 1950, 1951, 1953, 1954; Wales 1948; Wales and Coots 1949). More harvest data was reported by Lanse (1970) in an area of the upper Klamath River between Dutch Creek (rkm 147) to Iron Gate (rkm 304) and by Miller (1971) working in an area of the middle Klamath River from Johnson's (rkm 40) to the Salmon River (105.6 rkm). Steelhead comprised the majority of the sampled catches.

Creel census studies prior to 1978 consisted primarily of angler effort, species composition and catch per unit effort (CPUE) information. Some provided harvest and effort estimates within the sampled area. However, not until 1978 was an attempt made to estimate Chinook harvest by anglers throughout the Klamath River basin (Boydstun, 1979).

The Fishery and Conservation Management Act of 1976 established a 200-mile fishery conservation zone and created eight regional Fisheries Management Councils, one of which is the Pacific Fisheries Management Council (PFMC), the purpose of which was to develop and implement a Fishery Management Plan (FMP) for commercial and recreational salmon fisheries off the coasts of Washington, Oregon and California. All inland waters and those ocean waters out to the 3 mile mark are managed by the individual adjoining states, those waters off California are managed by CDFG.

The Klamath River is regarded as one of the more important producers of fall-run (fall) Chinook salmon in California's commercial and sport fisheries. PFMC management objectives include measures to rebuild and protect depressed Klamath River fall Chinook stocks (PFMC 1983). PFMC management practices have focused on harvest restrictions for commercial and recreational fisheries that were impacting Klamath River Chinook stocks. The California Fish and Game Commission (Commission), with management jurisdiction of fisheries in coastal waters from shore out 5 kilometers (3
miles) and in-river sport fisheries, has implemented Chinook salmon management practices and regulations supporting PFMC objectives. Thus, Klamath River adult fall Chinook run-size data has been a critical management component of the fall Chinook resource and its fisheries in northern California and southern Oregon.

The number of fall Chinook salmon entering the Klamath Basin (run-size) is determined by summarizing the number harvested in-river (both sport and tribal), the number returning to the two basin hatcheries, natural spawning escapement (fish spawning in natural areas) and drop-off net and angler mortaility. Angler harvest of Klamath River fall Chinook salmon has been monitored by CDFG to provide data for fall Chinook salmon run-size estimates since 1978. Annual reports summarizing these activities have been written through the 2008 season (Boydstun 1979, 1980; Lee 1984a, 1984b, 1985, Lau 1992-1997; Pisano 1998; Borok 1999-2004, Hanson 2005-2008).

This report covers the period from July 1, 2009 through June 30, 2010. It provides data and a description of the CDFG fall Chinook salmon angler harvest monitoring program in the main stem Klamath River from the mouth of the Klamath River to the Highway (Hwy) 96 Bridge at Weitchpec (rkm 68.8) excluding the Trinity River.

For the purposes of this study the Klamath River and Trinity River are divided into sample reach areas. The Klamath River is divided onto 3 areas, from the mouth of the river to the Hwy 101 Bridge, from the Hwy 101 Bridge to the Hwy 96 Bridge at Weitchpec and from Hwy 96 Bridge at Weitchpec up to Iron Gate Dam. The Trinity River is divided into 2 areas from the confluence with the Klamath River up to Cedar Flat and from that point up to the Old Lewiston Bridge in Lewiston (245.7 rkm). This is to determine angling effort and harvest by section. The CDFG uses this information to determine in real time when sport anglers have reached the in-river sport harvest subquota for each section of fall adult Chinook salmon. This report covers the lower 2 sections of the Klamath River from the ocean to the Hwy 96 Bridge in Weitchpec.

The Klamath River Chinook quota is implemented in the following manner: Fifty per cent of the total in-river quota is dedicated to the lower Klamath River (rkm 0 to 68.8). The other half is apportioned to the mid and upper Klamath River (17\%) (rkm 68.8 to rkm 306) and the Trinity River (33\%). CDFG monitors or models each of the areas for the fall Chinook harvest and determine when the quota of each portion has been met. Once a sub -quota in any of the sections is met, an adult Chinook salmon harvest closure goes into effect in that section of river. Anglers are still permitted to fish, but must release any adult Chinook salmon caught. Meanwhile, anglers in the other portions of the river are still permitted to harvest adult Chinook. After all sub-quotas are met, fishing for grilse Chinook and other legal species is still permitted but the entire river is closed to the harvest of any adult Chinook. However, once the hatcheries (Iron Gate Hatchery and Trinity River Hatchery) have reached mitigation egg take goals, special exempted fisheries for adult Chinook are permitted from Iron Gate Dam to where Interstate 5 crosses the Klamath River and downstream of Old Lewiston Bridge to the mouth of Indian Creek Bridge on the Trinity.

Starting in 1999 CDFG implemented an "impact quota" for the Klamath and Trinity Rivers. From this impact quota a ten percent hooking mortality factor was accounted for within the quota and this number was used as the quota trigger. This trigger closure was to account for increased hook and release mortalities when the quota was met early in the season. The impact quota was divided among each of the areas in the same manner as the division of the basin quota.

During the 2009 season, fishing regulations allowed anglers to harvest three Chinook salmon per day (up to two adult Chinook) and one hatchery trout or one hatchery steelhead per day. These regulations started on August 15, 2009 in the Lower Klamath River and September 1, 2009 in the Trinity River and the Klamath River above the Hwy 96 Bridge in Weitchepec. The limit of hatchery steelhead for the Trinity River (only) was increased to two per day and four in possession. Regulations stated one "hatchery" trout or one "hatchery" steelhead could be harvested, which eliminated the cutthroat trout fishery in the Klamath basin. No harvest of coho salmon was permitted in the entire Klamath Basin. Adult Chinook are defined in the regulations as Chinook 22 inches ( 56 cm ) total length or greater. Grilse or jacks are the Chinook under 22 inches ( $<55 \mathrm{~cm}$ ).

## METHODS

## Description of the Fishery and Creel Sample Area

To estimate angler catch and effort, CDFG divides the main stem Klamath River from the mouth to Iron Gate Dam into three areas. The mouth of the river to the Hwy 96 Bridge in Weitchpec (Areas 1 and 2) are included in this report. The area upstream of the Hwy 96 Bridge in Weitchpec to Iron Gate Dam (Area 3) was not directly surveyed by CDFG this season. Chinook harvest in this area is estimated using a ratio estimator based on catch in the lower Klamath River.

Area 1: This area consisted of $4.5 \mathrm{rkm}(2.8 \mathrm{mi})$ of river from the mouth of the Klamath to the Hwy 101 Bridge and is referred to as the estuary. All shore angling effort in this area took place at the mouth of the river in 2009. River mouth configuration, which changes annually, determines which side (north or south) affords better angling. A creel sample of shore anglers was conducted at the mouth location. During the 2009 season fishing the mouth was not closed at any time. If $15 \%$ of the lower river quota had been caught below the Hwy 101 Bridge (3,375 adult fall Chinook salmon) the spit (100 yards of the channel through the sand spit formed at the Klamath River mouth) would be closed to sport fishing, it was not met this season.

All boat angling effort in the estuary originated from ten resort boat docks in the estuary area. Three resort docks (Golden Bear RV Park, Riverside RV Park, and Panther Creek RV Park) and south side Mouth access were sampled this season for angler effort and catch.

Area 2: This area extended from the Hwy 101 Bridge at Klamath (rkm 5) to the Hwy 96 Bridge (rkm 68) in Weitchpec. The division was formerly the falls at Coon Creek (54.4 rkm) near the community of Johnson's riffle (Pecwan Creek), but to make the distinction clearer for anglers it was changed. Shore angling effort is generally confined to two popular riffles (Lower Klamath Glen and Blake's) located in the lower 5 km of this area easily accessed by shore anglers. One former resort boat dock (Klamath Glen) and a public boat launch (Roy Rook), also located in this section 5 km , are the principal boat facilities in the area. Creel sampling occurred at these locations.

Angler access routes at Lower Klamath Glen and Blake's riffles were limited to specific routes in and out enabling a complete accounting of angler effort and catch during a sample day at these locations. Boat anglers were also confined to access at the launching ramp or resort boat dock enabling a complete sample of angler effort and catch for each sample day.

Shore angling access above Blake's Riffle was limited to three access points: The mouth of Blue Creek (rkm 26.3), Ah Pah Creek (rkm 27.5), and Bear Riffle (rkm 29.8). These points are all accessible by vehicle but accounted for an estimated less than one percent of angling effort from data in past surveys.

## Creel Census Methods

Study methods and procedures used in Areas 1 and 2 during the 2009 season were essentially the same as those described for the 1983-1987 seasons (Hopelain 2001). Data is presented in standard Julian week (JW) format throughout this report (Appendix 1).

Each of the sites identified in the area description on the lower Klamath River were sampled three days per Julian week; for weeks that were sampled other than that, the data is expanded accordingly. Each angling access site is sampled throughout the day to account for total catch and effort for that particular site. Scientific aids interviewed anglers as they departed the fishing site and recorded the following information:

1) Was the angler finished fishing for the day at this time?
2) Total hours spent fishing (to the nearest half hour).
3) The first three numbers of their Zip Code (to find their general area of residence).
4) Fish harvested are identified to species, fork length is measured and they are inspected for marks, external tags and unusual conditions. Also, a scale sample was collected.
5) For Chinook salmon missing an adipose fin, (possessed a CWT) the head was removed and retained by staff.
6) The number and species of fish caught and released (actually released not lost) by the angler was recorded as juveniles, grilse or adults.
7) In Area 1 only, the angler was questioned weather they fished the mouth or
from a boat and if fish were harvested above or below the Hwy 101 Bridge.
8) Was this a professionally guided trip?

## Harvest and Effort Estimating Procedures

Data was stratified for each creel census location by Julian week (Appendix 1). Angler catch and effort estimates are calculated for each week. The catch-effort estimate formula used was:

$$
\text { Estimate total }=\sum_{\mathrm{l}=1}^{\mathrm{n}} \text { Daily total }(\mathrm{N} / \mathrm{n})
$$

where: Estimate total = estimates of catch or effort
Daily total = Daily counts of catch or effort
$\mathrm{N}=$ Number of fishing days in week
$\mathrm{n}=$ number of sample days
I = boat sampling ratio
Area 2: Harvest estimates for the area above Highway 101 to the Hwy 96 Bridge at Weitchpec was calculated by multiplying the observed harvest and effort by a sampling ratio. This ratio is the weekly expansion value. This value is a simple ratio based on the number of days sampled to the number of legal fishing days within the week ( 7 days week / 3 days sampled $=2.33$ ). All sites are totaled for the week to obtain the weekly harvest estimate for Area 2. This procedure applies to both boat and shore harvest. No additional expansion for the boat harvest in Area 2 is needed since total boat catch and effort were accounted for in the creel sampling.

Area 1: The procedure for the area below 101 is identical with Area 2 except for the addition of a boat expansion factor. The boat expansion factor accounts for the harvest by boat anglers not sampled. The boat expansion formula is:

## (Boats at the non-sampled docks + Boats at sampled docks) Boats at Sampled docks

The product of this formula yields a ratio used to expand catch and effort data for nonsampled boats anglers. This ratio is obtained by counting the number of boats at all the docks (both sampled and non-sampled) below Hwy 101. This count occurs usually between 1100 to 1500 hrs . Although not all the boats will be at their docks at this time the assumption that the percentage of boats that do not return to their docks is the same between both the unsampled and sampled docks. It is also assumed that the effort and catch are equal between the non-sampled boats and sampled boats.

A boat count is made every day Area 1 is sampled. This count excludes all boats used in the Indian gill-net fishery. An average of these daily values is used to arrive at the
average boat expansion value for the week. The closer the expansion value is to one, the greater the total coverage we have in the estuary.

## Daily Real Time Harvest Estimates and Projections

As in previous seasons, the KRP computed harvest and effort estimates daily (real time) as we neared the quota to help prevent any over-harvesting. In addition, CDFG estimated one, two, and three day harvest projections to allow lead time of any adult Chinook salmon fishery closures.

## RESULTS

Rounding numbers to whole numbers may cause some slight addition discrepancies in these results. Spring-run Chinook numbers are included in totals. All graphic fork lengths representations are smoothed by a moving average of five.

The creel census for the lower Klamath River began on August 6 and ran through November 4 (JW 32 through 44) of 2009. Chinook salmon harvested in the lower Klamath fishery ranged in size from 36 to 107 cm in fork length (Figure 1). The adult portion of Chinook harvested ranged in size from 59 to 107 cm FL and averaged 73.4 cm FL. The grilse component of the angler harvest ranged in size from 36 to 58 cm FL and averaged 48.4 cm FL. The shift in size for adults from the stated size in the regulations is based on the fork length distribution below.

Harvested steelhead ranged in size from 34 to 79 cm FL and averaged 59.4 cm FL (Figure 2). Any steelhead less than 42 cm FL is considered to be a half-pounder, and those larger are considered adults. Steelhead less than 25 cm FL are considered resident trout and not anadromous. Half-pounder steelhead ranged in size from 34 to 41 cm FL and the adult steelhead ranged in size from 42 to 79 cm FL .

Figure 1. Fork length frequency of Chinook salmon harvested in the lower Klamath River during the 2009 season.

Figure 2. Fork length frequency of steelhead harvested in the lower Klamath River during the 2009 season.

## Estimated Angler Effort and Harvest

During the 2009 season, CDFG estimate that anglers made a total of 14,736 trips in Areas 1 and 2 combined. Of the 14,736 trips; 6,627 were in Area 1, and 8,109 were in Area 2 (Table 1). These trips resulted in a total effort of 67,160 fishing hours. As in previous seasons, boat anglers out-numbered shore anglers in both Areas (Table 1).

A total of 5,133 (3,197 adults and 1,936 grilse) Chinook salmon and 200 (192 adults and 8 half-pounders) steelhead were harvested (Table 1). During Julian weeks 32 and 33, 49 ( 38 adult and 11 grisle) spring-run Chinook salmon were harvested. The total of fall Chinook harvested was 5,084(3,159 adults and 1,925 grilse) fish. Eleven adult coho salmon were estimated harvested this season.

Table 1. Summary of estimated angler effort and harvest during the 2009 lower Klamath River creel census.

| Site | Angler |  | Steelhead |  | Chinook Salmon |  |

| 2007 | 13,913 | 64,101 | 7 | 767 | 255 | 3,388 |

## 2009 Harvest and Effort Patterns

The average trip length during the 2009 season was 4.6 hours (Table 2) and was consistent with years 2002-2007. Average trip length over the previous 17 years (19922008) was 4.0 hours per trip. The 2008 season was an anomaly; anglers fished longer trips, caught fewer adult fish, but caught a great deal more grilse Chinook.

Table 2. Number of angler trips, hours, and average length of trip in the lower Klamath River sport fishery for the last eighteen seasons, 1992-2009.

| Year | Total Angler |  | Average <br> Hours/Trip |
| ---: | ---: | ---: | ---: |
|  | Trips | Hours | 3.0 |
| 1992 | 11,190 | 33,080 | 3.2 |
| 1993 | 16,081 | 51,889 | 3.6 |
| 1994 | 15,100 | 54,748 | 3.2 |
| 1995 | 19,881 | 63,369 | 3.3 |

| 2006 | 8,902 | 41,792 | 4.6 |
| 2007 | 13,913 | 64,101 | 5.2 |
| 2008 | 10,827 | 56,005 | 4.6 |

Figure 3. Harvest per hour of Chinook salmon from the sport fishery during the lower Klamath River creel survey, 1980 - 2009.

## Catch and Release

Catch and release data were recorded as part of the creel interview. Anglers were specifically asked if fish were released rather than lost. This data should only be used as an estimation of trends as they can be highly subjective. CDFG estimated anglers released 924 half-pounders, 485 adult steelhead, 338 grilse, and 292 adult Chinook salmon (Tables 3 and 4). In addition an estimated 5 grilse and 34 adult coho salmon were released this season. The majority of coho salmon harvested and released occurred in Area 2. Anglers tend to fish later into the season in Area 2 when coho are present. As in all years, if the quota is met early the number of adult Chinook released increases. The quota was not met during the 2009 season.

Table 3 Estimated number of Chinook and coho salmon and steelhead caught and released from the lower Klamath River, 1994-2009.

| Year | Chinook |  | Steelhead |  | Coho |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Grilse | Adults | $<42$ |  | Grilse |  |

## Harvest Timing

Angler effort and Chinook harvest peaked in Julian week 37 for both grilse and adults (Figure 4 and 5). Harvest of adult steelhead peaked in Julian week 36 (Figure 6), while the peak week of half pounder catch and release fishing was JW 32 (Figure 7). Very few half-pounders (7) were harvested this season.

Figure 4. Estimated harvest of Chinook salmon by Julian week in the lower Klamath River during the 2009 creel survey.

Table 5. Angler effort, fish harvested and fish released by Julian week during the 2009 lower Klamath River creel census.

## Coded-Wire Tag Recovery

KRP personnel recovered the heads of 78 adipose fin-clipped and coded-wire-tagged (Ad+CWT) Chinook salmon during Julian weeks 33 through 42 of the 2009 season. There were four non-random recoveries (NRR), wherein anglers and or resort owners saved their fish heads for our personnel. These NRRs are not used to estimate the harvest of marked hatchery origin (Ad+CWT) Chinook salmon (Table 6). However, they are used to calculate harvest timing (Figure 8). CWTs were not recovered from eight
heads. This left 66 tags to decode. Of these 66 heads, 18 were adult salmon while 48 were grilse salmon.

No Trinity River Hatchery spring Chinook heads were recovered. Recoveries of adipose fin-clipped fall Chinook salmon adults ranged in size from 64 to 87 cm . Grilse ranged in size from 52 cm to 81 cm . All fin-clipped fish observed in the angler survey were assigned an individual head tag number which allowed tracking of each head through the extraction and decoding process.

## Hatchery Contribution

Randomly recovered, marked Chinook salmon composed 3.02 \% $(66 / 2,185)$ of the actual Chinook salmon sampled. Expansions were made for creel sampling and hatchery production multiplier for each tag group. Based on these expansions, CDFG estimated 1,013 hatchery fish were harvested (Table 7). Hatchery fish represented an estimated $19.74 \%(1,013 / 5,130)$ of the entire sport harvest in the lower Klamath River. All 66 randomly recovered tags were from Klamath and Trinity Basin origin Chinook salmon.

## Iron Gate Hatchery Origin Chinook Salmon

CDFG decoded 18 random recovered tags from Klamath River origin Chinook. These Chinook salmon represent 9 different tag codes; 2 from the 2005 Brood Year, 5 from the 2006 Brood Year and 2 from the 2007 Brood Year at Iron Gate Hatchery (Table 6). When expanded for creel sampling and hatchery production multipliers for each tag group, Iron Gate Hatchery origin fish account for $9.45 \%(485 / 5,130)$ of the total sport harvest (Table 7). The Iron Gate Hatchery origin Chinook were harvested between Julian Weeks 33 to 39 (Figure 8).

## Trinity River Hatchery Origin Chinook Salmon

CDFG decoded a total of 48 randomly recovered tags of Trinity River Hatchery fall Chinook origin. These Chinook salmon represent 7 different tag codes; 2 from the 2006 Brood Year and 5 from the 2007 Brood Year at Trinity River Hatchery (Table 6). Trinity River origin fish represented $10.29 \%(528 / 5,130)$ of the total sport harvest (Table 7). Trinity River Hatchery origin Chinook were harvested between Julian Weeks 36 to 42 (Figure 8).

During the 2009 season, sport in-river harvest by stock can be described as follows: The tail end of the Trinity River Hatchery spring-run Chinook salmon made up the majority of harvest up to Julian week 33 (assumed from past seasons), then Iron Gate Hatchery fall Chinook salmon were present and peaked at Julian week 36. The bulk of the Trinity River fall tags were collected during Julian weeks 37 and 39. No additional coded-wire tagged Chinook salmon were recovered after Julian week 42 (Figure 8).

Table 6. Actual coded-wire-tag recoveries by Julian week from Iron Gate Hatchery (IGH) and Trinity River Hatchery (TRH) for Chinook salmon obtained from the lower Klamath River, 2009 season.

Figure 8. Estimated harvest of hatchery produced fall Chinook salmon by Julian week in the lower Klamath River, 2009 season.

## DISCUSSION

During the 2008 creel census 3,879 grisle salmon were harvested.. A large run of two year old fish one season usually indicates there will be a large number of three year old fish in the system the following season. Anglers did catch more adult Chinook salmon in 2009 but not in the numbers anticipated considering the 2008 grilse predictions. Basin wide, anglers only harvested $18.3 \%(5,651 / 30,800)$ of their quota

Anglers are aware that the tribal commercial harvest is usually over after the Labor Day weekend. This season the peak in effort occurred the week following that holiday weekend. There has been a slight shift in effort patterns, in previous seasons the peak in effort was Labor Day weekend.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2009-2010 SEASON 

# TASK VI <br> JUVENILE COHO SALMON SUMMER DISTRIBUTION IN THE UPPER TRINITY RIVER 

by

John Hileman

#### Abstract

Habitat use along the upper part of the Trinity River below Lewiston Dam by juvenile coho salmon (Oncorhynchus kisutch) is essential data in the evaluation of the potential effects of restoration activities on the Trinity River. Coho salmon are a Federal and State listed species. The upper 30.4 kilometers (Rkm) of the main stem Trinity River were surveyed for juvenile (post fry, $>50 \mathrm{~mm}$ ) coho presence using snorkel apparatus. The flow discharge from Lewiston Dam at the time the surveys were conducted in August 2009 was at the base-flow of 450 cubic feet per second (cfs). A total of 5,551 juvenile coho salmon were counted across 226 point observations. The bulk of both the point observations and high density point observations were recorded from Old Lewiston Bridge, to Grass Valley Creek.

## INTRODUCTION

Summer juvenile coho salmon distribution in the upper Trinity River is highly clustered around slower backwater areas that have non-rooted aquatic vegetation. Large wood debris is a primary cover type preferred by juvenile coho (Garrison, 2008). Large woody debris cover is now infrequent in the upper Trinity River due to the loss of recruitment from damming of the river and loss of streamside mature forest from past logging and urban development. The intent of this study is to generate a generalized synoptic view of the abundance and distribution of juvenile coho salmon in the upper river basin during summertime base flows of 450cfs, as a means of gauging and monitoring the TRRP mechanical and flow based habitat modification efforts.

Coho salmon populations are currently listed as a State and Federal threatened species in the Southern Oregon- Northern California (SONC) Evolutionary Significant Unit (ESU). Information generated in Tasks I and III of this report document annual adult returns of hatchery and in-river compositions of the population.

The Trinity River Restoration Program (TRRP) is a consortium of agencies, tribes, and stakeholders. TRRP formed as a result of the 2000 Trinity River Record of Decision (ROD) (USDOI 2000). The ROD authorized increased flow regimes based on water year types, and recommended a Restoration and Implementation Group (RIG), and a Technical Management and Assessment Group (TMAG).

The 2008 run-size estimate for natural escapement of coho salmon in the main stem Trinity River above Willow Creek Weir was 4,794 individuals. An estimated $80.3 \%$ were of hatchery origin and marked with a right maxillary clip (RM) (Sinnen, et al., 2010). Carcass surveys in the fall of 2008 counted a total of 318 coho carcasses in the upper Trinity River, 91.82 \% of which were observed from Lewiston Dam to below Indian Creek (Hill, 2010). Based on a Generalized Additive Model (GAM), in the fall of 2008 an estimated 565.5 coho salmon redds occurred from Lewiston Dam to just downstream of Weaver Creek (Chamberlin, 2010). Trinity River Hatchery (TRH) in Lewiston, CA has an annual production goal of releasing 500,000 yearling hatchery-produced coho salmon by volitional release on or about March 15 each year. Between March 16, 2009 and March 23, 2009, 457,478 brood-year 2007 hatchery raised yearling coho salmon were volitionally released into the Trinity River (Sinnen, et al., 2010).

Naturally produced juvenile coho salmon utilize the upper main stem Trinity River and associated peripheral habitats for hatching out and rearing. During the summer base flows juvenile coho prefer habitats that provide flow and predator cover that is most frequently observed in off-channel areas, particularly side channels and backwaters that contain non-emergent vegetative cover or small woody debris (Garrison and Sinnen, 2008). The study design precludes any data information regarding juvenile coho salmon utilizing river side channels. Such information will be included in a separate report.

This study is limited to the presence / absence and enumeration of juvenile coho salmon in the upper main stem Trinity River from Lewiston Dam to the confluence of Indian Creek during the summer of 2009. At the time of this study in August 2009, post fry ( $>50 \mathrm{~mm}$ ) juvenile coho salmon in the study area were naturally produced from the brood-year 2008 cohort.

## METHODS

## Study area and survey period

The snorkel surveys for this study were conducted in August 2009 across two survey days in Julian week 31 and three survey days in Julian week 32. The study site included the upper 30.4 kilometers of the main stem Trinity River, from Lewiston Dam downstream to Indian Creek. Flow discharge rates during the study period were at the base flow release out of Lewiston Dam at 450 cfs. The study area has a temperature
regime (Figure 1) that supports juvenile coho salmon and encompasses a large section that is undergoing mechanical restoration (Garrison and Sinnen, 2008).

Figure 1. Lewiston Dam (Upper Trinity River) discharge (cfs) August 2009.

## Direct observation methods

Juvenile coho salmon point observations were made by two to three divers outfitted in a wet or dry suit using snorkel apparatus. The divers were accompanied by a raft and rower/data recorder. The river was surveyed in a downstream fashion. At each observation point the raft was anchored or beached until all the observation data was recorded (Appendix 1).

## Data Collection, Storage and Transfer

Each point observation was recorded on a field data sheet that included RKm, a GPS waypoint, right or left bank, number of juvenile coho salmon observed and comments. Observations were recorded to the nearest . 01 RKm, based on interpretation of aerial photos over-laid with a coordinate grid. GPS waypoints observations were recorded using a Garmin 12 XL GPS unit, rated for $<3$ meter accuracy. Waypoints were marked in decimal degrees, using WGS 84 map datum. Data were downloaded as a Microsoft Excel spreadsheet file from the GPS unit to a desktop computer. Files were converted into a GIS layer for use by TRRP.

## RESULTS

A total of 226 juvenile coho point observations were made from Lewiston Dam to Indian Creek. A total of 5,551 individuals were counted within these 226 point observations (Table 1). Densities of juvenile coho were neither uniform within nor across snorkel survey sections (Figure 2).

Distribution of juvenile coho within the upper river was clustered with highest densities observed just above the confluence of Rush Creek (Figure 3). The total number of point observations was highest in the section from Rush Creek to Bucktail, and lowest in the section from Poker Bar to Steelbridge. The total number of individual juvenile coho observations was highest in the section from Rush Creek to Bucktail and lowest in the section between Steelbridge to Indian Creek (Figures 4-6).

Table 1. Snorkel survey summary, upper Trinity River, August 2009.

| Sate <br> Snorkeled | Distance <br> $($ RKm $)$ | Point <br> Observations | Juvenile Coho <br> Observed |  |
| :--- | :---: | :---: | :---: | :---: |
| Lewiston Dam to Rush Creek | $8 / 3 / 2009$ | 5.43 | 41 | 1391 |
| Rush Creek to Bucktail | $8 / 4 / 2009$ | 4.84 | 71 | 2322 |
| Bucktail to Poker Bar | $8 / 10 / 2009$ | 4.93 | 54 | 1256 |
| Poker Bar to Steelbridge | $8 / 11 / 2009$ | 5.97 | 29 | 318 |
| Steelbridge to Indian Creek | $8 / 12 / 2009$ | 9.23 | 31 | 264 |
| Total | - | 30.40 | 226 | 5551 |

Figure 5. Aerial photograph of Trinity River, Lewiston, CA in vicinity of the confluence with Rush Creek. Overlay points in yellow indicate observations of 1 to 55 juvenile coho. Overlay points in bolded red indicate observations of 56 to 214 juvenile coho.

Figure 6. Aerial photograph of Trinity River, Lewiston, CA in vicinity of Salt Flat to Grass Valley Creek. Overlay points in yellow indicate observations of 1 to 55 juvenile coho. Overlay points in bolded red indicate observations of 56 to 214 juvenile coho.

The distribution of juvenile coho observations was not uniform across the survey sections. Empirically the largest numbers of juvenile coho were observed from Rush Creek to Bucktail (Figure 7). The largest numbers of point observations were also observed from Rush Creek to Bucktail (Figure 8), however the section of the river just upstream of Rush Creek had several clustered "hot spots". The highest density of juvenile coho per point observation per RKm was observed in the reach from Lewiston Dam to Rush Creek (Figure 9). This is most likely to the high density point observations from in the vicinity of Cemetery Hole and just upstream from Rush Creek, as those areas have habitat and flows suitable for juvenile coho rearing.

Figure 7. Point observations of juvenile coho per snorkel section in the upper Trinity River, August 2009.

Figure 8. Number of juvenile coho observed per snorkel section in the upper Trinity River, August 2009.

Figure 9. Ratio of juvenile coho per point observation per RKm in the upper Trinity River in August 2009.

Although the study design was limited in both scope and context, in a generalized sense the number of juvenile coho observed in August 2009 compared to coho carcasses found on the carcass surveys of fall of 2008 demonstrates an offset positive correlation (Table 2, Figure 10). Most carcasses were observed in the section from Lewiston Dam to Old Bridge. However the most juveniles in 2009 were located in the carcass section from Old Bridge to Bucktail, which includes the slow water Rush Creek "hot spots". (Figure 11).

Coho redd estimates for the fall of 2008, were highest in proximity to Lewiston Dam. (Chamberlin, 2010) (Table 3). However, the ratio of estimated redds in 2008 to observed juvenile coho was highest in proximity to Rush Creek (Figure 12). This is completely consistent with juvenile coho rearing habitat preference.

## DISCUSSION

The highest density point observations were recorded from Old Lewiston Bridge, to Grass Valley Creek. This is completely consistent with junvenile coho summer rearing habitat preference. This stretch of the Trinity River has reaches of slow water and has areas of non-rooted aquatic vegetation as well as relatively cool water summer temperatures. Additionally, although outside the scope of the study design, this reach of the Trinity River has several side channels and peripheral habitat.

The number of juvenile coho observed in summer 2009 compared with adult coho carcasses observed in fall 2008 is relatively low in the section closest to Lewiston Dam and peaked in the third section downstream of Lewiston Dam. This is consistent with juvenile habitat preference as there is minimal summer rearing habitat in close proximity to the dam. The highest ratio of the 2009 juveniles : 2008 carcasses was observed in the third carcass section. This is also consistant with juvenile habitat preference as there is suitable summer rearing habitat in the third carcass section.

The lack of juvenile coho salmon in suitable habitats whenever brown trout were present has been demonstrated in controlled experiments (Bugert and Bjornn 1991) and may explain why the number of coho observations decreased in the lower part of our study section, an area where brown trout become more common.

## RECOMMENDATIONS

Reconnect peripheral areas in the upper main stem Trinity River to provide essential winter habitat and/or flood protection habitat. Several studies have demonstrated the importance of off-channel habitat for winter rearing and flooding episodes. (Bell et al 2001, Beechie et al 1994, Swales and Levings 1989). Since the upper Trinity River is now managed for spring peak releases of up to $12,000 \mathrm{cfs}$, it may be vitally important that juvenile coho in the upper Trinity River have refugal areas during the high flow release period, which generally coincides with their emergence timing (March through May). Mechanical reconnections of side channel and peripheral juvenile coho habitat may be a good approach.

Evaluate the difference between several small patches of juvenile coho summer rearing habitat or a few large patches of habitat. Depending upon the intent of restoration efforts, it might be better to have several smaller patches of juvenile coho summer rearing habitat versus isolated pockets of high density juvenile coho summer rearing habitat.

Maintain the monitoring of "wild" to "hatchery" ratios in natural escapement estimates. Although 5,550 juvenile coho were observed in the survey, it is likely that upwards of $80 \%$ of these are from hatchery genetic stocks. A reduction of the TRH production goal of releasing 500,000 yearling coho annually may potentially reduce future natural
escapement of hatchery stocks. Designing and implementing a molecular genetic sampling protocol to evaluate naturally produced juvenile coho for stock heredity, may be a valuable tool in managing this issue (i.e. determine what percentage of naturally produced juvenile coho are from hatchery stocks versus wild stocks).

Design and implement a method of evaluating, enumerating or monitoring brown trout abundance and impact on the juvenile coho populations in the upper river. As of current there is no way of numerically discerning what effects predatory brown trout have on juvenile coho populations and densities. Brown trout prey upon juvenile coho and are distributed in the upper river.
