## Foreword

This is the California Department of Fish and Game's (CDFG) Trinity River Basin Salmon and Steelhead Monitoring Project's twenty-second annual report to the United States Bureau of Reclamation (Reclamation). The activities conducted January 1, 2010 through December 31, 2010 were performed under terms of Cooperative Agreement Number R11AC20520. The field work was conducted by personnel of the CDFG Klamath-Trinity Program. Cooperators of CDFG field studies include the Hoopa Valley Tribal Fisheries (HVTF), Yurok Tribal Fisheries Program (YTFP), U.S. Fish and Wildlife Service (USFWS) and U.S. Forest Service (USFS). The HVTF, YTFP, and USFWS were contracted separately by Reclamation for cooperative and singular work performed during FFY 2010. Please refer to those respective agency/tribal fisheries departments or Reclamation for information regarding other projects/studies.

This year's CDFG work was comprised of six separate projects (Tasks) performed on the lower Klamath River, the main stem Trinity River, and at Trinity River Hatchery. The necessity for performing our Klamath-Trinity basin monitoring activities are outlined in several Acts of Congress including Public Law 386 (69 Stat. 719), August 12, 1955; Public Law 98-541, October 24, 1984; the "Trinity River Basin Fish and Wildlife Management Reauthorization Act" of 1995; and the Trinity River "Record of Decision", 2000.

## Acknowledgements

Thanks to the CDFG technicians without whom our data collection would not be possible: Nancy Barnes, Linda Battin, Michael Bradford, Jason Coburn, Becky Dutra, Melissa Gordon, Mark Kerr, Stephen Marten, Sherry Mason, Sarah Meese, Carl Meredith, Scott Merlette, Gaytha Morningstar, Todd Newhouse, Eric Ojerholm, Roddy Park, Jane Sartori, Garth Savage, Guy Smith, Ron Smith, Cindy Walker, Eileen Williams, Paula Whitten, and Andy Yarusso. And thanks, as always, for the administrative support from Brenda Tuel and Mary Kuehner.

We are grateful for the help of the many biologists, technicians, crew, staff, and volunteers from HVTF, YTFP, USFWS, USFS, and other CDFG projects who worked cooperatively with us on our field projects.

We appreciate the cooperation of the CDFG Trinity River Hatchery staff during salmonid recovery, and landowners Doris Chase, Tom O'Gorman, Pierre LeFuel, the Bureau of Land Management and the U.S. Forest Service for access and general project support.

The CDFG monitoring program was approved by the Trinity Management Council (TMC) and funded through the Trinity River Restoration Program (TRRP) office in Weaverville, CA. We thank Jennifer Faler and the TRRP staff for their input and effort administering our projects and contracts.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2010-11 SEASON 

TASK 1

## ANNUAL RUN-SIZE, HARVEST, AND SPAWNER ESCAPEMENT ESTIMATES FOR TRINITY RIVER BASIN CHINOOK AND COHO SALMON AND STEELHEAD

by
Mary Claire Kier

#### Abstract

The California Department of Fish and Game's Trinity River Project conducted tagging and recapture operations from July 2010 through March 2011 to obtain adult spring-run (spring Chinook) and fall-run (fall Chinook) Chinook salmon (Oncorhynchus tshawytscha), coho salmon (O. kisutch), and fall steelhead (O. mykiss) run-size, angler harvest, and spawner escapement estimates in the Trinity River basin. The information from Task 1 is used by the Trinity River Restoration Program (TRRP) to evaluate program objectives outlined in the Integrated Assessment Plan (TRRP, 2009)

Two weirs installed in the main stem Trinity River near the towns of Junction City and Willow Creek trapped 1,525 Chinook salmon, 911 coho salmon, 938 fall steelhead and 144 brown trout (Salmo trutta). Using a Petersen mark-recapture methodology, fish tagged at the weirs and recovered at Trinity River Hatchery (TRH), we estimated a run size of 11,285 spring Chinook migrated into the Trinity River basin upstream of Junction City weir. Using tags returned by anglers we estimated 454 spring Chinook were harvested, yielding an escapement of 10,831 fish. An estimated run-size of 40,792 fall Chinook migrated past Willow Creek weir (WCW), of which an estimated 315 were harvested by anglers, yielding and escapement of 40,476 fish. The coho salmon (coho) run-size and escapement in the Trinity above Willow Creek was estimated at 7,947 fish. No coho were reported harvested by anglers. An estimated 8,451 (3,811 naturally produced and 4,640 hatchery produced) adult fall steelhead returned to the Trinity River basin upstream of WCW. Anglers harvested an estimated 197 adult fall steelhead above the WCW, leaving 8,254 fish as potential spawners.

The coho salmon (coho) run-size and escapement in the Trinity River basin upstream of WCW was estimated at 7,947 fish. No coho were reported harvested by anglers. An estimated run-size of 8,451 ( 3,811 naturally produced and 4,640 hatchery produced) adult fall steelhead returned to the Trinity River basin upstream of WCW. Anglers harvested an estimated 197 adult fall steelhead, yielding an escapement of 8,254 fish.

## TASK OBJECTIVES

- To determine the size, composition, distribution, and timing of adult Chinook salmon, coho salmon, and steelhead runs in the Trinity River basin [Integrated Assessment Plan (IAP) assessment 13A - Monitor adult escapement of hatchery and naturally produced spring and fall Chinook, coho, and fall steelhead (TRRP, 2009)].
- To determine the in-river angler harvest and spawner escapements of Trinity River Chinook salmon and coho salmon, and steelhead (IAP assessments 16A,17A,18A, 19A - Monitor harvest (tribal, sport and commercial) of naturally produced spring Chinook, fall Chinook, coho salmon and steelhead).

## INTRODUCTION

The California Department of Fish and Game's (CDFG) Trinity River Project (TRP or Project) estimates the run-size and spawner escapement of fall-run Chinook salmon (Oncorhynchus tshawytscha), coho salmon (O. kisutch), and fall-run steelhead ( $O$. mykiss) in the Trinity River basin upstream of a weir near Willow Creek, California, and estimates spring-run Chinook salmon upstream of a weir near Junction City, California. The project is conducted in cooperation with the Hoopa Valley Tribal Fisheries Department (HVTF). Run size is the number of fish estimated to migrate from the ocean into the Trinity River basin, while spawner escapement is the number of fish that survive in-river harvest to spawn in natural areas or enter Trinity River Hatchery (TRH). A Peterson type mark-recapture analysis is used to make the estimations. This is a continuation of studies that began in 1977 with the trapping, tagging, and recapture of fall-run Chinook salmon (fall Chinook), coho salmon (coho), and fall-run steelhead (steelhead).

The information from Task 1 is used by the Trinity River Restoration Program (TRRP) to help evaluate program objectives [13A, 17A, 16A, 18A and 19A] outlined in the Integrated Assessment Plan (IAP)(TRRP 2009). The current escapement goals in the Trinity River basin for naturally-produced adults are 62,000 fall Chinook; 6,000 spring Chinook; 1,400 coho; and 40,000 steelhead. Similar goals for hatchery adult production are 9,000 fall Chinook; 3,000 spring Chinook; 2,100 coho; and 10,000 steelhead. Task 1 data are used to assess progress toward the goal of increasing harvest opportunity for dependent fisheries found in the Record of Decision (ROD) (Interior, 2000). Task 1 data are used in the short term to assess management decisions and add to long term trend analysis in pre- and post-ROD fish populations. The data also serve as baseline for current and future cross-functional ecological and physical evaluations, to estimate angler harvest numbers, the composition (race and proportion of hatchery-marked ${ }^{1 /}$ or Project-tagged ${ }^{2 /}$ fish), distribution, and timing of salmonid runs in the Trinity River basin.

[^0]Additionally, tagging provides information to determine angler harvest and growth rates of brown trout.

## METHODS

## Trapping and Tagging

## Trapping Locations and Periods

Trapping and tagging operations were conducted from July 29, 2010 through October 22, 2010 by TRP and HVTF personnel at two temporary weir sites located on the main stem Trinity River (Figure 1). The Junction City weir (JCW) is located 132.7 river kilometers (rkm) ( $\sim$ river mile (rm) 81.7) upstream from the Klamath River confluence ( $40^{\circ} 41^{\prime} 5.51^{\prime \prime} \mathrm{N}, 123^{\circ} 01^{\prime} 35.55^{\prime \prime}$ W) near the town of Junction City. The JCW was operated July 29 through September 29, 2010, and is primarily operated to capture, measure, and tag spring-run Chinook salmon (spring Chinook). The Willow Creek weir (WCW), is located 36.5 rkm ( $\sim \mathrm{rm} 22.7$ ) upstream from the Trinity River's confluence with the Klamath River ( $40^{\circ} 58^{\prime} 29.85^{\prime \prime} \mathrm{N}, 123^{\circ} 38^{\prime} 8.61^{\prime \prime}$ W) and was operated August 19 through October 22, 2010. The WCW is primarily operated to capture, measure, and tag fall-run Chinook salmon (fall Chinook).

Trapping at both weirs is scheduled five nights a week, beginning around dusk of each trapping night, and continuing until mid-day the next day. Each trapping day the weir is opened for at least five hours to allow fish to pass unimpeded through the weir, and it is generally opened over the weekend as well. Occasionally, trapping schedules are modified to allow for holidays or high flows which prevent trapping in a safe manner. Trapping and tagging are not conducted if stream temperatures exceeded $22^{\circ}$ Celsius.

## Weir and Trap Design

Since 1989, a Bertoni (Alaskan) weir design has been used at both sites (Figures 2-4). The weir is supported by wooden tripods set 2.5 m apart. Weir panels consisted of 3.0 $\mathrm{m} \times 1.9 \mathrm{~cm}(10 \mathrm{ft} \times 3 / 4 \mathrm{in})$ electrical conduit spaced 5.1 cm apart on center, leaving a gap of 3.2 cm between conduits. Conduit pieces are supported by three sections of aluminum channel arranged 0.92 m apart, which are connected to the supporting tripods. The tripods are anchored with cable to 1.8 m stakes driven into the stream bottom. The weir panels are angled at roughly a $45^{\circ}$ angle, with the top of the weir standing 1.8 m above the river bottom.

Figure 1. Location of trapping/tagging weirs near Willow Creek and Junction City, and Trinity River Hatchery, in the Trinity River basin, 2010 season.

Figure 2. Photograph of Alaskan-style weir tripods, support channels and conduit (looking upstream).

Figure 3. Photo (looking downstream) of 2010 Willow Creek weir. Note the boat gate (left side of picture) and two trap boxes.

Figure 4. Typical Junction City weir configuration (looking downstream). Note the single trap box (on left) and boat gate (on right).

The traps are made of 1.9 cm electrical conduit spaced 2.5 cm apart and welded into panels. The panels are wired together at the corners to produce a 2.4 m square box which is bolted to a plywood floor and covered with a plywood lid to prevent fish from jumping out. A fyke, also made of conduit panels, is installed on the downstream side of the trap to guide fish into the trap box and prevent their escape. The trap is placed on the upstream side of the weir, directly in front of 12 raised conduit pieces creating an opening approximately 60 cm . This opening allows fish to pass through the weir, through the fyke, then into the trap. To allow boat passage, gates approximately 5.3 m wide were inserted between two weir panels. The gate at JCW was constructed of welded conduit panels with 2.5 cm spacing between pieces of conduit and was perpendicular to the stream substrate. The gate at WCW was constructed of 4.0 cm mesh chain-link fencing supported by two livestock gates and was sloped downstream, even with the weir.

## Processing of Fish

At both weirs, all trapped salmonids are identified to species, measured to the nearest cm fork length (FL), and examined for hook, predator, or gill-net wounds or scars, fin clips, and tags. Each untagged, un-spawned salmonid judged in good condition is tagged with a serially numbered Floy Tag and Manufacturing, Inc. FT-4-3/ spaghetti tag (Project-tagged). Tags are inserted using an applicator needle through the fish's back approximately two cm below the base of the dorsal fin and $1 / 4$ the length of the dorsal fin, anterior of the posterior edge of the dorsal fin. At both weirs one-third of the Chinook

[^1]received $\$ 10$-reward tags, while the remaining two-thirds received non-reward tags. At WCW one-half of the adult steelhead received reward tags while the remaining fish received non-reward tags. All steelhead tagged at JCW are tagged with non-reward tags. Juvenile, or "half-pounder", steelhead are not tagged at either weir. Coho at both weirs are tagged with non-reward tags. At JCW, brown trout are tagged with serially numbered (Floy) FD-94 anchor tags; had there been any brown trout trapped at WCW in 2010 they would have been tagged with non-reward FT-4s.

In addition, scales are collected from one of every two Chinook captured in good condition at the weirs. Post season these scale samples are mounted and read by HVTF staff to inform the Klamath River Technical Team's Klamath River age composition analysis (KRTT, 2011).

Separation of Spring and Fall Chinook Runs at the Weirs and at Trinity River Hatchery Each year there is temporal overlap of the spring and fall Chinook runs in the Trinity River, but the run timing varies year to year so dates must be ascertained to separate the two races, for analytical purposes, at each of the weirs and TRH. The separation dates are derived utilizing coded-wire-tag information from fish recovered at TRH.

Approximately 25 percent of TRH-reared Chinook have coded-wire tags (CWTs) implanted in their snouts before their release from TRH. These fish are identifiable by the absence of their adipose fin, which is clipped off (ad-clipped) during the CWT tagging process. When these salmon are recovered at the hatchery their heads are removed and stored for later CWT extraction and de-coding. Each code identifies it as either a spring- or fall-run fish, among other information of origin (for CWT-related methods see Task 2 of this report). Each ad-clipped Project-tagged fish recovered at TRH is identified (after having their CWTs extracted and read) as a spring or fall run fish in the same manner. The Julian week (JW) in which the proportion of fall Chinook exceeds spring Chinook at each weir is then designated as the first week of the fall Chinook run at each weir. If there are two consecutive weeks with nearly identical proportions, then the first week is designated as spring run and the following as fall run.

Project-tagged (and non-Project tagged) fish without CWTs are classified as either spring or fall fish based on the date they enter the hatchery. If they enter the hatchery during the period associated with the spring run (based on CWT recoveries at the hatchery) they are considered spring Chinook. The Chinook entering the hatchery during the period associated with the fall run (based on CWT recoveries) are considered fall Chinook.

To help isolate and minimize spawning of spring-run with fall-run Chinook at Trinity River Hatchery, CDFG personnel annually close the TRH fish ladder for a ten-day period which in 2010 was between October 12 and October 22, 2010 (JW 42 plus days on each side of JW 42). The timing of the annual ladder closure is the period historically associated with the arrival of the fall Chinook to TRH. If after CWTs are analyzed the separation of the two Chinook races should have been other than JW 42 any mixed race eggs are destroyed.

Estimation of Numbers of Spring and Fall Chinook at Trinity River Hatchery
To estimate the respective numbers of spring and fall Chinook without CWTs that enter TRH, the numbers of tags recovered from each returning CWT group are expanded by the CWT production multiplier (the ratio of tagged to total Chinook released by same strain, brood year (BY) release site, release group and date). For example, 244,661 marked fall yearling Chinook of CWT group 06-88-09 plus 751,089 unmarked fall yearling Chinook were released from TRH in October of 2008. The expanded estimate for each return from this group is $4.06992((244,661+751,089) / 244,661)$. Each CWT return is expanded by its production multiplier to estimate the total number of spring or fall Chinook that entered the hatchery. If more Chinook entered the hatchery on a particular sorting day than could be accounted for by the expansion of all CWT groups, the additional fish are considered naturally produced. Conversely, if fewer Chinook entered the hatchery on a particular sorting day than could be accounted for by expansion of all CWT groups that lack of fish would be a recorded as a negative number of naturally produced fish in the daily CWT expansion...but that has not ever occurred (Sinnen, DFG, pers. com) These fish are designated as either spring run or fall run in the same proportions that were determined by the expansion of the CWT groups on that day.

Determining the Separation between Summer, Fall, and Winter Steelhead Runs at the Weirs
Throughout this report we refer to fall-run adult steelhead, when actually we are reporting on a mix of runs. Most of the steelhead we encounter at the WCW are fall-run steelhead, but there is temporal overlap in the run-timing of the summer, fall, and winter runs, as evidenced by a higher proportion of fish caught without ad-clips early in our sampling season (ie mid-August), and again toward the end of the season (November). The TRH endeavors to produce fall-run steelhead ( $100 \%$ of which are marked with an ad-clip). Until such time as we can distinguish the runs from each other we will continue to refer to all the steelhead we catch at Willow Creek weir as fall-run steelhead.

## Size Discrimination Between Adult and Grilse Chinook and Coho Salmon

The size separating adult and grilse spring and fall Chinook is based on two criteria; length frequency data obtained at the two trapping sites and TRH, and length data obtained from groups of CWTed fish that enter TRH whose exact age are known. Chinook and coho salmon length-frequency data collected at the weirs and TRH are smoothed with a moving average of five 1-cm increments to determine the nadir separating grilse and adults. Fork length data from TRH Chinook was only used from weeks in which $\geq 90 \%$ of the Chinook could be designated as either spring run or fall run as explained by the expansion of CWTs.

Coho salmon do not receive CWTs, nor are scales retained for age analysis; therefore exact ages of coho are unknown. The separation of grilse and adult coho is based entirely on length-frequency analysis.

Size Discrimination Between Adult and Immature Steelhead
All steelhead $>41 \mathrm{~cm}$ FL are considered adults, and steelhead $<41 \mathrm{~cm}$ FL captured at the weirs are considered sub-adults or "half-pounders". These "half-pounders", which spend only 2 to 4 months in the ocean before returning to the river in late summer and early fall are sexually immature fish which feed extensively in freshwater and are highly prized by sport anglers. Half-pounders over-winter in the river without spawning before returning to the ocean and return as mature adults during subsequent migrations. Halfpounders have a very limited geographic distribution and are known to exist only in the Rogue, Klamath-Trinity, Mad, and Eel River systems. Half-pounders that enter TRH are tallied and returned to the river.

## Recovery of Tagged Fish

## Weir Recovery

All salmonid carcasses recovered at the weir were measured to the nearest cm FL and examined for wounds, tags, fin clips, and spawning condition. All heads from ad-clipped fish were removed for the potential recovery and decoding of the CWT. After processing, all carcasses were cut in half to prevent recounting and returned to the river downstream of the weir.

## Tagging Mortalities

Tagged salmonids recovered dead at the weir, in spawning surveys, or reported dead by anglers were considered tagging mortalities if there was no evidence they had spawned and they were recovered dead less than 30 days after tagging. Tagged fish recovered dead more than 30 days after tagging, or those that had spawned, regardless of the number of days after tagging, were not considered tagging mortalities.

## Angler Tag Returns

All the tags placed on fish at the weirs were inscribed with the TRP Arcata field office address and the word RETURN. The information from returned Project-tags by anglers and river enthusiasts allowed for estimation of angler harvest and catch and release rates for all species marked. All anglers that returned tags were sent questionnaires asking the date and location of their catch and whether they harvested (kept) or released their catch. The questionnaire informed them of the fish's tagging date and tagging location.

Tags returned to the TRP Arcata field office through May 31, 2011 were included in assessing harvest and catch and release rates. The limited number of 2010 tags returned after that date were processed for payment but not used for analysis.

## Trinity River Hatchery Returns

The TRH fish ladder was opened September 3, 2010, closed October 12-22 to separate spring and fall Chinook and closed for the season March 8, 2011. The first spring Chinook spawning date was September 7. Hatchery personnel typically conduct fish spawning operations two days per week during the Chinook and coho spawn.

Additional spawn days occur during the peak of the runs in November. Steelhead spawning operations ensued one day per week from January 1 to March 8. 2011

All salmon and steelhead entering TRH are identified to species, sexed, examined for tags and clips, and measured to the nearest cm FL. Coho and adult steelhead that enter the hatchery prior to the start of spawning of those species receive upper caudal fin clips prior to live release to the river. Each salmon and steelhead that enters the TRH spawning house is measured to the nearest cm FL only once at the time of first TRH entry. Both coho and steelhead are known to make multiple returns to the hatchery within the same spawning season. We refer to these marked returns as "reruns". The purpose of the upper caudal clip is to prevent double counting of fish that have been released live to the river but return on subsequent days.

For spawning purposes, TRH staff initially sort fish as either sexually ripe or unripe. Ripe salmon are either spawned or killed, and ripe steelhead either spawned or returned to the river. Unripe Chinook salmon are either moved to holding tanks (becoming "hold-overs") for further ripening (up to 14 days) or are killed, and unripe steelhead are either held for further ripening or returned to the river. Prior to transferring to the holding tanks, unripe fish with ad-clips or Project tags are given a week-specific fin clip to indicate which week they entered TRH. Unripe fish without an ad-clip or a Project tag are tallied prior to being transferred to the holding pond. Held fish are then processed on a later spawning day, after the "fresh" fish are sorted and processed. Entry week fin clips are recorded from all holdover fish when processed.

The "hold-overs" TRH keeps at the beginning of the spawning of each of the races of Chinook, coho and steelhead are to ensure that during the course of the spawning of each of those species enough eggs will be available to meet the hatchery's egg need to produce the number of fish intended. Once the TRH egg-take quota is reached they cease to hold fish over.

For analytical purposes, Project-tagged salmon and steelhead recovered at TRH are generally assigned the FL recorded for them at the weir. The heads of all ad-clipped salmon are removed and placed individually in plastic bags with serially-numbered head tags noting the date, location of recovery, species, sex, and FL. Project personnel later perform extraction and decoding of CWTs.

## Spawner Surveys

With crews from U.S. Fish and Wildlife Service, U.S. Forest Service, the Yurok Tribe, and Hoopa Valley Tribal Fisheries Program, TRP staff conducted spawner surveys in the upper Trinity River from Cedar Flat (rkm 78) upstream to Lewiston Dam (rkm 180) and from Hawkins Bar (rkm 64) to Weitchpec (rkm 0). Fish recovered in these surveys were examined for spawning success and Project tags. Results of these surveys are presented in Task 4 of this report.

## Statistical Analyses

## Effectively Tagged Fish

The number of effectively tagged fish is estimated by subtracting from the total number of tagged fish the number of fish classified as tagging mortalities, tagged fish recovered downstream of the tagging site, and tagged fish that an angler caught and removed the tag before releasing the fish.

## Run-size Estimates

Run-size estimates were calculated using Chapman's version ${ }^{4 /}$ of the Petersen Single Census Method (as modified by Ricker (1975), wherein subtracting one from the fraction is dropped as it is viewed as having negligible effect):

$$
N=\frac{(M+1)(C+1)}{(R+1)} \text {, where }
$$

$\mathrm{N}=$ estimated run-size
$M=$ the number of effectively tagged fish
$\mathrm{C}=$ the number of fish examined at TRH
$R=$ the number of Project-marked fish recovered in the hatchery sample.
Assumptions of the Peterson run size estimates are:

- Fish trapped and released from the weirs are a random sample representative of the population;
- Tagged and untagged fish are equally vulnerable to recapture at TRH;
- All Project tags are recognized upon recovery;
- Tagged and untagged fish are randomly mixed throughout the population and among the fish recovered at TRH;
- All tag loss is taken into account, and,
- The population is closed (that population being made up of individuals upstream of each respective weir in the Trinity River basin)

Annually, TRP staff attempt to tag and recover enough fish to obtain 95\% confidence within $\pm 10 \%$ of the run-size estimate. The confidence interval estimator is selected using criteria established by Chapman (1948), and written into a program in dBase, that indicates, after the trapping and tagging data are input, which of the approximations, Normal or Poisson is appropriate to use. In the 2010-11 spawning season there were not enough spring Chinook, fall Chinook, or coho salmon caught to stratify grilse and adult salmon and obtain the 95\% confidence interval on each of the stratified portions of the run, therefore the estimate we used in each case was for the (un-stratified) run size as a whole. We then used the proportion of grilse/adults observed at each of the weirs for each species and applied those proportions to the run-size estimates to break them into grilse/adult numbers.

[^2]All steelhead run-size estimates are for adults only. All TRH-produced steelhead since the 1997 brood year have received ad-clips. The proportion of the run that was hatchery-produced is based upon the percentage of ad-clipped steelhead observed at WCW.

## Angler Harvest and Catch and Release Rates and Harvest Estimates

When reward tags are returned by anglers at a higher rate than non-reward tags, only returns from reward tags are used to determine harvest rates. When non-reward tags are returned at higher rates than reward tags, harvest rates are determined by combining the returns of both reward and non-reward tags.

Harvest rates are calculated for each species (and run of Chinook) by dividing the number of angler-returned tags from harvested fish by the number of effectively tagged fish. Independent harvest rates are calculated for grilse and adult salmon. Catch and release rate for each species (and run of Chinook) are calculated by dividing the number of angler-returned tags from caught and released fish by the number of fish effectively tagged plus the number of fish reported as released.

The number of fish harvested upstream of each weir is estimated by multiplying the harvest rates (for each species/race) by their respective run-sizes upstream of each weir.

## Use of Standard Julian Week

Weekly sampling data collected by Project personnel at the weirs and TRH are presented in Julian week (JW) format. Each JW is defined as one of a consecutive set of 52 weekly periods, beginning January 1 , regardless of the day of the week on which January 1 falls (Appendix 1). The extra day in leap years is included in the ninth week. This procedure allows inter-annual comparisons of identical weekly periods.

## RESULTS

## Trapping and Tagging

## Chinook Salmon

Spring/Fall Chinook Separation and Run Timing
Trinity River spring Chinook run between April and September while fall Chinook migrate August through December. For purpose of analysis, we designate the spring/fall separation point as a hard date; although in reality the timing of the two runs overlaps (Figure 5). Using CWT analysis we designated JW 37 as the last week of spring Chinook at JCW. No TRH origin spring run Chinook identified by CWT were observed at the WCW, nor were any WCW tagged Chinook captured during the spring spawning period at TRH. Therefore, all Chinook trapped at WCW in 2010 were designated fall Chinook.

We were unable to install the JCW until July 29, 2010 (JW 31) due to high river velocity at the weir site. The numbers of spring Chinook trapped were highest the first two weeks at 8.6 fish and 7.4 per night respectively; the fall Chinook comprised the majority of the run (as determined by CWT analysis) by JW 38 (Table 1, Figure 6). The weir was removed from the river September 29, 2010, on schedule.

At WCW in 2010, we installed the weir on August 19; we trapped that first night, and performed our first tagging of the season August 20 (JW 34). During the first three weeks of WCW trapping only 13 of 475 Chinook were marked with adipose clips indicating they were of hatchery origin, meaning the majority of the fish trapped were from natural production. Julian week 40 was our peak catch of fall Chinook with an average of 39.6 fish trapped per night. The catch dropped off after that, and during JW 43 we had only a single night of trapping before we had to remove the weir on October 22 for a storm event. We were unable to re-set the weir for the remainder of the season.

## Size of Trapped Fish

Spring Chinook trapped at JCW and TRH averaged 69.4 and 73.7 cm FL, respectively, with a combined average 73.4 cm FL (Figure 8, Appendix 4). In 2010 the nadir separating grilse from adult spring Chinook was between 57 and 58 cm FL. Data from known age, hatchery-marked spring Chinook that entered TRH supported the minimum adult fork length of 58 cm . While there was some overlap between sizes of age 2 and age 3 fish (Appendix 2), the mean FL of those CWTs were distinctly different. Applying the minimum adult size of 58 cm FL to the observed population, an estimated $13.8 \%$ of the spring Chinook observed were grilse at JCW, and $9.1 \%$ at TRH. Historically the nadir between grilse and adult spring Chinook fork lengths averages 52 cm , and has only been greater than 56 cm two years since 1977. We graphically present the fork length data as moving averages of five 1-cm increments to smooth the appearance, especially of those lengths we encountered less frequently, allowing the reader to more
readily identify the nadir between grilse and adult. Non-averaged data are presented in the appendices.

Fall Chinook trapped at JCW, WCW and TRH averaged 65.0, 68.4 and 74.7 cm FL, respectively, with a combined mean FL of 73.9 cm . (Figure 9). The nadir on the fork length distribution between grilse and adult fall Chinook indicated a maximum grilse size of 61 cm FL. Data from known age, hatchery marked fall Chinook entering TRH supported this separation between grilse and adults; there was very little overlap between sizes of age 2 and age 3 fish (Appendix 3 ).

Using the maximum grilse size of 61 cm , fall Chinook grilse comprised $30.8 \%$ and $15.8 \%$ of the run observed at WCW and TRH respectively.

The number of fish at each fork length is shown as a moving average of five, $1-\mathrm{cm}$ increments. The arrow denotes the size used to separate grilse and adults for analysis.

Figure 9. Fall Chinook fork lengths (cm) observed at Junction City weir, Willow Creek weir and Trinity River Hatchery and all sites combined during the 2010-11 season. The number of fish at each fork length is shown as a moving average of five, 1-cm increments. The arrow denotes the size used to separate grilse and adults for analysis.

## Effectively Tagged Fish

A total of 167 spring Chinook were trapped at JCW, of which 166 (23 grilse and 143 adults) were effectively tagged (Appendix 4). There was one tagging mortality detected and zero caught and released spring Chinook from which anglers reported removing tags (Appendix 8). A total of 53 (32.3\%) spring Chinook were tagged with reward tags ( 10 grilse and 43 adults); the remaining fish received non-reward tags. There were 55 (18 grilse and 37 adult) fall Chinook trapped at JCW in 2010, all of which were effectively tagged.

There were no spring Chinook trapped at WCW in 2010. A total of 1,303 fall Chinook were trapped at WCW, of which 1,281 were tagged. Of those 1,281 tagged fish (398 grilse and 883 adults), 1,266 of them ( 396 grilse and 870 adults) were effectively tagged (the number of effectively tagged fish excludes fish that were not tagged, tagging mortalities, and fish that had their tags removed by anglers (Appendix 5). There were 11 (two grilse and nine adult) tagging mortalities detected, and four (zero grilse, four adults) caught and released fall Chinook from which anglers reported removing tags (Appendix 9). Reward tags were placed on 427 (121 grilse and 306 adults), or $33.3 \%$, of the fall Chinook trapped at WCW; non-reward tags on the remaining fish ( 277 grilse and 577 adults).

## Incidence of Tags and Fin Clips

ad-clipped fish comprised 10.2\% of the spring Chinook captured (17 of 167) at JCW (Appendix 4). Forty four (26.3\%) of the 167 spring Chinook and six (35.5\%) of the 17 ad-clipped spring Chinook tagged at JCW were subsequently recovered at TRH (Appendix 8). Four of those six TRH-recovered ad-clipped fish were released from the hatchery as yearlings.

Of the 1,303 fall Chinook trapped at WCW, 10.0\% (130) were ad-clipped and of the 55 fall Chinook trapped at JCW, seven (12.7\%) were ad-clipped (Appendix 5). Two hundred and eighty-five of the 1,281 (22.2\%) fall Chinook tagged at WCW, and 18 of the 55 (32.7\%) fall Chinook tagged at JCW were recovered at TRH. Of the 285 fall WCW recovered at TRH, 58 had ad-clips. Five of the seven ad-clipped fall Chinook tagged at JCW were also recovered at TRH.

## Incidence of Gill-net Wounds, Hook Scars, and Predator Wounds

Four (2.4\%) of the 167 spring Chinook trapped at JCW had gill net wounds, as did five (9.1\%) of the falls. Crews also observed four wounds of unknown origin, 19 lamprey wounds, and two non-lamprey predator wounds on spring Chinook at JCW, and four lamprey wounds on the JCW fall Chinook.

Of the 1,303 fall Chinook trapped at WCW 189 (14.5\%) had gill net wounds. Also observed were seven fish with ocean (healed) hooking scars; five (fresh) hooking wounds, 38 wounds of unknown origin, 61 with predator wounds; four with lamprey wounds, and two with fungus and/or disease.

Table 3. Release data and recoveries of coded-wire tagged (CWT) and maxillary-clipped salmon trapped in the Trinity River at Willow Creek weir (WCW) and Junction City weir (JCW), and subsequently recovered at Trinity River Hatchery (TRH) during the 2010-11 season.

| CWT and release type ${ }^{\text {a }}$ | Species | Race | Brood <br> year | Date | Number of CWT fish | Origination Site | Number recovered / tagging site: |  |

[^3]b/ Fish with shed CWTs were designated as either spring or fall Chinook based on the date they were trapped at the weirs.
c/ These fish were raised at TRH but were used as screw trap quality control and released off-site within the Trinity River basin. d/ Since 1996, all coho produced at TRH have received a right maxillary clip (RM). Coho $<56 \mathrm{~cm}$ FL were classified as brood year 2008 and coho $>55 \mathrm{~cm}$ FL were classified as brood year 2007. Age cutoff based on fork length distribution.

## Coho Salmon

Run timing
Three coho salmon were trapped at JCW in 2010. At WCW we trapped our first coho of the season during JW 36. The largest component of the coho run passed through the weir during JW 40, with a mean of 65.4 per night trapped, decreasing through the rest of the season (Table 4, Figure 10), with a sampling season mean of $\sim 19.8$ fish trapped per night. A total of 908 coho salmon were trapped (146 grilse and 762 adults) at WCW during the 2010 season.

## Size of Trapped Fish

The average FL of coho trapped at WCW and TRH was 63.8 and 66.3 cm , respectively (Figure 11, Appendix 6). The size separating grilse from adult was based on the combined fork length data from coho salmon trapped at WCW and those that entered TRH, smoothed with a moving average of 5 1-cm increments. This year all coho salmon <56 cm FL were considered grilse. Grilse comprised 16.1\% and 11.9\% of the coho salmon trapped at WCW and TRH respectively.

## Effectively Tagged Fish

All three of the coho trapped at JCW were effectively tagged. Of the 908 coho trapped at WCW, 895 (144 grilse and 751 adults) were effectively tagged (Appendix 6). Due to poor condition (wounds or other stressors) 11 coho trapped at WCW were not tagged. There is no legal recreational coho fishery, though two coho were caught and released by anglers (Appendix 10). To discourage anglers from targeting coho, all coho were tagged with non-reward tags.

## Incidence of Tags and Fin Clips

Eight hundred seven of the 908 (88.9\%) coho trapped at WCW (140 grilse and 667 adults) bore right maxillary (RM) clips (Appendix 6), as did all three of the coho trapped and tagged at JCW. Four hundred ninety seven (55 grilse and 442 adults) of the WCWtagged coho were recovered at TRH (Table 3), whereas only one of the three JCW coho was recovered at TRH.

Incidence of Gill-net Wounds, Hook Scars and Predator Wounds
Gill net wounds were found on 92 of the coho trapped at WCW; two had healed (ocean) hooking scars, three had fresh hooking wounds, 43 had unknown wounds; 81 had predator wounds (including lamprey marks); and five had fungus, or looked diseased. One of the three coho trapped at JCW had gill net marks; no other wounds were present.

a/ Trapping at Willow Creek weir took place from August 20 - October 22, 2010.
b/ Coho < 56 cm FL were considered grilse.
c/ The right maxillary clipped fish are presented as a subset of the total grilse or adult coho caught.

Figure 10. Mean catch of coho trapped in the Trinity River at Willow Creek weir during 2010.

Figure 11. Coho salmon fork lengths (cm) observed at Willow Creek weir, Trinity River Hatchery and both sites combined during the 2010-11 season. The number of fish shown at each fork length is shown as a moving average of five, 1-cm increments. The arrow denotes the size used to separate grilse and adults for analysis.

## Fall Steelhead

## Run Timing

At JCW, 21 (18 adult and three half-pounder) steelhead were trapped all season, of which 10 adults, and the two half-pounder, had ad-clips. Julian week 39 yielded the highest number of fish trapped (eight), averaging 2.0 per night (Table 5, Figure 12). Of the 21 steelhead trapped, 13 were tagged, 12 of which had ad-clips. One JCW tagged steelhead was later recovered at TRH. The results of this particular tagging are purely qualitative in nature.

Nine hundred seventeen fall-run steelhead were trapped at WCW in 2010 (Table 6, Figure 13); 101 half-pounders ( $<42 \mathrm{~cm} \mathrm{FL}$ ) and 816 adults. The peak of the run was during JW 38 with an average of 63.2 fish per night trapped. The biggest week for halfpounders was also JW 38, when 39 were caught.

## Size of Fish Trapped

Steelhead caught at JCW, WCW, and TRH averaged 56.0, 57.3 and 60.6 cm FL, respectively (Figure 14), with a mean combined FL for the three sites combined of 59.6 cm . Adult steelhead ( $>41 \mathrm{~cm} \mathrm{FL}$ ) made up $85.7 \%$ and $88.9 \%$ of the steelhead trapped at JCW, and WCW, respectively.

## Effectively Tagged Fish

Of the 816 adult steelhead trapped at WCW in 2010, 809 were tagged. Only adult fish were tagged. Seven were not tagged due to poor condition and one was deemed a tagging mortality (anytime a fish is found on the weir within 30 days of tagging and has not spawned it is considered a tagging mortality). Anglers reported removing tags from 75 caught and released fish, leaving 733 effectively tagged adult steelhead. Of the 809 tagged fish, reward-tags were attached to 402 while the remainder (406) received nonreward tags.

## Incidence of Tags and Fin Clips

Ad-clips were found on 12 (57.1\%) of the 21 steelhead at JCW, 448 (48.9\%) at WCW and $2,100(98.3 \%)$ at TRH (Appendix 7). Three of the steelhead at WCW we had tagged in previous years. All steelhead released from TRH have been ad-clipped prior to release since brood year 1997.

## Incidence of Gill-net Wounds, Hook Scars and Predator Wounds

There were no wounds or scars seen on any steelhead at JCW in 2010. On the steelhead trapped at WCW we noted the following: 26 gill-net wounds; seven old hooking scars; one fresh hooking wound; 41 unknown wounds or scars; and 71 predator wounds.

## Brown Trout

## Capture Timing

During the 2010 sampling season, 144 brown trout were captured during 43 nights of trapping at JCW (Table 7, Figure 15). The highest catch occurred during Julian week 31 with a mean fish/night rate of 10.8. There were no brown trout trapped at WCW during 2010.

## Size of Trapped Fish

Brown trout captured this season ranged in size from 33 to 63 cm FL (Table 8, Figure 16).

## Effectively Tagged Fish

Of the 144 brown trout tagged at JCW in 2010, all of which were effective tags. Two Project-tagged brown trout were found in the carcass survey and one tag was found unattached to a fish. All of the brown trout at JCW were tagged with non-reward tags.

Incidence of Gill-net Wounds, Hook Scars and Predator Wounds
There were no gill-net wounds detected on brown trout at JCW in 2010, but 28 of the fish had readily discernible lamprey wounds on them. Two others had predator wounds of unknown origin.

a/ Trapping at Junction City weir took place July 30 - September 29, 2010 (Julian weeks 31 - 39).

Figure 16. Fork length distribution of brown trout trapped in the Trinity River at Junction City weir during 2010.

## Recovery of Tagged Fish

## Total Recoveries

Fish tagged at JCW and WCW were recovered from four different sources: Angler returns; upper Trinity River spawner surveys, Trinity River Hatchery, and tagging mortalities found on or near the tagging weirs. Length frequencies of spring and fall Chinook, coho, and steelhead tagged at the weirs and subsequently recovered are presented in Appendices 8-11.

Of the 167 tagged spring Chinook at JCW 36.5\% were recovered, whereas only $28.20 \%$ of the 1,336 fall Chinook tagged at JCW and WCW were recovered. Of the 900 coho tagged at WCW, $58.2 \%$ were recovered, as was $32.6 \%$ of the 820 adult fall steelhead recovered throughout the Trinity basin. Most of the recoveries, for all species, occurred at TRH.

## Tag Returns by Anglers

The adult fall Chinook in-river quota for the Klamath River basin during the 2010-11 season was 12,000 split evenly between the lower (below the Highway 96 Bridge in Weitchpec) and upper basins. Thirty three percent of that $12,000(3,960)$ is the Trinity River sport allocation, which is split 50/50 between two areas: Old Lewiston Bridge to Cedar Flat and Cedar Flat to Hawkins Bar. In addition to the quota, the fishing regulations were such that anglers were allowed to retain two spring Chinook or two daily bag limits which could equate to an angler possessing a total of nine fall Chinook (no more than six of those over 22 inches total length) four ad-clipped steelhead on the Trinity, only one on the Klamath. The take of coho was prohibited, while there was a total possession limit of 10 brown trout.

## Spring Chinook

Anglers returned two reward (zero grilse and two adult) and one (zero grilse, one adult) non-reward tags from harvested spring Chinook tagged at JCW. Based on those tag returns, the estimated total harvest rate of Project-tagged spring Chinook upstream of JCW was $0 \%$ for grilse, $4.8 \%$ for adults. There were no tags reported from the catch and release fishery, and one found tag (with no fish still attached) (Appendix 8).

## Fall Chinook

Anglers returned three reward (one grilse and two adult) and six (three grilse and three adult) non-reward tags from harvested fall Chinook tagged at WCW. Based on those tag returns, the estimated harvest rate of Project-tagged fall Chinook upstream of WCW was $1.0 \%$ for grilse and $0.6 \%$ for adults. Anglers reported the catch and release of zero grilse and three adult reward-tagged fall Chinook from WCW, and zero grilse and one adult non-reward tagged fish (Appendix 9). Using those numbers, the catch/release rates for fall Chinook upstream of the WCW were estimated at $0.0 \%$ of the tagged grilse and $1.0 \%$ of the tagged adults.

## Coho Salmon

To discourage the harvest of threatened coho salmon, all coho salmon tagged at WCW and JCW received non-reward tags. No tags were returned from any harvested grilse or adult coho salmon tagged at WCW, though we did receive two tags from caught and released adult coho (Appendix 10). Catch and release rates for coho salmon above the WCW were estimated at $0.0 \%$ for grilse and $0.3 \%$ for adults based on that return.

## Fall Steelhead

Anglers returned 89 tags from steelhead tagged at WCW. Of those 89 tags, 75 tags were from steelhead reported as caught/released, 13 from harvested fish, and one was a tag found loose (not attached to a steelhead when found) (Appendix 11). Based on tag return, an estimated $9.3 \%$ of the tagged steelhead migrating upstream of WCW were caught and released, and an estimated $2.4 \%$ (3.7\% of ad-clipped, $0.7 \%$ non-adclipped) of the (reward-tagged) steelhead were harvested.

## Brown Trout

All brown trout tagged at JCW received non-reward tags during 2010. Anglers returned four tags from caught and released tagged brown trout and two tags were recovered in the upper main stem spawner surveys.

## Spawner Surveys

Main stem Trinity spawner surveys were conducted by Project personnel in cooperation with YTFP, HVTF, USFS and the USFWS from September 07, 2010 to December 21, 2010 from TRH to Weitchpec. During the spawner surveys 12 spring (Appendix 8) and five fall Chinook tagged at JCW, and 41 fall Chinook (Appendix 9) and 23 coho (Appendix 10) tagged at WCW were recovered. There were zero Project-tagged steelhead, and only two Project-tagged brown trout recovered in the spawner survey in 2010. For additional information on the 2010 spawner survey refer to Task 4 of this report.

## Trinity River Hatchery

## Operation Dates

The fish ladder was opened September 03, with trapping and fish processing at TRH from September 07, 2010 (JW 36) through March 08, 2011 (JW 10). The ladder and trap were closed during parts or all of Julian weeks 41-43 to separate the spring and fall runs of Chinook. The ladder may have been also occasionally closed at the discretion of the hatchery manager for fish health concerns or labor constraints.

## Spring Chinook

Based on CWT recoveries, spring Chinook began entering TRH during JW 36 and continued through JW 40 (Figure 17, Table 9). Recovery of spring Chinook was highest the first week TRH was open (JW 36) when 185 CWTed fish entered the facility and decreased thereafter with only 10 CWTs recovered in JW 41 (and one straggler each in JWs 43 and 44). A total of 2,702 spring Chinook were recovered at TRH, from which

609 CWTs were recovered (Table 9). Based upon CWT expansion, an estimated 2,387 hatchery-origin spring Chinook entered TRH (Figure 17).

Of the 167 spring Chinook tagged at JCW, 39 (23.4\%) were recovered at TRH. The mean FL for spring Chinook trapped at JCW was 69.4 cm , whereas the spring Chinook recovered at TRH averaged 73.4 cm FL (Figure 8, Appendix 4). There were no spring Chinook tagged at WCW in 2010.

Spring Chinook age composition at TRH based on CWT analysis was 7.7\%, 26.5\%, and $65.8 \%$ age 2, 3, and 4 year old fish, respectively (See Task 2 of this report). There were no 5 year old spring Chinook detected in 2010.

## Fall Chinook

Based on the recovery of CWTs, the first fall Chinook entered TRH during JW 38 of 2010 (Figure 17, Table 11). The fall run peaked during JW 44 when an estimated 1,700 Chinook entered the facility, decreasing thereafter until the last Chinook entered during JW 51 of 2010. A total of 9,207 fall Chinook entered TRH, from which 2,143 CWTs were recovered (Table 11). Using CWT expansions, an estimated 8,356 (hatcheryorigin) fall Chinook entered TRH.

There were 55 fall Chinook trapped at JCW in 2010. Thirteen of those 55 (23.6\%) were recovered at TRH. Of the 1,281 tagged fall Chinook at WCW, 285 (22.2\%) were recovered at TRH. The mean FL for fall Chinook trapped at JCW was 65.0 cm , at WCW was 68.4 cm , and at TRH was 74.7 cm (Figure 9). For all three sites combined the mean FL for fall Chinook 73.9 cm .

Fall Chinook age composition at TRH based on CWT analysis was $14.6 \%, 45.5 \%$, and $39.8 \%$ age 2, 3, and 4 year old fish, respectively. There were no known-age 5 year old fall Chinook detected at TRH in 2010.

a/ The fish ladder was open September 03, 2010 through March 08, 2011 (JWs 36-10; closed parts or all of JWs 41-43).
b/ Entry week was the week that fish were initally sorted, although they may have actually entered the hatchery during the previous sorting week.
c/ Release types are either fingerling (f) or yearling (y).
$\mathrm{d} /$ The hatchery was closed to fish entry this week.
e/ No CWTs were recovered from these ad-clipped fish. Chinook with shed or lost tags recovered after October 07,2010 (JW 40 ) were considered fall Chinook.

## Coho Salmon

The first coho entered TRH during JW 40 of 2010. The coho run peaked during JW 43 and the last coho entered TRH during JW 2 of 2011 (Table 12). A total of 4,425 coho ( 3,899 adults and 526 grilse) were recovered at TRH during the season. Four hundred ninety eight of the 908 coho trapped at WCW were recovered at TRH ( $55.6 \%$ of the effectively tagged fish). The mean FL of coho trapped at WCW was 63.8 cm and the mean FL of all coho salmon recovered at TRH was 66.3 cm (Figure 11).

Of the 4,425 coho entering TRH, 4,222 (95.4\%) were observed to have right maxillary (RM) clips, indicating they were of TRH origin, while 203 (4.6\%) had no clips. These unclipped fish are believed to be either naturally produced coho salmon which entered the hatchery or TRH-produced fish which received no or poor clips prior to release from the hatchery (Table 12).

Based on length frequency analysis, TRH-produced, RM-clipped coho salmon were apportioned into two brood years. Coho < 56 cm FL (516) were considered grilse (age 2) from the 2008 brood year and accounted for $11.7 \%$ of the total trapped, while the remaining RM-clipped 3,706 (83.8\%) >55 cm FL were considered adults (age 3) from the 2007 brood year. The 203 non-RM clipped coho ( $4.6 \%$ of total) which entered the hatchery were also considered grilse or adults based on their length (Table 12).

## Fall Steelhead

Adult steelhead were recovered every week that the fish ladder and trap at TRH were open, though they did not arrive in sizeable numbers until the last week of October (JW 43) (Table 13). A total of 2,137 steelhead ( 2,037 adults $>41 \mathrm{~cm}, F \mathrm{~F}$ ) entered TRH during the season. Of the 809 adult fall steelhead tagged at WCW, 176 were recovered at TRH (Table 13, Appendix 7). The mean FL of effectively tagged steelhead at WCW was 59.9 cm and the mean FL of all adult steelhead recovered at TRH was 61.8 cm

Ad-clipped adults composed 55.0\% of the steelhead trapped at WCW (448 of the 816) and $98.2 \%(2,000 / 2,037)$ of the steelhead that entered TRH this season (Appendix 7). Beginning with the 1997 brood year, all steelhead released from TRH have been adclipped prior to their release.

## Run-size, Angler Harvest, and Spawner Escapement Estimates

## Spring Chinook Salmon

An estimated 11,285 (9,731 adults and 1,554 grilse) spring Chinook migrated into the Trinity River basin upstream of JCW. Based on the Poisson Approximation, the 95\% confidence interval for the spring Chinook run-size estimate was 8,426-15,765 (Table 14). Spawning escapement above JCW was an estimated 10,822 fish, including 2,702 spring Chinook that entered TRH (Table 15). This year's run-size estimate is $65.0 \%$ of the 31 year average spring Chinook run-size of 17,350 . Estimated spring Chinook runsize has ranged from 2,381 fish in 1991 to 62,692 fish in 1988 (Appendix 12). Anglers were estimated to have caught and kept 463 adults and zero grilse from the spring run.

## Fall Chinook Salmon

An estimated 40,792 (28,238 adults and 12,554 grilse) fall Chinook migrated into the Trinity River basin upstream of WCW. Based on the Poisson Approximation, the 95\% confidence interval for the fall Chinook run-size estimate upstream of WCW was 36,427-45,945 (Table 14). Trinity River fall Chinook spawner escapement, upstream of WCW, was estimated at 40,476 (12,427 grilse, 28,050 adult) fish, including 9,207 fall Chinook that entered TRH (Table 15). Harvest rates generated from tags applied at WCW were used to estimate 127 grilse and 188 adult fall Chinook harvested by anglers. The estimated total fall Chinook run-size, upstream of WCW, has ranged from 9,207 fish in 1991 to 147,888 fish in 1986 (Appendix 13). This year's fall Chinook estimated run-size of 40,792 is $97.1 \%$ of the 41,991 mean run-size for the years since 1977.

## Coho Salmon

An estimated 7,947 (6,669 adults and 1,278 grilse) coho migrated into the Trinity River basin upstream of the WCW in 2010. Based on the Normal Approximation, the 95\% confidence interval for the coho run-size estimate upstream of WCW was 7,305-8,619 fish (Table 14). Of those estimated 7,947 fish, 4,425 are estimated to have entered TRH (Table 15). Estimated coho run-size, upstream of WCW, has ranged from 852 fish in 1994 to 59,079 fish in 1987 (Appendix 14). This year's run-size estimate was 46.6\% of the 17,040 fish 34 -year average. No tags were returned from harvested coho; therefore harvest rates generated from tags applied at WCW were estimated to be zero for both grilse and adults (Table 15).

## Adult Fall Steelhead

An estimated 8,451 adult fall steelhead migrated upstream of WCW this season. The 95\% confidence interval for the estimate, based on the Normal Approximation, was 7,305-9686 adult steelhead (Table 14). The adult steelhead spawning escapement was estimated at 8,254 , of which 2,037 entered TRH. An estimated 25 naturallyproduced and 172 TRH produced steelhead were harvested by anglers above WCW (Table 15). In the 27 years for which we have data since 1980, run-size estimates have ranged from 2,972 in 1998 to 53,885 in 2007 (Appendix 15). The mean estimated runsize for fall adult steelhead in the Trinity River above WCW across the period of record is 14,706 fish. This year's run was $57.5 \%$ of the average.

Table 14. Run-size estimates and $95 \%$ confidence limits for Trinity River basin spring and fall Chinook and coho salmon, and adult fall steelhead during the 2010-11 season.

| Species/race | Area of Trinity River basin for run-size estimate | Stratum ${ }^{\text {a }}$ | Number effectively tagged ${ }^{\text {b }}$ | Trinity River Hatchery recoveries |  | Run-size estimate ${ }^{d}$ | Confidence limits$1-p=0.95$ | Confidence limit estimator |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Number examined for tags ${ }^{\text {c }}$ | Number of tags in sample |  |  |  |
| Spring Chinook | Upstream of | Grilse | 23 | 245 | 8 | 1,554 | 8,426-15,765 | Poisson Approximation |
|  | Junction City weir | Adults | 143 | 2,457 | 31 | 9,731 |  |  |
|  |  | Total | 166 | 2,702 | 39 | 11,285 |  |  |
| Fall | Upstream of | Grilse | 396 | 1,458 | 46 | 12,554 | 36,427-45,945 | Poisson Approximation |
| Chinook | Willow Creek weir | Adults | 870 | 7,749 | 239 | 28,238 |  |  |
|  |  | Total | 1,266 | 9,207 | 285 | 40,792 |  |  |
| Coho | Upstream of Willow Creek weir | Grilse | 144 | 526 | 56 | 1,278 | 7,305-8,619 | Normal Approximation |
|  |  | Adults | 751 | 3,899 | 442 | 6,669 |  |  |
|  |  | Total | 895 | 4,425 | 498 | 7,947 |  |  |
| Fall run steelhead | Upstream of Willow Creek weir | Adults | 733 | 2,037 | 176 | 8,451 | 7,305-9,686 | Normal Approx |

a/ Stratum: Grilse = two year old salmon; Adults = three years or older; Steelhead adults = fish greater than 41 cm FL.
b/ The number of effectively tagged fish was corrected for tagging mortalities, fish not tagged and fish which had their tags removed (caught and released).
c/ Numbers of spring and fall Chinook were estimated from expansion of coded wire tag recoveries at Trinity River Hatchery; coho and steelhead numbers were actual recoveries.
d/ Run-size estimates for coho were based on the proportion of grilse to adults observed at Willow Creek weir and Trinity River Hatchery combined; for spring Chinook on Junction City weir grilse/adult ratio only; and fall Chinook on the Willow Creek weir ratio.

Table 15. Estimates of Trinity River basin spring and fall Chinook and coho salmon, and adult fall-run steelhead run-size, angler harvest, and spawner escapement during the 2010-11 season.

| Species/ race | Area of Trinity River basin for run-size estimate | Stratum ${ }^{\text {a }}$ | Run-size estimate | Angler Harvest |  | Spawner Escapement |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Harvest rate ${ }^{\text {b }}$ | Number of fish ${ }^{\text {c }}$ | Natural area spawners ${ }^{\text {d }}$ | Trinity River Hatchery | Total |
| Spring | Upstream of | Grilse | 1,554 | 0.0\% | 0 | 1,309 | 245 | 1,554 |
| Chinook | Junction City weir | Adults | 9,731 | 4.8\% | 463 | 6,811 | 2,457 | 9,268 |
|  |  | Total | 11,285 |  | 463 | 8,120 | 2,702 | 10,822 |
| Fall | Upstream of | Grilse | 12,554 | 1.0\% | 127 | 10,969 | 1,458 | 12,427 |
| Chinook | Willow Creek weir | Adults | 28,238 | 0.7\% | 188 | 20,301 | 7,749 | 28,050 |
|  |  | Total | 40,792 |  | 315 | 31,270 | 9,207 | 40,476 |
| Coho | Upstream of | Grilse | 1,278 | 0.0\% | 0 | 752 | 526 | 1,278 |
|  | Willow Creek weir | Adults | 6,669 | 0.0\% | 0 | 2,770 | 3,899 | 6,669 |
|  |  | Total | 7,947 |  | 0 | 3,522 | 4,425 | 7,947 |
| Fall-run adult steelhead | Upstream of | Natural | 3,811 | 0.7\% | 25 | 3,749 | 37 | 3,786 |
|  | Willow Creek weir | Hatchery | 4,640 | 3.7\% | 172 | 2,468 | 2,000 | 4,468 |
|  |  | Total | 8,451 |  | 197 | 6,217 | 2,037 | 8,254 |

a/ Stratum: Grilse = two year old salmon, Adults = three years old or older, Steelhead adults were fish greater than 41 cm FL.
b/ Harvest rates were based on the return of reward tags for fall and spring Chinook and steelhead. There was no coho harvest.
c/ Calculated as the run-size times the harvest rate.
d/ Calculated as run-size minus angler harvest minus hatchery escapement. Natural area spawners includes both wild and hatchery fish that spawn in areas outside Trinity River Hatchery.

## DISCUSSION

Before the 2000 Record of Decision, spring flow releases from Lewiston Dam were much lower than the currently-mandated flows. JCW was historically installed in the beginning of May, trapping peak numbers of spring Chinook in late May to mid-June. Now the Trinity River main stem flows rarely recede to the 800 cubic feet per second (cfs) at Junction City (because of the scheduled water releases from Lewiston Dam) that JCW is able to be installed prior to mid-June, and sometimes not until much later. In 2010 the water year designation of "Normal" (flow and schedule) adopted by the Bureau of Reclamation, after input from the Trinity Management Council, had the river at a level precluding installation of JCW until the end of July, effectively missing all but the tail end of the spring Chinook run. Once installed, we were able to maintain a five night per week sampling schedule, excluding holidays, getting in 43 days of trapping at JCW before it was pulled on schedule at the end of September. The effect of this flowshortened sampling season was a relatively small proportion of fish marked at JCW and associated large confidence intervals (25.33\%-39.70\%) around our 11,285 spring Chinook population estimate. We are actively scouting new Junction City weir sites that would allow for a longer sampling window and more robust data upon which to estimate that population.

The numbers of spring Chinook returning to the TRH was largest during the first week of hatchery operations (JW 36) for the 2010-11season. That peak during the first week likely occurred because spring Chinook had been holding in the river over the summer months below the hatchery, at the end of anadromy caused by Lewiston Dam.
Although it has been suggested to open the ladder earlier in the season to avoid the first week peak, TRH management prefers not to allow these fish into the hatchery until they are nearly ripe for spawning.

In 2010 there was no late-August Hoopa Tribe Ceremonial Boat Dance (an oddnumbered year event only) so we were able to install WCW in JW 34. Our site was plagued by a near-nightly infiltration of five bears, which may have caused an unquantifiable decline in the number of fish trapped despite our best efforts to keep the bears at bay. We did not see bear-gnawed fish carcasses on the river bank, but the bears spent a lot of time in and around the traps and weir and we speculate more salmon than normal were staying away from the weir until it was opened up for quick passage mid-day (we noticed, anecdotally, an increase in the number of fish holding below the trap in the late mornings). We also had an increase in bear-induced damage or activity (bending or raising of conduit leaving gaps in the weir wide enough for salmon to get through, and breaking of the upper boat-gate panels (the jump screens)).

Other than the bear battles we had no disruption to our five nights per week trapping schedule until October 22, when we pulled the conduit to prepare for a predicated storm. The flows forecast for the weekend of October 23-24 should have been such the weir could ride it out with conduit pulled (especially in light of the fact little rain had yet fallen so the ground would need be saturated before the flows increased much), but the storm front was unseasonably wet (a typhoon remnant, it was later revealed) that
increased the flow substantially above the predicted volume. The river topped out at 12,200 cfs (USGS Hoopa gauge), well above the 3,500 cfs predicted, causing a catastrophic weir blow out, effectively ending the 2010 season. It continued to rain on and off for the remainder of the fall without the river receding to a trappable level.

The extremely strong grilse component to both the spring and fall Chinook runs in 2008 continued to contribute robustly to the runs as four year olds, comprising $62.9 \%$ of the springs, and $39.5 \% \%$ of the falls in 2010 (see Task 2).

The disproportion of fall Chinook grilse trapped at WCW versus those trapped at TRH was not as pronounced in $2010(30.8 \%$ v. $15.8 \%)$ as in 2009 ( $20.3 \%$ grilse at WCW versus $1.9 \%$ at TRH), but the possibility that the weir is somehow selectively trapping grilse has been suggested by some. We maintain much of this difference can be explained simply by larger numbers of grilse being naturally-produced than are hatchery-produced and that those naturally-produced grilse are escaping to the South Fork Trinity, the New River and other tributaries rather than to TRH. That the proportion of ad-clipped fall Chinook grilse to the total number of fall Chinook trapped is similar at both WCW and TRH (both sites less than $3.5 \%$ in 2010, and less than $1.0 \%$ in 2009), supports this supposition.

Too few grilse spring or fall Chinook or coho salmon were tagged to generate independent estimates for adults and grilse, therefore we used numbers of adults and grilse combined to generate the total tagged, total recaptured and total recovered fish when calculating spawning escapement and run-size estimates for each species or race. We then applied the proportion of grilse/adults caught at each respective weir only to the total estimate of spring Chinook or fall Chinook to come up with the proportion of grilse/adults in the run. For coho the division between grilse and adult was made purely by length frequency. The steelhead estimates above WCW are for adults only.

The escapement estimate is generated by subtracting from the run size estimate the harvest estimates, which are based on Project tags returned by anglers. In 2010 we received very few returned tags (ie nine of 1,265 fall Chinook tags) which has prompted us to come up with ideas to increase angler participation. We anticipate running a study with increased reward amounts in the near future to inform this process.

There were three coho caught at JCW in 2010; they were not included in the WCW coho discussion or figures. The WCW was installed prior to the arrival of the coho salmon run, which was concentrated there in Julian weeks 39 through 41. Only two coho were trapped at WCW in the two final weeks of sampling. Slightly more than half of all WCW-tagged coho were eventually recovered at TRH, and $92 \%$ of them were RMclipped (hatchery-origin) fish. The coho numbers at TRH dropped dramatically after JW 49, and the last coho of the season was trapped at TRH JW 2.

Unaccounted tagging mortality creates a positive bias in all mark-recapture studies (Hankin 2001). We attempt to account for tagging mortalities through recovery of
tagged fish found dead at the weirs and in carcass surveys, although we are not sure all tagging mortalities are found. Most of our tagging mortalities from WCW are observed during the early part of the season when water temperatures are high (near $22^{\circ} \mathrm{C}$ ). We believe that tagging mortality is not a constant rate and is a function of water temperature. This postulation leads to difficulty in applying a potential tagging mortality rate for the season. Hankin (2001) concluded that tagging mortality could substantially positively bias our estimates. Using Hankin's example: If $90 \%$ of untagged fish passing WCW survive to arrive at TRH (assuming that they are otherwise programmed to arrive at that destination), but only $75 \%$ of WCW tagged fish survive to arrive at TRH, then the approximate positive proportional bias would be almost $30 \%$. We have attempted to address this concern through our tagging protocol at the weirs. Fish are not tagged if deemed in poor condition or if they have already spawned, and all trapping is suspended if water temperatures exceed $21^{\circ} \mathrm{C}$. We identified 13 total tagging mortalities ( $0.4 \%$ ) out of more than 3,295 fish handled at the two weirs.

## RECOMMENDATIONS

1. In light of the continued need by the TRRP for the information used to evaluate the objectives outlined in the IAP and the numeric goals stated in the ROD, tagging and recapture operations for adult spring and fall Chinook and coho salmon, and adult fall steelhead in the Trinity River basin should be continued during the migration season, using the capture sites near Willow Creek and somewhere above the North Fork Trinity or Junction City.
2. Funding for re-instated monitoring of the South Fork Trinity River should be sought/identified/acquired. It is the largest tributary in the Trinity River Basin and has great production potential for fall Chinook and steelhead.

a/ Trapping at Junction City took place July 30 - September 29, 2010 (Julian weeks 30-39). Chinook caught prior to Julian week 38 were considered spring Chinook.
b/ Tagged fish found dead and unspawned within 30 days of tagging.
c/ Fish recovered in upper Trinity River spawner surveys.
d/ The fish ladder was open September 03, 2010 - March 08, 2011 (closed all or parts of JW 41-43).
e/ There were no spring Chinook tagged at JCw and reported as caught and released by anglers in 2010.
$\mathrm{f} /$ Fish reported as harvested by anglers.
$\mathrm{g} /$ Tags found on dead fish or found unattached.
h/ Spring Chinook <58 cm FL were considered grilse.

Appendix 9. Fork length (FL) distribution of fall Chinook tagged at Willow Creek and Junction City weirs and subsequently recovered during the 2010-11 season. ${ }^{\text {a }}$

a/ Trapping at Willow Creek took place August 20 - October 22, 2010; trapping at JCW took place July 30 - September 29, 2010.
b/ Tagged fish found dead and unspawned within 30 days of tagging.
c/ Fish recovered in upper Trinity River carcass surveys. There were no steelhead recovered in the 2010 survey.
d/ The fish ladder was open September 03, 2010 - March 08, 2011 (closed all or parts of JW 41-43).
e/ Fish reported as caught and released by anglers.
$\mathrm{f} /$ Fish reported as harvested by anglers.
g/ Tags found on dead fish or found unattached.

Appendix 12. Spring Chinook run-size, spawner escapement, and angler harvest estimates for the Trinity River upstream of Junction City weir, 1977 - 2010.

a/ Natural area spawners includes both wild and hatchery fish that spawn in areas outside Trinity River Hatchery
b/ The 1978 sport harvest of spring Chinook was limited by a salmon fishing closure beginning August 25, 1978.
c/ The sport harvest of adult spring Chinook was subject to seasonal and size limit restrictions.

Appendix 12 (continued). Spring Chinook run-size, spawner escapement, and angler harvest estimates for the Trinity River upstream of Junction City weir, 1977-2010.

Appendix 13. Fall Chinook run-size, spawner escapement, and angler harvest estimates for the Trinity River upstream of Willow Creek weir, $1977-2010$.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2010-11 SEASON 

# TASK 2 <br> SURVIVAL AND CONTRIBUTIONS TO THE FISHERIES AND SPAWNER ESCAPEMENTS MADE BY CHINOOK SALMON PRODUCED AT TRINITY RIVER HATCHERY 

by

Wade Sinnen and Mary Claire Kier

#### Abstract

A key objective of Task 2 is to estimate adult (age $\geq 3$ ) escapement of naturally- and hatchery-produced stocks of fall-run (fall) and spring-run (spring) Chinook salmon (Oncorhynchus tshawytscha). These estimates are derived from methods and data provided in Task 1 of this Annual Report. The escapement data provide short-term feedback to management actions and adds to long term trend analysis needed to help the Trinity River Restoration Program (TRRP) assess natural salmonid escapement objectives. Task 2 also provides return rate estimates from coded-wire-tagged groups of hatchery produced fingerling and yearling Chinook. These data provided a basis for Chinook salmon cohort reconstructions and are used to evaluate annual cohort performance.

For the 2010-2011 season we estimate a run-size of 6,780 naturally-produced and 4,505 hatchery-produced spring Chinook returned upstream of Junction City weir and a run-size of 24,393 naturally-produced and 15,853 hatchery-produced fall Chinook salmon returned to the Trinity River above the Willow Creek weir. After subtracting sport harvests and removing the grilse component, we estimate adult escapement of 5,213 naturally-produced and 3,781 hatchery-produced spring Chinook returned to the Trinity River above the Junction City weir. We estimate adult escapement of 14,616 naturally- and 13,335 hatchery-produced fall Chinook returned to the river above the Willow Creek weir. The annual adult escapement goals set by the TRRP for Trinity River are 6,000 naturally-produced and 3,000 hatchery adult spring Chinook and 62,000 naturally-produced and 9,000 hatchery-produced adult fall Chinook. For the 2010 season, the escapement of naturally-produced spring Chinook met approximately 91 percent of the TRRP production goal and the escapement of natural fall Chinook was approximately 24 percent of the goal.

Chinook in-river return rates (expressed as a percentage of release numbers) for the completed 2005 BY ranged from 0.044\% to 0.202\% for spring Chinook CWT groups, and from $0.017 \%$ to $0.296 \%$ for fall Chinook groups.

## TASK OBJECTIVES

- To determine relative return rates and the contribution to spawning escapement and in-river sport fisheries made by naturally- and hatchery-produced Chinook salmon, and to evaluate hatchery management practices aimed at increasing adult returns, while reducing competition between hatchery- and naturally-produced salmon.
- Develop cohort reconstructions for Chinook and evaluate cohort performance or year class strength, and population growth rate.

## INTRODUCTION

California Department of Fish and Game's (CDFG) Trinity River Hatchery (TRH) personnel annually propagate and release approximately 4.3 million juvenile Chinook salmon (Chinook). These include approximately one million spring-run (spring) and three million fall-run (fall) Chinook. The Chinook produced at TRH are mitigation for the loss of salmon and their habitat in the Trinity River upstream of Lewiston Dam. About two-thirds of the Chinook are released into the river from TRH in early June as "fingerlings" and the remaining fish are released in early October as "yearlings". Before they are released, approximately 25 percent receive coded-wire-tag (CWT) implants and adipose fin clips (ad-clips) to identify them. The Hoopa Valley Tribal Fisheries Department (HVTF) conducts CWT implanting operations at TRH and CDFG's efforts are directed at recovery and analysis of the information collected from CWTs.

Escapement estimates for spring and fall Chinook are produced with a Peterson type mark and recapture methodology. "Chinook escapement" is the number of Chinook that survive sport harvest (or associated mortality) to return to the Trinity River basin to either spawn in the river upstream of Junction City weir (for spring Chinook), or Willow Creek weir (for fall Chinook) or return to TRH. The escapement and harvest data provide information to help evaluate TRH and Trinity River Restoration Project (TRRP) management goals, and provide baseline data describing the current status and trends in TRH- and naturally-produced Chinook in the Trinity River basin. The annual escapement goals for Trinity River fall Chinook are 62,000 naturally produced and 9,000 hatchery produced fish. Escapement goals for spring Chinook are 6,000 naturally produced and 3,000 hatchery fish. These goals are mandated in the United States Department of Interior Record of Decision (2000) and have been incorporated into the TRRP's Integrated Assessment Plan (TRRP 2009).

This study is a continuation of previous studies conducted by the CDFG and is reliant on data presented in Sinnen, 2009, 2010a, 2010b, and 2011.

## METHODS

## Marking of Chinook Salmon at Trinity River Hatchery

Hoopa Valley Tribal Fisheries staff implant CWTs in the snouts of approximately 25 percent of all Chinook produced at TRH. Each fish implanted with a CWT is also marked with an ad-clip which identifies them as tagged. Before their release into the river HVTF conducts quality control to ascertain the true number of marked individuals after subtracting for fish with shed tags, poor ad-clips and mortalities. The estimated number of effectively tagged and ad-clipped fish is recorded on standard release forms and sent to the CDFG tagging coordinator for dissemination. The release forms detail the number of fish marked, the corresponding CWT tag code used for individual lots of fish and the estimated number of un-marked fish that are part of the lot. The number of marked fish plus the number of un-marked fish are summed and then divided by the number of marked fish to produce an expansion multiplier. The multiplier is used to estimate the number of hatchery produced fish for each CWT recovery (i.e. approximately four for every recovery). TRP staff maintain a file of all CWT codes, the corresponding biological information (species, brood year, race, size at release, date of release) and the expansion for each code. This information is then used to develop total hatchery contribution rates for escapement and harvest above weir sites in the Trinity River basin.

## Chinook Processing at Main Stem Weirs

We examine all salmon captured at two main stem Trinity River weirs (near the towns of Willow Creek and Junction City). The upper site, Junction City weir (JCW), is located approximately 47 rkm downstream of Lewiston Dam, the uppermost point of anadromy. The lower site, Willow Creek weir (WCW), is located 143 rkm downstream of Lewiston dam and approximately 36.5 rkm upstream of the Trinity River and Klamath River confluence near Weitchpec.

Both weirs are operated to capture a sample of migrating salmon and steelhead using mark-recapture methods (See Task 1 of this report for complete methods and results). The JCW is operated to estimate spring Chinook runs while WCW is utilized to estimate fall Chinook runs as well as coho and adult fall-run steelhead runs. At both weir sites all Chinook captured are examined for the presence or absence of adipose fins, as well as other biological information such as length, scarring, predator wounds, etc. A missing adipose fin indicates the fish is of hatchery origin and should contain a CWT. Each Chinook deemed in good condition is tagged with a serially numbered Floy Tag and Manufacturing, Inc. FT-4 ${ }^{1 /}$ spaghetti tag (Project-tagged) and immediately released. After the weirs are removed for the season the number and ratio of ad-clipped to non-ad-clipped Chinook is used to estimate the proportion of each run that is of hatchery origin.

[^6]
## Coded-Wire Tag Recovery

## Trinity River Hatchery

All Chinook salmon which enter TRH are examined for adipose fin clips (ad-clips) and Project tags, as well as other biological information. All Chinook salmon with ad-clips are given a unique head tag number and the head of that salmon is removed, placed into a bag with the head tag, and stored in a freezer for later CWT extraction and decoding in the laboratory. The CWT code identifies the race, release type (fingerling or yearling) and brood year (BY) of each fish.

## Chinook Salmon CWT Dissection

Heads from Chinook salmon recovered at TRH are processed in our office lab. The process for dissection is the following:

1) Heads and corresponding head tag numbers are removed from the storage bag one at a time.
2) Each head is run through a Northwest Marine Technologies FSD-I field metal detector. A beep from the machine indicates the presence of the tag or any other metal.
3) The head is cut into smaller pieces and passed through the detector until a small piece of head is left that contains the tag. The tag can then be visually detected and removed using a magnetized pencil.
4) The tag is placed into a $2 \times 3$ inch sealed baggie and is stapled to the corresponding head tag. If no tag is detected in the initial and subsequent passes through the metal detector, then it is assumed the fish had shed its tag prior to recovery at TRH. In this case, a code (100000) is assigned to the head tag. If the tag was initially detected but lost during the dissection process a separate code (300000) is assigned to the head tag to indicate such.

All recovered CWTs are read using a Leica Stereozoom 5 microscope equipped with a 10X wide-field eyepiece. The microscope has a continuous magnification zoom range of 7 X to 30X. The code is identified and transferred to the head tag. All head tags and corresponding CWT codes are entered into a database and merged into the TRH recovery database based on the common "head tag" field. Thus, each CWT code, along with the corresponding release information and TRH recovery information is a single record in our database ready for analysis.

## Estimation Techniques

Estimating the total return of individual CWT groups depends on a basin run-size estimate. In evaluating the return of CWT hatchery Chinook, we report on the individual year's return along with a summary of each CWT group throughout their five-year life cycle.

Total run-size and CWT return estimates for spring and fall Chinook are calculated for the Trinity River basin upstream of the JCW and the WCW, respectively. Escapement and harvest and corresponding CWT estimates for natural escapement areas below the
respective weirs and harvest in the ocean are not included in the estimates presented in this report.

We estimated contribution rates of TRH-produced Chinook salmon to total spring and fall Chinook run-sizes by expanding each of the individual CWT estimated run-sizes by its corresponding hatchery expansion factor (total releases represented by each CWT release group/CWTed fish released). In doing this, we assume that marked fish are representative of their unmarked counterparts.

The information needed to estimate the numbers of salmon of a specific CWT group that returned to the Trinity River basin and contributed to the fisheries and spawner escapement are:

1) Grilse and adult total run-size,
2) Angler harvest rate of grilse and adults,
3) Proportion of the run comprised of marked fish,
4) Proportion of CWT groups recovered at TRH, and,
5) Independent estimates of spring and fall Chinook run-size and angler harvest rates for each race of Chinook are required.

Methods to determine total run-size and angler harvest rate estimates were presented in Task 1 of this report.

To estimate the number of grilse and adult salmon above a specific weir site with a CWT, we used the equation:
$N_{c w t}=\frac{N W_{\text {adclip }}}{N W} \times \frac{N H_{\text {adcwt }}}{N H_{\text {adclip }}} \times N_{\text {runsizeestimate }}$
where:
$N_{\text {cwt }}=$ estimated number of Chinook salmon above the weir with a CWT;
$N W_{\text {adclip }}=$ number of salmon observed at the weir with an ad-clip;
$N W=$ total number of salmon observed at the respective weir;
NHadwct = number of salmon observed at TRH with an ad-clip and a CWT;
$N H_{\text {adclip }}=$ total number of ad-clipped salmon observed at TRH; and
Nrunsizeestimate $=$ run-size estimate.
Independent estimates were generated for grilse (2-year-old) and adult (ages 3-5) salmon.

Using the various CWT groups recovered at TRH, we estimated the fraction of the population upstream of the weir with a specific CWT with the equation:
$F_{\text {cwtgroup }}=\frac{N H_{\text {cwtgroup }}}{N H_{\text {adcwt }}}$
where:
$F_{\text {chtgroup }}=$ fraction of the salmon population with a specific CWT code;
NHcwtgroup= number of salmon observed at TRH with a specific CWT code; and

NHadcwt $=$ number of salmon observed at TRH with an ad-clip and a CWT.
We estimated the total number of grilse and adult Chinook salmon upstream of the weir with a specific CWT code with the equation:
$N_{\text {cwtgroup }}=N_{\text {cwt }} \times F_{\text {cwtgroup }}$
where:
$N_{\text {cwtgroup }}=$ estimated total number of salmon of a specific CWT group.
The estimated number of fish from each CWT group caught in the Trinity River sport fishery upstream of the weir was then estimated by the equation:
$S_{\text {cwtgroup }}=N_{\text {cwtgroup }} \times N_{\text {harvestrateestimate }}$
where:
SF cwtgroup $=$ number of salmon of a specific CWT group caught in the Trinity River sport fishery; and
$N_{\text {harvestrateestimate }}=$ harvest rate estimate .
We estimated the total number of fish of a specific CWT code group available to the spawner escapement by the equation:
$N_{\text {cwtescapement }}=N_{\text {cwtgroup }}-S F_{\text {cwtgroup }}$
where:
Ncwtescapement $=$ the total number of salmon of a specific CWT group available to the spawner escapement.

The estimated number of salmon of specific CWT code group available to natural spawner escapement was:
$N_{\text {cwtnaturalescapement }}=N_{\text {cwtescapement }}-N H_{\text {cwtgroup }}$
where:
$N_{\text {cwtnaturalescapement }}=$ the estimated number of a specific CWT group contributing to natural spawning escapement.

## RESULTS

## Coded-Wire Tag Recovery

We recovered 11,909 Chinook salmon at TRH in 2010, of which 2,753 (23.1\%) had ad clips. We recovered CWTs from 588 known spring Chinook and 2,041 known fall Chinook (Table 1). The remaining 124 ad-clipped fish had either shed their CWT (104) or the CWT was lost or unreadable (20). Chinook with shed, lost, or unreadable CWTs were classified as either spring- or fall-run based on their date of entry into TRH. Spring Chinook CWTs were represented by 11 release groups from the 2006 through 2008 BYs. Fall Chinook CWTs were composed of 23 release groups representing the 2006 through 2008 BYs (Table 1).

## Run-size, Angler Harvest, and Escapement of Coded-wire Tagged Salmon

## Spring Chinook

Based on estimated total Chinook run-size above JCW, the ad-clip rate of spring Chinook at JCW, the estimated angler harvest rate, and recovery of spring-run CWT fish at TRH, we estimate 1,117 (132 grilse and 985 adults) CWT spring Chinook returned to the Trinity River above JCW during the 2010 season (Table 2) and 47 adult and zero grilse CWT fish were harvested by anglers during the season. Escapement of CWT spring Chinook was divided between 546 fish recovered at TRH and 392 estimated to spawn in natural areas (Table 2). Based on CWTs, the known age composition of the 2010 spring Chinook run was composed of 132 (11.8\%) age 2; 283 (25.3\%) age 3; 702 (62.9\%) age 4; and zero (0.0\%) age 5 fish (Table 2).

## 2005 Brood Year

The 2010 spawning season was the last year for returns of the 2005 BY. Anticipated returns of this brood were low in 2010 both because the age five component is historically very small for Trinity River Hatchery Chinook stocks and because the 2005 BY produced low returns for ages two, three and four. In fact, no known age five fish (CWT identified) were observed at TRH or elsewhere in the upper Trinity River basin in 2010. The total contribution of the 11 (eight yearling and three fingerling) 2005 BY tag code release groups that returned to the Trinity River were relatively low and ranged from 0.044 to 0.202 percent (Table 3). The final total return rate for the 2005 BY spring Chinook release group was approximately 0.115 percent.

## 2006 Brood Year

Spring Chinook from the 2006 BY have returned at age two, three and four. This brood continues to return in strong numbers (especially the yearling CWT group 065360), with approximately 1.26 percent of this release group returned as of the 2010 spawning season (Table 3).

## 2007 Brood Year

Four 2007 BY release groups (three fingerling and one yearling) returned as three-year-
olds this season. The yearling CWT group, 068810, continues to return at the highest rate of the BY (Table 3). Spring Chinook from this BY are expected to return as fourand five-year-olds during the next two years.

## 2008 Brood Year

Three 2008 BY release groups (all fingerling) returned as two year olds this season. Their return rate averaged 0.057 percent. Spring Chinook from this BY are expected to return as three, four and five-year-olds during the next three years.

## Fall Chinook

Based on the estimated total Chinook run-size above WCW, the ad-clip rate of fall Chinook at WCW, the estimated angler harvest rate, and recovery of fall-run CWT fish at TRH, we estimate 3,906 CWT ( 600 grilse and 3,306 adult) fall Chinook salmon returned to the Trinity River above WCW during the 2010-11 season and that anglers harvested six grilse and 22 adult CWT fall Chinook. Escapement of CWT fall Chinook was divided between 2,058 fish recovered at TRH and 1,819 estimated to have spawned in natural areas this season (Table 2).

The fall Chinook CWT run was composed of 600 (15.4\%) age 2 fish, 1,763 (45.1\%) age 3 fish, 1,543 (39.5\%) age 4 fish, and zero ( $0.0 \%$ ) age 5 fish.

## 2005 Brood Year

The 2005 BY continued its pattern of low contribution in 2010, with zero fall Chinook 2005 BY fish identified in the run. Through age five, then, the total returns for the five fingerling and one yearling groups ranged from $0.017 \%$ to $0.296 \%$ (Table 4). Age three returns were the most numerous for all release types of this BY. The fish released from this BY are considered to have completed their life cycle this season.

## 2006 Brood Year

Five release groups (four fingerlings and one yearling) have returned to date as twothree and four-year-old fish (Table 4). The yearling group, 065361, has experienced the best returns to date, with $1.344 \%$ through age four. Fish from this BY should return as five year olds in 2011.

## 2007 Brood Year

Six CWT groups (five fingerling and one yearling) from the 2007 BY returned as three-year-olds during the 2010 season (Table 4). Age two return rates were low for this BY, ranging from $0.000 \%$ to $0.025 \%$, and not much improved as three-year-olds, with the exception of the yearling group which had a surprising $0.649 \%$ return. Adult returns from these groups will occur over the next two years.

## 2008 Brood Year

Twelve CWT groups (ten fingerling and two yearling) from the 2008 BY returned as two-year-olds during the 2010 season (Table 4). Percent return ranged from 0.039\% $0.168 \%$. Adult returns from this BY will occur over the next three years.

a/ CWT = coded-wire tag.
b/ Chinook salmon released during June were smolts, those released in October were yearlings.
c/ TRH = Trinity River Hatchery.
d/ Totals are presented only for brood year 2005. These fish have reached five years of age and are considered to have comleted their life cycle.
e/ The term "adults" includes Chinook aged three through five.

Table 3. (continued) Run-size, percent return, in-river sport catch and spawner escapement estimates for Trinity River Hatchery-produced, coded-wire tagged, spring Chinook salmon returning to the Trinity River basin upstream of Junction City weir during the period 2007-2010.

a/ CWT = coded-wire tag.
b/ Chinook salmon released during June were smolts, those released in October were yearlings.
c/ TRH = Trinity River Hatchery.
d/ Totals are presented only for brood year 2005. These fish have reached five years of age and are considered to have completed e/ The term "adults" includes Chinook aged three through five.
f/ Experimental release group. Fish used in screw trap efficiency studies; released near North Fork Trinity River or Willow Creek.

## Contribution of Hatchery Produced Chinook to Total Estimated Run-Size

The TRH-origin spring Chinook component of the total run of spring Chinook returning to the Trinity River upstream of JCW was composed of 4,505 (535 grilse and 3,970 adult) fish of TRH origin. This represents $34.4 \%(535 / 1,554)$ of the grilse, $40.8 \%$ $(3,970 / 9,731)$ of the adult run, and $39.9 \%(4,505 / 11,285)$ overall (Table 5). The total escapement of natural and hatchery produced adult spring Chinook is estimated at 5,487 and 3,781 fish respectively.

The contribution of TRH-produced fall Chinook, upstream of WCW, was estimated to be 15,853 (2,429 grilse and 13,424 adults), which represents $38.9 \%(15,853 / 40,792)$ of the total estimated fall Chinook run. Trinity River Hatchery-produced fall Chinook were estimated to contribute $19.3 \%(2,429 / 12,554)$ of the two-year-olds (grilse) and 47.5\% $(13,424 / 28,238)$ of the total adult run this season.

Table 5. Estimated run-size, angler harvest, and spawner escapement estimates for Trinity River Hatchery-produced, spring and fall Chinook salmon expanded for unmarked releases (hatchery multiplier) returning to the Trinity River during the 2010-11 season. ${ }^{\text {a }}$

a/ Estimates are upstream of Junction City and Willow Creek weirs for spring and fall estimates respectively.
b/ CWT=coded-wire tag code. Fish are of the same race and release type (smolt or yearling).
c/ $B Y=b r o o d$ year.
d/ Expansion factor used to account for untagged releases of the same BY and release type for each CWT group.
e/ Run-size times TRH expansion factor.
f/ TRH=Trinity River Hatchery.
g/ Experimental groups released off-site for screw trap efficiency studies.

## DISCUSSION

Since CWT estimates are based, in part, on the overall run-size estimates for each race of Chinook, they are subject to the precision and potential biases associated with the mark-recapture estimates performed under Task 1 of this report. The impact of this would be most relevant to the number of fish estimated spawned in "natural" areas, due to the fact that hatchery recoveries are actual counts, while CWT fish estimated to spawn naturally are the estimated number of fish remaining after hatchery CWTs and estimated angler harvest are subtracted from the overall CWT estimate. Return rates are also affected by ocean and in-river harvest and escapement below the weir sites, which is not included in our estimates. Harvest and stray rates in these sectors can greatly affect river returns upstream of respective weir sites in any given year.

Run-size estimates have the potential for bias (see Task 1), which under most scenarios would tend to be positive. This bias should not affect hatchery contribution rates, however, since total CWT run-sizes are based on ad-clip rates observed at either JCW or WCW times the estimated runs above these sites. Thus, even if total run-size was adjusted lower, the ad-clip rate would remain the same, resulting in the same hatchery contribution rates. If, however, hatchery-produced fish are more vulnerable to capture, or their run-timing coincides more so than their natural counterparts with dates of weir operations (i.e. spring Chinook at JCW), the estimated contribution of hatchery fish could be biased. Yet another source of potential bias is vulnerability of capture. Assumptions of our CWT estimate include both equal probability of capture for hatchery or natural fish and equal probability of capture of Chinook throughout the entire run.

Run-timing is also a potential source of bias. Trapping constraints at JCW preclude operating there until late June, or as was the case this year, late July, so may affect our spring Chinook CWT estimates, while early storms (which seem to be increasing in frequency) can cause us to miss segments of the fall Chinook run at WCW, potentially affecting our fall CWT estimates. By the time the weir was blown out effectively ending trapping in 2010, however, most of the fall run Chinook had already passed (see Task 1, Table 2, Figure 7)..

We also assume that CWT fish that enter the hatchery are representative of the entire CWT population, but if an age or release type of hatchery-produced Chinook is more likely to stray than others, the proportional CWT run estimate, based on fish recovered at TRH, will over- or under-estimate the true proportions of each CWT group.
Recoveries of TRH-produced Chinook during the 2010 carcass surveys (Task 4) were generally consistent with TRH recoveries; although no 2008 BY spring CWT group Chinook were recovered this year.

Estimated in-river 2005 BY spring Chinook return rates of fingerling (0.12\%) and yearling ( $0.10 \%$ ) TRH releases fell well below the 20 year data set averages of 0.53 percent and 1.06 percent, respectively (Appendix 1). Fall Chinook fingerlings from the 2005 BY experienced an even lower return than their spring counterparts, returning at a meager rate of 0.03 percent. While the fall Chinook yearling releases fared an order of
magnitude better, returning at a rate of 0.3 percent, that return was still only roughly 20 percent of the average return over the 20 years on record (Appendix 2).

The contribution of hatchery-produced spring Chinook to total run-size was estimated at 39.9 percent of the run upstream of Junction City weir (Appendix 3), the second lowest annual contribution to the overall run and only the second year in 20 that the contribution has been less than 40 percent. Similarly, the contribution of hatcheryproduced fall Chinook to total run-size, upstream of Willow Creek weir, was estimated at 38.9 percent (Appendix 4). The reason for the low rate of hatchery fish in both the spring and fall runs of Chinook this year is unknown, but may be related to improved freshwater conditions for natural Chinook and/or habitat and flow improvements made by the Trinity River Restoration Program.

## RECOMMENDATIONS

1. Coded-wire tagging and release of smolt and yearling Chinook salmon, and the monitoring of adult salmon returns at Trinity River Hatchery, should be continued in 2011-12.
2. Monitor the annual TRH-produced Chinook salmon contribution rates to the overall runs to determine the relative status of naturally-produced Chinook salmon in the Trinity basin.
3. Continue spawner carcass surveys (Task 4) in the upper Trinity River to evaluate straying of TRH produced fish.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2010-11 SEASON 

TASK 3

# RELATIVE RETURN RATES AND CONTRIBUTIONS TO SPAWNING ESCAPEMENT MADE BY NATURALLY- AND HATCHERY-PRODUCED COHO IN THE TRINITY RIVER BASIN 

## by

## Steve Cannata and John Hileman

#### Abstract

Task 3 of this report provides quantitative estimates of the annual run-size and escapement of naturally- and hatchery-produced coho salmon (Oncorhynchus kisutch) in the Trinity River for the 2010-11 spawning season. Petersen type mark- recapture methods are used to estimate escapement numbers. The coho escapement estimates provide short term feedback to assess adaptive management actions and help evaluate success of long term Trinity River Restoration Program goals. The response from coho to recent changes in flow management is particularly important as they are listed as threatened under both the federal and State endangered species acts.

For the 2010-11 spawning season, we estimate a run-size of 7,947 coho ( $95 \% \mathrm{CI}=$ $7,305-8,619$ ) returned to the Trinity River, upstream of the Willow Creek weir (WCW). The run was composed of approximately 1,278 jacks (age 2 ) and 6,669 adult (age 3) coho. Approximately 89 percent ( 7,086 fish) of the run was composed of fish propagated and released from TRH. These include 4,222 returning to TRH and an estimate of 2,864 TRH stock returning to natural spawning areas. Approximately 861 naturally produced coho ( 709 adults and 52 grilse) returned to the Trinity River above the WCW with 204 of these entering TRH. Escapement targets set by the TRRP are for 2,100 coho to return to the TRH and 1,400 naturally produced coho to spawn in natural areas. The 2010-11 coho run-size estimates were below the target goal for naturally produced coho but exceeded target returns to the TRH. We estimate 0.36 percent of BY 2007 returned as two-year-olds in 2009-2010 and 1.27 percent returned as three-year-olds in 2010-2011 for a total BY return of 1.63 percent. We estimate 0.30 percent of the TRH BY 2008 coho returned as two-year-olds in 2010-2011. In April 2011, approximately 491,000 yearling coho of the 2009 BY were marked and released from TRH.

## TASK OBJECTIVE

- To determine the relative return rates and contributions to spawning escapement and the fisheries made by naturally- and hatchery-produced coho in the Trinity River basin.

## INTRODUCTION

A fundamental objective of the Trinity River Restoration Program (TRRP) is to increase natural production of anadromous salmonid populations in the Trinity River.
Assessments of the number of adults returning to spawn (escapement) of key species such as coho salmon (Oncorhynchus kisutch) therefore provide essential short-term feedback to annual TRRP management actions and for evaluation of long-term natural fish production objectives (TRRP 2009). The California Department of Fish and Game's (CDFG) Trinity River Project (TRP) staff perform empirical studies to provide the annual escapement estimates recommended by the Trinity River Restoration Program (2009). This report updates the existing baseline assessments for the 2010-11 spawning season. The coho escapement data are particularly important because Trinity River coho are listed as "threatened" under both the federal and State endangered species acts. Current status and trend information is needed to monitor recovery of the species.

The Trinity River coho population is composed of both naturally- and hatchery-produced stocks. Mixing of these stocks occurs during migration to natural spawning areas and within the TRH. For this report, natural spawning areas are considered mainstem and tributary reaches upstream of the Willow Creek weir (WCW) located on the main-stem Trinity River at river kilometer (rkm) 35 to TRH located at the base of Lewiston Dam (rkm 180) which is a barrier to upstream migration. The annual natural coho escapement target set by the TRRP is 1,400 adult fish in natural areas. Since 1997 the annual escapement estimate of natural coho to natural areas has ranged from 232 to 7,830 and met or exceeded the TRRP target in five years [i.e. 2001, 2003, 2004, 2005 and 2006 (Table A1)]. Each year the TRH propagates and releases approximately 500,000 yearling coho salmon to compensate for the loss of their habitat and production in the Trinity River upstream of Lewiston Dam. A Task 3 objective to identify 100 percent of the TRH produced coho with right maxillary clips (RM) enables separate escapement estimates for hatchery and natural coho stocks. Since 1997, the annual escapement goal to TRH of 2,100 coho has been exceeded except for the 1997 spawning season even though more TRH produced coho stray to natural areas than enter the hatchery (Table A1).

The coho run-size is estimated with Peterson mark-recapture methods using the Willow Creek weir to capture and mark fish. Recapture of fish occurs at the TRH. Run-size is the number coho estimated to migrate to the Trinity River Basin above the Willow Creek weir and spawner escapement is the number of those fish that survive in-river harvests. However, because coho are listed as threatened under both the federal and State
endangered species acts, sport take of coho is not permitted within the study area so run-size and escapement estimates should be equal. All estimates are stratified to jack (or grilse) and adults and include annual return rates for each brood year (BY) produced at TRH. Quantitative results are mainly drawn from analysis of coho population estimates presented in Task 1 of this report.

## METHODS

## TRH-Produced Coho Run-Size, Escapement, and In-River Harvest

The escapement total is estimated with a Peterson type mark-and-recapture study that is reliant on marking upstream migrating fish with spaghetti tags (tags) at the WCW and recapture of fish as they enter the TRH. Trapping and tagging operations at the WCW were conducted August 20, 2010 to October 22, 2010. The first coho was captured at the weir the week of September 3, 2010. All coho entering TRH are counted, inspected for tags and measured to the nearest centimeter (cm) fork length (FL). Coho were collected at TRH from the week of October1, 2010 to the week of January 8, 2010. The fish are stratified into grilse and adult classes based on the length frequency distribution. A detailed description of mark and recapture methods, the population estimator used, and the assumptions underlying the validity of run-size estimates are provided in Task 1 of this report. To estimate the contribution of TRH-produced coho to run-size, escapement and in-river angler harvest above WCW, the following information is required:

1. Marking of coho production released from TRH.
2. Recovery totals of marked and unmarked coho returning to TRH.
3. Total coho run-size above WCW.
4. The percentage of marked coho salmon observed at WCW.
5. In-river angler harvest rates on coho above WCW.
6. Specific age class determinations.

Additionally, we assume that coho right-maxillary clipss do not regenerate and that the mark is recognizable.

To estimate the TRH-produced component of the run above WCW, we use the equation:

$$
N_{R M}=\frac{N W_{R M}}{N W} \times N_{\text {cohorun }}
$$

$N_{R M}$ = the estimated number of coho above WCW with a right-maxillary clip;
$N W_{R M}=$ the number of coho observed at WCW that were right-maxillary clipped;
$N W=$ the total number of coho observed at WCW; and
$N$ Cohorun $=$ the total estimated run of coho above WCW.

To estimate the number of un-marked coho above the weir we use the equation:

$$
N_{N}=N_{\text {Cohorun }}-N_{R M}
$$

where, $N_{N}$ = the estimated number of naturally produced coho above WCW.
The size separating grilse and adult coho is determined by performing length frequency analysis using WCW and TRH data sets. The number of grilse and adults in the coho run was determined by multiplying the proportion of each observed at WCW times the total run-size estimate. The number of RM coho for each age strata is estimated by multiplying the ratio of marked to unmarked coho observed at Willow Creek weir with the total age stratified run-size estimate. The remaining coho are considered naturally produced.

Coho harvest rate estimates are developed using angler tag return data presented in Task 1. Harvest rates are applied to the age stratified coho run to produce a harvest estimate. The estimate is apportioned to either RM clipped or naturally produced coho based on tag returns. Coho escapement is determined by the following equation:

$$
N_{\text {escapement }}=N_{\text {cohorun }}-H_{\text {coho }}
$$

where, $H_{\text {coho }}=$ the estimated number of coho harvested by anglers upstream of WCW.
Escapement is divided into Trinity River Hatchery escapement and natural escapement. Hatchery escapement is a direct count of RM clipped and unmarked coho that entered TRH, while natural escapement is estimated by the following equation:
$N_{\text {Naturalescapement }}=N_{\text {escapement }}-N_{\text {TRHescapement }}$
where $N_{\text {Naturalescapement }}=$ the estimated number of coho that spawned above WCW in natural areas; and $N_{\text {TRHescapement }}=$ the number of coho salmon that entered TRH. All estimates are stratified by grilse and adults and by RM-marked and unmarked coho.

Additional data compilation and analysis methods are reported in Sinnen and Null, 2002; Sinnen and Moore, 2000; Sinnen, 2004a, 2004b, 2005, 2006, 2008; and Sinnen and Hileman, 2009, 2010a and 2010b.

## Juvenile Coho Marking at Trinity River Hatchery

Marking of all TRH yearling coho is performed by CDFG personnel in a marking shed placed parallel to the raceways. The shed is moved along raceways with a fork lift, utilizing slots in each shed for this purpose. Raceways containing coho are segregated with removable barriers to isolate clipped from un-marked coho.

Coho are anaesthetized with carbon dioxide and their right maxillary (RM) bone removed with a pair of sharp surgical scissors. Marked fish are tallied with a manual
counter and returned to hatchery raceways. Observed mortalities of marked coho are counted and subtracted from the daily effectively marked total.

To determine overall marking success, we examine a sample of approximately five percent of the marked coho just prior to their release into the river. These fish are anaesthetized with carbon dioxide, measured to the nearest millimeter ( mm ) fork length (FL), and checked for quality of the maxillary clip. If more than $3 / 4$ of the bone was excised it is considered a good clip; less than that is considered a poor clip and the fish is re-clipped. Fish with no clips are counted, then clipped and returned to the raceway. After five percent of the fish are examined the total number of no clips is divided by the total sample x 100 to obtain the percent marking error.

## RESULTS

TRH-Produced and Natural Coho Run-Size, Escapement, and In-River Harvest
Nine hundred-eight coho were trapped at the WCW in 2010. From these, 895 were effectively tagged for the mark-recapture sample population. Using a Peterson type mark-recapture formula (Task 1) we estimate the total coho run-size for the 2010-11 season above WCW was $7,947(95 \% \mathrm{CI}=7,305-8,619)$ fish (Table 1).

We observed 89.2 percent of the coho captured and tagged at the WCW with right maxillary-clips, which indicates the proportion of TRH fish in the run-size estimate. Therefore, we estimate the run consisted of approximately 7,086 TRH-produced fish and 861 naturally-produced fish. A total of 204 coho without RM clips entered the TRH indicating approximately 657 naturally produced coho (619 adults and 42 grilse) returned to natural areas.

The size separating grilse and adults was determined at 56 cm FL (Task 1). Therefore 139 grilse (21\%) and 659 adults with RM clips were captured and marked at the WCW. Five grilse (5.2\%) and 92 adults tagged in the sample were without RM clips indicating they are most likely from natural production. From these data we estimate the 2010-11 coho run was composed of 1,278 grilse and 6,669 adults.

Anglers did not return any tags from harvested coho salmon in 2010, therefore we estimate that no harvest occurred upstream of WCW. With no detected harvest, the coho run-size and spawner escapement are equal in number. Although the sport take of coho, a state and federally listed threatened species on the Trinity River, has been prohibited since 1995; some fish are occasionally harvested by unknowledgeable anglers due to mistaken identity or a lack of knowledge concerning the closure.

After their return to spawn in 2010, coho from the 2007 BY completed their typical threeyear life cycle. Based on age three coho run-size estimates presented above (Table 2) and age two estimates for 2009, the percent return rate for 2007 BY TRH-produced coho was 1.63 percent (Table 2). This (2010) is the first year for returns of the TRH
produced coho from the 2008 BY. The percent return of age 2 coho from the 2008 BY coho was $0.30 \%$. These fish will return during the 2011-12 season as three-year-olds.

Estimated spawning escapement of 2007 BY TRH-produced coho consisted of 3,706 (63.3\%) fish that entered TRH and 2,146 (37.7\%) fish estimated to have spawned in natural areas (Table 3).

## Juvenile Coho Marking at TRH

Trinity River Project personnel performed RM clips on approximately 493,648 2009 BY coho, representing the entire production at TRH. We began marking coho in January and finished in early March, 2011. Approximately 2,810 coho were recorded as post clipped mortalities.

a/ Identifying clip. Beginning with the 1994 brood year, all coho salmon released from Trinity River Hatchery received right maxillary (RM) clips.
b/ Number of marked (RM) coho estimated released.
c/ Age classes are determined using length frequency analysis.
d/ TRH= Trinity River Hatchery, actual count.

We conducted a quality control check to determine our clipping effectiveness for coho March 4-9, 2011. We measured and examined approximately 2\% of the coho in each raceway. The percentage of coho with proper clips within each raceway ranged from $99.9 \%$ to $100 \%$ and averaged $99.9 \%$ for the 10,058 fish examined. Based on these data we estimate that 490,839 coho were effectively clipped and released (Table 1). Coho averaged 159 mm FL and ranged in size from 80 to 289 mm FL. We estimate that 149 unmarked coho were released for a total release number of 490,988 fish. All BY 2009 coho were volitionally released from TRH March $15-28,2011$. These fish are expected to return as grilse and adults in 2011 and 2012, respectively.

Table 3. Production, marking totals, and quality control data for 2009 brood year coho salmon reared at Trinity River Hatchery and volitionally released March 15 through March 28, 2011.

## DISCUSSION

The 2010 coho escapement estimate of 7,947 fish is ranked the fourth lowest return to the Trinity River of the past thirteen coho spawning seasons. The total annual run-size estimates of coho salmon returning since 1997 have ranged from approximately 5,400 to 38,000 fish (mean and $95 \% \mathrm{Cl}=17,013 \pm 6521$ ). The 2010 escapement of 696 naturally produced adult coho to natural areas continued to be below the TRRP goal of 1,400 adults for the fourth consecutive year. Since 1997 the annual escapement estimate of natural coho to natural areas has ranged from 232 to 7,830 and met or exceeded the TRRP target in five years [i.e. 2001, 2003, 2004, 2005 and 2006 (Table A1)]. Several factors may influence natural coho production in the Trinity River, including the loss of juvenile rearing areas, TRRP management actions, and interactions with hatchery stocks. In addition, ocean conditions play a large role in coho production. Because escapement of TRH coho has also declined in recent years, similar factors may be acting on both hatchery and natural coho stocks.

In all but four years, including this year, the estimated number of hatchery-produced coho that spawned in natural areas has surpassed those that entered TRH (Appendix 1). This indicates that TRH-produced coho stray at substantial rates. Our main stem carcass surveys (Task 4) have demonstrated that, similar to TRH-produced Chinook, TRH-produced coho do spawn outside of the facility and that coho carcass recoveries are greatest in areas near TRH.

This season we recovered 169 coho carcasses in the main stem Trinity River (Task 4). Of these, 106 (62.7\%) were RM clipped. Based on WCW trapping data, coho runs returning to the upper Trinity basin are heavily supported by TRH production. Coho run estimates, upstream of WCW, (for years in which all TRH-produced coho have been 100 percent marked) has consistently shown that the marked percentage of coho has been substantial, 77 to 94 percent of the total estimated (Appendix 1). This season we estimated that approximately 90 percent of the run was composed of TRH-produced coho. While interactions with TRH stocks are viewed as detrimental to natural coho for many reasons the hatchery also protects the population from catastrophic losses, and could take on a very important role in the protection and recovery of this population (NOAA 2012).

Total life cycle in-river returns of the 2007 coho BY produced at TRH was estimated at 1.63 percent. This is the fourth lowest in-river return rate over the last thirteen coho cohort cycles (Appendix 1). Return rates have ranged from a low of 0.98 percent for BY 2004 coho to 6.61 percent for BY 2001 coho. Return rates of coho to the Trinity basin, unlike Chinook salmon, are in theory minimally affected by commercial and sport harvest, since the take of coho has been prohibited in these fisheries since 1994. The Native American gill-net fisheries may harvest substantial numbers of coho, but it is doubtful that this harvest rate approaches historical harvest rates for all combined fisheries (ocean sport, commercial, in-river sport, and gill-net).

A potential source of estimate bias, not trapping through the entire run, could be a factor this season. Trapping catch per unit effort (Task 1. Table 4, Figure 10) at WCW indicated that the run of coho was declining, but not completely over, prior to weir removal due to high flows on October 22, 2010. We typically strive to operate the WCW into mid-November. Since our efforts represent the majority of work to quantify the hatchery vs. wild runs and survival and contribution rates of returning coho, we feel it is important to present the available information. It must be noted that any bias in coho run-size estimates would be reflected in natural areas since the number entering the hatchery are actual counts.

## RECOMMENDATIONS

1. Continue marking all hatchery coho stocks
2. Continue mark-recapture population study using WCW.
3. Study hatchery interactions with natural coho stocks
4. Perform life-cycle monitoring of natural coho stocks
5. Coho management should be consistent with federal and state strategies and objectives.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2010 SEASON 

TASK 4<br>CHINOOK SALMON SPAWNING SURVEYS IN THE UPPER TRINITY RIVER

by

Andrew Hill

#### Abstract

The California Department of Fish \& Game's Trinity River Project in cooperation with the Yurok Tribal Fisheries Program, Hoopa Valley Tribal Fisheries and the U.S. Fish and Wildlife Service perform annual salmon carcass and redd surveys in the main stem Trinity River. This report presents data collected from carcass surveys conducted September 7, 2010 to December 20, 2010, from the area of Lewiston Dam to Cedar Flat [(101.6 river kilometers (rkm)] and from Hawkins Bar to Weitchpec (rkm 64.1). Survey data includes carcass abundance, sex ratio, age, spatial and temporal distribution, and pre-spawning mortality of Chinook (Oncorhynchus tshawytscha) and coho salmon (O. kisutch). These data provide short-term and add to long-term trend information to help assess management actions of the Trinity River Restoration Project (TRRP) and to monitor progress of the TRRP goals to restore habitat and increase natural salmonid production in the Trinity River.

This year's survey identified 3,871 Chinook, 693 coho salmon, 19 steelhead (O. mykiss), and 91 brown trout (Salmo trutta) carcasses. Coded wire tag (CWT) recoveries from adipose fin-clipped Chinook indicate spring Chinook carcasses outnumbered fall Chinook carcasses through Julian week 43 (ending October 28, 2010). With this Julian week separation, 1,006 spring Chinook carcasses and 2,865 fall Chinook carcasses were recovered. Coded wire tag recoveries also allow separation of 2 year old grilse from adults (greater than 2 years of age). Analysis of CWTs indicates 95.45 percent of spring Chinook and 83.51 percent of fall Chinook were adults. Recovery of adipose fin-clipped Chinook carcasses also indicate 1.7 percent of the spring and 5.5 percent of the fall Chinook carcasses observed were of hatchery origin. Over the course of the survey, 604 Chinook carcasses were marked, of which (204) 33.8 percent were recaptured. The Schaefer with Law's Adjustment mark-recapture model estimates the lowest in-river escapement of 10,668 Chinook salmon (2,010 spring Chinook and 6,188 fall Chinook). The Weekly Peterson model provides the highest estimate of 11,508 Chinook salmon ( 2,186 spring Chinook and 6,730 fall Chinook). The recovery of hatchery clipped coho salmon and adipose-clipped steelhead carcasses indicate that 86.7 percent of coho salmon and 42.1 percent of

steelhead carcasses were of hatchery origin. Adult coho salmon represented 97.36 percent of all coho salmon recovered.

## TASK OBJECTIVES

- To determine the size, sex composition, and hatchery component of Chinook and coho salmon spawning populations in the main stem Trinity River.
- To determine the incidence of pre-spawning mortality among naturally spawning Chinook and coho salmon in the main stem Trinity River.
- To determine the temporal and spatial distribution of the naturally spawning populations of Chinook and coho salmon within the main stem Trinity River.
- To estimate in-river escapement of spring and fall Chinook utilizing markrecapture and multiple estimators.

## INTRODUCTION

The California Department of Fish \& Game's (CDFG) Trinity River Project (TRP) in cooperation with the Yurok Tribal Fisheries Program (YTFP), Hoopa Valley Tribal Fisheries (HVTF) and the U.S. Fish and Wildlife Service (USWFS) conducted a carcass and redd survey in the main stem Trinity River. The survey was funded through the Trinity River Restoration Program (TRRP). The U.S. Forest Service (USFS) also participated in the survey using internal funding. USFS participation was limited to enumerating redds in the uppermost reach from Lewiston Dam to Old Bridge (Reach 1).

Reporting responsibilities for the project were divided into two parts: 1) CDFG was responsible for reporting on the carcass survey portion of the study, and 2) the USFWS for the redd enumeration part of the study (Chamberlain et al 2012). Redd survey information included in this report was summarized by the USFWS.

Spawner surveys have been conducted intermittently on the Trinity River since 1955. Spawning surveys prior to 1964 included river sections located above river mile 111.9 (rkm 180.1), the site of present day Lewiston dam.

Results from spawner surveys can be utilized to improve our understanding of the preand post- treatment effectiveness of flow and habitat manipulations being implemented by the TRRP to improve salmon spawning conditions. These include assessment of management actions intended to reduce temperature related pre-spawning mortality and protect in-vivo egg viability of anadromous spawners in the main stem Trinity River (IAP Objective 3.1.3), minimize impacts of predation and genetic interactions between and among hatchery and natural anadromous fish (IAP Objective 3.3.3), increase escapement of naturally produced fall Chinook salmon adults to 62,000 (IAP Objective
4.1.1), and increase escapement of naturally produced spring Chinook salmon adults to 6,000 [(IAP Objective 4.2.1) TRRP 2009]. Pertinent metrics to be analyzed over time include spawner density, spawner distribution, and pre-spawn mortality rates in the upper main-stem Trinity River. Additionally, estimates produced from the markrecapture carcass survey can be used to validate and refine estimates produced in Task 1 of this report.

## METHODS

The study area included the main stem Trinity River from its upstream limit of anadromy at Lewiston Dam downstream to the Cedar Flat Recreational Area and from Hawkins Bar to Weitchpec. The stretch from Cedar Flat to Hawkins Bar is not surveyed due to hazardous conditions. The study area was divided into 14 reaches (Table 1, Figure 1). Reaches were surveyed between September 7, 2010 and December 20, 2010. Two rafting teams consisting of DFG and Yurok Tribal Fisheries crews attempted to survey reaches 1-5 weekly by starting at reaches one and working downstream through reach five. USFWS and HVTF crews also attempted to survey reaches six and seven weekly, while reaches 8-10 and 12-14 were surveyed on a bi-weekly basis. However, logistical constraints caused some reaches to be occasionally excluded (Table 2).

Table 1. Main stem Trinity River spawner survey reach descriptions.

| Reach | Start | End |
| :---: | :--- | :--- |
| 1 | Lewiston Dam (rkm 180.1) | Old Lewiston Bridge (rkm 176.9) |
| 2 | Old Lewiston Bridge (rkm 176.9) | Bucktail Launch (rkm 169.0) |
| 3 | Bucktail Launch (rkm 169.0) | Steel Bridge (rkm 158.8) |

Figure 1. Survey reaches for 2010 Trinity River main stem spawner survey. Map courtesy of USFWS.

Surveys were conducted using inflatable rafts equipped with rowing frames. Each raft was staffed by two crew members, one rower/recorder and one technician responsible for recovering carcasses and enumerating redds. Each rafting crew covers one side of the river (right bank to middle and left bank to middle) as the crews proceed down stream. Additionally, all side channels are walked by the crew covering the bank of origin. Carcasses were recovered from all accessible areas in the river and along the shoreline. Fish in deeper areas were recovered using telescoping poles with attached gigs.

## Spring/ Fall Chinook Separation

In the Trinity River, there is a temporal and spatial overlap in the spring and fall Chinook runs. Since there is annual variation in spring and fall Chinook run timing, a date separating the two races is determined. Most adipose fin-clipped Chinook carcasses recovered during the survey contained coded wire tags (CWTs), which are implanted in their snouts prior to release from Trinity River Hatchery (TRH). CWTs are race and
brood year specific and are currently implanted in approximately 25\% of all TRH Chinook juveniles. The week separating spring and fall Chinook runs was established when the percentage of fall Chinook recoveries (based on CWT analysis) was greater than spring Chinook.

Carcasses encountered in the survey were given a condition rating in order to describe their stage or degree of decomposition. During the survey, carcasses were separated into one of three categories: 1) condition-1 was a carcass with at least one clear eye, 2) condition-2 was a carcass with both eyes cloudy, and 3) condition-3 was skeletal remains. All condition-1 Chinook carcasses were marked with week specific jaw tags and returned to moving water. These carcasses were then available for recapture providing the means to estimate an in-river escapement using several mark-recapture estimators. More decomposed (condition-2 and condition-3) carcasses are not marked due to theoretical reduced probability of being recaptured. Estimators used to calculate the estimate include a pooled Petersen (Chapman, 1951), a weekly stratified Petersen, the Schaefer (Ricker, 1975) and a modified Schaefer (Law, 1994).

Carcasses that were recovered during the survey were identified to species and gender, and examined for hatchery clips and any tags (Trinity River Project (Project), or other tags). Carcasses were measured to the nearest cm fork length (FL). Trinity River Hatchery (TRH) clips included adipose fin-clips (ad-clips) on Chinook and steelhead and right maxillary clips (RM) on coho salmon. Additionally, all TRH ad-clipped Chinook salmon are implanted with a CWT. At TRH, approximately $25 \%$ of all juvenile Chinook and $100 \%$ of coho salmon and steelhead are clipped prior to release. Heads of all recovered ad-clipped Chinook were removed and retained for later CWT tag recovery. The CWTs are extracted and read by the Department's Trinity River Project staff. All Project tags, applied at the two main stem weirs, were removed and recorded.

Field crews examined all condition-1 and condition-2 female salmon for spawning condition by visual observation of the carcass and questionable carcasses are sliced open for determination. Fish were classified as either spawned or un-spawned based upon percent egg retention and/ or observation of size of the abdomen condition of the vent. Females with swollen abdomens and non-distended vents and retaining the majority of their eggs were classified as un-spawned; conversely females retaining very few eggs, hollow abdomens, and distended vents were determined to have spawned. Due to the difficulty in accurately determining if a male has successfully spawned, male spawning condition was not assessed. All condition-1 Chinook carcasses were marked with a week specific jaw tag and returned to moving water. All condition-2 and condition-3 Chinook, marked recaptures, coho salmon, steelhead, and brown trout carcasses encountered during the survey were cut in half with a machete to prevent recounting the same fish on later surveys.

To estimate in-river escapement in the main stem Trinity River, two generally accepted mark-recapture models were employed. The simplest of these models used is the Petersen mark-recapture estimator as described by Ricker (1975). The Petersen
estimator calculates seasonal escapement by incorporating data from the entirety of the survey period. We also employed a weekly stratified Petersen to further analyze weekly population substructure. The second model used is the Schaefer estimator as described by Schaefer (1951). We also employed a modified Schaefer estimator as described by Law (1994). This model differs from the original Schaefer in that the number of tags applied after the first week is subtracted from the population estimate to account for sampling with replacement. Schaefer's original model was based on sampling without replacement. However, sampling with replacement occurs during the salmon spawning season.

The Petersen model as described by Ricker (1975):
$N_{i j}=\left(\left(M_{i}\right)\left(C_{j}\right) / R_{\mathrm{ij}}\right)$
Where: $\quad \mathrm{N}_{\mathrm{ij}}=$ population size in tagging period $i$ recovery period $j$, $\mathrm{M}_{\mathrm{i}}=$ number of carcasses tagged in the ith tagging period, $\mathrm{C}_{\mathrm{j}}=$ number of carcasses recovered in the jth recovery period, and, $\mathrm{R}_{\mathrm{ij}}=$ number of carcasses tagged in the ith spawning period recaptured in the jth recovery period.

The Schaefer model as described by Schaefer (1951):
$N_{i j}=\sum\left(R_{i j}\left(\left(M_{i} / R_{i}\right)\left(C_{j} / R_{j}\right)\right)\right)$
Where: $\quad \mathrm{N}_{\mathrm{ij}}=$ population size in tagging period $i$ and recovery period $j$, $\mathrm{R}_{\mathrm{ij}}=$ number of carcasses tagged in the ith spawning period and recaptured in the $j$ th recovery period, $\mathrm{M}_{\mathrm{i}}=$ number of carcasses tagged in the $i$ th tagging period, $\mathrm{C}_{\mathrm{j}}=$ number of carcasses recovered in the jth recovery period, $R_{i}=$ total recapture of carcasses tagged in the ith tagging period, and $R_{j}=$ total recapture of carcasses tagged in the $j$ th tagging period

The Schaefer model as modified by Law (1994):
$N_{i j}=\sum\left(R_{i j}\left(M_{i} C_{j} / R_{i} R_{j}\right)-M_{i}\right)$
Where: $\quad \mathrm{N}_{\mathrm{ij}}=$ population size in tagging period $i$ recovery period $j$, $\mathrm{R}_{\mathrm{ij}}=$ number of carcasses tagged in the $i$ th spawning period and recaptured in the jth recovery period, $M_{i}=$ number of carcasses tagged in the $i$ th tagging period, $C_{j}=$ number of carcasses recovered in the jth recovery period, $R_{i}=$ total recapture of carcasses tagged in the ith tagging period, and $R_{j}=$ total recapture of carcasses tagged in the jth tagging period.

## RESULTS

## Spring/ Fall Chinook Separation

From CWT extraction of adipose fin-clipped carcasses, the only overlap of spring and fall Chinook runs occurred during Julian week 44. Spring Chinook carcasses were predominant through Julian week 43 (October 22, 2010 to October 28, 2010), after which fall Chinook recoveries were most numerous. For the purpose of analysis, all Chinook recoveries prior to and during Julian week 43 are classified as spring Chinook and all subsequent carcass recoveries are classified as fall Chinook (Figure 2).

Figure 2. Weekly proportion of coded-wire tagged spring and fall Chinook observed in the 2010 main stem Trinity River spawner survey

## Temporal Carcass Distribution

A total of 3,871 Chinook carcasses were encountered during the survey. Recovery of Chinook carcasses peaked during Julian week 48 (November 26, 2010 to December 2, 2010) when 897 carcasses were counted. The first coho salmon carcass was recovered during Julian week 43 (October 22, 2010 to October 28, 2010). A total of 693 coho salmon carcasses were recovered during the survey with peak recovery number of 192 during both Julian week 48 (November 26, 2010 to December 2, 2010) (Figure 3). It should be noted that temporal coverage of the coho run was incomplete because the survey efforts ended prior to the end of spawning activity. To fully enumerate coho salmon spawning activity in the main stem, survey efforts would need to continue at least through January.

Figure 3. Chinook and coho salmon carcasses collected by Julian week during the 2010 Trinity River main stem spawner survey.

## Carcass Distribution

A total of 3,871 Chinook carcasses were recovered during Julian weeks 36 to 51 (September 7, 2010 to December 20, 2010) in the 14 survey sections (Table 2). Of the 3,871 Chinook carcasses encountered, 2,450 (63.3\%) were recovered in reaches 1 and 2, and 1,588 (41.1\%) of the carcasses were recovered in reach 1 alone. Reaches 8 and 10 had the fewest carcasses (5 in both reaches) and 380 (9.8\%) of encountered carcasses were downstream of reach 5 (Table 2).

## Spring Chinook Salmon

A total of 1,006 Chinook carcasses were classified as spring-run during the survey, of which 352 were classified as condition-one (Table 3). Spring Chinook carcass recovery by reach ranged from 235 in reach 4 to zero in reach 12. Spring Chinook carcass density was greatest in reach 1 at 36.06 fish/rkm.

Table 3. Number, density, incidence of ad-clips, project tags, and condition of spring Chinook recovered during the 2010 main stem Trinity River spawner survey 1/

1/ All Chinook recovered prior to Julian week 44 (Oct. 29 - Nov. 4) were considered spring
2/ Condition-1 fish are those with at least one clear eye
3 / Condition-2 fish are those with both eyes cloudy
4/ Adipose clipped Chinook presumed to contain CWT
5/ Spaghetti tags applied at Junction City weir

## Fall Chinook Salmon

A total of 2,865 Chinook carcasses were classified as fall-run during the survey, of which 339 were classified as condition-one (Table 4). Fall Chinook carcass recovery by reach ranged from 1,469 in reach 1 to 0 in both reaches 8 . Fall Chinook carcass density was greatest in reach 1 at 445.15 fish/rkm and dropped considerably to 97.18 fish/rkm in reach 2. Below reaches 1 and 2 carcass density was considerably less.

1/ All Chinook recovered after Julian week 43 (Oct. 22 - Oct. 28) were considered fall Chinook
2/ Condition-1 fish are those with at least one clear eye
3/ Condition-2 fish are those with both eyes cloudy
4/ Adipose clipped Chinook presumed to contain CWT
5/ Spaghetti tags applied at Junction City weir

## Coho Salmon

A total of 693 coho salmon carcasses were recovered during the survey, of which 211 were classified as condition-one (Table 5). Coho carcass recovery by reach ranged from 345 (49.78\%) in reach 1 to zero in reaches $8,9,10,13$, and 14. Coho salmon carcass density was greatest in reach 1 at 104.55 fish/rkm and dropped considerably to 38.17 fish/rkm in reach 2. Coho salmon carcass density downstream from reach 4 was less than 2 fish per kilometer.

Table 5. Number, density, incidence of right maxillary (RM) clips, project tags, and condition of coho salmon recovered during the 2010 main stem Trinity River spawner survey.

4/ Spaghetti tags applied at Willow Creek weir

## Steelhead and Brown Trout

A total of 19 steelhead carcasses and 91 brown trout carcasses were recovered during the survey (Table 6). Steelhead density with and without the adipose fin clip was highest in reach 1, which is closest to the hatchery. Brown trout density was highest in reach 1 with greatest numbers recovered in reach 3. No project tags were recovered from steelhead carcasses in 2010.

1/ Adipose clipped steelhead presumably from Trinity River Hatchery with 100\% hatchery 2/ Spaghetti tags applied at Willow Creek and Junction City weirs

## Size Composition

Only condition-1 and condition-2 fish were measured and included in the size composition analysis. Condition-3 fish were assumed to have decomposed to a point where length measurements were no longer accurate. The size separating grilse and adults for spring-run and fall-run Chinook and coho salmon was determined using length frequency analysis of fish trapped at the Willow Creek weir, Junction City weir, and the Trinity River Hatchery. For additional information regarding grilse and adult fork length separation see Task 1 of this report.

Fork lengths of spring Chinook ( $\mathrm{n}=967$ averaged 76.03 cm . and ranged between 35105 cm . (Figure 4). Grilse (FL < 58 cm ) accounted for $4.55 \%$ (44/967) of the measured spring Chinook.

Figure 4. Length frequency histogram for all condition 1 and 2 spring Chinook measured during the 2010 main stem Trinity spawner survey.

## Fall Chinook Salmon

Fork lengths obtained from fall Chinook ( $\mathrm{n}=2,607$ ) averaged 74.83 cm and ranged between 30-114 cm. (Figure 5). Grilse (FL <62 cm) accounted for 16.49\% $(430 / 2,607)$ of measured fall Chinook.

Figure 5. Length frequency histogram for all condition 1 and 2 fall Chinook measured during the 2010 main stem Trinity spawner survey.

## Coho Salmon

Fork lengths of measured coho salmon $(\mathrm{n}=645)$ averaged 68.48 cm and ranged from $41-87 \mathrm{~cm}$. (Figure 6). Grilse (FL < 56 cm ) accounted for $2.64 \%$ (17/645) of measured coho salmon.

Figure 6. Length frequency for all condition-1 and -2 coho salmon measured during the 2010 main stem Trinity River spawner survey.

## Adult Sex Composition and Female Pre-Spawn Mortality

## Spring Chinook Salmon

Of the spring Chinook recovered that were sexed; 426 were sexed as males and 553 as females, a male to female ratio of 0.77:1 (Table 7). Gender was indiscernible on 27 fish due to advanced decomposition. Forty four (7.96\%) of the 553 female spring Chinook carcasses evaluated were determined to be pre-spawn mortalities.

Table 7. Male to female ratio and prespawn mortality of spring Chinook during 2010 main stem Trinity River spawner survey

## Fall Chinook Salmon

Of the fall Chinook recovered that were sexed; 1,373 were sexed as males and 1,306 were sexed as females, for a male: female ratio of 1.05:1 (Table 8). Gender was indiscernible on 186 fish due to advanced decomposition. One hundred and sixteen (8.88\%) of the 1,306 adult female fall Chinook carcasses examined were determined to be pre-spawn mortalities.

## Coho Salmon

Of the 693 coho salmon recovered that were sexed; 324 were sexed as males and 353 were sexed as females, for a male: female ratio of 0.92: 1 (Table 9). Grilse have been included in number of males, and gender was indiscernible on 16 fish due to advanced decomposition. Fifty two (14.73\%) of 353 female coho salmon carcasses examined were determined to be pre-spawn mortalities.

## Incidence of Hatchery Produced Chinook and Coho Salmon

## Spring Chinook Salmon

During the spring-run period, $2.56 \%(n=9)$ of condition-one and 1.69\% ( $\mathrm{n}=17$ ) of all spring Chinook bore ad-clips. One hundred percent of all ad-clipped spring Chinook were recovered above reach 6. CWTs were recovered from 14 Chinook encountered during the spring Chinook recovery period, all but one were spring-run. During the period associated with the spring-run, 3 ad-clipped Chinook were recovered in which no CWTs were found. The majority of CWTs were represented by the 2006 spring-run yearling release group ( $\mathrm{n}=7,41.18 \%$ ) and 2006 spring-run fingerling release group ( $\mathrm{n}=4,23.53 \%$ ). All other CWTs were represented by 2007 brood year spring-run yearling ( $n=2,11.76 \%$ ) and 2007 brood year fingerling release groups ( $n=1,5.88 \%$ ).

|  |  |  |  |  |  |  |  |  |  |
|  |  |  |  | Grand Totals | 16 | 126 | 142 |  | 504.188 |

1/ Release types: Sf-Spring Chinook fingerling, Sy-Spring Chinook yearling; Ff-Fall Chinook fingerling, Fy Fall 2/ Hatchery production multiplier used to account for untagged releases of the same brood year, race and 3/ Spring Chinook recovery period was September 14, 2009 to October 28, 2009. Later recoveries were all 4/ CWT was not present or was lost during recovery.

Based on expansion of all CWT codes recovered during the spring period, an estimated 57 (5.9\%) of the 969 condition 1 and condition 2 fish recovered were of TRH origin (Table 3). Based on expansions of all spring-run CWT groups, an estimated age structure of TRH spring Chinook recovered in the main stem Trinity River spawner survey was $4.43 \%$ age 4 and $1.21 \%$ age3 (Table 10).

## Fall Chinook Salmon

During the fall-run period 17.99\% $(n=61)$ of the condition-1 and $5.51 \%(n=158)$ of all fall Chinook bore ad-clips (Table 4). Observed ad-clip rates in reach 1 and 2 for fall Chinook were 16.8\% ( $n=57$; condition-1) and $5.27 \%$ ( $n=151$; all carcasses) respectively. In reach 3, fall Chinook ad-clip rates of 1.18\% ( $n=4$; condition-1) and 2.09\% ( $n=6$; all carcasses) were observed. CWTs were recovered from 110 of the total Chinook encountered during the fall Chinook recovery period; all of which were fall Chinook. During the period associated with the fall-run, 15 ad-clipped Chinook were recovered in which no CWTs were found. The majority of CWTs during the fall-run recovery period were represented by 2007 fall yearling releases ( $n=37$; 29.60\%). All other CWTs were represented by the following brood year groups; 2006 fall brood year yearlings ( $n=36$, 28.8\%), 2006 fall brood year fingerlings ( $n=10,8.0 \%$ ), 2007 fall brood year fingerling ( $n=14,11.2 \%$ ), and 2008 spring brood year fingerling ( $n=13,10.4 \%$ ).

Based on expansion of all CWT codes recovered during the fall-run period, an estimated 448 (17.2\%) of the 2,608 condition 1 and condition 2 fish recovered were of TRH origin (Table 4). Based on expansions of all fall CWT groups, the estimated age structure of TRH fall Chinook recovered in the main stem Trinity River spawner survey was $6.55 \%$ age $4,7.23 \%$ age 3 , and $1.84 \%$ age 2 (Table 10).

## Coho Salmon

During the course of the survey, 85.78\% ( $\mathrm{n}=181$ ) of condition-1 and 86.72\% ( $\mathrm{n}=601$ ) of all coho salmon recovered bore right maxillary (RM) clips (Table 5). Coho RM clip rates for condition-1 carcasses were highest in reach one. Based on a 100\% clip rate of Trinity River Hatchery (TRH) produced juvenile coho salmon, an estimated 86.72\% of adult coho salmon recovered during the survey were of TRH origin.

## Incidence of Project Marked Salmon

## Spring Chinook Salmon

A total of 17 Project tags applied at the Junction City and Willow Creek weirs were recovered in survey reaches 1 through 14 (Table 3). Five of these were recovered on condition-1 carcasses. No spring Chinook Project tags were found on carcasses downstream of reach 9 (Table 3). During the course of the survey, 11 tags from the

Junction City weir and 6 tags from the Willow Creek weir were recovered prior to Julian week 44.

## Fall Chinook Salmon

A total of 45 Project tags applied at Junction City and Willow Creek weirs were recovered during the survey (Table 4). Six of these were recovered on condition-1 carcasses. During the course of the survey, 39 tags from the Willow Creek weir and 6 tags from the Junction City weir were recovered after Julian week 43. Spaghetti tags were found in all reaches except 8 through 13, and 25 (55.56\%) were found in reaches 1 and 2 (Table 4).

## Coho salmon

A total of 22 Project tags applied at the Willow Creek weir were recovered during the survey (Table 5). Nine of these were recovered on condition-1 carcasses. None of these were recovered below reach 5 .

## Steelhead/Rainbow trout

No Project tags were found on steelhead carcasses during this survey.

## Brown Trout

Two Project tags were found on a brown trout carcass during this survey in reach 3 and reach 6 during Julian Week 46.

## In-river Escapement Estimates

This season, a mark-recapture methodology was employed on the upper Trinity River to estimate in-river escapement of Chinook (Tables 11, 12, \&13). Mark-recapture techniques were historically used on the Trinity, and were recently reintroduced during the carcass survey in 2005. During the 2010 survey, crews marked all condition-1 Chinook with week specific jaw tags. Fish are subsequently recaptured to produce weekly estimates. During the course of the survey, six hundred and four (15.60\%) of Chinook were marked, and two hundred and four (33.77\%) of those fish were subsequently recaptured (Appendix 6). The upper reaches (reaches 1-5) had a lower marking rate of $14.52 \%$ and a slightly higher recapture rate of $38.66 \%$ than the survey in its entirety (Appendices 5\&6). The lower reaches (reaches 6-10) had a marking rate of $25.53 \%$, and a recapture rate of $8.25 \%$ (Appendix 6). Estimates could not be made for spring-run in the lower reaches due to low numbers of recaptures (2 recaptures). All estimators used in this report require at least 25 recaptures to produce reliable results.

Table 11. In-river escapement estimates for Chinook collected during the 2010 Trinity River spawner survey.

| Estimator | Reaches <br> $1-5$ | Reaches <br> $1-14$ | Reaches 1-5 <br> $(95 \% \mathrm{CI})$ | Reaches <br> $1-14$ <br> $(95 \% \mathrm{CI})$ |
| :--- | :---: | :---: | :---: | :---: |
| Petersen | 9,004 | 11,426 | 956 | 1,238 |
| Weekly Stratified Petersen | 8,916 | 11,508 | 995 | 1,240 |
| Schaefer | 8,705 | 11,272 | 973 | 1,241 |
| Schaefer with Law's adjustment | 8,198 | 10,668 | 973 | 1,241 |

The different estimators produced estimates which range from 10,688 to 11,508 Chinook for the entire survey, and from 8,198 to 9,004 for the upper reaches 1-5 (Table 11). Adding in the 95\% Confidence interval, the estimates ranged from 9,447to 12,748 for the entire survey, and from 7,225 to 9,960 for the upper reaches. These results indicate there is a $5 \%$ chance that the true estimate falls outside of the confidence intervals.

Table 12. In-river escapement estimates for spring and fall Chinook collected during 2010 Trinity River spawner survey above Junction City.

| Estimator | Spring | Fall | Ratio of spring to fall <br> Chinook |
| :--- | :---: | :---: | :---: |
| Petersen | 2,208 | 6,796 |  |
| Weekly stratified Petersen | 2,186 | 6,730 |  |
| Schaefer | 2,134 | 6,570 |  |
| Schaefer w/ Law's adjustment | 2,010 | 6,188 |  |

Estimates for the different runs in the entire survey ranged from 2,772 to 2,969 for spring Chinook and 67,895 to 8,517 for fall Chinook (Table 13). The estimates for the upper reaches ranged from 2,010 to 2,208 for spring Chinook and 6,188 to 6,796 for fall Chinook (Table 12). The results of the carcass survey indicate spring to fall Chinook ratios of 0.3511:1 for the entire survey and 0.3249:1 for the upper reaches (Tables 12 \& 13).

Table 13. In-river escapement estimates for spring and fall Chinook collected during 2010 Trinity River spawner survey in all reaches.

| Estimator | Spring | Fall | Ratio of spring to fall <br> Chinook |
| :--- | :---: | :---: | :---: |
| Petersen | 2,969 | 8,487 |  |
| Weekly stratified Petersen | 2,991 | 8,517 |  |
| Schaefer | 2,929 | 8,343 |  |
| Schaefer w/ Law's adjustment | 2,772 | 7,895 |  |

## DISCUSSION

When looking at the spring and fall runs as a whole, year to year variation in numbers of salmon carcasses recovered on the upper Trinity River is fairly minimal when examined as an order of magnitude (with the exception of the 2003 Chinook season) and normally tracks well with the number of fish recovered at Trinity River Hatchery (see Task 1). During the 2010 season, crews recovered slightly more total Chinook than during the 2009 field season (Appendix 1). Coho salmon carcass numbers were the highest since 2005. When comparing yearly data, it is important to acknowledge differences in survey timing and periodicity, as well as climatic events and budgetary constraints that inhibit survey timing and periodicity. In some years, surveys ran into January, therefore covering a greater proportion of the coho salmon run. Additionally, in some years weekly survey periodicity was far from perfect due to extreme weather and high flows.

Prior to 1996, CDFG conducted mark recapture carcass recovery surveys which allowed for estimation of the total numbers of spawners in each survey reach. Due to inclusion of redd data collection and other crew constraints during the 1996-2004 seasons, carcass totals were then solely based on total numbers of carcasses recovered. With the reintroduction of a mark recapture methodology in 2005, we will continue to display the number of carcasses observed per reach, independent of mark recapture, for comparison with past years. Current mark recapture efforts do not produce reach escapement estimates, as weekly efficiencies by reach are sporadic and highly variable.

## Carcass Distribution

As in past years, Chinook and coho salmon carcass densities were highest in the uppermost reaches and were negatively associated with increased distance from Lewiston Dam and TRH (Appendices 1, 2, \& 3). Salmon imprint upon the waters in which they rear, and subsequently home on those waters when returning to spawn. If more spawners utilize upper reaches and their progeny rear in those reaches, then it is logical to speculate that the majority of returning salmon would then subsequently spawn in those same upper reaches. Other potential factors contributing to the observed high densities in the upper reaches include hatchery fish spawning in-river instead of returning to the hatchery, blockage of further upstream migration by Lewiston Dam, and availability of suitable spawning habitat.

This years' Chinook numbers as a whole show this same trend, but a deviation from this trend has occurred for the second time with spring Chinook and not for fall Chinook. This year, reach 4 had the greatest percentage of spring Chinook (235/1,006; 23.36\%) than any other reach. This deviation may be due to decreased hatchery contribution to the spring run (Table 14). This decrease has resulted in more naturally spawning spring Chinook in the Trinity River which may be due to restoration activities.

Table 14. Hatchery contribution from previous years to spring Chinook spawning in the main stem Trinity River.

| Year | Hatchery Contribution (\%) |
| :---: | :---: |
| 2002 | $38.00 \%$ |
| 2003 | $25.20 \%$ |
| 2004 | $25.20 \%$ |
| 2005 | $32.50 \%$ |
| 2006 | $18.14 \%$ |
| 2007 | $19.28 \%$ |
| 2008 | $10.27 \%$ |
| 2009 | $8.37 \%$ |
| 2010 | $5.67 \%$ |

Adult Sex Composition and Female Pre-spawn Mortality
For all races and species of salmon carcasses recovered on the upper Trinity, female adults out-numbered male adults when number of grilse is subtracted from the total number of males recovered. Previous studies on the Trinity River presented in Aguilar (1996), suggest this is common for Chinook salmon. If a portion of males return as grilse (two year olds), then adult females would then make up a higher percentage of adults. Another factor that could possibly skew male to female ratios is unequal capture probability by sex. Zhou (2002) modeled and analyzed 12 years of Salmon River, Oregon fall Chinook carcass data and found that male Chinook were underestimated by $8 \%$, while female Chinook were overestimated by 12\%. Assuming similar bias in Trinity River carcass composition results, male to female ratios including grilse have been estimated as follows: 0.77:1 for spring Chinook and 1.05:1 for fall Chinook.

Trinity River Chinook salmon pre-spawn mortalities for years when more than 100 females were examined have ranged from 0.0 to $62.8 \%$ for spring Chinook, and 0.7 to 43.7\% for fall Chinook (Appendices 4). Pre-spawn mortality rates observed this year were $7.96 \%$ for spring Chinook and $8.88 \%$ for fall Chinook. For years in which more than 100 female coho salmon were examined, pre-spawn mortality rates have ranged from 8.5 to $15.9 \%$. The coho salmon pre-spawn mortality rate observed this season was $14.73 \%$. It is unclear how this rate is influenced by a truncated survey season, although if pre-spawn mortalities die sooner than successful spawners, this rate would most likely be overestimated. It has also been noted, most recently by Zuspan (1998), that pre-spawn mortality may be density dependent and is positively related to run-size in the Trinity River. As in the past, pre-spawn mortality numbers fluctuate similarly to fluctuating escapement numbers.

## Mark Recapture Estimators

Carcass mark recapture or capture recapture estimators are commonly used by the Department to estimate in-river escapement of salmon; these estimators have been used in Central Valley tributaries including the American and Sacramento since the early 1970's (Snider, Reavis and Hill, 1999). In the Klamath basin, the Department currently utilizes both the Petersen and Schaefer estimators to produce in-river escapements from carcass survey data (S. Borok, pers comm, 2005). It is important to acknowledge the limitations and potential biases associated with these estimators. If basic assumptions are violated, or bias is excessively high, options should be pursued to refine these estimators or another estimator should be selected.

The Petersen estimator is the most popularly used mark recapture model in fisheries management. However, it is often portrayed as a crude application because it is a closed population model, and its assumptions concerning zero births or death (immigration and survival) are rarely met. With respect to salmon carcass surveys, the Petersen model has been found to consistently overestimate population estimates, sometimes exceeding $250 \%$ of the true population (Law, 1994). Stratifying Petersen estimates by week can minimize some of the bias created by births and deaths..

The Schaefer estimator is commonly used as an alternative to the simple pooled Petersen when the assumptions of equal mixing, homogenous capture, or homogenous recapture probabilities will not hold (Schwarz et al, 2002). When these assumptions are violated, stratifying capture and recaptures by time or location and using either a stratified Petersen or Schaefer estimator may be appropriate. Law (1994) found the Schaefer estimator to be less positively biased than the Petersen estimator, but cautioned that it also overestimates populations, especially at low survival and low catch rates. Law (1994) suggests the use of the Jolly-Seber open population mark recapture model for use in salmon carcass population estimates, but recognized that on larger rivers, the Jolly-Seber may produce estimates that are consistently low. It is also possible that the basic assumption of equal mixing of tagged carcasses with all carcasses may be violated, in which case, recaptured carcasses may constitute a different sub-population.

## Other Possible Sources of Bias

Problems or biases associated with salmon carcass surveys should be identified and subsequently minimized in order to produce more accurate and precise estimates. Some problems are inherent to survey design or human nature, while others are specific to situations or crews working on the Trinity River.

Inter-observer variation is a source of bias affecting all types of fish surveying methods. During this survey, we attempted to minimize this variation by maintaining the same rower/observer teams and rotating sides of the river by week. By rotating banks weekly, bias concerning memory of where marked carcasses were released was minimized.

Maintaining the same crew throughout the season is also important to minimize variation in data collection methods and ensure data consistency between weeks and sections.

Carcass condition is a potential source of bias in the mark-recapture estimators due to the fact that fall Chinook carcass eyes appear to rot more quickly than spring Chinook carcasses. The decrease in marking rates is apparent as the season progresses. Only condition-1 carcasses are marked, and that criterion is met when at least one of the carcass eyes is clear. Since fall Chinook carcasses rot quicker and both eyes are often cloudy even at the time of spawning, a lower percentage of fall Chinook carcasses (11.83\%) were classified as condition-1 than spring Chinook carcasses (34.99\%) (Tables 3 and 4). This accounts for the different marking rates between spring and fall Chinook. Therefore, due to the higher marking rates for spring Chinook, the estimates may be more efficient for spring Chinook than fall Chinook due to the higher marking rate.

Weather is an uncontrollable factor, which most likely has a great effect on consistency of survey methods. High flow events reduce carcass capture efficiency due to higher instream velocities and increased turbidity. Extreme high flow events may also cause exclusion of weekly surveying efforts on dropped reaches. Capture efficiency can also possibly be reduced by excessive cloud cover or glare associated with the azimuth of the sun.

Sufficient survey periodicity is necessary to ensure proper temporal coverage in recovery of salmon carcasses. Weekly survey periodicity is most convenient when surveying long sections, necessitating the use of four crews. In reaches 8 to 10 and 12 to 14 , bi-weekly surveys were conducted due to logistical constraints. Fresh carcasses were available for recapture for four to five weeks following initial capture, thus only fresh carcasses were tagged and used to calculate capture efficiency. An additional problem which may necessitate more frequent surveying is predation and removal of carcasses. No direct evidence of carcass removal by predation was observed during the 2010 season, but we assume that predation does exist. High carcass predation rates reduce the efficiency of carcass recovery. If predation rates are found to be inversely proportional to run size (ie predators remove a higher ratio of carcasses when less carcasses exist) then survey periodicity should be increased in lower run-size seasons. Conversely, there could be a density dependent relationship between run-size and attraction of predators, which would also necessitate increased survey periodicity.

Hatchery contribution estimates may be underestimated due to problems associated with identification of hatchery fish. Poor detection of fin clips or errors in recording those fin clips can negatively skew hatchery contribution rates. The right maxillary clip exhibited by TRH released coho salmon is very easy to miss if special attention is not paid to detecting that clip. Advanced decomposition of salmon carcasses may also inhibit the ability to detect hatchery clips. Poor detection or loss of adipose clipped
salmon heads or CWTs extracted from those heads also could negatively skew hatchery contribution rates.

## RECOMMENDATIONS

1.) Annual spawner surveys incorporating a mark-recapture methodology should be continued for future seasons, facilitating future comparisons of mark recapture escapement estimates.
2.) Mark recapture estimators should be statistically evaluated for bias, and the JollySeber model should be considered if bias is found to be excessive, thus minimizing the potential of producing unacceptable estimates.
3.) In future years, the entire survey area should be surveyed on a consistent temporal basis (e.g. once each week) if possible.
4.) If recovery of coho salmon becomes a high priority, the temporal coverage of the surveys will need to be extended into January. If surveys are extended into January, a mark-recapture methodology should be initiated for coho salmon.
5.) More research into carcass deterioration rate differences between spring-run and fall-run Chinook and how it may influence the mark and recapture estimates.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2010-11 SEASON 

TASK 5
ANGLER CREEL SURVEYS IN THE LOWER KLAMATH RIVER
by

Sara Borok

#### Abstract

A creel census was conducted along the lower Klamath River (Ocean to Hwy 96 Bridge in Weitchpec) August 6, 2010 through November 4, 2010 to estimate the sport fishery harvests of upstream migrating Chinook salmon (Oncorhynchus tshawytscha), coho salmon (Oncorhynchus kisutch) and steelhead trout (Oncorhynchus mykiss). A goal of the creel census is to determine the contribution of Trinity River salmonids to the annual sport harvest in the lower Klamath River. The information provided by the creel census will help assess the production and harvest goals of the Klamath River Project and Trinity River Restoration Program.

Results from the creel census indicate a total of 3,562 (2,057 adults and 1,505 grilse) Chinook salmon and 61 ( 61 adults and 0 half-pounders) steelhead were harvested. The 2010 in-river sport quota of 12,000 adult Chinook salmon was not met. Twenty-eight Chinook salmon ( 9 adults and 19 grilse) caught before August 15, 2010 are considered spring-run fish. Hatchery fish represented an estimated 24.45 percent $(871 / 3,562)$ of the sport harvest in the lower Klamath River. Trinity River Hatchery (TRH) origin fish represented 16.00 percent of the estimated harvest and 8.45 percent were of Iron Gate Hatchery origin. Seasonal summaries and comparisons of angler effort and catch, catch timing, length frequencies, species composition, hatchery fin clips and tag recoveries are presented.

## TASK OBJECTIVES

- Quantify total catch, angler effort and catch per effort for salmonids (harvest and catch/release) from the lower Klamath River.
- Determine the contribution to sport harvest from fish produced at Trinity River and Iron Gate hatcheries

## INTRODUCTION

The Klamath River is regarded as one of the most important producers of Chinook salmon to California's commercial and sport fisheries. The lower Klamath fishery resources are composed of both natural and hatchery produced salmonids originating from the Klamath and Trinity river basins. A goal of this creel census is to determine how many Trinity River salmon are harvested from the lower Klamath River by sport anglers. The information provided by the creel census is used to help assess the production and harvest goals of the Klamath River Project and the Trinity River Restoration Program.

Angler harvest of Chinook salmon has been monitored by CDFG to provide data for runsize estimates since 1978 (Boydstun 1979, 1980; Lee 1984a, 1984b, 1985, Lau 19921997; Pisano 1998; Borok 1999-2004, Hanson 2005-2009). This report covers the period from July 1, 2010 through June 30, 2011. It provides sport harvest data and a description of the CDFG fall-run Chinook salmon angler harvest monitoring program conducted in the main stem Klamath River from the mouth of the Klamath River to the Highway 96 Bridge at Weitchpec (rkm 68.8).

For the purposes of this study the Klamath River and Trinity River are divided into sample reach areas. The Klamath River is divided onto 3 areas, from the mouth of the river to the Hwy101 Bridge, from the Hwy 101 Bridge to the Hwy 96 Bridge at Weitchpec and from Hwy 96 Bridge at Weitchpec up to Iron Gate Dam. The Trinity River is divided into 2 areas from the confluence with the Klamath River up to Cedar Flat and from that point up to the Old Lewiston Bridge in Lewiston (245.7 rkm). This is to determine angling effort and harvest by section. The CDFG uses this information to determine in real time when sport anglers have reached the in-river sport harvest sub-quota for each section of fall-run adult Chinook salmon. This report covers the lower 2 sections of the Klamath River from the ocean to the Hwy 96 Bridge in Weitchpec.

## Quotas and harvest management

The Klamath River Chinook quota is implemented in the following manner: Fifty per cent of the total in-river quota is dedicated to the lower Klamath River (rkm 0 to 68.8). The other half is apportioned to the mid Klamath River (17\%) (rkm 68.8 to 306) and the Trinity River (33\%). CDFG monitors or models each of the areas for the fall-run Chinook harvest and determine when the quota of each portion has been met. Once a sub -quota in any of the sections is met, an adult Chinook salmon harvest closure goes into effect in that section of river. Anglers are still permitted to fish, but must release any adult Chinook salmon caught. Meanwhile, anglers in the other portions of the river are still permitted to harvest adult Chinook. After all sub-quotas are met, fishing for grilse Chinook and other legal species is still permitted but the entire river is closed to the harvest of any adult Chinook. However, once the hatcheries (Iron Gate Hatchery and Trinity River Hatchery) have reached mitigation egg take goals, special exempted fisheries for adult Chinook are permitted from Iron Gate Dam to where Interstate 5
crosses the Klamath River and downstream of Old Lewiston Bridge to the mouth of Indian Creek Bridge on the Trinity.

Starting in 1999 CDFG implemented an "impact quota" for the Klamath and Trinity Rivers. From this impact quota a ten percent hooking mortality factor was accounted for within the quota and this number was used as the quota trigger. This trigger closure was to account for increased hook and release mortalities when the quota was met early in the season. The impact quota was divided among each of the areas in the same manner as the division of the basin quota.
During the 2010 season, fishing regulations allowed anglers to harvest three Chinook salmon per day (up to two adult Chinook) and one hatchery trout or one hatchery steelhead per day. These regulations started on August 15, 2010 in the lower Klamath River and September 1, 2010 in the Trinity River and the Klamath River above the Hwy 96 Bridge in Weitchepec. The limit of hatchery steelhead for the Trinity River only was increased to two per day and four in possession. No harvest of coho salmon was permitted in the entire Klamath Basin. Regulations stated: One "hatchery" trout or one "hatchery" steelhead could be harvested, which eliminated the cutthroat trout fishery in the Klamath basin.

## METHODS

## Description of the Fishery and Creel Sample Area

To estimate angler catch and effort, CDFG divides the main stem Klamath River from the mouth to Iron Gate Dam into three areas. The mouth of the river to the Hwy 96 Bridge in Weitchpec (Areas 1 and 2) are included in this report. Areas upstream of the Hwy 96 Bridge in Weitchpec to Iron Gate Dam (Area 3) were not directly surveyed by CDFG this season. Chinook harvest in this area is estimated using a ratio estimator based on catch in the lower Klamath River.

Area 1: This area consists of $4.5 \mathrm{rkm}(2.8 \mathrm{mi})$ of river from the mouth of the Klamath to the Highway 101 Bridge and is referred to as the estuary. All shore angling effort in this area took place at the mouth of the river in 2010. River mouth configuration, which changes annually, determines which side (north or south) affords better angling. A creel sample of shore anglers was conducted at the mouth location. During the 2010 season fishing the mouth was not closed at any time. If 15 percent of the lower river quota had been caught below the Hwy 101 Bridge ( 3,375 adult fall-run Chinook salmon) the spit (100 yards of the channel through the sand spit formed at the Klamath River mouth) would be closed to sport fishing, it was not met this season.
All boat angling effort in the estuary originated from ten resort boat docks in the estuary area. Three resort docks (Golden Bear RV Park, Riverside RV Park, and Panther Creek RV Park) and south side Mouth access were sampled this season for angler effort and catch.

Area 2: This area extends from the Highway 96 Bridge (rkm 68) in Weitchpec downstream to the Highway 101 at Klamath (rkm 5) The division was formerly the falls at Coon Creek ( 54.4 rkm ) near the community of Johnson's riffle (Pecwan Creek), but to make the distinction clearer for anglers it was changed. Shore angling effort is generally confined to two popular easily accessed riffles (Lower Klamath Glen and Blake's) located in the lower 5 rkm of this area and are easily accessible to the shore angler. One former resort boat dock (Klamath Glen) and a public boat launch (Roy Rook), also located in this section 5 rkm, are the principal boat facilities in the area. Creel sampling occurred at these locations.
Angler access routes at Lower Klamath Glen and Blake's riffles are limited to specific routes in and out enabling a complete accounting of angler effort and catch during a sample day at these locations. Boat anglers are also confined to access at the launching ramp or resort boat dock enabling a complete sample of angler effort and catch for each sample day.

Shore angling access above Blake's Riffle is limited to three access points: the mouth of Blue Creek (rkm 26.3), Ah Pah Creek (rkm 27.5), and Bear Riffle (rkm 29.8). These points are all accessible by vehicle but accounted for an estimated less than one percent of angling effort from data in past surveys (Hopelain 2001).

## Creel Census Methods

Study methods and procedures used in Areas 1 and 2 during the 2010 season were essentially the same as those described for the 1983-1987 seasons (Hopelain 2001). Data is presented in standard Julian Week (JW) format throughout this report (Appendix 1).

Each of the sites identified in the area description on the lower Klamath River were sampled three days per Julian week.The initial start date of Aug 6 is set by the Julian week calendar. Which Area starts the Creel Census is random. Week Days are selected systematically based on the day the census starts. Weekend days switch back and forth over the course of the sampling season. For weeks that were sampled other than above, the data is expanded accordingly. Each angling access site is sampled throughout the day to account for total catch and effort for that particular site. California Department of Fish and Game scientific aids interviewed anglers as they departed the fishing site and recorded the following information:

1) Was the angler finished fishing for the day at this time?
2) Total hours spent fishing (to the nearest half hour).
3) The first three numbers of their Zip Code (to find their general area of residence).
4) Fish harvested are identified to species, fork length is measured and they are inspected for marks, external tags and unusual conditions. Also a scale sample was collected.
5) For Chinook salmon missing an adipose fin, (possessed a CWT) the head
was removed and retained by staff.
6 ) The number and species of fish caught and released (actually released not lost) by the angler was recorded as juveniles, grilse or adults.
6) In Area 1 only, the angler was questioned whether they fished the mouth or from a boat and if fish were harvested above or below the Hwy 101 Bridge.
7) Was this a professionally guided trip?

## Harvest and Effort Estimating Procedures

Data is stratified for each creel census location by Julian week (Appendix 1). Angler harvest, releases and effort estimates are calculated for each week. The estimate formula used is:

$$
\text { Estimate total }=\sum_{\mathrm{l}=1}^{\mathrm{n}} \text { Daily total }(\mathrm{N} / \mathrm{n})
$$

where: Estimate total = estimates of catch or effort
Daily total = Daily counts of catch or effort
$\mathrm{N}=$ Number of fishing days in week
$\mathrm{n}=$ number of sample days
I = boat sampling ratio

Area 2: Harvest estimates for the area above Hwy 101 to the Hwy 96 Bridge at Weitchpec was calculated by multiplying the observed harvest and effort by a sampling ratio. This ratio is the weekly expansion value. This value is a simple ratio based on the number of days sampled to the number of legal fishing days within the week (7 days week / 3 days sampled $=2.33$ ). All sites are totaled for the week to obtain the weekly harvest estimate for Area 2. This procedure applies to both boat and shore harvest. No additional expansion for the boat harvest in Area 2 is needed since total boat catch and effort were accounted for in the creel sampling.

Area 1: The procedure for the area below Hwy 101 is identical with Area 2 except for the addition of a boat expansion factor. The boat expansion factor accounts for the harvest by boat anglers not sampled. The boat expansion formula is:
(Boats at the non-sampled docks + Boats at sampled docks)
Boats at Sampled docks
The product of this formula yields a ratio used to expand catch and effort data for nonsampled boats anglers. This ratio is obtained by counting the number of boats at all the docks (both sampled and non-sampled) below Hwy 101. This count occurs usually between 1100 to 1500 hrs. Although not all the boats will be at their docks at this time the assumption that the percentage of boats that do not return to their docks is the
same between both the unsampled and sampled docks. It is also assumed that the effort and catch are equal between the non-sampled boats and sampled boats.

A boat count is made every day Area 1 is sampled. This count excludes all boats used in the Tribal gill-net fishery. An average of these daily values is used to arrive at the average boat expansion value for the week. The closer the expansion value is to one, the greater the total coverage we have in the estuary.

## Daily Real Time Harvest Estimates and Projections

As in previous seasons, the KRP thought it necessary to compute harvest and effort estimates daily (real time) as we neared the quota to help prevent any over-harvesting. In addition, CDFG estimated one, two, and three day harvest projections to allow lead time of any adult Chinook salmon fishery closures.

## Size Determination of Fish

Fishing regulations spell out the size of adult Chinook at 22 inches (total length) or 56 centimeters. This size is used to make adult - grilse determinations during the season. Post season the actual lengths are graphed, scales and coded wire tags are read to determine the actual age composition. For this report only the adult -grilse (or jack) age break is reported.

## RESULTS

Rounding numbers to whole numbers may cause some slight addition discrepancies in these results. Spring run Chinook numbers are included in totals. All graphic fork lengths representations are smoothed by a moving average of five centimeters.

The creel census for the lower Klamath River began on August 6 and ran through November 4 (JW 32 through 44) of 2010. Chinook salmon harvested in the lower Klamath fishery ranged in size from 22 to 105 cm in fork length (Figure 1). The adult portion of Chinook harvested ranged from in size 61 to 105 cm FL and averaged 79 cm FL. The grilse component of the angler harvest ranged in size from 22 to 60 cm FL and averaged 50 cm FL.

Figure 1. Fork length frequency of Chinook salmon harvested in the lower Klamath River during the 2010 season.

Harvested steelhead ranged in size from 37 to 77 cm FL and averaged 59.4 cm FL (Figure 2). Any steelhead less than 42 cm FL is considered to be a half-pounder, and those larger are considered adults. Steelhead less than 25 cm FL are considered resident trout and not anadromous. Half-pounder steelhead ranged in size from 34 to 41 cm FL and the adult steelhead ranged in size from 42 to 79 cm FL.

Figure 2. Length frequency of steelhead harvested in the lower Klamath River during the 2010 season.

## Estimated Angler Effort and Harvest

During the 2010 season, CDFG estimate anglers made a total of 11,516 trips in Areas 1 and 2 combined. Of the 11,516 trips; 4,003 were in Area 1, and 7,513 were in Area 2 (Table 1). These trips resulted in a total effort of 58,842 fishing hours. As in previous seasons, boat anglers out-numbered shore anglers in both Areas (Table 1).

Anglers did not meet their quota of 12,000 adult fall run Chinook for the basin this season. Nor did anglers in the lower Klamath River meet their 6,000 fish quota. A total of 3,562 (2,057 adults and 1,505 grilse) Chinook salmon and 61(61 adults and 0 halfpounders) steelhead were harvested (Table 1). During Julian week 32, 28 (9 adult and 19 grilse) spring-run Chinook salmon were harvested. The total of fall-run Chinook harvested was 3,534 (2,048 adults and 1,486 grilse) fish. Fourteen adult coho were estimated harvested this season.

## 2010 Harvest and Effort Patterns

The average fishing trip length during the 2010 season was 5.1 hours (Table 2). This is longer than the last few years (2002-2010) and longer than the 4.0 hours average trip length over the previous 19 years (1992-2010). Anglers fished longer trips, caught fewer adult fish, but a great deal more grilse Chinook.

Table 2. Number of angler trips, hours, and average length of trip in the lower Klamath River sport fishery for the last nineteen seasons, 1992-2010.

| Year | Total Angler |  | Average <br> Hours/Trip |
| ---: | ---: | ---: | ---: |

Figure 3. Chinook salmon harvested per hour of angler effort during the lower Klamath River creel survey, 1980 - 2010.

## Catch and Release

Catch and release data were recorded as part of the creel interview. These data are expanded in the same manner as harvest data. Anglers were specifically asked if fish were released rather than lost. This data should only be used as an estimation of trends as they can be highly subjective. CDFG estimated anglers released 1,188 halfpounders, 563 adult steelhead, 207 grilse, and 92 adult Chinook salmon (Tables 3 and 4). In addition an estimated 7 grilse and 76 adult coho salmon were released this season. The majority of coho salmon caught and released occurred in Area 2. Anglers tend to fish later into the season in Area 2 when coho are present. As in all years, if the quota is met early the number of adult Chinook released increases as anglers are still permitted to fish for jacks, but must release adult Chinook salmon. The quota was not met in 2010.

Table 3 Number of estimated Chinook and coho salmon and steelhead caught and released from the lower Klamath River, 1994-2010.

| Year | Chinook |  | Steelhead |  | Coho |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Harvest Timing

Angler effort and Chinook harvest peaked in JW 37. This week was true for both grilse and adult Chinook salmon (Figures 4 and 5).

Fewer steelhead were harvested than last season. Harvest of adult steelhead peaked in JW 33 (Figure 6). The peak week of half-pounder catch and release was JW 34 (Figure 7). No half-pounders were reported harvested this season.

Figure 4. Estimated harvest of Chinook salmon in the lower Klamath River during the 2010 season.

## Coded-Wire Tag Recovery

KRP personnel recovered the heads of 76 adipose fin-clipped and coded-wire-tagged (Ad+CWT) Chinook salmon during Julian Weeks 34 through 41 of the 2010 season. There were three non-random recoveries (NRR), wherein anglers and or resort owners saved their fish heads for our personnel. These NRRs are not used to estimate the harvest of marked hatchery origin (Ad+CWT) Chinook salmon (Table 6). However, they are used to calculate harvest timing (Figure 8). CWTs were not recovered from two
heads. This left 74 tags to decode. Of these 74 heads, three were from outside the basin (Columbia River). This left 71 CWT's of Klamath- Trinity Basin origin; 43 were adult salmon while 28 were grilse salmon.

No Trinity River Hatchery (TRH) spring Chinook heads were recovered. Recoveries of fin-Clipped, fall-run Chinook salmon adults ranged in size from 64 to 94 cm . Grilse ranged in size from 34 cm to 69 cm . All fin-clipped fish observed in the angler survey were assigned an individual head tag number which allowed tracking of each head through the extraction and decoding process.

## Hatchery Contribution

Randomly recovered, marked Chinook salmon composed 5.21 percent $(73 / 1,399)$ of the actual Chinook salmon sampled. Expansions were made for creel sampling and hatchery production multiplier for each tag group. Based on these expansions, CDFG estimated 871 hatchery fish were harvested (Table 7). Hatchery fish represented an estimated 24.45 percent $(871 / 3,562)$ of the entire sport harvest in the lower Klamath River

## Iron Gate Hatchery (IGH) Origin Chinook Salmon

CDFG decoded 17 random recovered tags from Klamath River origin Chinook. These Chinook salmon represent 11 different tag codes; one from the 2006 Brood Year, one from the 2007 Brood Year and nine from the 2008 Brood Year at IGH (Table 6). When expanded for creel sampling and hatchery production multipliers for each tag group, IGH origin fish account for 8.45 percent $(301 / 3,562)$ of the total sport harvest (Table 7 ). The IGH origin Chinook were harvested between Julian weeks 33 to 39 (Figure 8).

## Trinity River Hatchery (TRH) Origin Chinook Salmon

CDFG decoded a total of 54 randomly recovered tags of IGH fall-run Chinook origin. These Chinook salmon represent 11 different tag codes; none from the 2006 Brood Year, five from the 2007 Brood Year and six from the 2008 Brood Year at IGH (Table 6). TRH origin fish represented 16.00 percent $(570 / 3,562$ ) of the total sport harvest (Table 7). IGH origin Chinook were harvested between Julian Weeks 35 to 42 (Figure 8).

During the 2010 season, sport in-river harvest by stock can be presumed to be as follows: the tail end of the TRH spring-run Chinook salmon made up the majority of harvest up to Julian week 33(based on returns in past years), then IGH fall-run Chinook salmon were present and peaked at Julian week 36 and 38. The bulk of the Trinity River fall-run tags were collected during Julian weeks 37 and 39, No more coded-wire tagged Chinook salmon were recovered after Julian week 42 (Figure 8).

Table 6. Actual coded-wire-tag recoveries by Julian week from Iron Gate Hatchery (IGH) and Trinity River Hatchery (TRH) for Chinook salmon obtained from the lower Klamath River, 2010 season .

Figure 8. Timing by Julian week of coded wire tags, expanded for sampling and by individual tag code, recovered from Chinook salmon in the lower Klamath River 2010 creel season.

## DISCUSSION

The lower Klamath River sport Chinook fishery is composed of fish produced naturally from the Klamath and Trinity river basins and fish produced at IGH and TRH. Based on creel sampling and hatchery production expansion factors, the estimated 2010 sport harvest was composed of approximately 24.5 percent hatchery and 75.5 naturally produced Chinook. The hatchery contribution was composed of 8.45 percent IGH Chinook and 16 percent TRH Chinook. In contrast, the previous twelve years of hatchery contributions to lower Klamath River Chinook harvests have averaged 15 percent TRH Chinook and 23 percent IGH.. Identifying the contribution of naturally produced Trinity stocks to the sport fishery is beyond the scope of this report. Methods to produce quantitative estimates of natural Chinook contributions from each of the Klamath and Trinity basins to the sport fishery should be investigated. Addressing the contribution to the sport fishery from naturally produced Chinook will add to information to assess TRRP goal and objectives.

# ANNUAL REPORT <br> TRINITY RIVER BASIN SALMON AND STEELHEAD MONITORING PROJECT 2010-2011 SEASON 

TASK 6<br>JUVENILE COHO SALMON SUMMER DISTRIBUTION IN THE UPPER TRINITY RIVER

#### Abstract

California Department of Fish and Game (CDFG) used direct observation surveys with mask and snorkel to detect naturally produced juvenile coho salmon (Oncorhynchus kisutch) in side channel and alcove habitat in the upper Trinity River. The surveys were conducted during two days; June 22-23, 2010. Observations of coho young-of-the-year (YOY) were recorded at 41 side channel or alcove sites located in the upper Trinity River from river kilometer (rkm) 170 to rkm 180. Thirty-six of the observation sites have received habitat improvement treatments associated with the Trinity River Restoration Program. Habitat improvements include improving river and fish access and addition of woody debris. Unimproved sites were deemed to contain natural characteristics attractive to juvenile coho. The discharge from Lewiston Dam at the time the surveys was approximately 2,150 cubic feet per second (cfs). The numbers of YOY coho detected at each observation site ranged from 0 to 17 fish. Coho presence was detected at all sites except one habitat improvement site.

## INTRODUCTION

A past study conducted by California Department of Fish and Game (CDFG) found that summer juvenile coho salmon (Oncorhynchus kisutch) distribution in the upper Trinity River is highly clustered around slower backwater, off-channel areas, such as alcoves and side channels. Within these habitats, non-emergent vegetation and large and small wood debris is cover preferred by juvenile coho. Juvenile coho also preferred water column velocities of less than 1 foot per second, depths averaging less than 3 feet and water temperatures between 9 and $12{ }^{\circ} \mathrm{C}$ (Garrison and Sinnen 2008). Garrison and Sinnen (2008) made their observations during summer base flows of 450 cubic-feet-persecond (cfs). The present study was performed during higher flows of $2,150 \mathrm{cfs}$ to monitor juvenile coho salmon use of side channel habitats modified by TRRP and naturally functioning off-channel areas.

A goal of the Trinity River Restoration Program (TRRP) is to increase natural production of juvenile coho through habitat modifications based on the type of information provided by Garrison and Sinnen (2008) and this study. Increasing natural production in the
upper Trinity River by improving juvenile rearing habitat is included in CDFG's recovery strategies for State and federally listed as threatened coho (CDFG 2004). Recent improvements to side channel areas made by the (TRRP) include opening access to flow and addition of wood debris to increase channel complexity and to provide cover elements for juvenile coho side channels.

## METHODS

Direct observation surveys with mask and snorkel were conducted in seven side channel or alcove habitat areas located in the Upper Trinity River from river kilometer (rkm) 170 to rkm 180 (Figure 1). The surveys were performed by CDFG staff on June 22-23, 2010. Stream flow below Lewiston Dam at the time of the survey was approximately 2,150 cubic feet per second (cfs). River temperature was recorded at $10^{\circ} \mathrm{C}\left(50^{\circ} \mathrm{F}\right)$ for both survey days. The Sven Olbertson and Saw Mill areas were accessed by foot on June 22. The remaining areas were access by floating downstream in a raft on June 23.

Single count coho observations were made by two snorkelers moving upstream within side channels or alcoves. Observation points were identified based on upon observed presence or counts of coho within the side channel or alcove habitat area. Waypoints locating the observation points were determined by a third person on shore using a hand held Garmin ${ }^{\text {TM }}$ global positioning navigation device. ${ }^{\text {a }}$ The third person recorded all information on data forms including coho counts, waypoint datum, indicated if the fish were associated with the right or left bank or middle of the channel, and if observations were within a TRRP habitat improvement site. The observation waypoints were plotted on the study area map below.

## RESULTS

Observations of naturally produced juvenile coho were recorded at 41 sites located in the upper Trinity River from rkm 170 to rkm 180. The numbers of YOY coho detected at each observation site ranged from zero to 17 fish (Table 1). Coho presence was detected at all sites except one habitat improvement site located at site 19 within the Saw Mill side channel area. However, ten juvenile Chinook salmon (Oncorhynchus tshawytscha) were observed at site 19.

[^9]
## DISCUSSION

This study was not designed to detect coho preference for any naturally occurring or modified habitats. It was done to perform a low level qualitative assessment of juvenile coho use of a select area within the upper Trinity River including sites that have received habitat improvement treatments. However, this study further documents juvenile coho use of side channels and alcoves in the upper Trinity River. The fish were observed during flows of 2,150 cfs from June 22-23, 2009. The observations add to coho use of off-channel habitats baseline data. Previous surveys of the upper Trinity River found juvenile coho use of side channels and alcoves during July 25 and September 22, 2006 during summer base flows of 450 cfs (Garrison and Sinnen 2008). Several other studies (eg. Bell et al 2001, Beechie et al 1994, Swales and Levings 1989) have demonstrated the importance of off-channel habitat for winter rearing and flooding episodes. Collectively these other studies and our observations indicate slow flowing side channels and alcoves in the upper Trinity River are likely critical coho habitat during summer months and over a range of flows (450 and 2,150 cfs). Surveys for juvenile coho use of off-channel habitat in the upper Trinity River during the other seasons and flows would add to the upper Trinity River baseline data.

Garrison and Sinnen (2008) observed in-stream cover in off-channel habitat was predominantly provided by emergent vegetation and small wood debris. They reported infrequent abundance of large wood as protective cover for coho in off-channel areas. They also noted poor large wood recruitment potential to off-channel areas due to damming of the river and past logging projects. Given this information, additions of large wood should be considered when planning side channel improvement projects. Large wood will provide a beneficial increase in shelter complexity and can provide channel forming elements to maintain side channel morphology. In addition, the loss of ample supplies of cool water is identified as a primary factor associated with severely depleted or extirpated coho populations in many California streams (CDFG 2004). Utilizing the cool Trinity River flows to supply side channels and other off-channel habitats emerges as an important adaptive management strategy to increase quality of juvenile coho rearing area. Thus, careful planning to maintain or increase the area and complexity of slow flowing side channel and alcove habitat should remain a high priority goal of the TRRP.

## RECOMMENDATIONS

1. The TRRP should continue management efforts to improve habitat conditions to support natural juvenile coho rearing habitat in the upper Trinity River.
2. Carefully designed studies should be planned to monitor coho use of future coho habitat improvement sites prior to project construction and post construction to evaluate project effectiveness.
