This report should be cited as follows:

Wetlands are disappearing at a rapid rate. Although measures are actively being sought to stem wetland losses and restore wetland acreage, the rate of wetland conversion over the years has been dramatic.

This is the first of two reports to Congress on the status of wetland resources in the United States. This report, a one-time effort, focuses on documenting historical wetland losses that occurred from colonial times through the 1980's. It is a compilation of existing data from a variety of sources. The second report will update the information contained in STATUS AND TRENDS OF WETLANDS AND DEEPWATER HABITATS IN THE CONTIGUOUS UNITED STATES. The study effort for the second report will generate new information based on a statistical analysis of wetland changes from the 1970's to the 1980's. The status and trends report will be updated every ten years as required by the Emergency Wetlands Resources Act of 1986.

This report is the product of the Fish and Wildlife Service, National Wetlands Inventory. Special appreciation is extended to Constance Harriman, Assistant Secretary, Fish and Wildlife and Parks; John Turner, Director, Fish and Wildlife Service; Maryanne Bach, Chief, Office of Program Analysis; and Bill O. Wilen, Project Leader, National Wetlands Inventory.

EXECUTIVE SUMMARY

In 1989, the Congress directed the Secretary of the Interior to assess the estimated total number of wetland acres as of the 1780's and the 1980's in the areas that now comprise each state. Congress also required an assessment of the estimated percentage of loss of wetlands in each state during this 200-year timespan. This report has been prepared to fulfill those requirements.

In compiling the information in this report, an attempt has been made to present the most reliable data on wetland acreage. Information has been taken from a variety of sources and different types of data sets to generate these acreage estimates. The user is encouraged to refer to the source materials presented documenting acreage estimates for the time-frames for each state.

At the time of Colonial America, the area that now constitutes the 50 United States contained an estimated 392 million acres of wetlands. Of this total, 221 million acres were located in the lower 48 states. Another 170 million acres occurred in Alaska. Hawaii contained an estimated 59,000 acres.

Over a period of 200 years, the lower 48 states lost an estimated 53 percent of their original wetlands. Alaska has lost a fraction of one percent while Hawaii has lost an estimated 12 percent of its original wetland areas. On average, this means that the lower 48 states have lost over 60 acres of wetlands for every hour between the 1780's and the 1980's.

The data presented in this report indicate that 22 states have lost 50 percent or more of their original wetlands. California has lost the largest percentage of original wetlands within the state (91%). Florida has lost the most acreage (9.3 million acres). The data presented in this report should be interpreted in context. The estimated percent of wetlands loss for an individual state must be examined in context to the total estimated surface acreage of the state, the 1780's total estimated wetland acreage of the state, and the current 1980's estimated wetland acreage. For instance, the State of California has a total surface area of approximately 101 million acres and it is estimated that in the 1780's California had 5 million acres of wetlands, or approximately 5 percent of California's total acreage was considered wetlands. It is now estimated that California has less than 500,000 wetland acres remaining. This estimate represents a wetlands loss of 91 percent of the 1780's estimated acreage, but also means that currently less than one-half of 1 percent of California's total acreage is wetlands.

Wetland acreage data, by state, has been tabulated for the 200-year timespan.
INTRODUCTION

Throughout the United States, a wide variety of wetland types exist ranging from permafrost underlain wetlands in Alaska to tropical rain forests in Hawaii to riparian wetlands in the arid southwest. Although wetlands occur in every state in the Nation, they vary in size, shape, and type because of differing climate, vegetation, soils, and hydrologic conditions.

Since the time of Colonial America, wetlands have been regarded as a hindrance to productive land use. Swamplands, bogs, sloughs, and other wetland areas were considered wastelands to be drained, filled, or manipulated to "produce" other than natural services or commodities. Recently we have begun to recognize that wetlands are vital areas that constitute a productive and invaluable public resource. Wetlands are important for providing fish and wildlife habitats; for maintaining ground water supplies and water quality; for protecting shorelines from erosion; for storing floodwaters and trapping sediments that can pollute waterways; and for modifying climatic changes.

Because the values of wetlands and their overall environmental importance have been only recently recognized, the United States has a 200-year history of wetland conversion. Collectively, wetland losses have diminished the quality of our natural resource base to the point where we must carefully balance our economic, social, and environmental goals. The issue of how much wetland acreage has been lost in the United States has led to heated debates about limiting alteration of natural resources. Overstatements or misrepresentations of the remaining wetland acreage are usually the result of emotional arguments rather than factual data. This report and other forthcoming reports prepared by the Department of the Interior will provide the needed information on the acreage status of our Nation's wetlands.
FOCUS OF THE REPORT

Section 401(a) of the Emergency Wetlands Resources Act of 1986 [16 U.S.C. 3931(a)] was amended by section 18 of the North American Wetlands Conservation Act of 1989 (PL. 101-233). The amendment requires the following:

(A) an assessment of the estimated total number of acres of wetland habitat as of the 1780's in the areas that now comprise each state; and

(B) an assessment of the estimated total number of acres of wetlands in each state as of the 1980's, and the percentage of loss of wetlands in each state between 1780's and the 1980's.

The information presented in this report fulfills those requirements. Data on acres of wetland habitat as of the 1780's, total number of acres of wetlands in each state as of the 1980's, and the percent of wetlands lost have been estimated. This information is in a tabular format to give a factual, quantitative measure of the acreage losses sustained during the 200-year timeframe.

ESTIMATING WETLAND LOSSES

It is difficult to make accurate estimates of wetland acreage during colonial times. Two problems make it difficult to utilize original acreage surveys or land use reports: (1) Quantitative information on wetlands is not available from early engineer-

FIGURE 1: GEOGRAPHICAL CONFIGURATION OF COLONIAL AMERICA IN 1775

East and West Florida retroceded by Great Britain in 1783

Vermont extralegally self-governing 1777-1791

Data on existing (1980's) wetland acreage also must be interpreted with caution. For some states, the wetlands have been mapped for the entire state by the National Wetlands Inventory, and acreage summary reports are available detailing the extent of wetlands. However, for those states where wetlands are not completely mapped or where acreage summaries are not yet compiled, an accurate accounting of wetland acreage is not always available. For some states, there are conflicting data sets reflecting inconsistencies in inventory terminologies or techniques, inadequate inventory data, or simply outdated information. In several cases, published documentation on the extent of wetlands amounts to little more than speculation. In these instances, an effort was made to assess the validity of the information and reconcile acreage statistics with the best national or regional data sets available to determine statewide totals.

Additionally, the current status of wetlands in the United States is constantly changing. It is estimated that, on average, over 60 acres of wetlands have been lost every hour in the lower 48 states.
during this 200-year timespan. While some state and Federal agencies are attempting to restore wetlands in certain parts of the country, restoration falls far short of this loss rate. In all instances, data sources for state estimates have been referenced.

SUMMARY OF FINDINGS 1780’S - 1980’S

The land area that now comprises the United States originally contained almost 392 million acres of wetlands (221 million acres in the lower 48 states). Historical estimates of wetland distribution by state indicate that 21 states possessed three million acres or more of wetlands. Considerable change in wetland distribution and abundance has taken place since the 1780’s (refer to Figures 3 and 4). In the conterminous United States, an estimated 104 million acres of wetlands remained as of the 1980’s. This amounts to a 53-percent loss from the original acreage total. The 50-state total indicates that an estimated 274 million acres remain.

In the 1980’s wetlands constitute only 5 percent of the land surface in the lower 48 states; 12 percent if Alaska and Hawaii are included. The State of Alaska has the vast majority of wetland acres. An estimated 170 million acres are believed to exist in Alaska alone. This represents approximately 45 percent of the State’s total surface area.

Among the lower 48 states, Florida, Louisiana, Minnesota, and Texas are the 4 states with the greatest wetland acreage. Other states with considerable wetlands include Alabama, Georgia, Maine, Michigan, Mississippi, North Carolina, South Carolina, and Wisconsin.

The data on wetlands lost during this 200-year timespan indicate that the State of Alaska has lost the lowest percentage of its original wetland acreage (estimated less than 1% loss). The states of Hawaii, New Hampshire, and Rhode Island have lost the fewest wetland acres overall, 7,000, 20,000 and 38,000 acres respectively. However, this amounts to a 12-percent loss of wetlands statewide for Hawaii, 9 percent loss for New Hampshire, and a 37-percent loss for Rhode Island.

Ten states—Arkansas, California, Connecticut, Illinois, Indiana, Iowa, Kentucky, Maryland, Missouri, and Ohio—have lost 70 percent or more of their original wetland acreage. Overall, the data indicate that 22 states have lost 50 percent or more of their original wetland areas. The state with the highest percent loss of wetlands is California (an estimated 91 percent loss from the 1780’s to the 1980’s). Florida has lost approximately 9.3 million acres of wetlands during this 200-year timespan.

With the exception of Alaska, New Hampshire, and Hawaii, no state has lost less than 20 percent of its original wetland acreage.

* Figures are for the conterminous 48 states and do not include Alaska unless stated.

Correlation with Other Data Sets

There appears to be close agreement between the data tabulated in this report and other data from sources that have been used to estimate original or existing wetland acreage. The total wetland acreage reported here for the 1980’s is comparable with the findings of Frayer et al. given the statistical range of variability. Frayer et al. estimated 99 million acres existed as of the mid-1970’s in the conterminous U.S. ± 6.4%. Because the techniques for determining acreage totals for the various estimates are very different, it is useful to draw comparisons to other national data sets on wetlands.

Estimates of Original Wetland Acreage

Estimates of original wetland acreage have been made by a variety of researchers and agencies (refer to Table 2). There are four sources that have produced viable acreage information that can be used to approximate wetlands as they existed at the time of settlement in the lower 48 states. In 1954, Roe and Ayres conducted an analysis of land already drained and potential land drainage needed to put the maximum area into agricultural production. They estimated that an area of 215 million acres or 24 percent of all potential agricultural land in the lower 48 states would require drainage for optimum crop production. This figure has been used as an original wetlands estimate in several national reports.

Hydric soils data have also been used in some instances to approximate wetland acreage. Hydric soils are those soils described by the Soil Conservation Service that are saturated, flooded, or ponded long enough during the growing season to develop anaerobic conditions in the upper part. Under normal circumstances, these soils support wetland vegetation and can be used as an indicator of wetlands. The National Technical Committee for Hydric Soils has developed criteria to identify hydric soil series and has produced a list of soils within the United States that are hydric. The publication Soil Taxonomy lists soil...
acreage estimates for the United States. Because soil characteristics change slowly, even following drainage, summation of the soil acreages indicative of wetland conditions should approximate the wetland acreage that existed at the time of settlement. Summing the acreage estimates of soils with aquic suborders* results in a total for the lower 48 states of 211 million acres. There are an additional 165 million acres of soils with aquic suborders in Alaska. (refer to Table 2)

The U.S. Department of Agriculture's Economic Research Service has also estimated original wetland acreages for the lower 48 states. Their estimate was based upon land in drainage in 1950, plus the maximum of inventoried wetlands based upon the U.S. Fish and Wildlife Service's wetland trends study or the U.S. Department of Agriculture's national resources inventory, whichever was greater. The estimated total of original wetlands in the lower 48 states using this method was 217 million acres.

The final data set that is comparable on a national basis was also produced by the U.S. Department of Agriculture's Economic Research Service. It details farm drainage trends in the United States. Because a very high percentage of wetland losses has been due to agricultural conversion, these data may be used to approximate the percentage of wetland area lost to agricultural drainage over time. By adding drainage figures to estimated existing wetland acreage, this method indicates that a total of 213 million acres once existed in the conterminous 48 states. It is interesting to note that three of the national data sets hinge on estimates of agricultural drainage. This is not unreasonable given that the vast majority of wetland losses have been due to agricultural conversion. Figure 5 illustrates the extent and location of artificially drained agricultural land in the United States.

*Aquatic suborder soils, as defined by Soil Taxonomy, are those soils that have a reducing regime that is virtually free of dissolved oxygen because the soil is saturated by ground water or by water of the capillary fringe.
The national decline in wetlands from the 1780's to the 1980's is dramatic. Losses in particular regions of the country are even more startling. For example, the mid-western farm belt states of Illinois, Indiana, Iowa, Michigan, Minnesota, Ohio, and Wisconsin account for over 36 million acres of wetlands lost since the country was settled. This amounts to roughly one third of all wetlands lost in the history of our Nation. Alaska stands alone as the only state where wetland resources have not been substantially reduced.

Incomplete baseline data on the wetlands in the Nation prevent an accurate appraisal of the “health” of these remaining resources. However, population growth and distribution and agricultural development greatly affect land use patterns that impact wetlands. As evidenced by the data presented in this report, hundreds of thousands of acres have been drained annually, despite increased efforts to conserve wetlands through state and Federal legislation.

Our Nation continually faces the challenge of identifying and reconciling physical and environmental limits with the development of its natural resources. To meet the demand for resource development, the United States develops laws, regulations, and policies to increase the benefits of development while attempting to protect fish and wildlife, environmental quality, and socio-economic resource values. The stimulus for development of such protective measures is provided by insights regarding environmental trends. While some trends are very subtle, these data on the Nation’s wetlands loss provide a clear indication that continued loss will jeopardize a valuable resource. Over a 200-year timespan, wetland acreage has diminished to the point where environmental and even socio-economic benefits (i.e., ground water supply and water quality, shoreline erosion, floodwater storage and trapping of sediments, and climatic changes) are now seriously threatened.
