HCP conservation measures that provide a benefit to the northern spotted owl and its habitat have been implemented continuously since 1998 on all covered lands owned and managed under the Cedar River HCP. Excluding the lands managed under the Cedar River HCP from critical habitat designation will sustain and enhance the working relationship between the Service and the permit holder.

Excluding lands within HCPs from critical habitat designation can also facilitate our ability to seek new partnerships with future HCP participants including States, counties, local jurisdictions, conservation organizations, and private landowners, which together can implement conservation actions that we would be unable to accomplish otherwise. If lands within HCP plan areas are designated as critical habitat, it would likely have a negative effect on our ability to establish new partnerships to develop HCPs, particularly large, regional HCPs that involve numerous participants and/or address landscape-level conservation of species and habitats. By excluding these lands, we preserve our current partnerships and encourage additional conservation actions in the future.

Benefits of Exclusion Outweigh the Benefits of Inclusion—In summary, we determine that the benefits of excluding the Cedar River HCP from the designation of critical habitat for the northern spotted owl outweigh the benefits of including this area in critical habitat. The regulatory and informational benefits of inclusion will be minimal. Because one of the primary threats to the northern spotted owl is habitat loss and degradation, the consultation process under section 7 of the Act for projects with a Federal nexus will, in evaluating effects to the northern spotted owl, evaluate the effects of the action on the conservation or functionality of the habitat for the species regardless of whether critical habitat is designated for these lands. The analytical requirements to support a jeopardy determination on excluded land are similar, but not identical, to the requirements in an analysis for an adverse modification determination on included land. However, the additional benefits of inclusion on the section 7 process are relatively unlikely because a Federal nexus on these relatively remote forest lands would rarely occur. If one were to occur, it would most likely be a linear project such as a powerline, pipeline, or transportation. In the last 12 years of the permit, none have occurred.

In addition, the management strategies of the Cedar River HCP are designed to protect and enhance habitat for the northern spotted owl. The Cedar River HCP includes species-specific avoidance and minimization measures, monitoring requirements to track success and ensure proper implementation, and forest management practices and habitat conservation objectives that benefit the northern spotted owl and its habitat which further minimizes the benefits that would be provided as a result of a critical habitat designation.

On the other hand, the benefit of excluding these lands is that it will help us maintain an important and successful conservation partnership with a major city, and may encourage others to join in conservation partnerships as well. For these reasons, we have determined that the benefits of exclusion outweigh the benefits of inclusion in this case.

Exclusion Will Not Result in Extinction of the Species—We have determined that exclusion of approximately 3,244 ac (1,313 ha) of lands covered under the Cedar River HCP will not result in extinction of the northern spotted owl because the Cedar River HCP provides for the needs of the northern spotted owl by protecting and preserving thousands of acres of existing suitable northern spotted owl habitat in the Cedar River watershed, committing to the enhancement and recruitment of additional habitat over the term of the Cedar River HCP, and implementing species-specific conservation measures designed to avoid and minimize impacts to northern spotted owls. In addition, monitoring, research, and adaptive management programs were developed to track HCP progress and provide critical feedback on management actions that allow for management changes in response. Further, for projects having a Federal nexus and affecting northern spotted owls in occupied areas, the jeopardy standard of section 7 of the Act, coupled with protection provided by the Cedar River HCP, would provide a level of assurance that this species will not go extinct as a result of excluding these lands from the critical habitat designation. The species is also protected from take under section 9 of the Act. For these reasons we find that exclusion of these lands within the Cedar River HCP will not result in extinction of the northern spotted owl. Based on the above discussion, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude from this final critical habitat designation portions of the proposed critical habitat units or subunits that are within the Cedar River Watershed HCP boundary totaling about 3,244 ac (1,313 ha).

Green River Water Supply Operations and Watershed Protection Habitat Conservation Plan

In this final designation, the Secretary has exercised his authority to exclude lands from critical habitat, under section 4(b)(2) of the Act, totaling approximately 3,162 ac (1,280 ha) that are covered under Tacoma Water's Green River Water Supply Operations and Watershed Protection HCP (Green River HCP) in the State of Washington. The permit associated with this HCP was noticed in the **Federal Register** on August 21, 1998 (63 FR 44918), and issued on July 6, 2001. The term of the permit and HCP is 50 years. The Green River HCP addresses upstream and downstream fish passage issues, flows in the middle and lower Green River, and timber and watershed-management activities on 15,843 ac (6,411 ha) of Tacoma-owned land in the upper Green River Watershed. The Green River HCP covers 32 species of fish and wildlife, including the northern spotted owl and 10 other listed species, under an agreement designed to allow the continuation of water-supply operations on the Green River, forest management practice in the upper Green River watershed, and aquatic restoration and enhancement activities. The plan also provides for fish passage into and out of the upper Green River Watershed.

The City of Tacoma manages approximately 15,843 ac (6,411 ha) of covered lands in the upper Green River watershed for water quality benefits and timber harvest. The Green River HCP divides Tacoma-owned lands into three distinct management zones, and contains a series of conservation measures that address upland forest management, riparian buffers, and avoid or minimize impacts to covered species. Each management zone has specific goals and objectives that focus on water quality, fish and wildlife, and timber management. The Natural Zone contains 5,850 ac (2,370 ha). In this zone, Tacoma is committed to conduct no timber harvest management except for danger tree removal. The long-term goal is to allow these timber stands to develop into late-seral (greater than 155 years old) and mature timber (106–155 years old) conditions through natural succession. The Conservation Zone contains 5,180 ac (2,080 ha) of covered lands. In this zone, Tacoma will conduct no even-aged harvest in conifer stands and no harvest of any form in stands over 100 years old (except for danger tree removal). Tacoma may conduct uneven-aged harvest in stands less than 100 years old to improve stand condition. Once stands reach 100 years of age, no timber harvest will be conducted and stands will be allowed to develop through natural succession. The Commercial Zone contains 3,858 ac (1,561 ha) of covered lands. Stands in this zone will be managed sustainably for timber production on a 70-year rotation. A considerable area of late-seral and mature forest capable of supporting nesting, roosting, foraging, and dispersal of northern spotted owls is expected to develop over time in the Natural Zone, Conservation Zone, and to a lesser extent, riparian buffers. Over the term of the permit, the amount of late-seral forest is expect to increase from 41 ac (17 ha) to 292 ac (118 ha), and the amount of mature forest is expected to increase from 268 ac (108 ha) to 4,027 ac (1,630 ha).

At the time the permit was approved, there were 16 known northern spotted owl activity centers within 1.8 miles of covered lands. Fifteen were reproductive site centers and one was a single-resident site center. Only the single-resident site center was actually located on covered lands. Species-specific conservation measures are designed to protect habitat around known nest sites and minimize disturbance during the nesting season.

Benefits of Inclusion—We find that there is minimal benefit from designating critical habitat for the northern spotted owl within the Green River HCP because, as explained above, these covered lands are already managed for the conservation of the species over the term of the HCP. As discussed above the inclusion of these covered lands as critical habitat could provide some additional Federal regulatory benefits for the species consistent with the conservation standard based on the Ninth Circuit Court's decision in *Gifford Pinchot.* A benefit of inclusion would be the requirement of a Federal agency to ensure that their actions on these non-Federal lands would not likely result in the destruction or adverse modification of critical habitat. However, this additional analysis to determine whether a Federal action is likely to result in the destruction or adverse modification of critical habitat is not likely to be significant not only because a Federal nexus is unlikely (these covered lands are not under Federal ownership), any Federal agency proposing a Federal action on these covered lands would likely consider the conservation value of these lands and take the necessary steps to avoid adverse effects to northern spotted owl habitat. If a Federal nexus did occur, it would most likely be in the context of a linear project such as a powerline, pipeline, or transportation project. In the last 11 years of the permit, none have occurred.

Another factor that minimizes any regulatory benefits that might result from critical habitat designation is that the Green River HCP already provides for the needs of the northern spotted owl by protecting and preserving acres of existing suitable northern spotted owl habitat in the Green River watershed, committing to the enhancement and recruitment of additional area of suitable habitat over the term of the Green River HCP, and implementing species-specific conservation measures designed to avoid and minimize impacts to northern spotted owls. Monitoring was developed to track HCP progress over the term of the permit and provide critical feedback on management actions, which allow for management changes in response to this feedback or to larger trends outside the HCP boundaries such as climate change. Therefore, designation of critical habitat would be redundant on these lands, and would not provide additional measurable protections.

Another benefit of including lands in a critical habitat designation is that it serves to educate landowners, State and local governments, and the public regarding the potential conservation value of an area. This helps focus and promote conservation efforts by other parties by identifying areas of high conservation value for northern spotted owls. Designation of critical habitat would inform State agencies and local governments about areas that could be conserved under State laws or local ordinances, such as the Washington State Growth Management Act, which encourage the protection of ''critical areas'' including fish and wildlife habitat conservation areas. Any information about the northern spotted owl and its habitat that reaches a wider audience, including parties engaged in conservation activities, is valuable. However, the additional educational and informational benefits that might arise from critical habitat designation here have been largely accomplished through the public review and comment on the HCP, Environmental Impact Statement, and Implementation Agreement.

The designation of critical habitat may also indirectly cause State or county jurisdictions to initiate their own additional requirements in areas identified as critical habitat. These measures may include additional permitting requirements or a higher level of local review on proposed projects. However, in Washington, State forest practices regulations provide an exemption for review for lands managed under an HCP. Thus, even should the State respond to designation of critical habitat by instituting additional protections, the HCP will not be subject to those protections as the species is considered already addressed, and therefore no additional benefit would accrue through State regulations.

Benefits of Exclusion—The benefits of excluding from designated critical habitat the approximately 3,162 ac (1,280 ha) of lands currently managed under the HCP are substantial. HCP conservation measures that provide a benefit to the northern spotted owl and its habitat have been implemented continuously since 2001 on all covered lands owned and managed under the Green River HCP. Excluding the lands managed under the Green River HCP from critical habitat designation will sustain and enhance the working relationship between the Service and the permit holder.

Excluding lands within HCPs from critical habitat designation may also support our continued ability to seek new partnerships with future HCP participants including States, counties, local jurisdictions, conservation organizations, and private landowners, which together can implement conservation actions that we would be unable to accomplish otherwise. If lands within HCP plan areas are designated as critical habitat, it would likely have a negative effect on our ability to establish new partnerships to develop HCPs, particularly HCPs address landscape-level conservation of species and habitats. By excluding these lands, we preserve our current partnerships and encourage additional conservation actions in the future.

Benefits of Exclusion Outweigh the Benefits of Inclusion—In summary, we determine that the benefits of excluding the Green River HCP from the designation of critical habitat for the northern spotted owl outweigh the benefits of including this area in critical habitat. The regulatory and informational benefits of inclusion will be minimal. Because one of the primary threats to the northern spotted owl is habitat loss and degradation, the consultation process under section 7 of the Act for projects with a Federal nexus will, in evaluating effects to the northern spotted owl, evaluate the effects of the action on the conservation or functionality of the habitat for the species regardless of whether critical habitat is designated for these lands. The analytical requirements to support a jeopardy determination on excluded land are similar, but not identical, to the requirements in an analysis for an adverse modification determination on included land. However, any benefits from the section 7 process are unlikely because Federal projects would be rare on these relatively remote forest lands. The regulatory benefits of inclusion are even more minimal in light of the fact that the Green River HCP includes species-specific avoidance and minimization measures, monitoring requirements to track success and ensure proper implementation, and forest management practices and habitat conservation objectives that benefit the northern spotted owl and its habitat, which exceeds any conservation value provided as a result of a critical habitat designation. On the other hand, the benefit of excluding these lands is that it will help us maintain an important and successful conservation partnership with a major city, and may encourage others to join in conservation partnerships as well. Therefore, we find that the benefits of exclusion of the lands covered by Green River HCP outweigh the benefits of inclusion.

Exclusion Will Not Result in Extinction of the Species—We have determined that exclusion of approximately 3,162 ac (1,280 ha) of lands covered under the Green River HCP will not result in extinction of the northern spotted owl because the Green River HCP provides for the needs of the northern spotted owl by protecting and preserving acres of existing suitable northern spotted owl habitat in the Green River watershed, committing to the enhancement and recruitment of additional area of suitable habitat over the term of the Green River HCP, and implementing species-specific conservation measures designed to avoid and minimize impacts to northern spotted owls. Monitoring was developed to track HCP progress over the term of the permit and provide critical feedback on management actions, which allow for management changes in response to this feedback or to larger trends outside the HCP boundaries such as climate change. The conservation measures provided by this HCP have been implemented continuously since 1998 on all covered lands owned and managed under the Green River HCP. Further, for projects having a Federal nexus and affecting northern spotted owls in occupied areas, the jeopardy standard of section 7 of the Act, coupled with protection provided by the Green River HCP, would provide a level of assurance that this species will not go extinct as a result of excluding these lands from the critical habitat designation. The species is also protected by ESA section 9, which prohibits the take of listed species. For these reasons, we find that exclusion of these lands within the Green River HCP will not result in extinction of the northern spotted owl. Based on the above discussion, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude from this final critical habitat designation portions of the proposed critical habitat units or subunits that are within the Green River HCP boundary totaling about 3,162 ac (1,280 ha).

Plum Creek Timber Central Cascades Habitat Conservation Plan

In this final designation, the Secretary has exercised his authority to exclude lands from critical habitat, under section 4(b)(2) of the Act, totaling about 33,144 ac (13,413 ha) that are covered under the Plum Creek Timber Central Cascades HCP (Plum Creek HCP) in the State of Washington. The permit associated with the Plum Creek HCP was first noticed in the **Federal Register** on November 17, 1995 (60 FR 57722), issued on June 27, 1996, and later modified in December of 1999 as noticed on February 10, 2000 (65 FR 6590). The permit has a term of 50 years (with an option to extend to 100 years if certain conditions are met) and currently covers 84,600 ac (34,236 ha) of lands in the Interstate-90 corridor in King and Kittitas Counties, Washington. The HCP includes over 315 species of fish and wildlife, including the northern spotted owl and 7 other listed species. The plan addresses forest-management activities across an area of industrial timberlands in Washington's central Cascade Mountains, and provides for management of the northern spotted owl based on landscape conditions tailored to the guidelines provided by the NWFP by providing additional protection to northern spotted owl sites near late-successional reserves. Wildlife trees are retained in buffers of natural features (e.g., caves, wetlands, springs, cliffs, talus slopes) and streams, as well as scattered and clumped within harvest units. The HCP also requires Plum Creek to maintain and grow nesting, roosting, and foraging habitat as well as habitat that can be used for foraging and dispersal. They are also required to provide forests of various structural stages across all of their HCP ownerships. This commitment of owl habitat and forest stages, in combination with wildlife trees retained within harvest units and stream and landscape-feature buffers will provide a matrix of habitat conditions that complements the owl habitat provided in the Plum Creek HCP and nearby LSRs. Stands containing scattered leave trees following harvest will be expected to become more valuable for northern spotted owls at earlier ages than those harvested using previous methods.

At the time the permit was approved, there were 107 known northern spotted owl activity centers within 1.82 miles of covered lands, which included reproductive site centers, single-resident site centers, and historic sites. A detailed description of each sites history is provided in the HCP and associated technical papers.

Benefits of Inclusion—We find there are minimal benefits to including these lands in critical habitat. As discussed above, the designation of critical habitat invokes the provisions of section 7. However, in this case, we find the requirement that Federal agencies consult with us and ensure that their actions are not likely to destroy or adversely modify critical habitat will not result in significant benefits to the species because the possibility of a Federal nexus for a project on these lands is small unless it is a larger project covering adjacent Federal lands as well, in which case section 7 consultation would already be triggered and the Federal agency would consider the effects of its actions on the species. In addition, although the standards of jeopardy and adverse modification are different, the margin of conservation that could be attained through section 7 would not be significant in light of the benefits already derived from the HCP.

HCPs typically provide for greater conservation benefits to a covered species than section 7 consultations because HCPs ensure the long-term protection and management of a covered species and its habitat. In addition, funding for such management is ensured through the Implementation Agreement. Such assurances are typically not provided by section 7 consultations, which in contrast to HCPs, often do not commit the project proponent to long-term, special management practices or protections. Thus, a section 7 consultation typically does not afford the lands it covers similar extensive benefits as a HCP. The development and implementation of HCPs provide other important conservation benefits, including the development of biological information to guide the conservation efforts and assist in species conservation, and the creation of innovative solutions to conserve species while meeting the needs of the applicant. In this case, substantial information has been developed from the research, monitoring, and surveys conducted under the Plum Creek HCP.

There is minimal incremental benefit from designating critical habitat for the northern spotted owl within the Plum Creek HCP because, as explained above, these covered lands are already managed for the conservation of the species over the term of the HCP and the conservation measures provided by the HCP will provide greater protection to northern spotted owl habitat than the designation of critical habitat, which provides regulatory protections only in the event of a Federal action. The Plum Creek HCP provides for the needs of the northern spotted owl by protecting and preserving landscape levels of suitable northern spotted owl nesting, roosting, and foraging habitat as well as foraging and dispersal habitat over the term of the HCP in strategic landscapes, and implementing species-specific conservation measures designed to avoid and minimize effects to northern spotted owls. The HCP also provides for the ability to make ongoing adjustments in a number of forms including active adaptive forest management. The ability to change is crucial to meet new recovery challenges. The Service negotiated this plan with Plum Creek, which contains mandatory permit conditions in the form of HCP commitments, and continues to be involved in its ongoing implementation. The Service conducts compliance monitoring on the covered lands and routinely meets with Plum Creek to discuss ongoing implementation. The HCP contains provisions that address ownership changes and the outcomes expected by the Service. Monitoring was developed to track HCP progress over the term of the permit and provide feedback on management actions. Therefore, designation of critical habitat would be redundant on these lands, and would not provide additional measureable protections.

Another benefit of including lands in a critical habitat designation is that it serves to educate landowners, State and local governments, and the public regarding the potential conservation value of an area. This helps focus and promote conservation efforts by other parties by identifying areas of high conservation value for northern spotted owls. Designation of critical habitat would inform State agencies and local governments about areas that could be conserved under State laws or local ordinances, such as the Washington State Growth Management Act, which encourage the protection of ''critical areas'' including fish and wildlife habitat conservation areas. Any information about the northern spotted owl and its habitat that reaches a wider audience, including parties engaged in conservation activities, is valuable.

However, Plum Creek is knowledgeable about the northern spotted owl and the company has made substantial contributions in research and science for the species. The additional educational and informational benefits that might arise from critical habitat designation here have been largely accomplished through the public review and comment of the HCP, Environmental Impact Statement, and Implementation Agreement, as well as the supplemental Environmental Impact Statements associated with the modification of the HCP and the I–90 Land Exchange. Through these processes, this HCP included intensive public involvement. This HCP continues to receive a high degree of scrutiny and study by academics, as well as informational releases to the general public and has resulted in improved understanding by the public. This level of exposure in local newspapers and television stations exceeds the level of education that would come from a designation that would be read by few people in the public. Moreover, the rulemaking process associated with critical habitat designation includes several opportunities for public comment, and thus also provides for public education. Through these outreach opportunities, land owners, State agencies, and local governments have become more aware of the status of and threats to the northern spotted owl and the conservation actions needed for recovery.

The designation of critical habitat may also indirectly cause State or county jurisdictions to initiate their own additional requirements in areas identified as critical habitat. These measures may include additional permitting requirements or a higher level of local review on proposed projects. However, in Washington, State forest practices regulations provide an exemption for review for lands managed under an HCP. Thus, even should the State respond to designation of critical habitat by instituting additional protections, the HCP will not be subject to those protections as the species is considered already addressed, and therefore no additional benefit would accrue through State regulations.

Benefits of Exclusion—The benefits of excluding from designated critical habitat the approximately 33,144 ac (13,413 ha) of lands currently managed under the HCP are more substantial. The designation of critical habitat could have an unintended negative effect on our relationship with non-Federal landowners due to the perceived imposition of redundant government regulation. If lands within the Plum Creek HCP area are designated as critical habitat, it would likely have a negative effect on our continued ability to seek new partnerships with future participants including States, counties, local jurisdictions, conservation organizations, and private landowners, which together can implement conservation actions (such as SHAs, HCPs, and other conservation plans, particularly those that address landscape-level conservation of species and habitats) that we would be unable to accomplish otherwise. This HCP is currently serving as a model for ongoing and future efforts. Due to the high level of visibility in the Interstate-90 corridor and the overlap with recreational lands used by many residents of the Seattle metropolitan area, this HCP received an unusual amount of scrutiny. Because it was one of the first HCPs to address species using a habitat-based approach, it set a high standard for application of the best available science. Plum Creek has been a long-standing partner and advocate for HCPs across the nation. They are viewed as leaders in their industry and as an example in the HCP community. By excluding these lands, we preserve our current private and local conservation partnerships and encourage additional conservation actions in the future.

In addition, exclusion may encourage Plum Creek to engage in further land exchanges or sales of their lands for conservation purposes. This HCP is located in a key landscape between the I–90 and other Federal lands and represents a unique opportunity in maintaining northern spotted owls at the western extreme of the Cascades, which may support dispersal between the Cascades. This HCP contributes meaningfully to the recovery of the northern spotted owl and serves as an example to other industrial companies. Since issuance of the Plum Creek HCP, Plum Creek's ownership has decreased from about 170,000 ac (68,797 ha) to about 81,000 ac (32,780 ha). This decrease is mostly due to land exchanges and sales by Plum Creek for conservation purposes. Conservation sales have been completed on a number of sensitive sites. Plum Creek has worked to find conservation buyers and has responded to requests from agencies and conservation groups. They have sold lands to a various parties using differing funding mechanisms, but sold lands have been transferred to public ownership, primarily the U.S. Forest Service. All of these lands have been placed in conservation status. If lands within the Plum Creek HCP plan areas are designated as critical habitat, it would likely have a negative effect on the willingness of various groups and funding sources to accomplish these conservation sales, and could also negatively affect Plum Creek's willingness to participate in these acquisition processes.

Benefits of Exclusion Outweigh the Benefits of Inclusion—The benefits of including these lands in the designation are small. Because one of the primary threats to the northern spotted owl is habitat loss and degradation, the consultation process under section 7 of the Act for projects with a Federal nexus will, in evaluating effects to the northern spotted owl, evaluate the effects of the action on the conservation or functionality of the habitat for the species regardless of whether critical habitat is designated for these lands. The analytical requirements to support a jeopardy determination on excluded land are similar, but not identical, to the requirements in an analysis for an adverse modification determination on included land. However, the HCP contains provisions for protecting and maintaining northern spotted owl habitat that far exceed the conservation benefits afforded through section 7 consultation. It provides for comprehensive measures applied across a large landscape that will benefit spotted owls. Plum Creek personnel are knowledgeable in the ecology of the northern spotted owl and have contributed to the body of scientific information about the northern spotted owl. In this instance, the regulatory and educational reasons for inclusion have much less benefit than the continued benefit of the HCP, including the educational benefits derived from the HCP.

On the other hand, the benefits of exclusion will continue the positive relationship we currently have with Plum Creek and encourage others to engage in conservation partnerships such as HCPs as well. For these reasons, we determine that the benefits of excluding the Plum Creek Cascades HCP from the designation of critical habitat for the northern spotted owl outweigh the benefits of including this area in critical habitat.

Exclusion Will Not Result in Extinction of the Species—We have determined that exclusion of approximately 33,144 ac (13,413 ha) of lands covered under the Plum Creek HCP will not result in extinction of the northern spotted owl because the Plum Creek HCP provides for the needs of the northern spotted owl by protecting and preserving landscape levels of suitable northern spotted owl nesting, roosting, and foraging habitat as well as foraging and dispersal habitat over the term of the HCP in strategic landscapes, and implementing species-specific conservation measures designed to avoid and minimize effects to northern spotted owls. Monitoring was developed to track HCP progress over the term of the permit and provide feedback on management actions. The Plum Creek HCP provides for the ability to make ongoing adjustments in a number of forms, including active adaptive forest management. The ability to change is crucial to meet new recovery challenges. The HCP contains provisions that address ownership changes and the outcomes expected by the Service. Further, for projects having a Federal nexus and affecting northern spotted owls in occupied areas, the jeopardy standard of section 7 of the Act, coupled with protection provided by the Plum Creek HCP, would provide a level of assurance that this species will not go extinct as a result of excluding these lands from the critical habitat designation. We find that exclusion of these lands within the Plum Creek HCP will not result in extinction of the northern spotted owl. Based on the above discussion, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude from this final critical habitat designation portions of the proposed critical habitat units or subunits that are within the Plum Creek HCP boundary totaling about 33,144 ac (13,413 ha).

Washington State Department of Natural Resources State Lands Habitat Conservation Plan

Washington State lands totaling approximately 225,751 ac (91,358 ha) that are covered and managed under the Washington State Department of Natural Resources State Lands Habitat Conservation Plan (WDNR HCP), are excluded from this critical habitat designation under section 4(b)(2) of the Act. The WDNR HCP covers approximately 1.7 million ac (730,000 ha) of State forest lands within the range of the northern spotted owl in the State of Washington. The majority of the area covered by the HCP is west of the Cascade Crest and includes the Olympic Experimental State Forest. The HCP area on the east side of the Cascade Range includes lands within the range of the northern spotted owl. The permit associated with this HCP, issued January 30, 1997, was noticed in the **Federal Register** on April 5, 1996 (61 FR 15297), has a term of 70 to 100 years, and covers activities primarily associated with commercial forest management, but also includes limited nontimber activities such as some recreational activities. The HCP covers all species, including the northern spotted owl and other listed species.

The HCP addressed multiple species through a combination of strategies. The HCP includes a series of Natural Area Preserves and Natural Resource Conservation Areas. The marbled murrelet is addressed through a combination of steps culminating in the development of a long-term plan to retain and protect important old-forest habitat, which will also benefit the northern spotted owl. Riparian conservation includes buffers on fish-bearing streams as well as substantial buffers on streams and wetlands without fish, and deferring harvest on unstable slopes. Wildlife trees are retained in buffers of natural features (e.g., caves, wetlands, springs, cliffs, talus slopes) and streams, as well as scattered and clumped within harvest units. The HCP also requires WDNR to maintain and grow forests of various structural stages across all of their HCP ownerships. Specifically for northern spotted owls, they have identified portions of the landscape upon which they will manage for nesting, roosting, and foraging (NRF) habitat for northern spotted owls. These areas are known as NRF Management Areas (NRFMAs) and were located to provide demographic support that would strategically complement the NWFP's Late-Successional Reserves as well as those Adaptive Management Areas that have late-successional objectives. The NRFMAs also were situated to help maintain species distribution. Generally, these NRFMAs will be managed so that approximately 50 percent of those lands will develop into NRF habitat for the northern spotted owl over time. Within this 50 percent, certain nest patches containing high-quality nesting habitat are to be retained and grown. Since the HCP was implemented, within the NRFMAs, WDNR has carried out 5,100 ac (2,064 ha) of pre-commercial thinning and 7,800 ac (3,156 ha) of timber harvest specifically configured to enhance northern spotted owl habitat. WDNR's habitat-enhancement activities will continue under the HCP.

Some areas outside of the NRFMAs are managed to provide for dispersal and foraging conditions in 50 percent of the forests in those areas; these were strategically located in landscapes important for connectivity. The Olympic Experimental State Forest is managed to provide for northern spotted owl conservation across all of its lands. Even in areas not specifically managed for northern spotted owls, WDNR has committed to providing a range of forest stages across the landscape to address multiple species. This commitment of forest stages, in combination with wildlife trees retained within harvest units and stream and landscape-feature buffers, will provide a matrix of habitat conditions that will also provide some assistance in conserving northern spotted owls. Stands containing scattered leave trees following harvest will become more valuable for northern spotted owls at earlier ages than those stands harvested using previous methods. Northern Spotted owls across the WDNR HCP are expected to benefit from the combination of these strategies.

At the time the permit was approved, there were approximately 292 northern spotted owl site centers overlapping on WDNR covered lands, including 76 known site centers (excluding historic sites and non-territorial singles). There were approximately 484,717 ac (196,158 ha) of suitable habitat on covered lands, which comprised over 10 percent of all suitable habitat in Washington State at that time.

Benefits of Inclusion—We find there are minimal benefits to including these lands in critical habitat. As discussed above, the designation of critical habitat invokes the provisions of section 7. However, in this case, we find the requirement that Federal agencies consult with us and ensure that their actions are not likely to destroy or adversely modify critical habitat will not result in significant benefits to the species because the possibility of a Federal nexus for a project on these lands is small unless it is a larger project covering adjacent Federal lands as well, in which case section 7 consultation would already be triggered and the Federal agency would consider the effects of its actions on the species. In addition, although the standards of jeopardy and adverse modification are different, in this case, the benefits of applying the latter standard would be minimal in light of the benefits already derived from the HCP.

HCPs typically provide for greater conservation benefits to a covered species than section 7 consultations because HCPs ensure the long-term protection and management of a covered species and its habitat. Funding for such management is ensured through the Implementation Agreement. Such assurances are typically not provided by section 7 consultations, which in contrast to HCPs, often do not commit the project proponent to long-term, special management practices or protections. Thus, a section 7 consultation typically does not afford the lands the same benefits as a HCP.

The development and implementation of HCPs provide other important conservation benefits, including the development of biological information to guide the conservation efforts and assist in species conservation, and the creation of innovative solutions to conserve species while meeting the needs of the applicant. In this case, substantial information has been developed from the research, monitoring, and surveys conducted under the WDNR HCP.

There is minimal incremental benefit from designating critical habitat for the northern spotted owl within the WDNR HCP because, as explained above, these covered lands are already managed for the conservation of the species over the term of the HCP and the conservation measures provided by the HCP will provide greater protection to northern spotted owl habitat than the designation of critical habitat, which provides regulatory protections only in the event of a Federal action. The WDNR HCP provides for the needs of the northern spotted owl by protecting and preserving landscape levels of suitable northern spotted owl nesting, roosting, and foraging habitat as well as foraging and dispersal habitat over the term of the HCP in strategic landscapes, and implementing species-specific conservation measures designed to avoid and minimize effects to northern spotted owls. The HCP also provides for the ability to make ongoing adjustments in a number of forms, including active adaptive forest management. The ability to change is crucial to meet new recovery challenges. The Service continues to be involved in the implementation of this HCP. The Service conducts compliance monitoring on the covered lands and routinely meets with WDNR to discuss ongoing implementation. The HCP contains provisions that address ownership changes and the outcomes expected by the Service. Monitoring was developed to track HCP progress over the term of the permit and provide feedback on management actions. Therefore, designation of critical habitat would be redundant on these lands, and would not provide additional measureable protections.

Another benefit of including lands in a critical habitat designation is that it serves to educate landowners, State and local governments, and the public regarding the potential conservation value of an area. This helps focus and promote conservation efforts by other parties by identifying areas of high conservation value for northern spotted owls. Designation of critical habitat would inform State agencies and local governments about areas that could be conserved under State laws or local ordinances, such as the Washington State Growth Management Act, which encourage the protection of ''critical areas'' including fish and wildlife habitat conservation areas. Any information about the northern spotted owl and its habitat that reaches a wider audience, including parties engaged in conservation activities, is valuable. However, WDNR, as the State's natural resource agency, is knowledgeable about the species and has made substantial contributions to our knowledge of the species. In addition the additional educational and informational benefits that might arise from critical habitat designation here have been largely accomplished through the public review and comment of the HCP, Environmental Impact Statement, and Implementation Agreement, as well as the supplemental Environmental Impact Statements associated with the modification of the HCP. This HCP included intensive public involvement and continues to be an example used when discussing HCPs. The HCP is frequently a topic of open and public discussion during meetings of the Washington State Board of Natural Resources, whose meetings are open to the public and frequently televised. This level of exposure in local newspapers and television stations exceeds the level of education that would come from a designation that would be read by few people in the public. Moreover, the rulemaking process associated with critical habitat designation includes several opportunities for public comment, and thus also provides for public education.

Benefits of Exclusion—A benefit of excluding lands within this HCP from critical habitat designation is that it would encourage the State and other parties to continue to work for owl conservation. Since issuance of this HCP, a number of land transactions and land exchanges with the HCP area have occurred. These transactions have included creation of additional Natural Resource Conservation Areas and Natural Area Preserves (both land designations with high degree of protection) and have also included large land exchanges and purchases that have changed the footprint of the HCP. These land-based adjustments have facilitated better management on many important parcels and across larger landscapes than would otherwise have been possible. If lands within HCP plan areas are designated as critical habitat, it would likely have a negative effect on the willingness of various groups and funding sources to accomplish these land-ownership adjustments because of a reluctance to acquire lands designated as critical habitat as well as a reduced willingness on the part of WDNR to accommodate the Services goals. This HCP is located in key landscapes across the State and contributes meaningfully to the recovery of the northern spotted owl.

If lands within the WDNR HCP plan area are designated as critical habitat, it would also likely have a negative effect on our ability to establish new partnerships to develop HCPs, particularly large, regional HCPs that involve numerous participants and/or address landscape-level conservation of species and habitats. This HCP has served as a model for several completed and ongoing HCP efforts, including the Washington State Forest Practices HCP. By excluding these lands, we preserve our current private and local conservation partnerships and encourage additional conservation actions in the future because other parties see our exclusion as a sign that the Service will not impose duplicative regulatory burdens on landowners who have developed an HCP.

HCPs typically provide for greater conservation benefits to a covered species than section 7 consultations because HCPs ensure the long-term protection and management of a covered species and its habitat. In addition, funding for such management is ensured through the Implementation Agreement. Such assurances are typically not provided by section 7 consultations, which in contrast to HCPs often do not commit the project proponent to long-term, special management practices or protections. Thus, a section 7 consultation typically does not afford the lands it covers similar extensive benefits as an HCP. The development and implementation of HCPs provide other important conservation benefits, including the development of biological information to guide the conservation efforts and assist in species conservation, and the creation of innovative solutions to conserve species while meeting the needs of the applicant. In this case, substantial information has been developed from the research, monitoring, and surveys conducted under the WDNR HCP. Therefore, exclusion is a benefit because it maintains and fosters development of biological information and innovative solutions.

Benefits of Exclusion Outweigh the Benefits of Inclusion—The benefits of including these lands in the designation are small. Because one of the primary threats to the northern spotted owl is habitat loss and degradation, the consultation process under section 7 of the Act for projects with a Federal nexus will, in evaluating effects to the northern spotted owl, evaluate the effects of the action on the conservation or functionality of the habitat for the species regardless of whether critical habitat is designated for these lands. The analytical requirements to support a jeopardy determination on excluded land are similar, but not identical, to the requirements in an analysis for an adverse modification determination on included land. However, the HCP contains provisions for protecting and maintaining northern spotted owl habitat that far exceed the conservation benefits afforded through section 7 consultation. It provides for comprehensive measures applied across a large landscape that will benefit spotted owls. Washington State DNR personnel are extremely knowledgeable regarding the ecology of the northern spotted owl and have contributed to the body of scientific information about the northern spotted owl. In this instance, the regulatory and educational benefits of inclusion have much less benefit than the continued benefit of the HCP including the educational benefits derived from the HCP.

The WDNR HCP provides for significant conservation and management within geographical areas that contain the physical or biological features essential to the conservation of the northern spotted owl and help achieve recovery of this species through the conservation measures of the HCP. Exclusion of these lands from critical habitat will help foster the partnership we have developed with WDNR, through the development and continuing implementation of the HCP. Furthermore, this partnership may aid in fostering future cooperative relationships with other parties in other locations for the benefit of listed species.

For these reasons, we determine that the benefits of excluding the WDNR HCP from the designation of critical habitat for the northern spotted owl outweigh the benefits of including this area in critical habitat.

Exclusion Will Not Result in Extinction of the Species—We have determined that exclusion of approximately 225,751 ac (91,358 ha) of lands covered under the WDNR HCP will not result in extinction of the northern spotted owl. The WDNR HCP protects and preserves landscape levels of suitable northern spotted owl nesting, roosting, and foraging habitat as well as foraging and dispersal habitat over the term of the HCP in strategic landscapes, and implements species-specific conservation measures designed to avoid and minimize effects to northern spotted owls. Monitoring was developed to track HCP progress over the term of the permit and provide critical feedback on management actions. Adaptive management provides for responses to this feedback. Further, for projects having a Federal nexus and affecting northern spotted owls in occupied areas, the jeopardy standard of section 7 of the Act, coupled with protection provided by the WDNR HCP, would provide a level of assurance that this species will not go extinct as a result of excluding these lands from the critical habitat designation. We find that exclusion of these lands within the WDNR HCP will not result in extinction of the northern spotted owl. Based on the above discussion, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude from this final critical habitat designation portions of the proposed critical habitat units or subunits that are within the WDNR HCP totaling about 225,751 ac (91,358 ha).

West Fork Timber Habitat Conservation Plan

The Service has excluded approximately 5,105 ac (2,066 ha) of lands from final critical habitat designation, under section 4(b)(2) of the Act, that are covered under the West Fork Timber HCP (West Fork HCP) (formerly known as Murray Pacific Corporation) in the West Cascades Central CHU in Washington. The West Fork HCP was the first multispecies HCP on forested lands in the Nation. The permit associated with the West Fork HCP has a term of 100 years and was first issued on September 24, 1993; amended on June 26, 1995; and amended again on October 16, 2001 (66 FR 52638). The HCP includes 53,558 ac (21,674 ha) of commercial timber lands managed as a tree farm in Lewis County, Washington. The HCP is situated between an area of Federal land known as the Mineral Block and the larger block of Federal lands in the Cascades. The HCP was first developed to allow for forest-management activities and provide for the conservation of the northern spotted owl; the amended HCP provides for all species, including six listed species. The HCP is designed to develop and maintain northern spotted owl dispersal habitat across 43 percent of the tree farm, and must also meet quantitative measures of amount and distribution. As a result, total dispersal habitat will more than double in amount, and wide gaps between stands of dispersal habitat will be decreased.

In addition, the West Fork HCP provides for leaving at least 10 percent of the tree farm in reserves for the next 100 years. These reserves will primarily take the form of riparian buffers averaging at least 100 feet (30 m) on each side of all fish-bearing streams, as well as other buffers and set-a-side areas. Other provisions of the HCP are designed to ensure that all forest habitat types and age classes currently on the tree farm, as well as special habitat types such as talus slopes, caves, nest trees, and den sites, are protected or enhanced. Seasonal protection is provided within ¼ mile of an active northern spotted owl nest site.

At the time the permit was approved, there were approximately 4,678 ac (1,893 ha) of suitable habitat in small stands sporadically located, comprising about 8 percent of the ownership. The HCP included 3 resident northern spotted owls and included about 20 percent of the ownership in dispersal habitat.

Benefits of Inclusion—We find there are minimal benefits to including these lands in critical habitat. As discussed above, the designation of critical habitat invokes the provisions of section 7. However, in this case, we find the requirement that Federal agencies consult with us and ensure that their actions are not likely to destroy or adversely modify critical habitat will not result in significant benefits to the species because the possibility of a Federal nexus for a project on these lands is small unless it was a larger project covering adjacent Federal lands as well, in which case section 7 consultation would already be triggered and the Federal agency would consider the effects of its actions on the species. In addition, although the standards for jeopardy and adverse modification are not the same, the benefits of the section 7 prohibition on adverse modification would be minimal in light of the benefits already derived from the HCP.

HCPs typically provide for greater conservation benefits to a covered species than section 7 consultations because HCPs ensure the long-term protection and management of a covered species and its habitat. In addition, funding for such management is ensured through the Implementation Agreement. Such assurances are typically not provided by section 7 consultations, which, in contrast to HCPs, usually do not commit the project proponent to long-term, special management practices or protections. Thus, a section 7 consultation typically does not afford the lands it covers benefits similar to those provided by an HCP. The development and implementation of HCPs provide other important conservation benefits, including the development of biological information to guide the conservation efforts and assist in species conservation, and the creation of innovative solutions to conserve species while meeting the needs of the applicant.

There is minimal incremental benefit from designating critical habitat for the northern spotted owl within the West Fork HCP because, as explained above, these covered lands are already managed for the conservation of the species over the term of the HCP and the conservation measures provided by the HCP will provide greater protection to northern spotted owl habitat than the designation of critical habitat, which provides regulatory protections only in the event of a Federal action. The West Fork HCP provides for the needs of the northern spotted owl by protecting and preserving landscape levels of suitable northern spotted owl dispersal habitat over the term of the HCP in strategic landscapes, and implementing species-specific conservation measures designed to avoid and minimize effects to northern spotted owls. The HCP also provides for the ability to make ongoing adjustments in a number of forms, including active adaptive forest management. The ability to change is crucial to meet new recovery challenges. The Service continues to be involved in implementation of the HCP. It contains provisions that address ownership changes and the outcomes expected by the Service. Monitoring was developed to track HCP progress over the term of the permit and provide feedback on management actions. Therefore, designation of critical habitat would be redundant on these lands, and would not provide additional measureable protections.

Another benefit of including lands in a critical habitat designation is that it serves to educate landowners, State and local governments, and the public regarding the potential conservation value of an area. This helps focus and promote conservation efforts by other parties by identifying areas of high conservation value for northern spotted owls. Designation of critical habitat would inform State agencies and local governments about areas that could be conserved under State laws or local ordinances, such as the Washington State Growth Management Act, which encourage the protection of ''critical areas'' including fish and wildlife habitat conservation areas. Any information about the northern spotted owl and its habitat that reaches a wider audience, including parties engaged in conservation activities, is valuable. However, this landowner is knowledgeable about the species through its implementation of the HCP. In addition the additional educational and informational benefits that might arise from critical habitat designation here have been largely accomplished through the public review and comment of the HCP, Environmental Impact Statement, and Implementation Agreement. Through these processes, this HCP included intensive public involvement. Moreover, the rulemaking process associated with critical habitat designation includes several opportunities for public comment, and thus also provides for public education. Through these outreach opportunities, land owners, State agencies, and local governments have become more aware of the status of and threats to the northern spotted owl and the conservation actions needed for recovery.

The designation of critical habitat may also indirectly cause State or county jurisdictions to initiate their own additional requirements in areas identified as critical habitat. These measures may include additional permitting requirements or a higher level of local review on proposed projects. However, in Washington, State forest practices regulations provide an exemption for review for lands managed under an HCP. Thus, even should the State respond to designation of critical habitat by instituting additional protections, the HCP will not be subject to those protections as the species is considered already addressed, and therefore no additional benefit would accrue through State regulations.

Benefits of Exclusion—Compared to the minimal benefits of inclusion of this area in critical habitat, the benefits of excluding it from designated critical habitat are more substantial.

HCP conservation measures that provide a benefit to the northern spotted owl and its habitat have been implemented continuously since 1993 on all covered lands owned and managed under the HCP. Excluding these lands from critical habitat designation will sustain and enhance the working relationship between the Service and the permit holder.

A related benefit of excluding lands within HCPs from critical habitat designation is the unhindered, continued ability to seek new partnerships with future HCP participants including States, counties, local jurisdictions, conservation organizations, and private landowners, which together can implement conservation actions that we would be unable to accomplish otherwise. If lands within the West Fork HCP plan area are designated as critical habitat, it would likely have a negative effect on our ability to establish new partnerships to develop HCPs, particularly large, regional HCPs that involve numerous participants and/or address landscape-level conservation of species and habitats. If excluded, the willingness of the landowner to work with the Service to manage federally listed species will continue to reinforce those conservation efforts and our partnership, which contribute toward achieving recovery of the northern spotted owl. We consider this voluntary partnership in conservation important in maintaining our ability to implement recovery actions such as habitat protection and restoration, and beneficial management actions for species on non-Federal lands.

In summary, the designation of critical habitat could have an unintended negative effect on our relationship with non-Federal landowners due to the perceived imposition of redundant government regulation. If lands within the West Fork HCP area are designated as critical habitat, it would likely have a negative effect on our continued ability to seek new partnerships with future participants can implement conservation actions (such as SHAs, and HCPs) that we would be unable to accomplish otherwise. By excluding these lands, we preserve our current private and local conservation partnerships and encourage additional conservation actions in the future.

Benefits of Exclusion Outweigh the Benefits of Inclusion—The benefits of including these lands in the designation are comparatively small. Because one of the primary threats to the northern spotted owl is habitat loss and degradation, the consultation process under section 7 of the Act for projects with a Federal nexus will, in evaluating effects to the northern spotted owl, evaluate the effects of the action on the conservation or functionality of the habitat for the species regardless of whether critical habitat is designated for these lands. The analytical requirements to support a jeopardy determination on excluded land are similar, but not identical, to the requirements in an analysis for an adverse modification determination on included land. However, the HCP contains provisions for protecting and maintaining northern spotted owl habitat that far exceed the conservation benefits afforded through section 7 consultation. It provides for comprehensive measures applied across a large landscape that will benefit spotted owls. In this instance, the regulatory and educational benefits of inclusion have much less benefit than the continued benefit of the HCP including the educational benefits derived from the HCP.

The West Fork HCP provides for significant conservation and management within geographical areas that contain the physical or biological features essential to the conservation of the northern spotted owl and help achieve recovery of this species through the conservation measures of the HCP. Exclusion of these lands from critical habitat will help foster the partnership we have developed with West Fork, through the development and continuing implementation of the HCP. Furthermore, this partnership may aid in fostering future cooperative relationships with other parties in other locations for the benefit of listed species.

In summary, we determine that the benefits of excluding the West Fork HCP from the designation of critical habitat for the northern spotted owl outweigh the benefits of including this area in critical habitat.

Exclusion Will Not Result in Extinction of the Species—We have determined that exclusion of approximately 5,105 ac (2,066 ha) of lands covered under the West Fork HCP will not result in extinction of the northern spotted owl because the conservation measures identified within the HCP seek to maintain or surpass current habitat suitability for northern spotted owls. The HCP is designed to develop and maintain northern spotted owl dispersal habitat; as a result, total dispersal habitat will more than double in amount and wide gaps between stands of dispersal habitat will be decreased. In addition, the West Fork HCP provides for reserves for the next 100 years, ensuring that all forest habitat types and age classes currently on the tree farm, as well as special habitat types such as talus slopes, caves, nest trees, and den sites, are protected or enhanced. Seasonal protection is provided for active northern spotted owl nest sites. Further, for projects having a Federal nexus and affecting northern spotted owls in occupied areas, the jeopardy standard of section 7 of the Act, coupled with protection provided by the West Fork HCP, would provide a level of assurance that this species will not go extinct as a result of excluding these lands from the critical habitat designation. We find that exclusion of these lands within the West Fork HCP will not result in extinction of the northern spotted owl. Based on the above discussion, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude from this final critical habitat designation portions of the proposed critical habitat units or subunits that are within the West Fork HCP boundary totaling about 5,105 ac (2,066 ha).

Other Conservation Measures or Partnerships

State of California

Mendocino Redwood Company

In this final designation, the Secretary has exercised his authority to exclude lands from critical habitat, under section 4(b)(2) of the Act, owned by The Mendocino Redwood Company (MRC, the company) and totaling approximately 232,584 total ac (94,123 ha) in Unit 3—Redwood Coast, in Mendocino and Sonoma Counties, California. This land is distributed among three critical habitat subunits as described in the following. In subunit RDC–2, we proposed approximately 209,550 ac (84,802 ha) for critical habitat designation. In subunit RDC–3, we proposed approximately 22,733 ac (9,200 ha) for critical habitat designation. In subunit RDC–4, we proposed 301 ac (121 ha) for critical habitat designation. All company lands proposed for designation within these three subunits have been excluded from critical habitat designation under section 4(b)(2) of the Act.

MRC has a long-standing voluntary partnership with the Service to protect the northern spotted owl on MRC lands. MRC initially approached the Service in 1998 to develop a combined habitat conservation plan and a State-level counterpart draft natural communities conservation plan (HCP/NCCP). Knowing that the completion of an HCP/NCCP would take an extended period of time, MRC and the Service worked together to develop a set of interim standards and measures to conserve and protect the northern spotted owl and its habitat, pending the completion of the HCP/NCCP. These written interim standards and measures are detailed and specific and have been incorporated into each of MRC's timber harvest plans since their development. These interim standards and measures are detailed in MRC's January 15, 2010, Northern Spotted Owl Resource Plan/Management Plan (SORP) (MRC 2010, pp. 1–30). The SORP was intended to serve as a bridge document to reduce resource impacts to both the northern spotted owl and its habitat until the completion of the HCP/NCCP. The SORP includes monitoring and survey requirements and northern spotted owl habitat protection measures that are implemented across the landscape. The SORP describes methodologies to locate owls, assess reproductive status, and provide a framework that includes habitat definitions and protections associated with northern spotted owl activity centers which provide measurable standards for habitat conservation. MRC and the Service meet frequently to discuss northern spotted owl study results provided by the company and this information is used by both the Service and MRC to develop measures that conserve the species through an iterative process that will assist in the development of the HCP/NCCP. In reviewing the SORP and monitoring results, we find that the SORP and protective measures therein provide substantial conservation benefits for the northern spotted owl and its habitat at a landscape scale.

The standards and measures described in the SORP are included in the ''Planning Agreement'' (dated August 5, 2009) that MRC entered into with the California Department of Fish and Game (CDFG) for preparation of the NCCP element of the HCP/NCCP. Planning Agreements are mandatory under the California Natural Community Conservation Planning Act, and inasmuch as the northern spotted owl standards and measures are included in MRC's planning agreement, they are mandatory. MRC has revised them when requested by the Service, as part of a voluntary partnership with the Service.

In addition, MRC has two State-level planning documents that are in effect now and which contain substantial long-terms benefits for northern spotted owl habitat. One is the company's 2008 Option A plan, entered into with CALFIRE, which sets sustainable long-term timber harvest levels and controls on standing forest inventory, and the other is the companion 2012 Management Plan, also entered into with CALFIRE, which outlines company-specific management practices used in conjunction with the Option A harvesting program. Together, these documents have enabled the company to maintain its forest certification through the Forest Stewardship Council (FSC) which gives the company access to certain wholesale lumber markets that promote ''green'' certified wood products. The State-level planning documents have also enabled the company to obtain registration through the California Climate Action Registry which is the designated clearinghouse for carbon-credit sellers under California's developing cap-and-trade program. The company's long-term management direction under Option A (2008) and the Management Plan (2012) is to greatly expand their stock of standing forest inventory, with a near-doubling of that inventory over the next nine decades. While we do not consider here the northern spotted owl conservation measures in the company's proposed HCP in support of 4(b)(2) exclusion, since that plan is not yet finalized, we do note that practically all of the long-term habitat and demographic objectives in the proposed HCP are dependent on the forest inventory trajectory that is established and in effect under Option A and the Management Plan, and are partly dependent on the distribution and array of silvicultural treatments that is specified under the Management Plan. Time intervals, measurable targets, and enforcement mechanisms for forest inventory development are already in place through the State-level forest planning processes, whether or not the proposed HCP is finalized. The company's long term commitment to expanding standing forest inventory is also demonstrated by their status as a seller in the State's emerging carbon credit market. In order to sell carbon credits, the seller has to possess surplus carbon; in forest management terms, the only way to have a continuous supply of surplus carbon is to have a body of inventory that is on a continuous-net-growth trajectory. The 2012 Management Plan also explicitly documents some of the company's internal management direction on the northern spotted owl with regard to the linkages between future forest conditions and owl habitat utilization, direction on the acquisition and analysis of owl breeding site surveys, and future development of northern spotted owl habitat models.

Following are summaries of specific measures in the 2012 Management Plan that will have direct, indirect, near-term and long-term benefits for the northern spotted owl, and which are in effect currently: (1) The company, having inherited a severely depleted forest inventory from the previous owners, has a standing policy to rebuild inventories, which will result in a doubling of total standing volume by the ninth decade of the planning horizon; (2) total harvest levels through the 100-year planning horizon are constrained to a graduating percentage of periodic growth volume, from a current 48 percent to 84 percent in the tenth decade of the plan; (3) a shift in the use of uneven-aged silviculture from a current 65 percent of harvest acres to 99 percent in the fifth decade of the plan; (4) protection policies for unharvested old-growth stands and previously harvested stands containing residual old-growth trees; (5) wildlife tree and snag retention requirements that meet or exceed Service recommendations and exceed current State Forest Practice rules; (6) a minimum forest floor large woody debris (LWD) standard on general forest land of 70 cubic feet per ac (4.9 cubic meter per ha) based on minimum-sized logs 16 in (41 cm) diameter and 10 ft (3.3 m) in length, increasing to 98 cubic feet per ac (6.9 cubic meter per ha) in riparian areas; and (7) a hardwood management policy that maintains a minimum hardwood basal area of 15 square feet per ac (3.4 square m per ha) in mixed conifer-hardwood stands. Each policy outlined above will result in: (a) A long term increase in standing forest biomass per unit of land area; or (b) increased spatial continuity of vegetative types that are suitable northern spotted owl habitat; or (c) retention of specific features such as old-growth trees or stands, and retention of a minimum level of hardwoods, snags, and wildlife trees. All of these policies will either lead to maintenance or enhancement of northern spotted owl habitat suitability or lead to emergence of suitable habitat where it is currently not present, thereby benefiting the conservation of the northern spotted owl and its habitat.

The company has completed a draft of their proposed HCP/NCCP, and the northern spotted owl is one of the covered species in this document. The company has submitted the HCP application to the Service. If the HCP/NCCP is approved and permits issued, the term of the incidental take permit and counterpart State permit would be 80 years. The combined draft Environmental Impact Statement (EIS) and State draft Environmental Impact Report (EIR) is scheduled for issuance in fall of 2012, and a final HCP/NCCP and final EIS/EIR is anticipated in spring or summer, 2013. However, as noted above, we have not taken the proposed HCP/NCCP into account in determining the level of protection currently provided to the northern spotted owl on MRC land, as we have not completed processing the permit application and a final decision has not been made whether it meets issuance criteria. We cite to the development of this HCP/NCCP only in terms of evidence of MRC's commitment to partnering with the Service for the conservation of the northern spotted owl.

Benefits of Inclusion—We find there are minimal benefits to including MRC lands in critical habitat. As discussed above, the designation of critical habitat invokes the provisions of section 7. However, in this case, we find the requirement that Federal agencies consult with us and ensure that their actions are not likely to destroy or adversely modify critical habitat will not result in significant benefits to the species because the possibility of a Federal nexus for a project on these lands that might trigger such consultation is limited since there is little likelihood of an action that will involve Federal funding, authorization, or implementation. In addition, since the lands under in question are occupied by the northern spotted owl, if a Federal nexus were to occur, section 7 consultation would already be triggered and the Federal agency would consider the effects of its actions on the species through a jeopardy analysis. Because one of the primary threats to the northern spotted owl is habitat loss and degradation, the consultation process under section 7 of the Act for projects with a Federal nexus will, in evaluating effects to the northern spotted owl, evaluate the effects of the action on the conservation or function of the habitat for the species regardless of whether critical habitat is designated for these lands. Although the standards for jeopardy and adverse modification are not the same, the additional conservation that could be attained through the section 7 prohibition on adverse modification analysis would not likely be significant in this case because of the conservation agreements already in place.

Another potential benefit of including lands in a critical habitat designation is that the designation can serve to educate landowners, State and local government agencies, and the public regarding the potential conservation value of an area, and may help focus conservation efforts on areas of high conservation value for certain species. Any information about the northern spotted owl and its habitat that reaches a wider audience, including parties engaged in conservation activities, is valuable. However, in this case the educational value of critical habitat is limited. As evidenced by their extensive forest management planning, this forestland owner is knowledgeable about the species.

The designation of critical habitat may also indirectly cause State or county jurisdictions to initiate their own additional requirements in areas identified as critical habitat. These measures may include additional permitting requirements or a higher level of local review on proposed projects. However, CALFIRE has indicated to us that it is unlikely to impose any new requirements on project proponents if critical habitat is designated in areas already subject to California Forest Practice Rules. Therefore, we believe this potential benefit of critical will be limited.

Benefits of Exclusion—The benefits of excluding from designated critical habitat the approximately 232,584 ac (94,123 ha) of lands currently owned by the MRC are substantial. We have created a close partnership with the company through the development of the SORP and the resulting draft HCP/NCCP. The SORP contains provisions that will improve inventory of redwood, Douglas-fir, and other conifers across MRC's ownership and includes measures that will return forest types to those that support the northern spotted owl. In addition, the SORP stipulates a series of actions intended to increase canopy cover and move management of forest stands to uneven-aged management to promote multilayered canopies and protect old growth stands and individual trees with old-growth structural features. The SORP also contain provisions that will result in stands being grown in Watercourse and Lake Protection Zones (WLPZ) that exceed current State Forest Practice requirements and that meet the Service's recommended standards for standing tree basal area and retention of large woody debris in watercourse protection zones. All of these measures are consistent with recommendations from the Service for the conservation of the northern spotted owl, and will afford benefits to the species and its habitat.

Other MRC actions also demonstrate their commitment to the Federal-State-private partnership. The company's Management Plan in connection to their FSC forest certification is already in effect. That Plan has numerous measures within it that the company has been implementing on the ground for several years without any inducement from the cooperating Federal and State agencies. Much of the Management Plan is concerned with harvest scheduling and how the company will remedy its current deficit in standing forest inventory. The major part of that remedy is found in the 10-decade harvesting schedule in the Management Plan, which tightly constrains harvest levels in the early decades of the Plan and relaxes the constraint in later decades. The company has implemented the designed harvest schedule since 2000, which is supported in the certification audit reports of 2005 and 2010. This means that MRC has, in fact, foregone a portion of their potential short-term harvest revenues for nearly 12 years to fulfill a Management Plan that is not under Federal purview. Company policies embodied in the Management Plan will result in (a) a long term increase in standing forest biomass per unit of land area; or (b) increased spatial continuity of vegetative types that are suitable northern spotted owl habitat; or (c) retention of specific features such as old-growth trees/stands, retention of a minimum level of hardwoods, snags, and wildlife trees. All of these policies will either lead to maintenance of northern spotted owl habitat suitability or lead to emergence of suitable habitat where it is currently not present.

Excluding the approximately 232,584 ac (94,123 ha) owned and managed by MRC from critical habitat designation will provides significant benefit in terms of sustaining and enhancing the excellent partnership between the Service and the company, with positive consequences for conservation. The willingness of MRC to voluntarily undertake conservation efforts for the benefit of the northern spotted owl and work with the Service to develop new conservation plans for the species will continue to reinforce those conservation efforts and our partnership, which contribute toward achieving recovery of the northern spotted owl. We consider this voluntary partnership in conservation vital to our understanding of the northern spotted owl status of species on MRC lands and in the redwood region, and necessary for us to implement recovery actions such as habitat protection and restoration, and beneficial management actions for species.

The designation of critical habitat could have an unintended negative effect on our relationship with non-Federal landowners due to the perceived imposition of government regulation. If lands within the area managed by MRC for the benefit of the northern spotted owl are designated as critical habitat, it could have a chilling effect on our continued ability to seek new partnerships with future participants including States, counties, local jurisdictions, conservation organizations, and private landowners, which together can implement various conservation actions (such as SHAs, HCPs, and other conservation plans, particularly large, regional Conservation Plans that involve numerous participants and/or address landscape-level conservation of species and habitats) that we would be unable to accomplish otherwise. In addition, MRC serves as a model of voluntary conservation by a private landowner, and may aid in fostering future voluntary conservation efforts by other parties in other locations for the benefit of listed species. We consider the positive effect of excluding proven conservation partners from critical habitat to be a significant benefit of exclusion.

The Benefits of Exclusion Outweigh the Benefits of Inclusion—We have reviewed and evaluated the exclusion of approximately 232,584 ac (94,123 ha) of land owned and managed by MRC from the critical habitat designation. The benefits of including these lands in the designation are comparatively small, since the habitat on the covered lands is already being monitored and managed under the current Management Plan and the Timber Management Plan to improve the habitat elements that are equivalent to the physical or biological features that are outlined in this critical habitat rule. We therefore anticipate little, if any, additional protections through application of the section 7 prohibition on adverse modification due to the designation of critical habitat on these lands.

The potential educational benefits of inclusion are also limited. The company has an active monitoring program on over 150 northern spotted owl activity sites and is making increasing contributions to our knowledge of the species through focused research. In addition, there is a growing local constituency for current land management direction as a result of the company's outreach efforts in the form of public informational presentations and tours of the property. In this instance, any potential educational benefits of inclusion would have much less practical effect than any of the scientific and informational activities that the company has initiated to date.

In contrast, the benefits derived from excluding this ownership and enhancing our private lands partnership with MRC are significant. We have developed a solid working relationship with MRC, and expect this beneficial conservation partnership to continue. The benefits of this partnership are significant, because MRC has demonstrated that its actions will contribute substantially to the conservation of the northern spotted owl and its habitat and influence long-term management outcomes across the entire ownership. We noted the positive conservation benefits that accrue from exclusion from critical habitat, including relief from perceived potentially duplicative regulatory burden and the increased potential of pursuing additional conservation agreements with other private landowners. As discussed above, MRC has developed a long-standing practice of managing its lands in a sustainable nature that benefits the northern spotted owl and its habitat. We also discussed the long-term value of the partnership with MRC, and evidence of the company's commitment to that partnership through voluntary implementation and coordination of conservation actions. We will not repeat that discussion here, but point to it as the strongest among all factors we considered in the weighing of the benefits of exclusion against the benefits of inclusion.

We have determined that the additional regulatory benefits of designating critical habitat, afforded through the section 7(a)(2) consultation process, are minimal because of limited Federal nexus and because conservation measures specifically benefitting the northern spotted owl and its habitat are in place as a result of our partnership with the company and as demonstrated by the provisions of the SORP and other planning documents, as discussed above. The potential educational and informational benefits of critical habitat designation on lands containing the physical or biological features essential to the conservation of the northern spotted owl would be minimal, because MRC is making substantial contributions to our understanding of the ecology of the northern spotted owl and its habitats in the redwood region, and continues to disseminate useful information through public education events. Therefore, in consideration of the factors discussed above in the *Benefits of Exclusion* section, including the relevant impact to current and future partnerships, we have determined that the benefits of exclusion of lands owned by the MRC outweigh the benefits of designating these areas as critical habitat.

Exclusion Will Not Result in Extinction of the Species—We have determined that the exclusion of 232,584 ac (94,123 ha) from the designation of critical habitat for the northern spotted owl on lands owned and managed by MRC will not result in extinction of the species. Conservation efforts that are currently in effect through the SORP (and not taking into account the draft HCP/NCCP) will adequately protect the geographical areas containing the physical or biological features essential to the conservation of the species. For projects having a Federal nexus and affecting northern spotted owls in occupied areas, as is the case here, the jeopardy standard of section 7 of the Act, coupled with current land management measures that are not under Federal purview, would provide assurances that this species will not go extinct as a result of excluding these lands from the critical habitat designation. Based on the above discussion, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude from this final critical habitat designation portions of the proposed critical habitat units or subunits that are within the Mendocino Redwood Company ownership boundary totaling 232,854 ac (92,123 ha).

State of Washington

Scofield Corporation Deed Restriction (Formerly Habitat Conservation Plan)

In this final designation, the Secretary has exercised his authority to exclude 40 ac (16 ha) of lands from critical habitat, under section 4(b)(2) of the Act, that are covered under the Scofield Corporation Deed Restriction in the East Cascades North CHU. A incidental take permit based on an HCP, was issued to Scofield Corporation in 1996 (noticed February 20, 1996 (61 FR 6381), issued April 3, 1996). The permit had a duration for only one year, but as provided in the permit terms, the lands under this HCP are now covered by a Deed Restriction for those lands in perpetuity. This HCP and deed restriction include 40 ac (16 ha) of forest lands in Chelan County, Washington. The HCP-covered forest-management activities and the associated incidental take permit included only the northern spotted owl. The HCP provided for mitigation and minimization measures by retaining a buffer of intact habitat, implementing selective timber harvest practices, and placing a perpetual deed restriction on the property permanently prohibiting further timber harvest or tree removal except with the express written consent of the Service. These measures were designed to ensure the retention of some northern spotted owl habitat and approximately 72 percent of the total number of trees after harvest.

At the time the permit was approved, the HCP-covered lands included a single northern spotted owl site with most of its habitat on adjacent Federal lands. The amount of habitat was low, due to natural eastside Cascades characteristics and recent fire. Approximately 55 percent of the mature trees in the 40-acre project area were allowed to be removed, which in the short term further reduced the availability of potential nesting, roosting, or foraging sites for northern spotted owls. However, the adverse effects on this northern spotted owl pair due to loss of habitat was likely low, because the habitat was marginal Type C (young forest marginal) at best, and surveys in the project area suggested low use by northern spotted owls. In addition, the no-harvest buffer along the highway ensured that is less than 40 ac (16 ha) was affected by the action, which is a small portion of the suitable habitat that is available for use by northern spotted owls within the median home range of that site as well as the eastern Cascades.

Under the HCP, about 55 percent of the mature trees and 28 percent of the total number of trees in the project area were allowed to be harvested. Selective harvest resulted in retention of different size and age classes of trees to contribute to stand structure and species diversity, important components to northern spotted owl habitat. Thinning the stand will allow younger age-class trees to grow, and continue to contribute to the multilayer structure of the stand. Since the project area is being allowed to grow and develop into perpetuity, suitable northern spotted owl habitat will be available in the future. This potential habitat will complement habitat that is likely to occur on adjacent national forest lands being managed as late-successional forest. In the long-term, the potential for the project area to become northern spotted owl habitat and remain in that condition is substantially greater than it would have been without the HCP. In addition, the Deed Restriction identified in the land contract provides for the permanent protection of this habitat.

Benefits of Inclusion—We find that there is minimal benefit from designating critical habitat for the northern spotted owl within the Scofield Deed Restriction because, as explained above, these lands are already managed for the conservation of the species under the deed restrictions. Section 7 is unlikely to provide additional regulatory protection, not only because Federal actions on this small 40-acre parcel are unlikely, but also because any such Federal action would have to be consistent with the Deed Restriction. Thus the existence of this Deed Restriction reduces any incremental benefits that may be provided by section 7. The Deed Restriction provides for the needs of the northern spotted owl by providing northern spotted owl dispersal habitat and improving conditions. Therefore, designation of critical habitat would be redundant on these lands, and would not provide additional measureable protections. In addition, the conservation measures identified within the Deed Restriction seek to achieve conservation goals for northern spotted owls and their habitat, and thus can be of greater conservation benefit than the designation of critical habitat, which does not require specific management actions.

A potential benefit of including lands in a critical habitat designation is that the designation can serve to educate landowners and the public regarding the potential conservation value of an area, and may help focus conservation efforts on areas of high conservation value for certain species. However, the additional educational and informational benefits that might arise from critical habitat designation have been largely accomplished through the public review and comment of the HCP/Environmental Assessment, as well as the Implementation Agreement. In addition, through the Deed Restriction, the current landowner and any future owner are made fully aware of the needs of the northern spotted owl on this parcel.

Benefits of Exclusion—A benefit of excluding lands within HCPs from critical habitat designation is the unhindered, continued ability to seek new partnerships with future HCP participants including States, counties, local jurisdictions, conservation organizations, and private landowners, which together can implement conservation actions that we would be unable to accomplish otherwise. In particular, if lands within the Scofield Corporation Deed Restriction area are designated as critical habitat, it would likely have a negative effect on our ability to establish new partnerships to develop HCPs with smaller landowners who occupy key landscapes. It could be perceived as adding redundant Federal regulation on top of the HCP's requirement to protect the land in perpetuity. By excluding these lands, we may encourage additional conservation actions in the future.

Benefits of Exclusion Outweigh the Benefits of Inclusion—In summary, we determine that the benefits of excluding the Scofield Corporation lands subject to the Deed Restriction from the designation of critical habitat for the northern spotted owl outweigh the benefits of including this area in critical habitat. We find that including this area in the designation would result in minimal, if any, additional benefits to the northern spotted owl, as explained above. Excluding this parcel from critical habitat could result in real benefits by encouraging other small landowners to participate in northern spotted owl conservation efforts by demonstrating that we will not impose redundant regulatory burdens when they undertake meaningful conservation efforts. The management strategies of the Scofield Deed Restriction are designed to maintain and enhance habitat for the northern spotted owl. The Scofield Deed Restriction includes forest-management practices and habitat conservation objectives that benefit the northern spotted owl and its habitat, which exceeds any conservation value provided as a result of a critical habitat designation.

Exclusion Will Not Result in Extinction of the Species—We have determined that exclusion of approximately 40 ac (16 ha) of lands covered under the Scofield Deed Restriction will not result in extinction of the northern spotted owl because it provides northern spotted owl dispersal habitat and improves habitat conditions, and it the possibility for the project area to become northern spotted owl habitat and remain in that condition is substantially greater than without the HCP. Further, the protection provided by the Scofield Deed Restriction would provide a level of assurance that this species will not go extinct as a result of excluding these lands from the critical habitat designation. We find that exclusion of these lands within the Scofield Deed Restriction will not result in extinction of the northern spotted owl. Based on the above discussion, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude from this final critical habitat designation portions of the proposed critical habitat units or subunits that are covered by the Scofield Corporation Deed Restriction totaling about 40 ac (16 ha).

Exclusion of Private Lands

State of California

Our proposed designation included 123,348 ac (49,917 ha) of privately-owned lands without existing Federal conservation agreements in the State of California that we identified as critical habitat for the northern spotted owl.

Forest management and forest practices on private lands in California, including harvesting for forest products or converting land to another use are regulated by the State under Division 4 of the Public Resources Code, and in accordance with the California Forest Practice Rules (California Code of Regulations, (CCR) Title 14, Sections 895–1115). Under this framework, the California Department of Forestry and Fire Protection (CALFIRE) is the designated authority on forest management and forest practices on private lands in California.

All private land timber harvesting in California must be conducted in accordance with a site-specific timber harvest plan (THP) that is submitted by the owner and is subject to administrative approval by CALFIRE. The THP must be prepared by a State-registered professional forester, and must contain site-specific details on the quantity of timber involved, where and how it will be harvested, and the steps that will be taken to mitigate potential environmental damage. The THP and CALFIRE's review process are recognized as the functional equivalent to the environmental review processes required under the California Environmental Quality Act of 1970 (CEQA). The policy of the State with regard to the northern spotted owl can be characterized as one of take-avoidance. The Director of CALFIRE is not authorized to approve any proposed THP that would result in take of a federally-listed species, including the northern spotted owl unless that taking is authorized under a Federal Incidental Take Permit (review process is outlined in 14 CCR 919.9 and 919.10). This latter point creates an incentive for private landowners to enter into Federal safe harbor agreements or habitat conservation plans. CALFIRE also regulates the conversion permitting process in which private forest and woodland can be converted to agricultural uses (in contrast, conversions of forest and woodlands to residential, commercial, and industrial uses are evaluated and permitted under local land use planning authorities).

Benefits of Inclusion—We find there are minimal benefits to including these lands in critical habitat. As discussed above, the principal benefit of including an area in critical habitat is the requirement that Federal agencies consult with the Service under section 7(a)(2) of the Act to ensure actions they fund, authorize, or carry out are not likely to result in the destruction or adverse modification of any designated critical habitat. Section 7(a)(2) also requires that Federal agencies must consult with us on actions that may affect a listed species and refrain from undertaking actions likely to jeopardize the continued existence of such species.

Our Final Economic Analysis (IEC 2012b) concludes that critical habitat designation for the northern spotted owl is unlikely to directly affect timber harvests on private lands in California because of the low likelihood that such harvests would be simultaneously connected to a Federal permitting or funding action. Without a pending Federal action, there is no basis for initiating a consultation process under section 7 of the Act. In northern California, the Service has seen very few section 7 actions resulting from Federal permitting or funding activity on private lands. The U.S. Army Corps of Engineers (Corps) through the U.S. Environmental Protection Agency (EPA) are the Federal agencies responsible for regulating section 404 of the Clean Water Act, which deals with discharge of dredged or fill material into waters of the United States. In the areas identified as critical habitat for the northern spotted owl the Corps has not taken jurisdiction over activities associated with stream alteration or fill and has deferred to the State of California for regulating these activities. As a result many proposed actions involving water quality issues and stream disturbance are not referred to the Service for section 7 consultation. The majority of the water quality permitting actions in California are now administered by the California Department of Fish and Game (CDFG) and by Regional Water Quality Control Boards. Water quality permit reviews by the Corps are very uncommon. When Federal consultation does occur, the affected areas are typically limited to streams or roadways adjacent to streams and thus in areas not considered habitat for the northern spotted owl. CALFIRE has indicated (in its correspondence of July 6, 2012) that it has no plans to enact additional requirements for protection of the northern spotted owl in response to a possible critical habitat designation of private lands in the State.

We, therefore, conclude that the requirement that permitting and funding agencies consult with us and ensure that their actions are not likely to destroy or adversely modify critical habitat will not result in significant benefits to the species because the possibility of a Federal nexus for a project on these lands that might trigger such consultation is limited (there is little likelihood of an action that will involve Federal funding, authorization, or implementation). In addition, since the lands in question are occupied by the northern spotted owl, if a Federal nexus were to occur, section 7 consultation would already be triggered and the Federal agency would consider the effects of its actions on the species through a jeopardy analysis. Because the possibility of a Federal nexus on these private lands is limited, the additional regulatory benefits to the species and its habitat through inclusion in critical habitat, if any, are anticipated to be minimal. In addition, existing State regulations provide protections for the northern spotted owl and its habitat, and these protections are in continuous effect. The protections to the critical habitat of the northern spotted owl, by contrast, come into effect only in the event of a Federal action.

Another benefit of including lands in a critical habitat designation is that it serves to educate landowners, State and local governments, and the public regarding the potential conservation value of an area. This helps focus and promote conservation efforts by other parties by identifying areas of high conservation value for northern spotted owls. Any information about the northern spotted owl and its habitat that reaches a wider audience, including parties engaged in conservation activities, is valuable. In the case of the northern spotted owl, any potential educational benefits that might be attributable to critical habitat designation are minimized by the existing State regulatory framework for the northern spotted owl in timber harvest planning. Private landowners who harvest timber in proximity to northern spotted owl activity sites are required to conduct surveys of owl activity and report those results in their proposed timber harvest plans that are submitted to CALFIRE for approval, so critical habitat designation will not result in any additional data collection. While the State's existing take-avoidance strategy for the northern spotted owl does not necessarily provide for long term conservation of suitable habitat, it does serve an important informational service with private landowners through the timber harvest planning process. Thus, CALFIRE's existing regulatory framework provides adequate and consistent education to the affected community regarding the northern spotted owl and its conservation needs.

Similarly, the great majority of industrial and non-industrial forest landowners, along with the in-house and consulting biologists who conduct the owl survey work, already voluntarily submit their survey results to the CDFG for entry into the California Natural Diversity Database (CNDDB), which is the State's clearinghouse for occupancy, activity, and spatial data on special status species. It is highly unlikely that inclusion in the final critical habitat designation could cause any increases in landowner and biologist participation in the CNDDB reporting. Voluntary participation rates are currently very high, and we have no evidence to suggest that inclusion in critical habitat would increase those rates any further.

In this case the educational value of critical habitat is further limited by the fact that the northern spotted owl is a high-profile species, and most forestland owners in the range of the northern spotted owl are knowledgeable about the species. The release of the Revised Recovery Plan for the Northern Spotted Owl in 2011 was preceded by outreach efforts and public comment opportunities, and provided information about the northern spotted owl and its conservation needs to a wide constituency. Furthermore, we conducted extensive outreach efforts on the proposed revision of critical habitat, including multiple public information meetings and opportunities for public comment. Through these outreach opportunities, land owners, State agencies, and local governments have become aware of the status of and threats to the northern spotted owl, and the conservation actions needed for recovery.

Another potential benefit of the designation of critical habitat is that it may indirectly cause State or county jurisdictions to initiate their own additional protective requirements in areas identified as critical habitat. These measures may include additional permitting requirements or a higher level of local review on proposed projects. However, CALFIRE has indicated to use that it is unlikely to impose any new requirements on project proponents if critical habitat is designated in areas already subject to California Forest Practice Rules. Therefore, we believe this potential benefit of critical will be limited.

Finally, there may be some ancillary benefits if the designation resulted in changed timber management practices on these private lands. These benefits could include but are not limited to: public safety benefits by increasing resiliency of timber stands, improved water quality, aesthetic benefits, and carbon storage. However, as discussed above, the possibility of a Federal nexus on these private lands is limited, so changes in timber management as a result of critical habitat, and any attendant ancillary benefits, are anticipated to be minimal.

Benefits of Exclusion—The benefits of excluding from designated critical habitat the approximately 123,348 ac (49,917 ha) of private lands in California are relatively greater.

Excluding the approximately 123,348 ac (49,917 ha) of private lands from critical habitat designation will sustain and enhance the conservation partnership between the Service and CALFIRE. The Service is currently working with CALFIRE to explore avenues for more comprehensive conservation planning for the northern spotted owl in northern California that goes beyond the existing take-avoidance strategy. Development of a landscape scale analysis and plan (e.g., general conservation plan) would provide for greater protections to the northern spotted owl and could incorporate critical habitat conservation elements within that planning process. Current revisions and improvements to the CNDDB database would aid in the development of this plan, with the ability to evaluate status and trends across the region versus on a singular THP or Non-industrial Timber Management Plan (NTMP) level. Critical habitat designation would be viewed as another layer of regulatory process to that already overseen by CALFIRE and could impede landowner support for the development of this larger programmatic conservation plan and undercut the efforts of CALFIRE to contribute to such a discussion. We received several public comments objecting to this perceived redundancy in regulation. Excluding those private lands from the designation would avoid a chilling effect on the partnership between the Service and the affected State regulatory agencies in California regarding administration of their existing conservation programs to protect and conserve northern spotted owls on private lands. We consider the maintenance of our partnership between the Service and the affected State regulatory agencies in California to be a significant benefit of exclusion.

In addition, there are many other opportunities for private landowners to enter into conservation agreements without Federal involvement that will benefit northern spotted owls. Landowners can obtain ''green'' forest certification through the Forest Stewardship Council (FSC) or the Sustainable Forestry Initiative (SFI) that enables access to certain wholesale lumber markets. They can register their property with the California Climate Action Registry to gain access to the emerging carbon credit market in California, or they can sell conservation easement rights on their properties to a land trust. In all cases, the landowner gains immediate economic benefits in exchange for agreeing to a management program on their lands that meets the objectives of the certification or registration entity, or the land trust. All of these instruments, by design, involve the conservation and expansion of standing forest inventory and forest cover on the participating ownerships. Whether by design or not, that will lead to the long-term improvement of existing northern spotted owl habitat suitability and to the emergence of suitable habitat in areas where it is currently unsuitable. These market-based agreements have the long term potential for significantly more on-the-ground benefits for the northern spotted owl on private lands than would the limited regulatory and educational benefits that would result from critical habitat designation.

The economic incentives for landowners to enter into these agreements are independent of a critical habitat designation. We are not certain how designation might affect perceptions and priorities among the grantors in agreements (i.e., the certification and registration entities and the land trusts). For example, land trusts operate on limited funds and we do not know how critical habitat designation might influence them in prioritizing properties for easement acquisition; that is, whether it might lead them to look more or less favorably on designated lands, or treat some geographic areas preferentially over others. Thus, exclusion from designation could avoid any uncertain, and possibly detrimental, effects on both buyers (land trusts, certification entities) and sellers (landowners) in market-based conservation programs (IEC 2012b, p. 5–21).

Excluding these lands may reduce the perception that some private landowners have that they are being subjected to redundant and unnecessary regulation. As noted above, all private land timber harvesting in California must be conducted in accordance with a site-specific THP that is submitted by the owner and is subject to administrative approval by CALFIRE. The Director of CALFIRE is not authorized to approve any proposed THP that would result in take of a federally-listed species, including the northern spotted owl, unless that taking is authorized under a Federal Incidental Take Permit. The additional overlay of Federal critical habitat on these private lands may result in lack of support for the development of a programmatic conservation agreement with CALFIRE and their valuable contribution of information to the CNDDB due to their perception of duplicative and burdensome regulation specific to the northern spotted owl.

Benefits of Exclusion Outweigh the Benefits of Inclusion—We have reviewed and evaluated the exclusion of approximately 123,348 ac (49,917 ha) of privately-owned lands in the State of California from the critical habitat designation. The benefits of including these lands in the designation are comparatively small. We find there is little likelihood of a Federal nexus on these private lands that would trigger the regulatory protections of critical habitat under section 7 of the Act. We therefore anticipate little, if any, additional protections through a supplemental analysis of potential adverse modification due to the designation of critical habitat on these lands.

The potential educational benefits of inclusion are also limited. Under existing State regulations, private landowners who harvest timber in proximity to northern spotted owl activity sites are required to conduct surveys of owl activity consistent with the Service-recommended protocol and report those results in their proposed timber harvest plans that are submitted to CALFIRE for approval, so landowners are already aware of the presence of the northern spotted owl and its habitat needs, and critical habitat designation will not result in any additional data collection. The State of California's existing take-avoidance strategy for the northern spotted owl provides an important informational service with private landowners through the timber harvest planning process. Therefore, in this instance, any potential educational benefits of inclusion are minimal.

In contrast, the benefits derived from excluding private lands and enhancing our partnership with California State regulatory agencies are relatively greater. The minimal benefits of inclusion are outweighed by the benefits of fostering conservation partnerships with CALFIRE that would relieve private landowners of what they might perceive as duplicative regulations. Exclusion could also encourage the partnership and collaboration in development of the landscape conservation planning between the Service and CALFIRE by focusing efforts towards that planning effort versus applying a regulatory process that would have limited private land involvement.

We also considered the avoidance of potential issues associated with regulatory uncertainty due to critical habitat designation to be a significant benefit of exclusion. For example, there may be a significant benefit of exclusion from designation that would accrue due to the avoidance of any uncertain, and possibly detrimental, effects on both buyers (land trusts, certification entities) and sellers (landowners) in market-based conservation programs that stand to provide significant conservation benefits to the northern spotted owl.

We have determined that maintaining our partnership with California State regulatory agencies provides a greater benefit than would the regulatory and educational benefits of critical habitat designation. Therefore, in consideration of the factors discussed above, we have determined that the benefits of exclusion of private lands in California outweigh the benefits of designating these areas as critical habitat.

Exclusion Will Not Result in Extinction of the Species—We have determined that exclusion of 123,348 ac (49,917 ha) of private lands in northern California that are not currently under a Federal agreement from critical habitat for the northern spotted owl will not result in the extinction of the species. Habitat protection provisions in the current California forest practice regulation on private forestlands provide some level of protection for the species and its habitats. We reiterate here that under the California State Code (14 CCR 919.9 and 919.10), the Director of CALFIRE is not authorized to approve any proposed THP that would result in take of a federally-listed species unless that taking is authorized under a Federal Incidental Take Permit. For projects having a Federal nexus and affecting northern spotted owls in occupied areas, as is the case here, the jeopardy standard of section 7 of the Act, coupled with current land management measures that are not under Federal purview, would provide assurances that this species will not go extinct as a result of excluding these lands from the critical habitat designation. Further, the exclusion of these lands from the final critical habitat designation does not preclude advances in our scientific knowledge of the species and using that knowledge to effectively advocate future improvements in State forest practice policies and procedures. Based on the preceding analysis, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude private lands totaling 123,348 ac (49,917 ha) from the final critical habitat designation.

State of Washington

In Washington we proposed 133,895 ac (54,186 ha) of private lands within Spotted Owl Special Emphasis Areas (SOSEAs) as critical habitat; all of these lands were identified as under consideration for exclusion. However, as described in Changes from the Proposed Rule, many of the small, private parcels were removed from the final designation upon a determination that they did not meet the definition of critical habitat, leaving. The remaining areas of private lands in Washington contained in this designation covered by HCPs or SHAs and are private industrial forest lands; these private lands are not currently covered by HCPs or SHAs but are covered under the WDNR Forest Practices Rules (FPR) and largely located in SOSEAs. We have excluded areas covered by HCPs and SHAs because, for the reasons discussed above, the benefits of excluding them outweigh the benefits of including them in critical habitat. We sought to make our designation of private lands in Washington as consistent as possible with Washington State regulations governing forest practices on private lands. Most of the remaining private lands are located only within SOSEAs, areas designated by the State to provide for demographic and/or dispersal support as necessary to complement the northern spotted owl protection strategies on Federal land within or adjacent to the SOSEAs. We find that for these lands, too, the benefits of excluding them in critical habitat outweigh the benefits of including them.

In Washington, any private timber harvest must obtain a permit from, and comply with, the Washington Forest Practices Act (RCW 76.09) as well as the Washington Forest Practices Rules (WAC 222). In the absence of a federally-approved HCP covering northern spotted owls or a State-approved special wildlife management plan, suitable northern spotted owl habitat in State-designated SOSEAs on non-federal lands is protected by the special Washington Forest Practices Rules in State-designated SOSEAs. Within SOSEAs, the Forest Practices rules provide protection for suitable northern spotted owl habitat. The Washington Forest Practices Rules maintain the viability of each northern spotted owl site center by protecting: (a) All suitable spotted owl habitat within 0.7 mile of each spotted owl site center; and (b) a total of 2,605 acres of suitable spotted owl habitat within the median home range circle with a radius of 1.8 miles. Under the rules, proposed forest practices likely to adversely affect spotted owl habitat in either category (a) or (b) above are likely to have significant adverse impacts to the northern spotted owl, and such activities would require a Class IV special forest practices permit and an environmental impact statement per the State Environmental Policy Act. The overarching policy goal of the Washington Forest Practices Rules is to complement the conservation strategy on Federal lands, and as such the SOSEAs are adjacent to Federal lands. SOSEAs are designed to provide a larger landscape for demographic and dispersal support for northern spotted owls. The long-term goal is to support a viable population of northern spotted owls in Washington.

In Washington, the Forest Practices Board (the State regulatory rule-making body) has a long-standing relationship with the Service and collaborates extensively on northern spotted owl conservation. The Service provided extensive technical assistance in the development of the Board's existing northern spotted owl rules. The Board was recognized in Recovery Action 18 in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011, p. III–57) for its ongoing owl conservation efforts and encouraged to continue to use its existing processes ''to identify areas on non-federal lands in Washington that can make strategic contributions to spotted owl conservation over time. The Service encourages timely completion of the Board's efforts and will be available to assist as necessary.'' The Board convened the Northern Spotted Owl Implementation Team (NSOIT). The NSOIT has been tasked to develop incentives for landowners to conserve northern spotted owl habitat, identify the temporal and spatial allocation of conservation efforts on non-federal lands, and make recommendations to the Board, should any rules need to be updated. The NSOIT is also conducting a pilot project testing different thinning prescriptions in northern spotted owl habitat. These efforts have evolved over years of collaboration and are designed to change the dynamic away from fear and resistance to partnership and participation. On November 13, 2012, the Board took another step for northern spotted owl conservation and expanded the scope of the NSOIT to investigate and recommend, in coordination with the Service, voluntary programmatic tools for private landowners to support northern spotted owl conservation and provide regulatory certainty for landowners (WDNR *in litt.*). This step further demonstrates Washington's willingness to use its authority and processes to support northern spotted owl conservation. The Service has and continues to provide funding to support the work of the NSOIT.

Benefits of Inclusion—The areas of private land retained in our final designation at issue here support both essential demographic and dispersal needs of spotted owls, and highlight the important conservation roles of private lands in Washington. Designation of these private lands may raise public awareness of conservation actions needed for spotted owl recovery, although the educational benefit of the designation is somewhat limited currently since these areas have already been identified as SOSEAs, since 1997.

We find there are minimal benefits to including these lands in critical habitat. The designation of critical habitat invokes the provisions of section 7. Our Final Economic Analysis (IEC 2012b, p. ES–17) concludes that critical habitat designation for the northern spotted owl is unlikely to directly affect timber harvests on private lands in Washington because of the low likelihood that such harvests would be simultaneously connected to a Federal permitting or funding action. Without a pending Federal action, there is no basis for initiating a consultation process under section 7 of the Act. As discussed previously, the designation of critical habitat invokes the provisions of section 7. However, in this case, we find the requirement that Federal agencies consult with us and ensure that their actions are not likely to destroy or adversely modify critical habitat will not result in significant benefits to the species. The possibility of a Federal nexus for a project on these lands is small unless it was a larger project covering adjacent Federal lands as well, in which case section 7 consultation would already be triggered and the Federal agency would consider the effects of its actions on the species. In addition, most of the habitat on these private lands would be assumed to be occupied, further minimizing to some extent the margin of conservation that could be attained through section 7. Any incremental benefits would be further minimized because of the protections already in place In addition, it would be small in comparison to the benefits already derived under the WDNR FPR.

There is minimal incremental benefit from designating critical habitat for the northern spotted owl within private lands covered by the WDNR Forest Practices Rules (FPR) because these lands are already managed for the conservation of the species through the WDNR FPR. The conservation measures provided by that process will provide greater protection to northern spotted owl habitat than the designation of critical habitat, which provides regulatory protections only in the event of a Federal action. In addition, the final rule designation would provide for protection of fewer acres than the existing FPR. The WDNR FPR provides for the needs of the northern spotted owl by protecting and preserving landscape levels of suitable northern spotted owl nesting, roosting, and foraging habitat as well as foraging and dispersal habitat in strategic landscapes, and implementing species-specific conservation measures designed to avoid and minimize effects to northern spotted owls. The WDNR FPR also contains provisions that address ownership changes and provides for the ability to make ongoing adjustments in a number of forms, including active adaptive forest management. The ability to change is crucial to meet new recovery challenges. The Service continues to be work with WDNR to provide technical assistance in the implementation of these rules. The WDNR FPR contains provisions that address ownership changes and the outcomes expected by the Service. Therefore, designation of critical habitat would be redundant on these lands, and would not provide additional measureable protections.

Including lands in a critical habitat designation does serve to educate landowners, State and local governments, and the public regarding the potential conservation value of an area. This helps focus and promote conservation efforts by other parties by identifying areas of high conservation value for northern spotted owls. Designation of critical habitat would inform State agencies and local governments about areas that could be conserved under State laws or local ordinances, such as the Washington State Growth Management Act, which encourage the protection of ''critical areas'' including fish and wildlife habitat conservation areas. Any information about the northern spotted owl and its habitat that reaches a wider audience, including parties engaged in conservation activities, is valuable. However, WDNR, as the State's natural resource agency, is knowledgeable about the species and has made substantial contributions to our knowledge of the species. The additional educational and informational benefits that might arise from critical habitat designation here have been largely accomplished through the public review and comment during reviews of the FPR and associated with the modification of the FPR, and through implementation of the FPR by landowners. The existing public process for FPR development provides for extensive opportunities for engagement in the development and refinement of the rules. The FPR includes intensive public involvement and is frequently a topic of open and public discussion during meetings of the Washington State Forest Practices Board, whose meetings are open to the public and frequently televised. This level of exposure in local newspapers and television stations exceeds the level of education that would come from a designation that would be read by few people in the public. Moreover, the rulemaking process associated with critical habitat designation includes several opportunities for public comment, and thus also provides for public education.

Finally, there may be some ancillary benefits if the designation resulted in changed timber management practices on these private lands. These benefits could include but are not limited to: public safety benefits by increasing resiliency of timber stands, improved water quality, aesthetic benefits, and carbon storage. However, as discussed above, the possibility of a Federal nexus on these private lands is limited, so changes in timber management as a result of critical habitat, and any attendant ancillary benefits, are anticipated to be minimal.

Benefits of Exclusion—With regard to the benefits of exclusion from designation, although the final economic analysis (FEA) noted that one possible outcome of the critical habitat designation would be that the State could revise its regulations, and in a worst case scenario such revision could result in some private acres no longer being harvestable, we note that the likelihood of such revision actually occurring is characterized as speculative (IEC 2012b, p. 5–20). The FEA notes two possible outcomes of critical habitat designation, one being no change in Forest Practices Rules, the other is that State would revise their regulations and designate all suitable habitat overlapping with Federal critical habitat as ''critical habitat state.'' However, Washington DNR representatives only offered examples of potential responses to Federal designation of critical habitat in Washington, and did not comment upon the likelihood that any of these scenarios would occur (IEC 2012b, p. 5–11). The FEA also makes note of the potential indirect effects of critical habitat on private lands, in terms of private landowners possibly reacting by changing their timber harvest practices in response to perceived regulatory uncertainty as a result of critical habitat (IEC 2012b, p. 5–19).

In particular, a benefit of excluding lands covered under the WDNR FPR from critical habitat designation is that it would encourage the State and other parties to continue to work for owl conservation. If lands within the WDNR FPR area are designated as critical habitat, it would also likely have a negative effect on our ability to continue to partner with the WDNR on this conservation. In particular, the WDNR comment letter (WDNR 2012) states that if inclusion of private land is warranted, then WDNR requests that the Service ''create and bolster incentive based conservation opportunities for private landowners''. This recognizes the potential negative effects to their existing collaborative approach. By excluding these lands, we preserve our current private and local conservation partnerships and encourage additional conservation actions in the future because other parties see our exclusion as a sign that the Service will not impose duplicative regulatory burdens on landowners who are already have a regulatory responsibility under the WDNR FPR. As described in Changes from the Proposed Rule, many of the small, private parcels were removed from the final designation upon a determination that they did not meet the definition of critical habitat. The remaining areas of private lands (40,732 ac; 16,483 ha) in Washington contained in this designation are private industrial forest lands; these private lands are not currently covered by HCPs or SHAs but are covered under the WDNR Forest Practices Rules (FPR). Of these, 37,000 ac (14,974 ha) occur within the spotted owl circles currently regulated by the existing FPR. It is unlikely that the benefit of overlaying an additional regulatory burden within the SOSEAs to protect an additional 4,000 ac (1,619 ha) would be a significant benefit within the range of the owl. Excluding these private lands from the designation would avoid a chilling effect on the partnership between the Service and the affected State regulatory agencies regarding administration of their existing conservation programs to protect and conserve northern spotted owls on private lands. We consider the maintenance of our partnership between the Service and the affected State regulatory agencies to be a significant benefit of exclusion.

Benefits of Exclusion Outweigh the Benefits of Inclusion—The benefits of including these lands in the designation are small. The WDNR FPR contains provisions for protecting and maintaining northern spotted owl habitat that provides for comprehensive measures applied across a large landscape that will benefit spotted owls. WDNR personnel are extremely knowledgeable regarding the ecology of the northern spotted owl and have contributed to the body of scientific information about the northern spotted owl. The landowners subject to these State regulations are also informed by them. In this instance, the regulatory and educational benefits of inclusion have much less benefit than the continued benefit of the WDNR FPR including the educational benefits derived from the FPR.

The WDNR FPR provides for significant conservation and management within geographical areas that contain the physical or biological features essential to the conservation of the northern spotted owl and help achieve recovery of this species. Exclusion of private lands already covered under the WDNR FPR will help foster the partnership we have developed with WDNR. Furthermore, this partnership may aid in fostering future cooperative relationships with other parties in other locations for the benefit of listed species.

In summary, we determine that the benefits of excluding private lands already covered under the WDNR FPR from the designation of critical habitat for the northern spotted owl outweigh the benefits of including this area in critical habitat. We find that including these lands would result in minimal, if any, additional benefits to the northern spotted owl, as explained above. The WDNR FPR includes species-specific avoidance and minimization measures, rule enforcement procedures, and forest-management practices and habitat conservation objectives that benefit the northern spotted owl and its habitat, which exceeds substantially minimizes the incremental any conservation value provided as a result of a critical habitat designation. Given the active and ongoing efforts of the State of Washington to address northern spotted owl conservation, we have determined that maintaining our partnership with WDNR, in conjunction with the conservation measures under the WDNR FPR, provides a greater benefit to the northern spotted owl than would the regulatory and educational benefits of critical habitat designation. We also have determined that the potential incremental educational and ancillary benefits of critical habitat designation on lands containing the physical or biological features essential to the conservation of the northern spotted owl would be minimal, because WDNR has already made significant contributions to our understanding of the ecology of the northern spotted owl, and continues to do so through implementation of Recovery Action 18 and through participation in range wide demographic studies.

Exclusion Will Not Result in Extinction of the Species—We have determined that exclusion of approximately 40,732 ac (16,483 ha) of private lands covered under the WDNR FPR will not result in extinction of the northern spotted owl. The WDNR FPR protects and preserves landscape levels of suitable northern spotted owl nesting, roosting, and foraging habitat as well as foraging and dispersal habitat in strategic landscapes, and implements species-specific conservation measures designed to avoid and minimize effects to northern spotted owls. The Board has adopted a Wildlife Work Plan that requires rule review and revision should new information warrant that. We find that exclusion of private lands currently covered under the WDNR FPR will not result in extinction of the northern spotted owl. Therefore, the Secretary is exercising his discretion under section 4(b)(2) of the Act to exclude these private lands from this final critical habitat designation that are currently covered under the WDNR FPR totaling about 40,732 ac (16,483 ha).

Congressionally Reserved Natural Areas and State Park Lands

Our decision to exclude congressionally reserved natural areas and State park lands from this rule is based on the unique circumstances associated with this critical habitat designation. Before making a final decision of whether to exclude congressionally and State reserved natural areas, we weighed the relative benefits and costs a designation of these lands would confer and compared them to the costs and benefits of no designation. Our final decision is that these areas are essential to the conservation of the northern spotted owl, but a designation of these areas in this particular case would confer no current or potential regulatory benefit and a very minor education benefit. The primary habitat threat to the northern spotted owl is from commercial timber harvest. Since commercial timber harvest is not allowed on these lands, there would be little benefit to additional section 7 consultation on effects to critical habitat. We also agree with the National Park Service that a designation would impose some, albeit relatively small, additional administrative costs to land managers who would need to consult with the Service if their actions or programs might affect northern spotted owl critical habitat. Likewise, we find that State Park lands could experience some additional minor administrative costs as a consequence of this designation, especially those State Parks jointly managed with Redwood National Park and those that may use Federal funding for research and monitoring or program and capital improvements. However, we find that even these minimal costs would outweigh the minor informational benefits of including these areas in the critical habitat designation.

Benefits of Inclusion—The proposed critical habitat rule published on March 8, 2012 (77 FR 14062), as part of ''Possible Outcome 3'' in Table 1 (p. 14068), proposed to exclude 2,631,736 ac (1,065,026 has) of congressionally reserved lands and 164,776 ac (66,682 ha) of State Park lands from final critical habitat. These Federal reserved lands include all National Parks and Monuments, Wilderness Areas, Wild and Scenic Rivers, National Scenic Areas, and other congressionally designated areas identified in the proposed rule. State Parks lands included Iron Horse State Park in Washington, and all or portions of 30 State Parks in California, including Jedediah Smith, Del Norte Coast, Prairie Creek, Grizzly Creek, Humboldt Redwoods, DeWitt Redwoods, Richardson Grove, Reynolds Wayside, Smithe Redwoods, Standish-Hickey, Wm. Standley, Russian Gulch, Mendocino Headlands, Mendocino Woodlands, Van Damme, Montgomery Woods, Navarro Redwoods, Hendy Woods, Mailliard, Salt Point, Austin Creek, Armstrong State Reserve, Tomales Bay, Samuel P. Taylor, Mount Tamalpais, Robert Louis Stevenson, Bothe—Napa Valley, Sugarloaf Ridge, Jack London, and Annadel State Park.

A primary purpose of these congressional and State reserved natural areas is to conserve natural ecosystems, including those of the northern spotted owl and its habitat, and educate the public regarding the conservation of these areas. Unlike other Federal and State lands that have multiple use mandates that include commercial harvest of timber in the range of the spotted owl, such as National Forests, State Forests, and forests managed by the BLM, these reserved natural areas are unlikely to have uses that are incompatible with the purposes of critical habitat because the primary threat to spotted owl critical habitat—commercial timber harvest—is prohibited on these lands. These natural areas are managed under explicit Federal and State laws and policies consistent with the conservation of the northern spotted owl, and there is generally little or no timber management beyond the removal of hazard trees or fuels management to protect structures, roads, human safety, and important natural attributes. For example, the Wilderness Act provides conservation for the northern spotted owl because it prohibits commercial activities unrelated to wilderness recreation. Thus, not only is commercial timber harvest directly barred on these Federal lands, but the Wilderness Act also precludes the construction of roads and most uses of mechanical equipment. 16 U.S.C. 1133. The fundamental purpose of the National Park System, established by the Organic Act and reaffirmed by the General Authorities Act, as amended, begins with a mandate to conserve park resources and values. This mandate is independent of the separate prohibition on impairment and applies with respect to all park resources and values, even when there is no risk that any park resources or values may be impaired. *See* 16 U.S.C. sections 1–4.

Similarly, all of the State Parks lands proposed for exclusion occur in California except for 104 ac (42 ha) in Washington. California State Parks are managed by the California Department of Parks and Recreation. This Agency's mission is to ''administer, protect, provide for recreational opportunity, and develop the State Park System * * *'' We are unaware of any commercial timber harvests in California or Washington State Parks.

Therefore, any habitat-disturbing activities that might occur as the land managers carry out their conservation programs (e.g., trail maintenance, education and outreach, operations and maintenance, etc.) are likely to be relatively minor and are unlikely to be regulated by a critical habitat designation. On the Federal reserved lands, the section 7 prohibition on the destruction or adverse modification of critical habitat would be redundant and unlikely to add any protection to these important habitat areas. Likewise, many of these State Parks have close working relationships with Federal agencies and may experience, through those Federal partners, a section 7 nexus or other administrative costs if the States utilize Federal funds or require a Federal permit for their activities. For example, several State Parks in California (i.e., Del Norte Redwoods, Prairie Creek Redwoods, and Jedediah Smith Redwoods) are jointly managed with Redwood National Park through an agreement signed in 1994. In the San Francisco Bay Area, the National Park Service manages an inventory and monitoring program that includes actions by State Parks and other Federal partners such as the U.S. Geological Survey. Further, land managers monitor spotted owl territories within these reserved areas as part of long term population monitoring efforts, and barred owl populations are also monitored as part of spotted owl recovery efforts. For example, spotted owl territories in Crater Lake National Park have been monitored since 1992, and there are multiple spotted owl monitoring and conservation efforts occurring in many these parks throughout the species' range. A critical habitat designation on these State Parks may introduce some additional administrative costs but confer no increase in regulatory protection. Therefore, we believe there would be no regulatory benefits to inclusion of these lands in critical habitat.

We also believe that a critical habitat designation for these specific natural areas would confer minimal additional educational benefit toward spotted owl conservation. These areas are generally well known for their value to the conservation of listed species due to the education and communication programs of the natural area management agencies during the time since the listing of the spotted owl. Educational materials are distributed and other communication programs occur regarding the conservation of late successional forests and the species that inhabit them such as the spotted owl (see, e.g., Olympic National Park Web site featuring spotted owl information at *http://www.nps.gov/olym/naturescience/animals.htm,* or *http://www.nps.gov/muwo/naturescience/life-of-spotted-owls.htm* for NPS lands in central California). We also note that the management agencies overseeing these congressionally and State reserved natural areas have a positive history of over 20 years of conserving northern spotted owls and supporting research and conservation of the owl on their protected lands. While in other cases we have found benefits where critical habitat would highlight the importance of the habitat to owl conservation for future planning and management purposes, in the case of these lands, management is already consistent with habitat protection. Therefore, it is unlikely that designation of critical habitat of these areas would provide any significant informational benefits to the land managers or the public.

Benefits of Exclusion—We attempted to quantify the potential increase in administrative costs for the Service associated with a proposed designation of critical habitat in congressionally reserved land allocations. There is generally little or no timber management beyond removal of hazard trees or fuels reduction to protect structures and road maintenance, in addition to fire-management activities. Management guidelines for congressionally reserved lands are generally protective, so we do not anticipate requesting any changes of proposed management as a result of a critical habitat designation, and we would not anticipate reaching an adverse modification determination. In reserve areas where we do consult, the designation of critical habitat would likely add an adverse-modification analysis to an existing consultation.

Total incremental effects would likely be about 4–6 hours of staff time per action for both the action agency and the Service, although this estimate could vary widely depending on the size and scope of the action.

The final economic analysis (FEA) (IEC 2012b) quantified this potential for an increase in administrative costs, and they described the potential indirect impacts due to time delays for project processing and regulatory uncertainty. The analysis states, ''While critical habitat is not expected to generate changes to forest management practices or to testing or training missions on NPS or DOD lands, these areas may be subject to new or increasingly complex section 7 consultations as a result of critical habitat designation. Activities that may involve section 7 consultations include the construction or maintenance of visitor facilities on NPS lands and access roads to projects or military training including the use of vehicles, explosives, and soldiers. DOD and NPS will likely experience an additional administrative burden to provide biological assessments for projects in consultations with the Service as a result of critical habitat designation'' (IEC 2012b, p. 4–4). The FEA forecast an additional 16 informal consultations with NPS on planned or ongoing recreation and habitat management projects (IEC 2012b, p. 4–27). (Although the text refers to the NPS lands, the same rationale generally applies to other federally reserved lands in the proposed exclusion.) The FEA did not quantify the potential for direct incremental economic impacts on State Park lands, but it does identify the potential for indirect impacts due to time delays and regulatory uncertainty. Again, it is expected that these impacts would be relatively minor, but they nevertheless are not offset by a proportional increase in conservation benefits that would accrue as a consequence of this critical habitat designation on these lands.

Benefits of Exclusion Outweigh the Benefits of Inclusion—In sum, we find there are no regulatory benefits and such minimal educational benefits to including these lands in the designation that they are outweighed by the minor increase in administrative costs. We reach this conclusion for several reasons: (1) A critical habitat designation of these reserved areas in the range of the spotted owl would provide no additional regulatory benefits beyond what is already on these lands due to their permanent status as fully protected lands and, importantly, the fact that commercial timber harvest is not permitted on these lands under Federal and State law and policy; (2) the designation of these reserve areas would confer little additional educational benefits associated with the conservation of the spotted owl, as these educational messages are already being communicated in many of these areas under existing programs; and (3) as identified by the economic analysis and the NPS, there is the potential for a small but measureable increase in administrative costs, time delays, and regulatory uncertainty for the Service and Federal and State land managers if these lands were designated, without any offsetting positive conservation benefits to justify the increased administrative costs.

After weighing these relative costs and benefits, the Secretary has chosen to exercise his discretion under Section 4(b)(2) of the Act to exclude these lands from final critical habitat. As part of this review we have determined the Federal agencies are managing these reserved natural areas under statutes that already impose a clear conservation mandate consistent with the specific needs of the northern spotted owl, and a critical habitat designation would confer no additional conservation benefits to the spotted owl that offset the potential increase in administrative costs. In making this decision, we also note the historic role of congressionally and State reserved natural areas as part of northern spotted owl critical habitat. In 1992, the Service concluded that certain congressionally reserved parks and wilderness areas were essential to spotted owl conservation, but we declined to include these lands in the final designation of critical habitat because their current classification and management was deemed adequate to meet spotted owl conservation goals (January 15, 1992; 57 FR 1796, p. 1806). Likewise, in 2008, the Service revised northern spotted owl critical habitat and again concluded that congressionally reserved natural areas would not be included in final critical habitat for the same reasons as those identified in the 1992 decision (August 13, 2008; 73 FR 47325, p. 47334). Although not a factor in this section 4(b)(2) weighing, this determination will maintain the consistent management approach for spotted owls that has occurred on these lands over the last 20 years and should minimize the potential for confusion among land managers and the public.

This analysis is based in large part on the particular conservation requirements of the northern spotted owl and is specific to this designation. Thus, our determination that the benefits of exclusion outweigh the benefits of inclusion in this case does not necessarily have a bearing on future critical habitat designations.

Exclusion Will Not Result in Extinction of the Species—We conclude that this exclusion of congressionally and State reserved natural areas would not result in the extinction of the species. As described above, all of these areas are managed under State and Federal law to provide for the conservation of species and their natural habitat, including the northern spotted owl. A critical habitat designation would not enhance or incrementally improve this dedicated management or increase the protections of these lands, nor would its absence somehow fail to provide protections that otherwise would not be present. Therefore, this exclusion of lands from final critical habitat would not result in any appreciable risk of extinction to the species because these lands will continue to be managed to provide for the conservation of the spotted owl.

Cumulative Analysis—Exclusion Will Not Result in Extinction of the Species

We have determined that exclusion of approximately 4,056,759 ac (1,641,777 ha) of lands from this final designation of critical habitat will not result in extinction of the northern spotted owl. We have excluded these areas based, in part, on the significant conservation benefits afforded to the northern spotted owl and its habitat on these lands through the positive conservation measures provided through SHAs, HCPs, or other agreements with private landowner partners with a proven track record of conservation actions. Each of these agreements, as discussed here, provides significant conservation benefits to the species in terms of maintaining, enhancing, or recruiting additional suitable habitat for the northern spotted owl, and implementing species-specific conservation measures designed to avoid and minimize impacts to northern spotted owls. Further, for projects having a Federal nexus and affecting northern spotted owls in the excluded areas, all of which are occupied by the species, the jeopardy standard of section 7 of the Act provides a level of assurance that this species will not go extinct as a result of excluding these lands from the critical habitat designation. The species is also protected by section 9 of the Act, which prohibits the take of listed species. Congressionally and State reserved natural areas excluded are managed under State and Federal law and policy to provide for the conservation of species and their natural habitat, including the northern spotted owl. These lands will continue to be managed under a clear conservation mandate, and exclusion of these lands from critical habitat will not deprive the species or its habitat of any protections that are not already present. Although we did not assume that all private lands without specific conservation agreements would continue to fully provide for the conservation of the owl, we determined that the exclusion of these lands would not lead to the extinction of the species, due to existing State protections and the fact that the areas excluded constitute such a small percentage of the overall designation. For these reasons, we conclude that the exclusion of these areas under section 4(b)(2) of the Act will not cumulatively result in the extinction of the species.

Consideration of Indian Lands

In accordance with the Secretarial Order 3206, ''American Indian Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act'' (June 5, 1997); the President's memorandum of April 29, 1994, ''Government-to-Government Relations with Native American Tribal Governments'' (59 FR 22951); Executive Order 13175, ''Consultation and Coordination with Indian Tribal Governments'' (November 6, 2000, and as reaffirmed November 5, 2009); and the relevant provision of the Departmental Manual of the Department of the Interior (512 DM 2), we believe that fish, wildlife, and other natural resources on Indian lands may be better managed under Indian authorities, policies, and programs than through Federal regulation where Indian management addresses the conservation needs of listed species. In addition, such designation may be viewed as unwarranted and an unwanted intrusion into Indian self-governance, thus compromising the government-to-government relationship essential to achieving our mutual goals of managing for healthy ecosystems upon which the viability of threatened and endangered species populations depend.

In developing the proposed revised critical habitat designation for the northern spotted owl, we considered inclusion of some Indian lands. As described in the above section Criteria Used to Identify Critical Habitat, and detailed in our supporting documentation (Dunk *et al.* 2012b, entire), we evaluated numerous potential habitat scenarios to determine those areas that are essential to the conservation of the northern spotted owl. In all cases, we assessed the effectiveness of the habitat scenario under consideration in terms of its ability to meet the recovery goals for the species. Furthermore, the habitat scenarios under consideration included a comparison of different prioritization schemes for landownership; we prioritized areas under consideration for critical habitat such that we looked first to Federal lands, followed by State, private, and Indian lands. Indian lands are those defined in Secretarial Order 3206 ''American Indian Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act'' (June 5, 1997), as: (1) lands held in trust by the United States for the benefit of any Indian tribe or individual; and (2) lands held by any Indian Tribe or individual subject to restrictions by the United States against alienation. In evaluating Indian lands under consideration as potential critical habitat for the northern spotted owl, we further considered the directive of Secretarial Order 3206 that stipulates ''Critical habitat shall not be designated in such areas unless it is determined essential to conserve a listed species. In designating critical habitat, the Services shall evaluate and document the extent to which the conservation needs of the listed species can be achieved by limiting the designation to other lands.''

Although some Indian lands identified in our habitat modeling demonstrated the potential to contribute to the conservation of the northern spotted owl, our analysis did not suggest that these areas were essential to conserve the northern spotted owl. This determination was based on our relative evaluation of the various habitat scenarios under consideration; if the population performance results from our habitat modeling indicated that we could meet the recovery goals for the species without relying on Indian lands, we did not consider the physical or biological features on those lands, or the lands themselves, to be essential to the conservation of the species, therefore they did not meet our criteria for inclusion in critical habitat. Our evaluation of the areas under consideration for designation as critical habitat indicated that we could achieve the conservation of the northern spotted owl by limiting the designation of revised critical habitat to other lands. Therefore, no Indian lands are included in the revised designation of critical habitat.

XII. Summary of Comments and Responses

We requested written comments from the public on the proposed revised designation of critical habitat for the northern spotted owl during an initial 90-day public comment period, which opened with the publication of the proposed revised rule on March 8, 2012 (77 FR 14062), and closed on June 6, 2012. On June 1, 2012, we published the notice of availability of the draft economic analysis and draft environmental assessment associated with the proposed revised designation of critical habitat (77 FR 32483), and extended the comment period for the proposed rule an additional 30 days, through July 6, 2012, thereby providing a total comment period of 120 days. In addition, we held two public information meetings in Redding, California on June 4, 2012; two in Tacoma, Washington, on June 12, 2012; one in Portland, Oregon on June 20, 2012; and two in Roseburg, Oregon, on June 27, 2012. We also held a public hearing in Portland, Oregon, on June 20, 2012. In addition, we contacted appropriate Federal, State, County, and local agencies; scientific organizations; and other interested parties and invited them to comment on the proposed rule, draft economic analysis, and draft environmental assessment during these comment periods. In addition, in response to requests from several Counties, and to ensure that all affected Counties and State fish and wildlife agencies in Washington, Oregon, and California were able to thoroughly review and comment as provided by section 4(b)(5)(A)(ii) of the Act, the Service provided an additional opportunity for those entities to comment until August 20, 2012.

During the comment period(s), we received over 33,000 comments (many of which were form letters), directly addressing the proposed revised critical habitat designation. During the June 20, 2012, public hearing, eight individuals or organizations provided comments on the proposed revised designation. All substantive information provided by commenters has either been incorporated directly into this final designation or addressed below. Comments received were grouped into general categories specifically relating to the proposed revised critical habitat designation, and are addressed in the following summary, and incorporated into the final rule as appropriate. We received a number of highly technical comments regarding the modeling process used to develop critical habitat. These technical questions are addressed in the final Modeling Supplement (Dunk *et al.* 2012b) rather than in the following section. We also received several comments regarding perceived effects attributed to the original listing of the northern spotted owl (June 26, 1990; 55 FR 26114), but are not addressing those comments because they do not apply to this rulemaking, which is limited to the revised designation of critical habitat for the northern spotted owl.

Comments From Peer Reviewers

In accordance with our peer review policy published on July 1, 1994 (59 FR 34270), we solicited expert opinions from 40 knowledgeable individuals with scientific expertise that included familiarity with the species, the geographic region in which the species occurs, and conservation biology principles. We received responses from 15 of the peer reviewers.

We reviewed all comments received from the peer reviewers for substantive issues and new information regarding critical habitat for the northern spotted owl. The peer reviewers generally supported the modeling process used to inform the identification of critical habitat and the resulting size and distribution of the proposed revised designation. Reviewers were divided on the risks posed by climate change and forest health, and whether active management should be applied within critical habitat.

We asked reviewers to address a number of specific questions with regard to the proposed rule. The questions posed to the peer reviewers and a summary of their responses are provided below; peer reviewer comments, clarifications, and suggestions have been incorporated into the final rule as appropriate. Our responses to issues raised by the peer reviewers are presented in the subsequent summaries of comments and responses.

Question 1a: Given the assumptions about barred owl effects, does this critical habitat network provide a sufficient amount and distribution of habitat for the northern spotted owl?

Peer Review Response: Of the seven reviewers who provided a response to this question, four indicated that it was impossible to determine whether the critical habitat network was adequate with barred owls present across the area. Two reviewers believed the network was adequate, and one believed it was too small given barred owl impacts.

Question 1b: Have the physical or biological features that are essential to the conservation of the owl been properly described? Do the areas identified as proposed critical habitat adequately capture these features? Are there areas we identified that should not be included in the designation?

Peer Review Response: Of the five reviewers who addressed this question, all believed the physical or biological features were properly described. A number of these reviewers did have suggestions for revising descriptions of these features in specific forest types and we have incorporated these suggestions into the final rule.

Question 2: Does the critical habitat network adequately encompass the geographic range of the northern spotted owl and represent the range of habitat types used by the species?

Peer Review Response: Only three reviewers specifically addressed this question. All agreed that the network encompassed the geographic range and habitat types used by owls. One reviewer expressed concern that additional lands in the southwest Washington lowlands should be included to improve landscape connectivity, and a second reviewer indicated that maintaining areas of marginal habitat where northern spotted owls could persist in the face of encroachment by barred owls may be particularly important. See our response to *0* for a detailed discussion regarding inclusion of lands in southwest Washington and inclusion of marginal habitat.

Question 3: We have identified areas on Federal lands in the ''Matrix'' classification (i.e., areas designated for timber harvest under the NWFP) as proposed critical habitat, as well as some State and private lands where Federal lands are lacking. Do you agree or disagree with this approach? Why or why not?

Peer Review Response: Eight reviewers addressed this question, and all agreed that inclusion of matrix lands in critical habitat was supported. One reviewer noted that the barred owl issue needs to be addressed (see response to *0* for detailed discussion of this issue), and another reviewer was surprised that all habitat-capable lands in the western portion of the species' range were not included in critical habitat (see *0* for a more detailed discussion of this issue).

Question 4a: Does the proposed rule appropriately cite the scientific literature on ecological forestry to recommend restoration of ecological processes and the conservation of late-successional forests while also providing sufficient habitat conservation for northern spotted owls?

Peer Review Response: Ten reviewers addressed this issue. Most supported the idea that land managers consider the application of ecological forestry principles. Five believed the rule cited appropriate literature, and several other expressed general support, but recommended consideration of additional published research. Three reviewers disagreed with some of the science that was cited, or the interpretation of that science, and noted that the discussion did not adequately address studies that have documented negative effects of timber management on northern spotted owls and their prey. Several reviewers recommended that active management should be conducted in an adaptive management framework. We addressed these issues in revisions to the section *An Ecosystem-based Approach to the Conservation of the Northern Spotted Owl and Managing Its Critical Habitat.*

Question 4b: Do the proposed guidelines for vegetation management, including forest fuels treatments and restoration of fire regimes, represent an appropriate application of ecological science?

Peer Review Response: Responses to this question were varied. Eight reviewers expressed overall support for the concept, although several recommended providing more specific management information. Four reviewers indicated that parts of the document were unclear on whether ecological science was applied appropriately, and highlighted the lack of understanding about how such management actions may affect owls and their prey. Two reviewers specifically indicated that they did not think that approach is appropriate. Several recommended conducting active management activities in an adaptive management framework, until the science becomes clearer regarding how northern spotted owls are affected by projects intended to restore forest health or apply ecological forestry principles. We addressed active adaptive forest management in the section *An Ecosystem-based Approach to the Conservation of the Northern Spotted Owl and Managing Its Critical Habitat.*

Question 4c: Do you believe the proposed rule appropriately balances the potential risks of taking action with the potential risks of a passive (i.e., ''no action'') management approach, especially in the face of ongoing climate change and the need to manage for the entire forest ecosystem, not just northern spotted owls?

Peer Review Response: Peer reviewers were split in their opinions on this question, and responded with varying degrees of specificity. Eight reviewers generally supported the suggestion that land managers consider an active management approach in managing forest landscapes, although not all stated whether the discussion of this concept in the proposed rule balanced the respective tradeoffs. Five reviewers believed that the risks were not appropriately balanced, that the discussion was too vague in weighing the tradeoffs, or that there is too little specific scientific understanding of the explicit tradeoffs to conduct an informed discussion. Several of these reviewers indicated that there was too much emphasis on active management in the preamble to the proposed rule given the lack of understanding about how ecological forestry and restoration management might affect owls. In contrast, one reviewer noted that the consequences of not applying management in some areas (e.g., fire-prone areas) were not sufficiently addressed. We have addressed the need to conduct additional research in an adaptive management framework in the section *An Ecosystem-based Approach to the Conservation of the Northern Spotted Owl and Managing Its Critical Habitat.*

Question 5a: Is there relevant information available we did not incorporate into the critical habitat modeling process (thoroughness), and have we interpreted the existing scientific information in a reasonable way (scientific consistency)?

Peer Review Response: The 15 reviewers generally agreed that we did include the appropriate information and interpreted it in a reasonable way. Recommendations to incorporate more realistic barred owl encounter rates, use individual home ranges rather than pair ranges in the modeling process, and analyze the effects of proposed exclusions were suggested. We address these issues in our responses to *Comment (11), Comment (38),* and *Comment (139).* One reviewer questioned the accuracy of GNN data for identifying northern spotted owl habitat. We address the question regarding the accuracy of GNN data in our response to *Comment (19*). In addition, some reviewers asked for more detail regarding the modeling process. Many of the responses to comments provided here present such detail, and we have incorporated additional discussion in our separate Modeling Supplement (Dunk *et al.* 2012b).

Question 5b: The modeling process attempted to incorporate both scientific uncertainty and demographic (stochastic) variation. Were methods used to incorporate uncertainty and variability appropriate?

Peer Review Response: Six reviewers addressed this question specifically. Most had suggestions for improving our methods including addressing temporal variation in demographic rates, providing confidence intervals on estimates, and conducting sensitivity analyses. We address specific comments in more detail in the Modeling Comments section below, as well as in our separate Modeling Supplement (Dunk *et al.* 2012b).

Question 5c: Does the proposed critical habitat rule correctly express the key assumptions and uncertainties underlying the scientific and technical information it used, particularly in regard to northern spotted owl habitat, demographic trends, and influence of barred owls on northern spotted owls?

Peer Review Response: In general, the reviewers agreed that the rule did address key assumptions and uncertainties; however, most identified specific areas these could be improved. We address these comments in more detail in the Modeling Section below, as well as in our separate Modeling Supplement (Dunk *et al.* 2012b).

Question 5d: Was the combination of analytical methods (MaxEnt, Zonation, HexSim) with professional judgment (please see Criteria Used to Identify Critical Habitat, pp. 14096–14101 in the proposed rule (March 8, 2012; 77 FR 14062) for details) appropriate for identifying critical habitat? Are there additional analyses you would recommend?

Peer Review Response: Of the 15 peer reviewers, 1 thought that HexSim was not an appropriate model given its complexity, and 2 expressed concern about the utility of the MaxEnt model for identifying habitat. The majority of peer reviewers thought that the combination of analytical methods we used was appropriate. We address the question regarding the use of HexSim and MaxEnt in our responses to *Comments (20, 21, 22, 26, and 43)* as well as in our separate Modeling Supplement (Dunk *et al.* 2012b).

A number of peer reviewers had additional comments about the concept of active management. Since the preambles to the proposed and final rules discuss this concept, we have addressed their comments below. However, we emphasize that this rule does not take any action or adopt any policy, plan or program in relation to active forest management. The discussion is provided only for consideration by Federal, State, and local land managers, as well as the public, as they make decisions on the management of forest land under their jurisdictions and through their normal processes.

Additional peer reviewer comments are addressed in the following summary and incorporated into the final rule as appropriate.

Comments on Lands Included in Critical Habitat and Exclusions

Comment (1): Several reviewers commented that proposed critical habitat failed to include habitat that linked the Olympic peninsula to other regions, and also did not include low-elevation habitat along the margins of the Willamette Valley, Puget Trough, Umpqua Valley, and Rogue River Valley. Some reviewers indicated that they thought this was a fault of the modeling methods used.

Our Response: There are multiple reasons why the areas described in the above comments were not included in the revised critical habitat. First, the habitat model using MaxEnt was at the 500-ac (200-ha) scale, and was thus unlikely to identify small, isolated habitat fragments. This is not a failure of the modeling, but rather a consequence of these areas (identified in the comments) having very little northern spotted owl habitat; such small, fragmented areas do not meet our criteria for critical habitat, and are therefore not included in final the critical habitat designation. Second, to incorporate additional information such as connectivity and unique forest situations, the Service also utilized expert knowledge and current owl location data (among other factors) to determine what is essential for conservation of the species. In Phase 3 of the critical habitat development process, as described in Dunk *et al.* 2012b, we evaluated areas where connectivity appeared to be deficient, and added in habitat to strengthen connectivity. However, most of the areas identified in these comments (particularly in western Washington) consist largely of cutover industrial timberlands, are not occupied by northern spotted owls, do not contain the primary constituent elements for critical habitat, and are not otherwise essential to the conservation of the species because they do not provide high-quality habitat or areas where restoration of habitat is need to provide essential connectivity or demographic support. These areas were not included in the 1992 or 2008 critical habitat designations for the same reasons. Without additional information about the location and habitat conditions of specific parcels in the areas mentioned in this comment, we are unable to further evaluate the benefits of including them in the revised designation.

Comment (2): One reviewer questioned the fact that portions of several late-successional reserves (LSRs) including a portion of the Okanogan-

Wenatchee National Forest in the eastern Washington Cascades and lands in the Western Klamath region that were affected by the Biscuit Fire were not included in the critical habitat proposal.

Our Response: Both of the areas described in this comment generally exhibit low relative habitat suitability (RHS) values. The portion of the Okanogan-Wenatchee LSR that was not included contains much high-elevation forest and dry forest seldom occupied by the northern spotted owl. The Biscuit Fire area described by the reviewer is composed of low RHS due to a combination of fire effects and ultramafic soils.

Comment (3): One peer reviewer and several public commenters were concerned about congressionally reserved areas not being included in proposed critical habitat.

Our Response: All congressionally reserved lands that met the criteria for critical habitat were included in the proposed revised designation. We sought public comment on whether they should be excluded from the final critical habitat designation. Based on further analysis and public comment, they are excluded in the final revised critical habitat designation. Our final decision is that these areas are essential to the conservation of the northern spotted owl, but as these areas are managed under a conservation mandate that provides for the needs of the northern spotted owl, we could find no benefits to the designation that outweighed the minor administrative costs associated with including these areas. Therefore the benefits of exclusion outweighed those of inclusion, and since such exclusion will not result in the extinction of the species, these congressionally reserved areas have been excluded from the final designation.

Comment (4): Several reviewers highlighted the importance of keeping State lands, congressionally reserved lands, and some private lands without HCPs or other agreements in critical habitat.

Our Response: We agree that these lands are important for the conservation of northern spotted owls. However, Federal parks and wilderness areas (and any other congressionally reserved lands) including State parks, as well as private lands, have been excluded in the final revised designation of critical habitat for the northern spotted owl. Some State lands are included in the final critical habitat designation, unless such lands had an HCP, SHA, or other conservation measures in place that led to their exclusion under section 4(b)(2) (see Exclusions).

Comment (5): Several reviewers indicated that the largest reserve designs may be the best for northern spotted owl conservation.

Our Response: Designation of critical habitat is constrained by the statutory language in section 3(5) of the Act, which states that critical habitat must either have been occupied by the species at the time it was listed and contain the physical or biological features essential to the conservation of the species, or, if unoccupied at the time of listing, be essential to the conservation of the species. Furthermore, section 3(5)(c) of the Act specifies that except in rare circumstances, critical habitat should not include the entire geographical area which can be occupied by the species. We concur that in areas where high-quality habitat is lacking, designating all areas capable of developing in to suitable habitat in the future might provide more robust networks. However, the addition of large areas of currently unsuitable habitat as suggested in this comment would likely not meet the intent and mandate of the statute. If occupied at the time of listing, such lands would not provide the requisite essential features. If unoccupied at the time of listing, such lands would only be included in critical habitat if we found them to be essential to the conservation of the species. Our evaluation of various potential habitat networks as we developed this critical habitat designation demonstrated that these lands are not likely to contribute substantially more owls to the rangewide population than the area designated as final critical habitat, thus we did not consider them to be essential to the conservation of the species.

Comment (6): One reviewer stressed the need to retain Recovery Action 10 and 32 lands in critical habitat.

Our Response: Recovery Action 10 and Recovery Action 32 do not constitute specific areas of mapped lands that could be included in critical habitat designation. Rather, they are broad landscape-level conservation recommendations contained in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) for identification and conservation of important habitats that apply to all land ownership categories and Federal land management allocations, including designated critical habitat. While consistency with these and other recovery actions is not required, Federal land management agencies generally try to conduct activities in a manner consistent with the guidance provided in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011).

Comments on Competition From the Barred Owl

Comment (7): One reviewer indicated that recovery efforts need to focus on barred owl management in addition to critical habitat.

Our Response: Barred owls and loss or degradation of habitat are primary factors impacting northern spotted owls. As we noted in the proposed critical habitat rule, habitat protection is necessary, but not sufficient alone, to recover the northern spotted owl. This revised designation of critical habitat is only one of many conservation actions that will contribute to the recovery of the northern spotted owl. The Service is currently working on a final environmental impact statement under NEPA for experimental barred owl removal to address the threat posed to northern spotted owls by the barred owl. Nonhabitat-based threats, such as barred owls, are specifically addressed in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), and do not fall within the scope of this critical habitat rule. The Revised Recovery Plan, not this critical habitat rule, should be considered the comprehensive recovery document for the northern spotted owl.

Comments Regarding the Northwest Forest Plan (NWFP)

Comment (8): Several reviewers indicated that the relationship between proposed critical habitat and the Northwest Forest Plan was unclear.

Our Response: We have attempted to clarify the language regarding the relationship between critical habitat and the Northwest Forest Plan (NWFP). The NWFP provides land management guidance for most of the Federal lands identified as critical habitat, and we anticipate that the Standards and Guidelines for the NWFP will continue to direct management actions on these lands, unless amended sometime in the future. We emphasize that critical habitat does not replace or supersede the Standards and Guidelines of the NWFP. Active management is discussed in the preamble of this rule only to encourage land managers to consider the range of management flexibility already contained in the NWFP. We acknowledge the importance of the NWFP as a management strategy for conserving northern spotted owls and late-successional forest habitat, and our suggestions for special management considerations needed to address the threats to the physical or biological features essential to the conservation of the northern spotted owl (see Special Management Considerations or

Protections, above) are consistent with the directives of the NWFP.

Comment (9): One reviewer noted that LSR areas and locations on the East Cascades were designed under the assumption of static landscapes, not the dynamic landscapes we now recognize.

Our Response: We have recognized that the Standards and Guidelines for management under the NWFP differ across eastern and western forests, and that eastern forests are very dynamic. This condition was recognized in the NWFP, and the Standards and Guidelines of the NWFP allow for active management in such areas (USDA and USDI 2004, pp. C–12—C–13).

Comments on the Modeling Process

Here we provide a summary of general comments received on the modeling process that we used, in part, to identify revised critical habitat for the northern spotted owl. The habitat modeling framework we utilized was originally developed for the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), and Appendix C of the Revised Recovery Plan provides a detailed description of the modeling framework and the extensive testing and cross-validation that was done at each stage of development. In addition, we note that the modeling framework that we applied here to assist in the identification of critical habitat for the northern spotted owl was independently the subject of prior peer review and public comment for the recovery plan. Particularly detailed or technical comments on the habitat modeling that we received in relation to this critical habitat rule are addressed separately in our Modeling Supplement, Dunk *et al.* 2012b, in an effort to reduce the length and improve the readability of this rule.

Comment (10): One reviewer suggested that the modeling of habitat networks and scenarios should consider a wider range of options or composites with greater emphasis on sustainability of owl populations, not efficiency. The present document is biased in favor of efficiency, not conservation of old forest habitat.

Our Response: We evaluated each of the potential critical habitat networks with respect to the guiding principles we developed, which were based on the statutory definition of critical habitat and informed by the recovery criteria for the northern spotted owl as established in the 2011 Revised Recovery Plan. The recovery criteria for the northern spotted owl are aimed at achieving sustainable northern spotted owl populations across the range of the species. In terms of identifying critical habitat, we use the term ''efficient'' to convey that we sought to include the highest-quality habitat with the greatest potential contribution to recovery and minimize as much as possible the amount of relatively lower quality habitat in determining what is essential to conservation of the species. In areas of insufficient high-quality habitat, lower quality habitat may still provide the PCEs and may be essential in terms of providing sufficient habitat overall to sustain the population. We also sought to rely on public lands to the extent possible.

Efficiency never trumped owl performance in our selection process; the population performance of the northern spotted owl in response to the scenarios evaluated was our first concern. However, given two or more nearly equal population performance outcomes, we did look for efficient solutions; that is, given the choice between two nearly equivalent habitat networks in terms of northern spotted owl population performance, we chose the network that achieved roughly the same level of performance provided by a relatively greater proportion of public lands or smaller overall designation. Old forest habitat and areas of high RHS are nearly identically represented in the largest networks we evaluated (Z70, Composites 1, 3, 4, and 7).

Comment (11): One reviewer suggested the use of individual, rather than pair home range size estimates in the HexSim model.

Our Response: Because our spotted owl population model is a females-only model, it was most appropriate to use individual home range sizes. Thus our model will not simulate the resource constraints that could result from male owl's consumption of limited food resources. We strove to construct the simplest model structure that captured the essential ecological processes; doing so made our northern spotted owl model more straightforward to develop and easier to understand. We evaluated how well the HexSim model was calibrated to actual populations, by comparing simulated spotted owl populations from our model with actual densities of northern spotted owls as measured within demographic study areas (Appendix C, p. C–73). We found that simulated populations were quite similar to actual populations, suggesting that the females-only model produced reasonably accurate estimates. Finally, because we used the HexSim model to compare the relative differences in population size resulting from different reserve design assumptions, any biases that may have been introduced into the process from the use of a females-only model would essentially be zeroed out, since that bias would be the same across all populations; in such a case, the net relative difference would still be accurately reflected between populations.

Comment (12): One reviewer noted that we did not include baseline scenarios that provide clear insight concerning the contributions that State, private, and Indian lands might make in the long run. They note that excluding consideration of some large areas by virtue of land ownership may have attendant effects on demographic results by inadvertently imposing ''pinch points'' along the north-south axis of the critical habitat area. The main concern was that northern spotted owl recovery may be quite limited by the initial assumptions made about excluding State, private, and Indian lands based on their current conditions; remaining alternatives considered may all be poorer as a result.

Our Response: We did not make initial assumptions about the population contributions potentially made by State, private, and Indian lands, or about the feasibility of including those lands in proposed critical habitat. Our initial comparisons of Zonation-derived reserve designs included both ''ALL lands'' and ''PUBLIC lands'' scenarios (Appendix C, p. C–49–52); these habitat networks did not restrict our evaluation to particular land ownerships, but allowed us to evaluate all lands regardless of ownership. Thus, we evaluated the contribution of all land ownerships before narrowing down the habitat network designs based on policy and cost-benefit analyses (meaning the weighing of relative population performance versus total area in the designation), as fully described in our Modeling Supplement (Dunk *et al.* 2012b). As discussed in this rule and in that supplement, we sought to maximize the reliance on public lands to the extent possible, but only if it did not compromise the population metrics essential to conservation of the northern spotted owl. In addition, as described in the section Consideration of Indian Lands, we conducted this analysis in accordance with the Secretarial Order 3206 directive to consider ''the extent to which the conservation needs of the listed species can be achieved by limited the designation to other [non-Indian] lands.'' As we did not identify any Indian lands that were essential to the conservation of the northern spotted owl, we did not include any such lands in the designation.

Comment (13): One reviewer asked whether foraging habitat was considered separately from nesting/roosting habitat in the Step 1 modeling, or if suitable habitat was modeled as nesting/roosting/foraging?

Our Response: Foraging habitat was separate from nesting/roosting habitat, as explained in Appendix C to the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011, p. C–24).

Comment (14): One reviewer noted a potential failure to acknowledge the importance of winter migration behavior to spatial and habitat requirements of territorial northern spotted owls.

Our Response: We attempted to incorporate some degree of winter habitat requirements by using annual home ranges in HexSim. To our knowledge, the data we could use in HexSim to incorporate broader movements does not exist throughout the northern spotted owl's range. To the extent that northern spotted owls move away from their territories during the nonbreeding period, and if habitat use differs appreciably in the breeding season and nonbreeding season, it is possible that our approach did not include all areas that may be important to northern spotted owls. However, we are unaware of a consistent methodology that we could use to overcome this potential shortcoming.

Comment (15): One reviewer requested that we consider the effects of fire in the modeling process used to define critical habitat, and how critical habitat should be protected from the effects of fire.

Our Response: Our process incorporated several different possible vegetation growth and loss scenarios, and modeled a variety of potential northern spotted owl responses to differing management strategies. These scenarios were based on observed rates of habitat change measured between 1996 and 2006. As such, they incorporate habitat loss to fire and other causes, and project it into the future as a rate of change. We considered explicitly modeling fire probabilities and fire effects into the scenarios, but the complexity and high degree of uncertainty made this unfeasible. Incorporating fire impacts would have had a similar proportional effect to the relative outputs of each modeled scenario, thereby not elucidating real differences between the effectiveness of the modeled scenarios. The question of protecting critical habitat from the effects of fire is beyond the scope of this rulemaking.

Comment (16): One reviewer suggested that estimating the rate of population change (λ, or lambda) at 10-year intervals makes interpretation more difficult, especially with respect to the results from demographic studies, where λ is estimated as an annual interval.

Our Response: Our use and estimate of the finite rate of population change was not intended to be compared to estimates from demographic study areas or the meta-analysis (e.g., Forsman *et al.* 2011). We used lambda as one basis for comparison between the various alternative potential critical habitat networks considered to determine what is essential to the conservation of the northern spotted owl, using different assumptions related to the barred owl and the amount of suitable habitat. Thus, our use of lambda at 10-year intervals was appropriate for our intended use of relative population performance between habitat scenarios under consideration.

Comment (17): One reviewer indicated that one aspect that seemed to be lacking in the designation of critical habitat was whether the model correctly predicted areas currently occupied by northern spotted owls based on relative habitat suitability. The reviewer suggested that one way to accomplish this would be to examine the spatial distribution of critical habitat in relation to the existing demographic study areas and other areas with a history of surveys for northern spotted owls.

Our Response: To evaluate how well the modeling process identified areas likely to be occupied by northern spotted owls, we tested the predictive ability of the model by comparing our RHS model outputs with the distribution of known northern spotted owl locations (independent data sets) from the years 1996 and 2006, and in both cases found a high predictive accuracy. The results of this comparison are presented on pages C–38 to C–41 in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011).

Comment (18): One reviewer indicated that the models are likely to be ''overfit'' (an overfit model that is overly sensitive to small fluctuations in data inputs, and will consequently have poor predictive results), even though cross-validation results by modeling region showed that all models were relatively robust to prediction (Table C19, Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011)). The reviewer indicated that this point needs to be more clearly disclosed. Several commenters expressed concern about the number of covariates in the RHS models, and the potential for overfitting.

Our Response: We carefully evaluated the modeling procedures we used to identify spotted owl habitat and test the resulting models using both cross-validation and independent data sets. Based on the results of our evaluations, we disagree that our models are overfit. We have clarified the procedures used and results of model testing in the final Modeling Supplement (Dunk *et al.* 2012b). MaxEnt is designed to reduce the effects of the potential model over-fitting through its use of regularization. The main consequence of overfitting that we wished to guard against was that of having models so tightly fit to the training data that they were not generalizable (i.e., that they did not work well at classifying test data or data that did not contribute to the model's development). Our extensive cross-validation (randomly removing 25 percent of the data, each of 10 times within each modeling region) and evaluation of each model's full and cross-validated performance revealed that the models were not overfit (see Table C–16). Furthermore, where we had adequate independent data, the models performed almost identically on them as on the training data (see Table C–17). We share the reviewers concerns with overfitting models, and we directly evaluated whether the consequences of overfitting were realized and found that they were not. Thus, the conclusions on page C–41 of the Revised Recovery Plan (USFWS 2011) under ''Model evaluation summary'' remain valid.

Comment (19): Some reviewers and commenters suggested that the GNN database used to develop the relative habitat suitability (RHS) map is inappropriate for use in designating critical habitat because it does not depict what actual vegetative components exist on the ground but is a computer simulation of what might exist. The reviewer stated that since the base vegetation layer does not accurately represent stand conditions on the ground, it is impossible to show what stands contain PCEs and which do not. Several reviewers suggested that a formal accuracy assessment of the GNN data is needed and suggested that model predictions of habitat conditions should be verified. One reviewer indicated that inaccuracies in the GNN database probably led to errors with MaxEnt predictions of owl distributions. The reviewer suggested that there is little science to support the assumptions that GNN data for vegetative variables believed to be important to northern spotted owls were equally accurate across modeling regions, and there is little certainty that relevant processes were sufficiently captured so as to reliably predict owl population performance. The reviewer further claims the Service did not assess the accuracy of the GNN data. Finally, the reviewer states that Dr. Larry Irwin, National Council for Air and Stream Improvement (NCASI) conducted an analysis of how well the GNN–LT data correlated with actual measurements on the ground, and concluded that there is a very low correlation between GNN–LT predictions and reality. Further, the reviewer states that GNN–LT was developed for mid- to large-scale spatial analysis, not the designation of critical habitat.

Our Response: We concur that the RHS models and subsequent modeling steps are dependent on the reliability of the GNN vegetation layer. A description of our use of GNN and accuracy assessments for the GNN variables used in our RHS models are presented in detail on pages C–16 to C–19 of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011). Based on our data needs, these accuracy assessments, and independent verification of the performance of GNN estimates, we have determined that GNN represents the best scientific information available for habitat modeling throughout the range of the northern spotted owl.

As described in detail in Appendix C, we selected the GNN vegetation database for a number of reasons; most importantly it is the layer developed for use in the Northwest Forest Plan monitoring program. In addition, it is the only vegetation layer available that covers all land ownerships across the entire range of the northern spotted owl. Past efforts to model, map, and quantify habitat selection by northern spotted owls at regional scales have often suffered from lack of important vegetation variables, inadequate spatial coverage, or coarse resolution of available vegetation databases (Davis and Lint 2005). To develop rangewide models of relative habitat suitability for northern spotted owls, we required maps of forest composition and structure of sufficient accuracy to allow discrimination of attributes used for nesting, roosting, and foraging by northern spotted owls (the essential physical or biological features). GNN, developed for the NWFP's effectiveness monitoring program, provides detailed maps of forest composition and structural attributes for all lands within the NWFP area (coextensive with the range of the northern spotted owl). Although the GNN approach is a method for predictive vegetation mapping, it is based on input of empirical forest attribute data from inventory plots (Forest Inventory and Analysis, current vegetation analysis, etc.) and modeled relationships between plots and predictor variables from Landsat thematic mapper imagery, climatic variables, topographic variables, and soil parent materials.

The GNN maps come with a large suite of diagnostics detailing map quality and accuracy; these are contained in model region-specific accuracy assessment reports available at the LEMMA Web site (*http://www.fsl.orstu.edu/lemma/*). Accuracy assessments apply to the GNN model(s), rather than the satellite imagery. We provide Pearson correlation coefficients of GNN structural variables used in Table C–1 of the Revised Recovery Plan (USFWS 2011, pp. C–18 to C–19), and local accuracy assessments (kappa coefficients) for individual species' variables in Table C–2. For developing models of northern spotted owl habitat, we generally selected GNN structural variables with plot correlation coefficients greater than 0.5 for an individual modeling region (42 percent had correlation coefficients greater than 0.7). On a few occasions when expert opinion or research results suggested a particular variable might be important, we used variables with plot correlations from 0.31 to 0.5. For species composition variables, we attempted to use only variables with kappas greater than 0.3. However, because we combined species' variables into groups that expert opinion and research suggested may represent influent community types, we occasionally accepted variables with kappas greater than 0.2 and less than 0.3 for individual variables within a group.

The GNN vegetation database was specifically developed for mid-to large-scale spatial analysis, suggesting that accuracies at the 30-m pixel scale may be less influential to results obtained at larger scales. Because we were interested in the utility of GNN at our analysis area (500 ac (200 ha)) spatial scale, we additionally conducted less formal assessments where we compared the distribution of GNN variable values at a large sample of actual locations (known northern spotted owl nest sites and foraging sites) to published estimates of those variables at the same scale. In addition, we received comparisons of GNN maps to a number of local plot-based vegetation maps prepared by various field personnel. Based on these informal evaluations, we determined that GNN represents a dramatic improvement over past vegetation databases used for modeling and evaluating northern spotted owl habitat, and used GNN maps as the vegetation data for our habitat modeling.

Our primary objective in Step 1 of the modeling process was to develop MaxEnt models that perform well at predicting northern spotted owl habitat by developing models that had good discrimination ability, were well calibrated, were robust, and had good generality. Our detailed evaluations of model performance, cross-validation, and comparison with independent data sets (described in pages C–30 to C–41 in Appendix C of the Revised Recovery Plan) demonstrate that at the scale MaxEnt models were developed and evaluated, we met these objectives. Acknowledging that all vegetation databases will exhibit some degree of error, if the GNN layer was inadequate for predicting northern spotted owl habitat, we would not expect the reliable predictive models that we obtained. Thus, as described above, given our data needs, we believe the GNN database represents the best available information for the purposes of identifying critical habitat for the northern spotted owl. We are unaware of any alternative existing scientific information, and no viable suggestions were offered by reviewers or commenters.

Comment (20): One reviewer indicated that inaccuracies in the GNN database and inherent problems with MaxEnt probably led to errors with MaxEnt predictions of owl distributions. The reviewer suggested that there is little science to support the assumptions that GNN data for vegetative variables believed to be important to northern spotted owls were equally accurate across modeling regions, and there is little certainty that relevant processes were sufficiently captured so as to reliably predict owl population performance.

Our Response: As noted earlier, no vegetation database will be free of error; the important question is whether the database used is accurate enough to support the intended analysis objectives. We acknowledge that there may be some errors in the GNN database, yet the MaxEnt models we developed performed very well at predicting habitat suitability for northern spotted owls (one would not expect reliable predictive models if the underlying databases were highly inaccurate—one would expect poorly performing models). Our evaluation of the MaxEnt models developed indicate that the models for all modeling regions were well calibrated and showed quite similar patterns in terms of strength of selection (Figure C–5, USFWS 2011). Cross-validation results showed that all models were robust (i.e., equally accurate when applied to different subsets of the spotted owl sample; USFWS 2011, Table C–19), and comparison of model results with independent test data showed the models had good ability to predict known northern spotted owl locations (USFWS 2011, Table C–20). Overall, these evaluations suggest our models of relative habitat suitability were robust and have good generality (are good at predicting northern spotted owl habitat in areas other than areas that provided the data for development of the model). As detailed in our response to *0* based on our data needs, accuracy assessments, and independent verification, amongst other information, we believe the GNN database represents the best available scientific data for our purposes.

We are uncertain about what ''inherent problems with MaxEnt'' the reviewer may be referring to; MaxEnt has been thoroughly evaluated in the scientific literature and found to perform very well for predicting species distributions and habitat suitability. Peer-reviewed papers by Elith *et al.* (2006), Wisz *et al.* (2008), Graham *et al.* (2008), Phillips *et al.* (2009), and Willems and Hill (2009) all compared MaxEnt to other modeling tools on identical data sets (sometimes hundreds of species), sample sizes, and geographic areas. MaxEnt always performed very well and was consistently a top-performing model. Based on the accurate performance of the model and the thorough, independent scientific evaluations of MaxEnt on a number of taxa, geographic regions, and sample sizes, we believe we have utilized the best available scientific information to model habitat suitability for the northern spotted owl. We note that 13 out of the 15 peer reviewers agreed that the use of MaxEnt was appropriate for our purposes.

Comment (21): One reviewer stated that although the Service claimed in the proposed rule that the modeling process defined areas that contain the physical and biological features essential for conservation of the species, that in reality MaxEnt provides no scientific support for the PCEs described in the proposed rule, and the proposed rule cites no other scientific basis for them. The reviewer indicates that MaxEnt simply ranks pixels in an area based on the ''best'' habitat definition supplied to it, and that the habitat definitions chosen by MaxEnt do not represent what the spotted owl needs and do not delineate the physical or biological features essential for the conservation of the species.

Our Response: The comment mischaracterizes the relationship between our habitat modeling and the identification of PCEs for the northern spotted owl. We did not use the habitat modeling to define the PCEs for the species. As stated in the proposed rule (March 8, 2012; 77 FR 14062, p. 14082), and reiterated in this rule, the physical or biological features essential to the conservation of the species (and associated primary constituent elements (PCEs)) of critical habitat for the northern spotted owl, are identified based on ''* * * studies of the habitat, ecology, and life history of the species as described in the final listing rule published in the **Federal Register** on June 26, 1990 (55 FR 26114), the Revised Recovery Plan for the Northern Spotted Owl released on June 30, 2011, the Background section of this proposal, and the following information.'' The following section of the proposed rule, titled Physical or Biological Features, provided an expansive discussion of the scientific basis for the identification of the essential physical or biological features of critical habitat for the northern spotted owl, accompanied by numerous supporting citations from the scientific literature, which informed our description of the PCEs. The modeling was not used to describe the PCEs of critical habitat; rather, it was used to identify the areas most likely to contain the PCEs and the areas most likely to have been occupied by northern spotted owls based on habitat suitability at the time of listing, as well as identify the specific areas essential to the conservation of the species. This is an important distinction. The habitat models were constructed from a rigorous assessment of current knowledge of the physical and biological features that influence northern spotted owl habitat suitability, and are supported by a solid scientific basis. We recognize that there may have been some poorly worded statements in the proposed rule that led to some confusion regarding the intersection of the PCEs and the modeling framework. We have clarified the language in this final rule to make it clear that we did not use models to define the PCEs for the northern spotted owl, but that we used the PCEs to develop maps of relative habitat suitability across the range of the northern spotted owl as one step in the identification of critical habitat for the species.

Comment (22): One reviewer recommended that the Service: (a) evaluate the rate at which MaxEnt may misclassify locations that do not contain spotted owls; and (b) provide evidence that MaxEnt accurately incorporates the factors that reflect the best environmental conditions for optimal population performance among northern spotted owls.

Our Response: Our models were developed to identify areas likely occupied at the time of listing based on relative habitat suitability (RHS), not to identify areas that do not contain owls. Furthermore, the presence of owls on territories can vary across space and time. There any many possible reasons that an organism (northern spotted owl in this case) may not occupy apparently suitable habitat for a period of time (e.g., death, competition, population is not at equilibrium with its environment). We did not use the RHS values to predict the number of years a site would be occupied or the reproductive rates at territories. The RHS layers we developed have been subjected to rigorous cross-validation and testing with independent data, as explained in Appendix C of the Revised Recovery Plan (USFWS 2011). Our assessment of the estimated on-the-ground conditions at high, intermediate, and low RHS values corresponds very closely to the published literature on northern spotted owl habitat use and selection, thus addressing (b). See also our responses to *Comments (19), (20),* and *(21),* among others.

Comment (23): One reviewer stated that comparisons with other evaluations of northern spotted owl habitat demonstrate the flaws in the modeling. In comparison with NWFP land use allocations, the modeling process includes 2.7 million ac (1.1 million ha) of lands that, up until now, had not been viewed as being needed for the recovery of the spotted owl. Overlaying the proposed critical habitat designation with USDA Pacific Northwest Research Station's 2011 data on old growth forests shows that only 36 percent of proposed critical habitat comprises late-successional old growth forest. Overlaying the proposed designation with USDA Pacific Northwest Research Station's 2011 report allocating spotted owl habitat into unsuitable, marginal, suitable and highly suitable shows that 50 percent of proposed critical habitat is either unsuitable or marginal habitat, and only 24 percent of the acres are classified as highly suitable.

Our Response: The designation of critical habitat is guided by the statutory language of the Act, and is highly species-specific in terms of its direction to identify specific areas that provide the physical or biological features essential to the conservation of the listed species in question—in this case, the northern spotted owl. Late-successional reserves under the NWFP, on the other hand, were established for the conservation of multiple species of varying taxa (birds, mammals, amphibians, fishes, etc.) and, in some areas, encompass forest types not used by northern spotted owls. For these reasons, the comparison of critical habitat with NWFP land use allocations is inappropriate, because they are intended to serve different purposes. The 2.7 million ac (1.1 million ha) of lands the reviewer refers to are presumably the congressionally reserved natural areas (wilderness areas and national parks) that are now excluded in this designation. These lands have consistently been viewed as essential to the recovery of the northern spotted owl since the species was listed. However, they were not included in previous designations due to our interpretation of the definition of critical habitat under section 3(5)(A) of the Act at that time and because their current classification and management was deemed adequate to meet northern spotted owl conservation goals. A primary purpose of these congressionally reserved natural areas is to conserve natural systems, including threatened and endangered species and their habitats, including the northern spotted owl. These areas are managed consistent with the conservation of the northern spotted owl, and we could find no benefit of inclusion that would outweigh the potential administrative costs associated with the designation of critical habitat on these lands.

Based on our modeling process, we found that northern spotted owl population performance under a habitat network represented by the 1994 NWFP was relatively poor compared with several other reserve designs (Dunk *et al.* 2012b). This result is not surprising considering the influence of barred owls and continued habitat loss to wildfire. Similarly, the results of this commenter's comparison of proposed critical habitat to maps of old growth forest and the nesting habitat model from the 2011 NWFP monitoring report would be anticipated, because the NWFP models represent only a portion of the habitat elements and spatial extent used by northern spotted owls. In particular, the classification of habitat into unsuitable, marginal, suitable, and highly suitable pertains only to forest structure used for nesting at the pixel scale, whereas our models are based on landscape-level habitat selection and incorporate the broader array of habitats used by northern spotted owls (including non-old growth). We believe the commenter is attempting to make ''apples and oranges'' type comparisons of habitat, and for the reasons described above, we disagree with the statement that such comparison demonstrate flaws in our modeling.

Comment (24): One reviewer stated that the Zonation model was not designed to develop a conservation network and that this model does not make a judgment as to what is essential for the conservation of the species. As characterized by the reviewer, Zonation does not use the presence or absence of PCEs as input so it does not show where the PCEs are essential. According to the reviewer, what it does is take the relative habitat suitability index of the MaxEnt model (which itself does not depict the presence or absence of PCEs), further smooth them by assigning new values at the home range size of 3,424 ac, (1,386 ha) and determines how little land is required to capture some percent of habitat values based on the parameters provided by the Service. It does this by removing the areas with the lowest habitat values first until the specified percentage of the habitat values are left. The reviewer contends that the Service used Zonation outputs that captured 70 percent of the habitat values as the basis for the proposed revision of critical habitat, and that this in no way supports the premise that these areas are essential for the conservation of the species. The reviewer claims that Zonation only shows a computer's calculation of the minimum amount of land needed to encompass 70 percent of the habitat value, which is a purely artificial data point created from smoothed indices of a relative habitat suitability index based on biased spotted owl locations overlaid on a hypothetical landscape using conglomerated data. The reviewer states there is no way to determine if the areas captured by these solutions actually contain the PCEs, and the Service has no idea how accurate the model is in predicting use by spotted owls.

Our Response: We disagree with the reviewer's statement in that it mischaracterizes the intended purpose of Zonation, the way the model works, and how the Service used it. The Zonation model was designed specifically for the purpose of developing conservation networks (Moilanen and Kojala 2008). However, we did not simply employ the Zonation model to provide a critical habitat network. As described in our response to *Comment (21*), and as detailed at length in our Modeling Supplement (Dunk *et al.* 2012b), we used the PCEs for the northern spotted owl to develop maps of relative habitat suitability for the species across its range; this step then informed the development of the spotted owl habitat conservation planning model (Zonation), thus the presence of PCEs is the foundation of the entire habitat modeling framework, and is fundamental to our identification of critical habitat for the northern spotted owl. We used Zonation to provide a series of alternative networks that were then compared in terms of relative simulated spotted owl population performance (using HexSim). After comparing a wide range of Zonation-derived scenarios, the top-performing alternatives for each modeling region were assembled into composite maps for further evaluation in HexSim. Development of composite maps also involved modification of reserve designs based on expert opinion and policy. In many modeling regions, the proposed critical habitat deviates substantially from the strictly Zonation-derived reserve designs, because use of the modeling was only one step in the process of identifying critical habitat. Finally, the Service verified that the resulting proposed critical habitat met the statutory criteria of critical habitat by evaluating the proportion of proposed critical habitat that was occupied by known northern spotted owl home ranges at the time of listing and that provides the essential physical or biological features, and by evaluating any areas that may have been unoccupied at the time of listing to determine whether they are essential to the conservation of the species. In addition, to address any uncertainty regarding occupancy, we evaluated all of the critical habitat under the higher standard of section 3(5)(a)(ii) of the Act. Please see Criteria Used to Identify Critical Habitat for further information.

Comment (25): One reviewer stated that the process used by the Service to define what constitutes nesting, roosting, and foraging habitats in the proposed rule produced results in staggering differences compared to historical definitions. According to this reviewer, not only are they totally different from what has been viewed as valid definitions for almost 20 years, but they are also totally unrecognizable on the ground. The reviewer claims the proposed rule utilizes habitat definitions derived from analysis of the hypothetical GNN–LT vegetation layer coupled with abiotic factors, which only make sense in computer modeling. The reviewer states that MaxEnt does not use these definitions to identify NRF (nesting/roosting/foraging) habitat but rather assigns an RHS value based on how many of the factors are present. Finally, the reviewer says that the Service claims to be using these factors to determine if stands contain the PCEs when, in fact, they do not.

Our Response: We are unsure of the basis for this comment, since the definitions of nesting, roosting (NR) and foraging (F) habitats used in this critical habitat rule are very similar to definitions used in past assessments, including previous designations of critical habitat for the northern spotted owl, and the definitions we use are based primarily on the information found in the published scientific literature. In fact, all NR and F models tested were derived from literature reviews and expert opinion, including input from timber industry scientists and managers. The relative habitat suitability models incorporate these NR and F definitions (submodels), as well as broader environmental features such as elevation and slope position, that are also well-described in the northern spotted owl literature. The remainder of the comment mischaracterizes our habitat suitability modeling; a thorough explanation of that modeling is found in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011). In addition, please see our response to *Comment (19)* for details on how the PCEs were defined and incorporated into the process of mapping RHS.

Comment (26): One reviewer stated that the Service modified input variables given to HexSim to produce ''composites,'' and the Service cannot show that these contain the PCEs and that they are essential, and there is no statistical difference between the different composites. By only displaying mean values, the reviewer claims the Service creates a false appearance that the difference between these alternatives is real. The Service does not show that the differences result in any real difference in achieving recovery objectives, they merely state it as a matter of fact. This is a misuse of modeling data, the reviewer states, and not best available science.

Our Response: This comment misunderstands the process used to develop composite maps, and the subsequent comparison of HexSim results. Composite maps are maps where different reserve designs were selected for each modeling region based on their ability to achieve recovery goals. These region-specific designs were combined across the range of the owl to create a ''composite map.'' We evaluated composite maps in an iterative manner to identify the design that best met recovery goals and our guiding principles. Composites were not created by modifying HexSim input variables; rather, they represent a range of reserve design alternatives that were subsequently tested in HexSim. Appendix C and Dunk *et al.* (2012b) provide ample evidence that all of the composites contain the physical and biological features used by the owl; comparison of HexSim results is the process by which the Service evaluates what amount and distribution of these features is essential to the conservation of the northern spotted owl. As stated in our proposed rule, this final rule, and in Dunk *et al.* 2012b, we assessed various composites by comparing the relative (emphasis added) performance of various habitat scenarios. That is, we used metrics such as relative differences in extinction risk and population size (which include upper and lower confidence intervals) to evaluate the ability of different composites to achieve recovery objectives for the northern spotted owl. In fact, we expressly stated ''simulations from these models are not meant to be estimates of what will occur in the future, but rather provide information on trends predicted to occur under different network designs'' (March 8, 2012; 77 FR 14062, p. 14097). There were statistically significant differences in population performance, both at the modeling region and range-wide scales among our composites (see Appendix C, USFWS 2011 and the Modeling Supplement (Dunk *et al.* 2012b) for additional details). We therefore disagree with the commenter's claims about misuse of modeling data and best available science.

Comment (27): One reviewer stated that the boundaries of the proposed revision of critical habitat are impossible to identify on the ground. They can only be defined by use of global positioning satellite receivers that have had the boundaries created by the Zonation computer model inputted to them.

Our Response: Critical habitat is defined by the features as discussed in this final critical habitat designation and shown on accompanying maps. Specific coordinates and descriptions that define the boundaries of critical habitat are available online at *http://www.fws.gov/oregonfwo,* at *http://www.regulations.gov* at Docket No. [FWS–R1–ES–2011–0112], and from the Oregon Fish and Wildlife Office (see **FOR FURTHER INFORMATION CONTACT**); maps are available online at *http://criticalhabitat.fws.gov/crithab/.*

Comment (28): One reviewer states that the Service did not use pixel by pixel data, but conglomerated the pixel data into indices that represent the 500-ac (200-ha) circle around each pixel, which increased the error associated with the predictions. The reviewer claims this wipes out all the actual stands that might actually be used by spotted owls and instead assigns each pixel a conglomerate value for each habitat variable based on averages. Therefore, the reviewer asserts there are many areas that do not contain the PCEs.

Our Response: This comment mischaracterizes the method used to evaluate habitat quality, and the basic definition of habitat for northern spotted owls. As described in Appendix C of the Revised Recovery Plan (USFWS 2011), habitat suitability consists of several factors including, but not limited to, the actual forest ''stands'' used by owls. Our relative habitat suitability models are based on the amount, edge, and core of actual stands classified as nesting/roosting habitat and amount of foraging habitat; i.e., the PCEs identified in this rule. We therefore do not ''wipe out'' the actual stands as suggested by the reviewer, but rather measure their relative importance given additional landscape features such as elevation and slope position. This allowed us to better identify the landscape features where owls could establish a viable territory. Simply mapping out ''the actual stands that might be used'' would have provided a highly fragmented habitat network consisting of many ''stands'' not likely to be used by spotted owls. The comment also ignores the fact that we extensively tested the RHS model and found it accurately predicts spotted owl habitat, and we evaluated the proposed critical habitat network and found that the areas proposed were predominantly occupied by known spotted owl sites at the time of listing. See also our responses to *Comment (19)* through *Comment (24).*

Comment (29): One reviewer stated that Phase 1 results suggested that the Redwood Coast modeling region was among the most stable, but questioned how this could be when there are very few remaining northern spotted owls in Redwood National Park, where barred owls are now the predominate species. The reviewer states this was also not reflected in the Phase 2 modeling results (Table 6) (Dunk *et al.* 2012a).

Our Response: We obtained recent (2006) verified northern spotted owl location data from many sources in the Redwood Coast modeling region. These data strongly suggest that the high densities of barred owls observed within Redwood National Park are not occurring in the remainder of the modeling region, where large numbers of northern spotted owl territories persist. We therefore used demographic data from the Green Diamond monitoring study to parameterize (put variables into) HexSim for the region.

Comment (30): One reviewer suggested that we include an appendix that shows each of the decision points in the development of the proposed critical habitat network in systematic detail, and suggested this would be an adequate remedy and make the entire modeling process open and transparent, and repeatable by persons external to this process.

Our Response: We attempted to make explicit the key assumptions and decision points used in the modeling process, and the guiding principles we followed for application of professional judgment in refining reserve networks were included in the proposed rule. Much of what the reviewer asks for is presented in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011). In addition, we have tried to make assumptions and decision points more explicit in our final Modeling Supplement (Dunk *et al.* 2012b) that is available to the public at *http://www.regulations.gov.*

Comment (31): One reviewer suggested that a major flaw in the modeling is that the habitat is held constant for 350 years and any area with an RHS value less than 35 is assumed to be non-habitat. The reviewer states that by holding the habitat constant and not allowing it to grow, the Service greatly overestimates the amount of land needed to reach relative population levels. The reviewer claims this also results in a double standard for areas currently classified by MaxEnt as having low RHS values—in the modeling process they are excluded and not allowed to grow into habitat, yet they are included as critical habitat because the Service claims they will be necessary for population growth.

Our Response: The reviewer misunderstands the method we used to simulate habitat change through time. Habitat was not held constant during the HexSim simulations; we measured the rates of change in habitat quality (RHS) between the 1996 and 2006 GNN layers and projected those rates into the future. This allowed for losses in habitat quality caused by timber harvest, wildfires, and other causes as well as gains due to forest growth to occur through time in a plausible fashion. Because the remainder of this comment is based on this faulty premise, the other points in this comment are, in turn, unfounded.

Comment (32): One reviewer noted that throughout the modeling process, means of the response variables (e.g., Table 8 of Dunk *et al.* 2012a) should be accompanied by either standard errors or 95 percent confidence intervals. Otherwise, the reviewer states, it is difficult to determine how precise these estimates were, especially when comparing different scenarios.

Our Response: We agree, and this was an oversight that we have corrected in the final version of our Modeling Supplement (Dunk *et al.* 2012b).

Comment (33): One reviewer thought more could have been done to evaluate uncertainty in the original habitat suitability models by running replicate samples in MaxEnt and then capturing the range of variation in resulting habitat designations.

Our Response: Table C–19 in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) presents results from the cross-validation results, in terms of performance differences between models based on replicate samples. Those results showed that there was very little difference between the performance of the models when replicate samples were evaluated, giving us confidence in the generality of our model (that is, the model worked reliably well across a range of situations tested).

Comment (34): One reviewer requested additional sensitivity analysis to quantify the influence of different parameter settings within HexSim on modeled population performance, which would have been particularly useful for evaluating the implications of scientific uncertainty.

Our Response: We agree and in the final Modeling Supplement (Dunk *et al.* 2012b) we have incorporated the results of sensitivity analyses conducted on nine HexSim parameters.

Comment (35): One reviewer noted that the original supplement on habitat modeling that accompanied our proposed rule (Dunk *et al.* 2012a) did not report measures of variance in the population estimates or pseudo-extinction thresholds used to compare habitat network scenarios. The reviewer noted that reporting standard errors or ranges of those population estimates would help in the comparison of the efficacy of different network designs.

Our Response: Our failure to report measures of variation in population estimates was an oversight that we have corrected in the Modeling Supplement (Dunk *et al.* 2012b). The estimated extinction risk thresholds that we reported were the total number of simulations in which that threshold was exceeded (i.e., the population fell below the extinction threshold). It would not be appropriate to provide measures of variation around these. The measure itself is interpreted as the ''probability of exceeding pseudo-extinction threshold X.''

Comment (36): One reviewer noted that model results showed that the barred owl encounter rate can have a disproportionately large influence on persistence outcomes of the HexSim model. The reviewer states that the Service evaluated four barred owl scenarios (Dunk *et al.* 2012a), but none of these considered the more critical survival parameter and the major reductions in adult survival that barred owls generate in the model. Thus, the reviewer states that one is unable to assess the relative contributions of barred owl encounter rates versus barred owl survival reductions to persistence of simulated northern spotted owl populations.

Our Response: In the northern spotted owl HexSim model we used, barred owls only affected northern spotted owl survival, not occupancy or reproduction. Thus, the impact of barred owls in HexSim results is only from their reduction of northern spotted owl survival. Based on advice we obtained from species experts, we limited barred owl impacts on northern spotted owls to survival alone. We did not simulate barred owl impacts on reproduction, territory establishment, site fidelity, or movement behavior. We also did not simulate barred owl predation on northern spotted owl nestlings. This recommendation (to simulate barred owl impacts only on northern spotted owl survival) was a reflection of limitations on rangewide data availability regarding these factors.

Comment (37): One reviewer suggested that we allow the barred owl effect in the HexSim model to vary with resource acquisition class. For example, the barred owl effect on survival might be more severe when an owl is in the ''low'' resource class but incrementally reduced in the medium and high resource classes (i.e., as resources become less limiting so do the negative effects of competition with barred owls).

Our Response: Resource acquisition classes are a component of the HexSim model. In the model, resources available to an owl are a function of the mean RHS value of habitat within its home range and fall into three categories: High, medium, or low (USFWS 2011, p. C–60). This is a good suggestion, and could potentially help refine the HexSim model for the northern spotted owl. It would not, however, improve the model's ability to identify those specific areas that contain the physical or biological features essential to the conservation of the northern spotted owl, or that are essential to the conservation of the species (section

3(5)(a) of the Act). The relative performance of various composite potential critical habitat networks would be unlikely to change if we were to change the analysis as the reviewer suggests, because the proposed change would affect all potential critical habitat networks in the same way. The relative performance of the habitat networks under consideration, which is what we were able to assess (as opposed to absolute outcomes), would therefore remain the same, and our ultimate determination of the critical habitat network that provides what is essential to the conservation of the northern spotted owl in the most efficient design would be unchanged.

Comment (38): One reviewer suggested that modeling of habitat networks should incorporate more realistic encounter rates between northern spotted owls and barred owls, so that estimates of sustainability of northern spotted owl populations are not overly optimistic.

Our Response: As we have noted in both the proposed rule and this rule, the designation of critical habitat is only one of many conservation actions that may contribute to the recovery of the northern spotted owl. The designation of critical habitat is intended to help address habitat-based threats to a listed species; it is not expected to independently lead to recovery absent other actions to ameliorate additional, non-habitat based threats. We are also bound, however, by the statutory definition of critical habitat, which requires that we identify those areas that provide the physical or biological features essential to the conservation of the species, or are otherwise essential (if not occupied at the time of listing). The task of identifying where on the landscape these essential areas lay was complicated by the barred owl, a non-habitat based threat. In some cases, the negative influence of the barred owl on the simulated performance of our modeled northern spotted owl populations completely masked the potential contribution of varying areas of relative habitat suitability, thus rendering it impossible to determine which specific areas provide the essential physical or biological features. Our HexSim modeling suggested that if barred owl encounter rates within each modeling region were to be maintained at their currently estimated rates (from Forsman *et al.* 2011), there was little variation in northern spotted owl population performance among any of the potential critical habitat networks (even doubling the size of the habitat network produced no discernible difference). The only avenue that allowed us to discriminate between potential networks and isolate and evaluate the contribution of specific areas of habitat that are essential to the conservation of the northern spotted owl, as directed by the statute, was to adjust the encounter rates with barred owls to some reasonable level, as might potentially be achieved through management actions. This harkens back to our statement earlier that we do not assume critical habitat will provide for the recovery of the species in a vacuum; rather, we must assume that other recovery actions will occur in coincidence with the protections provided by critical habitat. We assumed changes in barred owl encounter probabilities in our comparisons of potential critical habitat networks that, in our judgment, represented changes that could realistically be achieved with management aimed at reducing encounter rates (and without prescribing the nature of that management). In most cases, only relatively modest changes to the currently estimated encounter probabilities between barred owls and northern spotted owls were required to allow us to discern the underlying differences between varying habitat network designs, and to enable the identification of the specific areas essential to the conservation of the species. In fact, for Phase 2 and 3 modeling (MaxEnt and HexSim; see Dunk *et al.* 2012b for details), we decreased barred owl encounter probabilities in only 3 of 11 modeling regions, and increased encounter probabilities in 8 of 11 modeling regions. The mean absolute value of change (from currently estimated encounter probabilities to what we assumed in Phases 2 and 3) among modeling regions was 0.081 (range = 0.005 (in the KLE) to 0.335 (in the OCR)). Our population performance results do not suggest that the habitat scenarios considered were overly optimistic in regard to sustainability of northern spotted owl populations (Dunk *et al.* 2012b).

Comment (39): One reviewer suggested incorporating the relative probability of controlling barred owls as part of the designation of various critical habitat units. The reviewer noted that to be able to assess habitat factors in the modeling process, the barred owl effect had to be set below known values in selected areas, suggesting that these designated critical habitat units will not contribute to northern spotted owl conservation in the absence of barred owl control. The reviewer further stated that the apparent sensitivity of the HexSim model to the barred owl covariate indicates that barred owl management will be the overriding factor in the success of critical habitat being able to achieve the northern spotted owl recovery goals. The reviewer suggested that if the Service wants to capture uncertainty in this modeling exercise, the probability of controlling barred owl numbers should be factored into the modeling process based on logistical, ownership, and social factors.

Our Response: We agree with the reviewer's suggestions in theory. However, we are unaware of currently available scientific information that would enable us to reliably estimate the influence of ''logistical, ownership, and social factors'' on the probability of effective barred owl control across the range of the northern spotted owl (over 50 million ac (20 million ha)). Lacking any such specific data, such exercise would be arbitrary and speculative, and would likely introduce greater uncertainty into the modeling. We appreciate that the reviewer recognizes the sensitivity of the model to barred owl encounter rates, and the reason why we had to make slight adjustments to those rates in some areas to identify critical habitat for the northern spotted owl (see our response to *Comment (38),* above).

Comment (40): One reviewer indicated that basing the demographic trends on the last meta-analysis (Forsman *et al.* 2011) is overly optimistic since these results are already badly outdated. The reviewer states that the last meta-analysis was conducted after the 2008 field season, with survival rates estimated through 2007 and realized rate of population change through 2006. The reviewer states that, according to personal communications with researchers in other demographic study areas, many of the study areas shown as stable in the 2008 meta-analysis are now in precipitous decline due to rapid increases in barred owl populations. The reviewers suggests that, although it would only be qualitative, the Service could contact the leads from the various northern spotted owl demographic study areas to see if there have been substantial changes in barred owl versus northern spotted owl numbers.

Our Response: This is a good point, and we heard similar comments from several field researchers and principal investigators of the northern spotted owl demographic studies. In Step 3 of the modeling process, we obtained the most recent annual reports from the demographic study areas and evaluated the more recent estimates of barred owl densities, and included a scenario representing high barred owl densities such as those described in this comment. Because we used more recent estimates of barred owl encounter rates, spotted owl population trends simulated in HexSim showed a more rapid decline than that estimated in the recent meta-analysis; this was especially evident in the Tyee demographic study area. We therefore believe that our modeling process incorporated the idea expressed in this comment.

Comment (41): One reviewer indicated that bounding experiments with HexSim are needed to suggest the sort of spatial, temporal, and population controls that may be needed for the barred owls to create a high likelihood of success for critical habitat. The reviewer suggests the Service has thus far determined the barred owl encounter rates that were needed to achieve reasonably stable northern spotted owl population dynamics.

Our Response: This is a good suggestion, but not necessary to identify lands meeting the definition of critical habitat. Because we evaluated northern spotted owl population performance across a gradient of barred owl encounter probabilities ranging from 0.0 to 0.7, our modeling already revealed that northern spotted owls are likely to do very poorly at high barred owl encounter probabilities. This provided a general understanding of the influence of various barred owl encounter rates and demonstrated the range of values (bounds) where population performance that met recovery criteria was possible. This is why we set 0.375 as a ceiling to barred owl encounter probabilities. The reviewer's suggestion is more relevant to the specifics of potential barred owl control efforts, such as have been recommended by the Revised Recovery Plan on an experimental basis (USFWS 2011). The Service is currently considering such efforts and has published an environmental impact statement on experimental barred owl removal options. That is a separate recovery effort, however, is not connected to this rulemaking.

Comment (42): Several reviewers expressed concern that the way that barred owl encounters were represented in the model as homogeneous probabilistic reductions in northern spotted owl survival may fail to capture important spatial patterns of interaction between the species within subregions, and it may overestimate (one reviewer) or underestimate (second reviewer) the negative impacts of barred owls on northern spotted owl population persistence. The reviewers suggested the uncertainty surrounding the specific impacts of barred owls, and the analysis in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl further justify the need for an intensive barred owl removal experiment to understand the overall impact that barred owls are having on northern spotted owls.

Our Response: This point is well taken by the Service. As the reviewer mentioned, ''empirical information required for a realistic representation of barred owl interaction effects across the range of the northern spotted owl is not available at this time.'' The Service did evaluate several different barred owl encounter probabilities, which largely differed among the 11 modeling regions, but were identical within modeling regions. The modeling framework we used is capable of including a spatially explicit barred owl effect, if such specific data should become available. Given the uncertainties about variation in barred owl impacts within modeling regions, it is possible that our modeling overestimated or underestimated negative barred owl impacts. However, because we used HexSim to compare relative population performance among alternative potential critical habitat networks, and used the best available estimates of barred owl effects, we believe the representation of barred owl impacts we used allowed us to accurately evaluate which networks, on a comparative basis, best met the objectives in our guiding principles for identifying lands meeting the definition of critical habitat for the northern spotted owl.

Comment (43): One reviewer believed that the HexSim model was not an appropriate choice for this modeling process because the reviewer indicated it was overly complex, too individually based, and included variables where there was no, little, or very incomplete data, such as territory searching behavior, and floater dynamics, etc. In addition, the reviewer expressed skepticism that the modeling approach used would be repeatable, because of its complexity.

Our Response: We disagree. We have articulated our rationale for using the HexSim model in Appendix C to the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011, pp. C–53–C–56) and again in our Modeling Supplement (Dunk *et al.* 2012b). We acknowledge that there are many possible approaches to identifying and evaluating alternative potential critical habitat networks. However, we contend that our approach represents the best available science and is appropriate for identifying areas meeting the definition of critical habitat because it enabled us to evaluate numerous possible networks of habitat and compare simulated population responses of northern spotted owls to environmental conditions in a spatially-explicit manner that enabled us to determine those areas that meet the definition of critical habitat for the species. Our approach is detailed in the section Criteria Used to Identify Critical Habitat, but in brief, the use of HexSim enabled us to evaluate which of the habitat scenarios under consideration had the greatest potential to meet the recovery objectives for the northern spotted owl, based on relative population performance.

To identify the areas that meet the definition of critical habitat for the northern spotted owl, we elected to use a spatially explicit, individual-based modeling approach. We did so because we required an approach that enabled comparison of a wide range of spatially explicit conditions such as variation in habitat conservation networks. Individual-based models allow for the representation of ecological systems in a manner consistent with the way ecologists view such systems as operating. That is, emergent properties such as population increases or declines are the result of a series of effects and interactions operating at the scale of individuals. Individuals select habitat based on what is available to them, disperse as a function of their individual circumstance (age), compete for resources, etc.

Grimm and Railsback (2005) noted that individual-based models need to be simple enough to be practical, but have enough resolution to capture essential structures and processes. We are fortunate to have a tremendous quantity and quality of data available for the northern spotted owl; the species is therefore ideally suited for a spatially-explicit, individual-based model, such as HexSim. While not developed specifically for the northern spotted owl, HexSim (Schumaker 2011) was designed to simulate a population's response to changing on-the-ground conditions by considering how those conditions influence an organism's survival, reproduction, and ability to move around a landscape. We developed a HexSim spotted owl scenario based on the most up-to date demographic data available on spotted owls (Forsman *et al.* 2011), published information on spotted owl dispersal and home range sizes, as well as a variety of other parameters. Evaluation and calibration of the HexSim output included comparison with owl numbers in demographic study areas and dispersal histograms. Based on our assessment of the model, we are confident it performs as intended, in terms of allowing us to reliably assess the relative performance of alternative habitat conservation networks. We further note that the majority of peer reviewers supported the modeling framework we applied in the identification of critical habitat for the northern spotted owl.

Comments on Active Forest Management

Comment (44): Five peer reviewers and numerous public commenters indicated that active forest management should be conducted in areas that are not currently high value for northern spotted owls and in an adaptive management framework given the uncertainties regarding how such management practices will impact northern spotted owls and their prey.

Our Response: The Service expects to support and design, in concert with the BLM, USFS, and researchers, scientific studies on the effects of ecological forestry projects in northern spotted owl critical habitat, to gain a better understanding of the short-term and long-term impacts of these silvicultural treatments on northern spotted owls, their prey and forest vegetative structure. We are currently designing and funding just such a study through Oregon State University for the pilot project in the Middle Applegate Watershed. We expect these types of research studies to inform the design of future ecological forestry projects within the range of the northern spotted owl.

A key difference between using active adaptive forest management to evaluate risks associated with ecological forestry and the Service's ongoing efforts to address risks associated with expanding barred owl populations is that, for barred owls, a single experiment has the potential to address many of the most important uncertainties pertinent to future management, allowing the Service to define a schedule for progress. Addressing uncertainties about ecological forestry will likely require multiple research efforts, each tailored to specifics of different geographic areas and different ecological interactions. Collaboration among programs, similar to the collaboration supporting long-term demographic studies of northern spotted owls, will likely be needed to conduct adaptive management studies of habitat treatments. Integrative initiatives, such as the USFS's Collaborative Forest Landscape Restoration Program, may also play an important role. Adaptive management of ecological forestry techniques will take time, and will require continuation of the ongoing dialogue between researchers and forest management practitioners regarding how to simultaneously meet the goals of forest restoration and northern spotted owl conservation. Coordination among research projects also will be essential to generating reliable information about diverse interactions as efficiently as possible.

Comment (45): One reviewer and a public comment suggested that the emphasis of management within northern spotted owl critical habitat should be on ecological restoration rather than ecological forestry.

Our Response: In general, in northern spotted owl critical habitat, we would like to see land managers consider activities to restore and maintain northern spotted owl habitat and the natural ecological processes (e.g., fire regime, natural vegetational succession patterns, etc.) of the owl's forest ecosystems. However, we also recognize that ecological restoration, in and of itself, is often not the management goal of all lands included in critical habitat. This critical habitat rule does not dictate what land managers do on Federal State, or private lands. However, in areas where land managers are considering competing land management goals (e.g., northern spotted owl habitat conservation vs. commercial timber harvest), we encourage them to consider an ecological forestry approach to better meet the needs of the northern spotted owl, the goals of the land managers, and long-term forest health. As described in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), the field of ''ecological forestry'' is emerging as a dominant paradigm of forest management; related to this emergence are concepts such as ''natural disturbance emulation'' and ''retention forestry'' (see, e.g., Gustafsson *et al.* 2012, entire; Franklin *et al.* 2007, entire; Kuuluvainen and Grenfell 2012, entire; North and Keeton 2008; Long 2009, entire; Lindenmayer *et al.* 2012; entire). The Service believes that application of these ecological forestry goals and principles, including those generally described in Johnson and Franklin (2009, entire; 2012, entire), may result, in some situations, in fewer adverse impacts to northern spotted owl critical habitat when compared to application of traditional silviculture as currently applied or permitted on private, State, and Federal matrix lands.

Comment (46): Several reviewers commented that studies have demonstrated negative effects of forest thinning on northern spotted owls and their prey, and expressed concern that negative effects of these practices may be further exacerbated by barred owls. These reviewers were uneasy with such types of activities occurring near owl territories, and recommended that if conducted, these actions be done at small scales and be subject to rigorous scientific scrutiny.

Our Response: We are not recommending that commercial thinning or other treatments be conducted near active owl territories or in good quality owl habitat. We also encourage an active adaptive forest management approach to improve the understanding about effects of ecological forestry approaches on northern spotted owl, barred owls, and other species of concern.

Comment (47): Three reviewers recommended that we give full consideration to recent publications of Hessburg *et al.* (2007) and Baker (2012) for guidance on how to restore and manage dry forests in the eastern Cascades.

Our Response: Both this final critical habitat rule and the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) cite Hessburg *et al.* (2007, p. 21), and we continue to recommend land managers consider their findings and recommendations regarding dry forest management within the range of the northern spotted owl. Since publication of the proposed critical habitat rule, we have reviewed Baker (2012, entire) as well as many other recently published studies addressing forest health and the risk of wildfire in the Pacific Northwest. We acknowledge some of the conclusions of Baker (2012, p. 21) and Williams and Baker (2012, p. 9) that portions of the dry forests of the Pacific Northwest experienced high-severity fires as well as mixed and low-severity fires. However, we also acknowledge the conclusions of many other researchers that large areas within the range of the owl that once burned frequently with low-moderate intensity regimes are currently outside of historical conditions (cited below). A variety of management measures (e.g., prescribed fire, mechanical treatment, etc.) can be considered in such areas where the goal is to influence wildfires to reduce adverse impacts of climate change, manage forest carbon levels, reduce fire severity and retain desirable forest conditions (i.e., conserve older trees), or protect high-value wildlife habitats (including northern spotted owls), riparian areas, and biodiversity (Davis *et al.* 2012, entire; Stephens *et al.* 2009, p.310–318; Stephens *et al.* 2012a, p. 12; Stephens *et al.* 2012b, entire; Chmura *et al.* 2012, p. 1134; Syphard *et al.* 2011,

p. 381; Safford *et al.* 2012, pp. 26–27; Roloff *et al.* 2012, pp. 7–9, Roberts *et al.* 2011, p. 617, Messier *et al.* 2012, pp. 67–70; Franklin *et al.* 2008, p. 46; Ager *et al.* 2007, pp. 53–55).

Such management considerations are completely consistent with the intent of the NWFP (Standards and Guidelines, p. C–12—C–13). We continue to recommend that land managers carefully distinguish and target areas that are high priority for ecological restoration (e.g., Franklin *et al.* 2008, p. 46; Schoennagel and Nelson 2011, entire; Ager *et al.* 2012, p. 280), and that they also minimize short-term impacts to northern spotted owls to the greatest possible extent. We suggest using a process such as provided by Spies *et al.* (2012, entire) to help prioritize actions and consider tradeoffs such as northern spotted owl conservation, restoration of ecological conditions, and other land management goals. Given the wide geographic area of this critical habitat designation and the variety of landscape conditions and fire regimes, more precise planning and implementation should be done at the appropriate landscape scales such as the National Forest scale, consistent with the goals of the Northwest Forest Plan.

Comment (48): One reviewer and a public comment recommended that the Johnson and Franklin (2009) ecological forestry framework should not be used because it is based on the wrong reference framework.

Our Response: While we recognize that there is some scientific disagreement about the specific ecological forestry practices recommended by Drs. Johnson and Franklin,we believe the commenters may have misinterpreted our references to this unpublished report. First, Johnson and Franklin (2009) is only referenced three times in the final critical habitat rule: Once as a general reference for ecological forestry, once in relation to how active management is generally not necessary to maintain old growth conditions in moist forests, and again to highlight that alteration of fuel loads in moist forest could have undesirable ecological consequences and thus should be discouraged. Second, we continue to encourage forest land managers to consider the application of ecological forestry principles to their commercial timber harvest (see response to peer review question 4a-c, above), and we believe that application of these principles in many instances may result in better long-term ecological conditions for northern spotted owls and other forest wildlife when compared to the application of traditional silviculture methods. The methods presented by Johnson and Franklin (2009) are one example of how ecological forestry can be applied. We recognize that there are a variety of approaches, and the best management practices for any area are highly dependent on site-specific conditions.

Comment (49): One reviewer recommended a zoning process for determining where active management would be appropriate. Such a zoning process would include identification of areas where management is not needed or should be avoided, areas where future habitat could be enhanced by treatment, and areas where management is needed to meet broader landscape goals. In addition, monitoring and reporting of progress towards desired goals is essential if this strategy is to be successful.

Our Response: The Service supports the concept of land managers identifying areas where active management would be appropriate on the lands under their jurisdiction. However, it is not appropriate for this critical habitat rule to attempt to do this; it should be done by land managers consistent with their planning procedures. As the reviewer also suggested, these details will need to be worked out at regional scales and planning levels (see response to peer review comment 4, above). Several examples of strategies for prioritizing landscapes for management treatment in eastern Washington include Davis *et al.* (2012, entire) and Franklin *et al.* (2008, pg. 46).

Comment (50): One reviewer encouraged the Service to recognize the highly transient nature of grand fir on the eastern Cascades.

Our Response: We have recognized this in the rule. While we did not explicitly identify all forest types in all regions, we have recognized the patchy and transient nature of east Cascades forests.

Comment (51): One reviewer asked that we identify which (specific) ecological processes will be enhanced by management and how management will be coordinated across large landscapes.

Our Response: We agree that additional guidance and coordination among management agencies would be helpful to coordinate landscape-level planning; however, such guidance and coordination is beyond the scope of this rulemaking. To the extent possible we have provided additional detail regarding restoration and management of ecological processes in revisions to the following sections of this rule: *An Ecosystem-based Approach to the Conservation of the Northern Spotted Owl and Managing Its Critical Habitat, Special Management Considerations or Protections,* and *Determination of Adverse Effects and Application of the ''Adverse Modification'' Standard.*

Comment (52): There were a number of general comments about analysis of fire risk and ecological benefits of contemporary fire regimes in dry and mixed-severity forests.

Our Response: The issue of forest health and fire risk in the Pacific Northwest is complex, and there is a wide variety of legitimate scientific viewpoints on forest management in the face of uncertainty. Although some scientists do not believe management intervention is appropriate and advocate a mostly passive (i.e., hands-off) approach to forest ecosystem management, many others believe science-based intervention is necessary to restore and maintain important ecological processes and components of biodiversity, including the northern spotted owl.

We agree with the majority of scientists who suggest that forest ecosystems at global, national, and regional levels are undergoing significant changes due to climate change and past management activities (Collins *et al.* 2012, pp. 8–12; Miller *et al.,* 2012, p. 201; Miller *et al.,* 2009, p. 28; Moritz *et al.* 2012, entire; Westerling *et al.* 2011, p. S459; Marlon *et al.* 2012, p. E541). Impacts from wildfire, changes in precipitation, insect and invasive weed outbreaks, and forest disease appear to be increasing when compared to historic patterns and are putting some components of native biodiversity at risk (Perry *et al.* 2011, p. 712). Although some researchers disagree on the magnitude of these changes and what to do about them (e.g., Hanson *et al.* 2009, p. 5; Baker 2012, p. 21; Williams and Baker 2012, p. 9; Dillon *et al.* pp. 18–20), our review of the recent scientific literature found that most researchers believe that changes in wildfire frequency, severity, and total burned area are occurring or are expected to varying degrees in the Pacific Northwest. Most of these researchers recommend consideration of certain types of active management responses to achieve goals such as increasing forest resilience to climate change, conserving extant biodiversity, and reducing wildfire severity (e.g., Stephens *et al.* 2009, pp. 316–318; Safford *et al.* 2012, pp. 26–27; Messier *et al.* 2012, p. 69; Hessburg *et al.* 2007, entire; Chmura *et al.* 2012, p. 1134; Stephens *et al.* 2012b, pp. 557–558; Fule *et al.* 2012, p. 76; Halofsky *et al.,* pp. 15–16; Reinhardt *et al.* 2008, pp. 2003–2004; Heyerdahl *et* *al.* 2008, p. 47; Latta *et al.* 2010; Littell *et al.* 2009, pp. 1018–1019, Littell *et al.* 2010, p. 154; Spies *et al.* 2010, entire). Several of these studies identify the potential for degraded ecological conditions and increased fire risk to affect northern spotted owls (Buchanan 2009, pp. 114–115; Healey *et al.* 2008, pp. 1117–1118; Roloff *et al.* 2012, pp. 8–9; Ager *et al.* 2007, pp. 53–55; Ager *et al.* 2012, pp. 279–282; Franklin *et al.* 2009, p. 46; Kennedy and Wimberly 2009, pp. 564–565). We recommend that these issues related to active management in dry forests be considered by Federal land managers as they follow the direction on pages C–12 and C–13 of the Northwest Forest Plan Standards and Guidelines.

Comment (53): One reviewer recommended that the Service prepare a draft environmental impact statement (DEIS) under NEPA with regard to active management in northern spotted owl critical habitat.

Our Response: This rule revises the critical habitat designation for the northern spotted owl by identifying those specific areas that meet the definition of critical habitat for the species. It does not take any action or adopt any policy, plan, or program related to active forest management. The only effect of critical habitat is that Federal agencies must consult with the Service on their activities that may affect designated northern spotted owl critical habitat, and our discussion of active forest management is not intended in any way to prescribe or mandate the types of activities Federal agencies must submit for consultation. It is provided only for Federal, State, local, and private land managers to consider as they make decisions on the management of forest land under their jurisdictions and through their normal processes.

Comment (54): One reviewer criticized the proposed rule for promoting ecological forestry for economic and political reasons rather than basing recommendations on sound science.

Our Response: We disagree. We have included a discussion of ecological forestry principles because, in many instances, it may represent a reasonable and solid scientific approach to managing forest ecosystems where multiple—and sometimes competing—management goals need to be reconciled or accommodated (see, e.g., Gustafsson *et al.* 2012, entire; Franklin *et al.* 2007, entire; Kuuluvainen and Grenfell 2012, entire; North and Keeton 2008, entire; Long 2009, entire; Lindenmayer *et al.* 2012, entire). Our primary goal in this critical habitat designation is to identify the specific areas that meet the definition of critical habitat for the northern spotted owl. In addition, we identify those types of measures that promote the conservation of critical habitat, identify special management measures that may be needed within critical habitat, and identify activities that may affect or adversely modify critical habitat. Our overall emphasis in this designation is clearly on the maintenance and restoration of northern spotted owl habitat, but we also provide general guidance for consideration by land managers on what types of activities may affect northern spotted owl habitat and how to minimize the adverse impacts of those activities. Reference to the principles of ecological forestry as a suggestion for land managers to consider is a scientifically appropriate way to help achieve this goal, and is consistent with the recommendations of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), as well as the Standards and Guidelines of the NWFP (e.g., USDA and USDI 1994, p. A–1, Standards and Guidelines, pp. C–12, C–13).

Comment (55): A number of reviewers submitted line-specific edits and revisions.

Our Response: These revisions have been made to the text, where appropriate.

Comments From Federal Agencies

Comment (56): The USFS and several public commenters supported the inclusion of congressionally reserved areas including Wilderness Areas, National Parks, and similar lands for a variety of reasons, including accurately reflecting the area contributing toward recovery, highlighting the conservation value and role of this minimally managed habitat, and to encourage barred owl and other needed management activities.

Our Response: National parks, wilderness areas, and similar lands provide large areas of high-quality habitat for the northern spotted owl. All congressionally reserved lands (e.g., wilderness areas, national parks) proposed for designation have been excluded in this final designation of critical habitat. We agree that such areas play an important role in the conservation of the northern spotted owl under their current management. However, their current conservation value is so great that we could not find any minimal benefits of including them in that outweighed the relatively minor administrative costs of including them in critical habitat, therefore the benefits of excluding them outweighed the benefits of including them. In addition, exclusion of these lands will have no negative conservation impact on their future management and they will continue to function as intended for spotted owl recovery.

Comment (57): The Bureau of Land Management (BLM) and several public commenters identified specific concerns with the proposed critical habitat maps, including revisions to land ownership or management on both public and private land, and questions regarding the mapping scale and resolution. Several commenters submitted revised or corrected maps for the Service to consider in developing the final rule.

Our Response: We thank the commenters for the information provided. We have replaced the NWFP ownership designations used on the proposed critical habitat map with an updated BLM ownership map to correct many errors. In cases where mapping errors may have been made in our proposed critical habitat, such errors were corrected.

Comment (58): The BLM requested we provide maximum clarity with regard to the Act's section 7 consultation process in an effort to reduce the cost and burden of the consultation process.

Our Response: We have provided background and information to help the Federal action agencies assess whether their projects ''may affect'' proposed northern spotted owl critical habitat, the standard to determine whether consultation is required. If further clarification is needed, the Service is glad to provide action agencies with technical assistance to help determine whether or not their proposed action has the potential to affect critical habitat.

Comment (59): The BLM requested additional clarification about how the proposed critical habitat sought to ''ensure sufficient spatial redundancy in Critical Habitat within each recovery unit,'' and the purpose and expectations for these inclusions.

Our Response: In the development of habitat conservation networks, the intent of spatial redundancy is to increase the likelihood that the network and populations can sustain habitat losses by inclusion of multiple populations unlikely to be affected by a single disturbance event. This is essential to the conservation of the northern spotted owl because disturbance events such as fire can potentially remove large areas of habitat with negative consequences for northern spotted owls. Redundancy provides a type of ''emergency back-up'' system to sustain populations in the wake of such events. While the modeling and evaluation process used by the Service did not formally analyze redundancy, we incorporated spatial redundancy at two scales: By (1) making critical habitat subunits large enough to support multiple groups of owl sites; and (2) distributing multiple critical habitat subunits within a single geographic region. This was particularly the case in the fire-prone Klamath and Eastern Cascades portions of the range.

Comment (60): The BLM provided additional data and mapping layers as well as an alternative approach for designating critical habitat on public lands.

Our Response: Through a series of meetings and work sessions, the Service has reviewed the materials provided by the BLM, and we evaluated and incorporated many of their suggested changes, where appropriate and consistent with our criteria for identifying critical habitat, in developing the final critical habitat designation. Based on BLM's suggestions, we removed relatively small areas of lower quality habitat that had been included in proposed critical habitat and added in relatively small areas of high-quality habitat that improved connectivity or created larger habitat blocks.

Comments From State Agencies

Comment (61): Washington DFW requested that the rule clarify the extent to which management actions with short-term negative impacts to northern spotted owl habitat is consistent with the recovery needs of the northern spotted owl, particularly in areas of Washington State where northern spotted owl populations are greatly depressed.

Our Response: Each situation should be considered on a case-by-case basis, but, generally, actions that have short-term negative impacts may be consistent with the recovery needs of northern spotted owl when the intent of the action is (1) to improve long-term conditions for the species or (2) to improve the overall condition of the ecosystem. It could be argued either that where populations are greatly depressed there is more need for these actions or, conversely, that there is less flexibility to conduct these actions depending on the specifics of the action and the habitat needs of the owl in that area. These are issues that must be addressed in consultation and through the level one team process; assessing that level of detail is beyond the scope of this rulemaking. We have revised the rule (see section: An Ecosystem-based Approach to the Conservation of the Northern Spotted Owl and Managing Its Critical Habitat) to provide additional suggestions regarding what management actions may benefit northern spotted owls and what actions are unlikely to do so. Additional guidance is available in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011).

Comment (62): The Washington Department of Fish and Wildlife supported a coordinated and strategic management plan for dry forest landscapes and expressed a need for the critical habitat rule to consider coordination to implement effective management, reduce conflict, and explore the possibility of Federal funding for landscape strategies.

Our Response: The landscape assessment approach for the East Cascades provides the best basis for development of strategies to manage dry forest landscapes. Products of the landscape assessment can be used to describe the rationale for management actions. The Service is available to work with land managers to assist in the development and implementation of landscape assessments, but this rule does not mandate any specific management within the critical habitat network, which would be beyond the scope of this rulemaking.

Comment (63): Several State and public commenters disagreed with the need to include private lands (and in some cases State lands) in the final rule for a variety of reasons. The commenters did not provide specific information on any particular lands, but provided general reasons that they thought the broad categories of private and State lands should be excluded from the final designation, including concerns of economic issues, uncertainty, private land stewardship, added regulatory burdens (including a disproportionate burden on small landowners), reduction in land value, State land overlays, consistency with existing laws and policy, potential disincentives for conservation or negative impacts to habitat, the need to maintain partnerships with landowners, the need to develop incentives for conservation partnerships, the need to compensate for lack of land use, the need to focus protections on public lands, the lack of notification of private landowners by the Service about the proposed rule, concern that designation penalizes landowners who have retained suitable habitat, and a lack of need for or benefits from additional protections. One commenter suggested that Congress intended the Federal agencies to acquire any private or State lands that are designated as critical habitat.

Our Response: We recognize that the greatest benefit of critical habitat may be realized on actively-managed Federal lands, since the regulatory effect of critical habitat is the requirement that Federal agencies ensure that any actions that they carry out, fund, or authorize do not destroy or adversely modify designated critical habitat. In addition, Federal agencies have a mandate under section 7(a)(1) of the Act to carry out programs for the conservation of endangered species and threatened species. For these reasons, we looked first to Federal lands for the critical habitat essential to the conservation of the northern spotted owl, as described in the section Criteria Used to Identify Critical Habitat and supporting methodology (Dunk *et al.* 2012b).

Section 3(5)(A) of the Act states that critical habitat is defined as (1) the specific areas within the geographical area occupied by the species at the time it was listed that provide the physical or biological features essential to the conservation of the species and which may require special management considerations or protection; and (2) specific areas outside the geographical area occupied by the species at the time it was listed, upon a determination by the Secretary that such areas are essential for the conservation of the species. Further, section 4(b)(2) of the Act mandates that such determinations shall be made on the basis of the best scientific data available and after taking into consideration the economic impact, the impact on national security, and any other relevant impact, of specifying any particular area as critical habitat.

The language of the Act does not restrict the designation of critical habitat to specific land ownership such as Federal lands; thus, lands of all ownerships are considered if they meet the definition of critical habitat. Areas may be excluded from the final designation if the Secretary finds that the benefits of exclusion outweigh the benefits of inclusion under section 4(b)(2) of the Act, or if we determine, based on public comment or other information received following the issuance of the proposed rule, that such areas do not meet the definition of critical habitat (for example, areas that were occupied at the time of listing but do not provide the essential physical or biological features, or areas that may not have been occupied at the time of listing and were proposed for designation, but are not essential to the conservation of the species).

As described in the proposed rule (March 8, 2012; 77 FR 14076, p. 14099), we evaluated critical habitat scenarios that prioritized Federal lands first as well as scenarios without regard to land ownership in determining what is essential to the northern spotted owl. In all cases, if the scenarios under consideration provided equal contribution to recovery, we chose the scenario that prioritized publicly owned lands. State and private lands were included only if they were essential to the conservation of the species (i.e., were determined to have been occupied at the time of listing and contain the physical or biological features essential to northern spotted owl conservation or may have been unoccupied at the time of listing but are essential to the conservation of the owl). However, based on information received during the public comment period, in several cases we refined the critical habitat boundaries to remove areas of private lands that we determined do not meet the criteria and therefore do not meet the definition of critical habitat. In other instances, the Secretary has chosen to exert his discretion to exclude lands, including private lands, based on a careful weighing and balancing of the benefits of inclusion versus the benefits of exclusion, as provided in section 4(b)(2) of the Act, including consideration of conservation agreements, such as HCPs or SHAs, and the Service's desire to support existing and effective State conservation programs (see Exclusions). However, such exclusion does not indicate that these areas are not essential for the conservation of the species, only that the benefits of exclusion outweigh those of inclusion.

We retained some State-owned lands in all three states included in this critical habitat designation. In general we retained these lands because we found they provided essential contributions to the conservation of spotted owls, especially in terms of complementing the distribution of habitat on Federal lands or filling gaps in Federal ownership. We also found that the benefits of inclusion associated with public education and raising State and local agency awareness of the conservation needs of spotted owls outweighed anticipated minor increases in regulatory requirements, when Federal involvement occurred. See Changes from the Proposed Rule for more information on State lands retained in the final critical habitat designation.

The Service does not compensate private or State landowners for perceived limitations on land use associated with critical habitat designation. Designation of private or other non-Federal lands as critical habitat has no regulatory impact on the use of that land unless there is Federal involvement in proposed management activities. Identifying non-Federal lands that are essential to the conservation of a species alerts State and local government agencies and private landowners to the value of habitat on their lands, and may promote conservation partnerships. There is no indication that Congress intended the Service to acquire all private and State property that is essential to the conservation of listed species and designated as critical habitat.

We provided advance public notice of the proposed rule to revise critical habitat for the northern spotted owl through several avenues. Notice was provided with publication of the proposed rule in the **Federal Register** on March 8, 2012 (77 FR 14062) as well as through numerous local press releases at that time. In addition, notice of public information meetings in each of the three States affected by the proposed rule, as well as a public hearing, was published in the **Federal Register** on May 8, 2012 (77 FR 27010) and again on June 1, 2012 (77 FR 32483); the meetings and hearing were also announced in newspapers of local circulation in the affected areas.

Comment (64): Numerous commenters (State and public) requested that the final rule exclude lands already covered by conservation agreements, such as habitat conservation plans and safe harbor agreements, for a variety of reasons, including concerns about additional or duplicative Federal overlays and regulatory burdens, a lack of need for inclusion, policy consistency, the potential for designation to jeopardize existing agreements or remove incentives for additional conservation, and a recognition of the past conservation benefits of these voluntary agreements. In addition, it is argued that there is no need for an additional Federal overlay on lands that already have conservation designations or governing regulations such as parks, wilderness areas, HCPs, SHAs, and State forest practices rules.

Our Response: Please see our response to *Comment (63),* above. As described, we individually evaluated each conservation agreement in place within the proposed critical habitat designation, including State and private lands with HCPs, SHAs, conservation easements, or other established conservation partnerships. Following a careful weighing of the benefits of exclusion versus inclusion, the Secretary has chosen to exert his discretion to exclude lands covered by such agreements. In addition, the Secretary has chosen to exclude all congressionally-reserved natural areas (wilderness areas, national parks), State parks, and private lands from the final designation. Please see the Exclusions section of this document for details of the analyses that led to the exclusion of these areas from the final designation.

Comment (65): Numerous State commenters (CALFIRE, Oregon Department of Forestry, Washington Department of Fish and Wildlife, Washington Department of Natural Resources), Federal (USFS, BLM), and public commenters disagreed with the need to include public lands including Federal lands (e.g., ''matrix'' land, adaptive management areas, experimental forests, O&C Lands, and congressionally reserved wilderness areas, national scenic areas, and national parks), State lands (e.g., State parks, State forests, State forest trust lands), and county lands in the final rule for a variety of reasons, including additional and redundant regulatory burdens and requirements, economic and social impacts, potential inconsistency with existing laws and policy, existing protections, a lack of additional conservation benefits, limits on research or needed management activities (e.g., fuel reduction, restoration, or insect control), mapping errors, insufficient justification supporting inclusion, and potential disincentives for preserving habitat.

On the other hand, numerous commenters (both from other State agencies, as well as the public) supported the inclusion of public lands including Federal lands, State lands, tribal lands, and county lands for a variety of reasons, highlighting the conservation the value of this habitat, consistency with the best available science, the need for increased protections in some lands, and the realization there would be limited to no impacts to management.

Our Response: The critical habitat designation includes those lands that meet the definition of critical habitat in the Act, and which the Service has determined are essential to provide for the conservation of the northern spotted owl. In designating these lands, we have further considered their ownership, management, contribution to northern spotted owl conservation, existing protections, economic impacts, and other relevant factors, and determined it is appropriate and necessary to include them in the final critical habitat network to best ensure successful northern spotted owl conservation.

Where possible we prioritized the inclusion of Federal lands over other land ownerships, but where Federal lands were sparse or nonexistent we incorporated other ownerships in order to design and designate an effective critical habitat network. As noted in our response to *Comment 64,* in cases where our analysis of the benefits of exclusion outweighed those of inclusion, such as when conservation agreements and partnerships have been developed with the Service, we have excluded State or other public lands from the final designation (see Exclusions).

Our proposed rule (77 FR 10462; March 8, 2012) identified several different possible outcomes of that proposed revision, depending on various areas considered for exclusion. Among the exclusions of public lands under consideration were all congressionally-reserved natural areas and all State lands. Of the congressionally-reserved natural areas under consideration, we have excluded all congressionally-reserved natural areas and State Parks from this final designation (see Exclusions). In addition, private lands were also excluded, following a careful analysis of the benefits of inclusion versus exclusion. In other cases, lands were retained in the final designation for a variety of reasons; for lands that were considered or proposed for exclusion, but not excluded in this final designation, those decisions are described in the section Changes from the Proposed Rule.

We recognize the concern over the inclusion of certain Federal lands in the designation of critical habitat for the northern spotted owl, and particularly of lands in the matrix land use allocation or the O&C lands. As described in the section Criteria Used to Identify Critical Habitat and elsewhere in this rule, we looked to Federal lands first for the conservation of the northern spotted owl, in part because Federal agencies have a statutory mandate to contribute to the conservation of listed species. Secondly, because the protections of critical habitat are triggered only in the case of a Federal nexus, those protections are always in place on Federal lands; thus the benefit of including Federal lands in critical habitat can potentially be significant. Finally, we only included lands in the designation if they meet the definition of critical habitat; that is, if they play a truly essential role in the conservation of the species. In some areas, for example the O&C lands, our modeling results indicated that those Federal lands make a significant contribution toward meeting the conservation objectives for the northern spotted owl in that region, and that we cannot attain recovery without them. Likewise, in addition to our modeling results, peer review of both the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) as well as our proposed rule to revise critical habitat, suggested that retention of high quality habitat in the matrix is essential for the conservation of the species. Population performance based on reserves under the NWFP, for example, fared very poorly compared to this final designation of critical habitat. As described in the section Changes from the Proposed Rule, we tested possible habitat networks without many of these matrix lands, which resulted in a significant increase in the risk of extinction for the northern spotted owl.

Similarly, for the reasons outlined above, we have retained experimental forests on Forest Service lands in critical habitat. This designation includes areas within seven Forest Service experimental forests: H.J. Andrews Experimental Forest, Pringle Falls Experimental Forest, South Umpqua Experimental Forest, and Cascade Head Experimental Forest in Oregon; Wind River Experimental Forest and Entiat Experimental Forest in Washington; and Yurok Redwood Experimental Forest in California. Three of these seven experimental forests are already included in the 2008 critical habitat designation. Our evaluation of these seven experimental forests demonstrates that these areas contain high value occupied habitat for northern spotted owls within their borders. In many cases, the habitat in these experimental forests represents essentially an island of high value habitat in a larger landscape of relatively low value habitat; this is especially true in the Coast Range, a region where peer reviewers particularly noted a need for greater connectivity and preservation of any remaining high quality habitat. These considerations, in conjunction with the inherent benefits of critical habitat on Federal lands, described above, lead us to conclude that there are significant benefits to the inclusion of these experimental forests in critical habitat. As discussed earlier in this document, we recognize the valuable role of these experimental forests, and we encourage continued research and adaptive management on these forests. All of these forests are occupied by the northern spotted owl and we are already consulting with the Forest Service in these areas under the jeopardy standard. The incremental impact of critical habitat is therefore limited to the cost of consultation for the additional adverse modification analysis and any potential project modifications to avoid adverse modification or destruction, if needed; we did not consider the benefit of avoiding these costs through exclusion to outweigh the benefits of inclusion for these areas. As noted in this document, we fully support the research activities in these experimental forests and intend to continue working cooperatively with the Forest Service to ensure the successful continuation of their scientific mission in these areas.

In sum, the best scientific information available indicates that the Federal lands we have included in this final designation are essential to the conservation of the species, and we have retained such areas in the final designation.

Comment (66): Several State and public commenters noted that the northern spotted owl critical habitat designation includes areas of younger forest that may not include the PCEs, and questioned whether this was an artifact of the modeling process or an intentional inclusion of lands for the future development of PCEs and expansion of the northern spotted owl population, as stated in the rule.

Our Response: The essential conservation goal of the critical habitat network is to provide for a stable or increasing northern spotted owl population trend, which we determine will result from, in part, the retention of existing high-value habitat and the development of additional habitat to support more northern spotted owls than currently exist. Some areas of younger forest that do not currently contain all of the PCEs are essential for this purpose. In such cases, we evaluated these areas as if they were unoccupied at the time of listing, and included them in the designation only if we determined that they are essential to the conservation of the species.

Comment (67): Several commenters (State and public) identified specific concerns with the proposed critical habitat maps, including revisions to land ownership or management on both public and private land, noting the inadvertent inclusion of some lands that did not meet the definition of critical habitat and questions regarding the mapping scale and resolution. Several commenters submitted revised or corrected maps for the Service to consider in developing the final rule.

Our Response: We thank the commenters for the information provided. Numerous edits and changes were made to the maps in the final rule, where appropriate, including assessment of specific lands identified to determine whether they met the definition of critical habitat. For example, in the State of Washington, we determined that many small woodlot owners possess lands that do not provide the PCEs for the northern spotted owl, or that the lands initially identified in the proposed rule are too fragmented or isolated to be essential to the conservation of the species (see *Comment (107)*); such lands were removed from the final designation because they do not meet the definition of critical habitat. In several cases, landowners contacted us and asked for the exclusion of their lands, but we determined that those landowners were not included in the proposed critical habitat. In some cases, changes have been addressed narratively (e.g., the clarification that no private lands in Oregon met the definition of critical habitat and, therefore, were not included in the proposed rule and are not included in the final designation). In cases where mapping errors may have been made in our proposed critical habitat, such errors were corrected.

Comment (68): Several State, Federal (USFS and BLM), and public commenters requested clarification on the implementation of, or modification of, the 500-ac (200-ha) circle we recommended for assessing the effects of an action to critical habitat.

Our Response: Based on both public and agency comment and requests for clarification, the final rule does not identify the 500-acre (200-ha) circle as a recommended scale for determining the effects of an action, but does reference it as a potentially useful scale that could be used in the section 7consultation process. How to best apply it, or other potential scales, will be determined during the consultation process initiated by Federal action agencies proposing projects that may affect areas designated as critical habitat by this rule.

Comment (69): Several State and public commenters questioned the relationship of the impact of barred owl competition on the northern spotted owls, and amount of habitat needed in the critical habitat designation and whether recovery can be achieved without addressing the impacts of the barred owl. Some of these commenters believe barred owl management should occur prior to designation of additional critical habitat areas.

Our Response: The survival of northern spotted owls depends in large part on the protection of habitat. This protection remains crucial to the recovery of the northern spotted owl regardless of whether barred owls are present or not. However, given that barred owls and northern spotted owls are now occupying similar habitats, it is essential to maintain sufficient habitat that meets the needs of northern spotted owls. The extent to which northern spotted owls persist (sometimes undetected) on areas with high barred owl densities is unclear; however, with a second species competing for similar habitat, providing more of that habitat is predicted to increase the ability for northern spotted owls to persist in the presence of barred owls. We identified critical habitat for the northern spotted owl with this essential need in mind. The potential management of barred owls is beyond the scope of this rulemaking, which is limited to the identification of critical habitat for the northern spotted owl. If management of barred owls is implemented and assessed, as is currently occurring under a separate process, the Service may reconsider this critical habitat designation and revise as appropriate.

Comment (70): Two comments suggested the definition of northern spotted owl habitat and patterns of habitat use were inadequate.

Our Response: Northern Spotted owls require areas that are primarily closed canopy with sufficient roost sites and small mammal populations to provide prey. Descriptions of these habitats vary across the range of the species, beyond the simple categories of moist and dry forest, making a specific definition at the landscape scale problematic. In developing the final critical habitat designation for the species, we have provided what we believe are the most specific and useful descriptions of the PCEs for northern spotted owls possible, based on the best scientific information available at this time. We have and will continue to seek new, more detailed information on habitat use over time.

Comment (71): A number of comments (State and public) encouraged an ecosystem approach to land management.

Our Response: The designation of critical habitat for the northern spotted owl is consistent with the NWFP and the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), both of which take an ecosystem approach to management and recovery actions. The requirement of any such management approach, however, is beyond the scope of this rulemaking, which is limited to the identification of critical habitat for the northern spotted owl.

Comment (72): Several comments (State and public) suggested approaches that provide incentives for landowners to conserve habitat.

Our Response: The Service administers several programs promoting incentive-based conservation efforts on non-Federal land (e.g., Safe Harbor Agreements, Habitat Conservation Plans, and Partners for Fish and Wildlife agreements). We highly encourage landowners to explore opportunities to participate in these and other conservation programs.

Comment (73): The Washington Department of Natural Resources suggested the Service better align designated critical habitat with the agency's management objectives, to more efficiently manage for northern spotted owl conservation.

Our Response: California, Oregon, and Washington have their own natural resource management paradigms; we intend to work with each State within the context of their management objectives to protect northern spotted owl critical habitat and work together toward the recovery of the species.

County Comments

Comment (74): Jefferson County, Washington, requested that we apply critical habitat protections to a considerable amount of owl habitat, and suggested considering additional habitat designations between the Olympics and the Cascade Mountains, in order to increase connectivity and ensure owl recovery.

Our Response: In our process of identifying areas that meet the definition of critical habitat for the northern spotted owl, we identified a critical habitat network that provides the essential life-history functions for the northern spotted owl, including demographic support and connectivity between populations. Our modeling results indicate the spatial extent of the critical habitat designation throughout the range, including between the Olympic Peninsula and the Western Cascades in Washington is sufficient to meet essential recovery requirements. Other areas outside the designation, such as those suggested by the county, do not meet the definition of critical habitat because they are not essential to the conservation of the species, even though we agree with the county that these lands are important and will increase connectivity.

Comment (75): Wasco County, Oregon, commented that it was in the interest of the community to minimize regulatory burdens from designated critical habitat.

Our Response: We recognize that the designation of critical habitat is often perceived as a potential regulatory burden. However, we wish to reiterate that the regulatory effect of critical habitat is the requirement for Federal agencies to consult with the Service on actions they carry out, fund, or authorize that may affect the designated critical habitat of threatened species or endangered species. Critical habitat does not directly impose regulatory restrictions on State land managers or on private landowners where there is no such Federal nexus. We do not believe the designation of critical habitat will result in a significant regulatory burden on Federal land activities because of (1) the cooperative nature of our consultation process under the Act with the Forest Service and BLM, and (2) because of the existing requirement that these agencies have to consult on the effects of proposed actions on northern spotted owls. Our approach was to design a critical habitat network that provides for essential northern spotted owl recovery needs but designate as small an area as possible, and to rely primarily on public lands. We have excluded all congressionally-reserved natural areas (wilderness areas, national parks), State parks, and private lands from this final designation of critical habitat.

Comment (76): Del Norte County, California, expressed concern that the proposed critical habitat designation will create a regulatory hurdle that will impede the construction of vital infrastructure projects (roads, bridges, power lines, and other utilities).

Our Response: Chapter 7 of the DEA discusses the potential economic impacts to road and bridge construction and maintenance, and installation and maintenance of power transmission lines and other utility pipelines. The analysis concludes that all potential conservation efforts associated with linear projects are expected to result from the presence of the northern spotted owl, not the designation of critical habitat, and are thus considered baseline impacts (see paragraphs 315 through 320 of the DEA). Incremental costs attributable to critical habitat are limited to the administrative costs of additional staff time spent by Federal agency staff and the Service to include critical habitat effects analyses in the section 7 consultation on these projects. Therefore, we do not believe that the designation of critical habitat for the northern spotted owl will result in significant regulatory burden to these projects.

Comment (77): Del Norte County, California; Wasco County, Oregon; and Klickitat and Skamania Counties, Washington, requested exclusion of all lands including Federal, State, and private lands within these counties in the final rule. They expressed concern regarding economic issues, a lack of appropriate northern spotted owl habitat within the counties, a lack of evidence that including these lands would actually help the species recover or avoid extinction, and a lack of need for or benefits from additional protections due to existing standards and guidelines.

Our Response: The critical habitat designation includes those lands the Service determined are essential to provide for the conservation of the northern spotted owl through a state-of-the-art modeling process that incorporated the latest expert knowledge on the habitat needs of northern spotted owls. In designating these lands we have considered their ownership, management, contribution to northern spotted owl conservation, existing protections, economic impacts, etc., and determined it is appropriate and necessary to include them in the final critical habitat network to best ensure successful northern spotted owl conservation. Each of these counties contains habitat that supports northern spotted owl populations that are essential to the conservation of the species.

We recognize that the greatest benefit of critical habitat is realized on Federal lands since the regulatory effect of critical habitat is the requirement that Federal agencies ensure that any actions that they carry out, fund, or authorize do not destroy or adversely affect designated critical habitat. In addition, Federal agencies have a mandate under section 7(a)(1) of the Act to carry out programs for the conservation of endangered species and threatened species. For these reasons, we looked first to Federal lands for the critical habitat essential to the conservation of the northern spotted owl, as described in Criteria Used to Identify Critical Habitat, above, and supporting methodology (Dunk *et al.* 2012b).

Section 3(5)(A) of the Act states that critical habitat is defined as (1) the specific areas within the geographical area occupied by the species at the time it was listed that contain the physical or biological features essential to the conservation of the species and which may require special management considerations or protection; and (2) specific areas outside the geographical area occupied by the species at the time it was listed, upon a determination by the Secretary that such areas are essential for the conservation of the species. Further, section 4(b)(2) of the Act mandates that such determinations shall be made on the basis of the best scientific data available and after taking into consideration the economic impact, the impact on national security, and any other relevant impact of specifying any particular area as critical habitat.

The language of the Act does not restrict the designation of critical habitat to specific land ownership such as Federal lands; thus, lands of all ownerships are considered if they satisfy the scientific criteria indicating that they meet the definition of critical habitat for the specific species. Areas may be removed from the final designation should the Secretary exercise his discretion to exclude such areas subsequent to a weighing of the benefits of exclusion versus inclusion under section 4(b)(2), or if we should determine, based on public comment or other information received following the issuance of the proposed rule, that such areas do not meet the definition of critical habitat (for example, areas that were occupied at the time of listing but do not provide the essential physical or biological features, or areas that may not have been occupied at the time of listing and were proposed for designation, but are not essential to the conservation of the species).

As described in the proposed rule (March 8, 2012; 77 FR 14076, p. 14099), we evaluated critical habitat scenarios that prioritized Federal lands first as well as scenarios without regard to landownership. In all cases, if the scenarios under consideration provided equal contribution to recovery, we chose the scenario that prioritized publicly owned lands. State and private lands were included only if they were essential to achieve conservation of the species after considering the contribution of Federal lands. Based on information received during the public comment period, in several cases we refined the critical habitat boundaries to remove areas of private lands that do not meet our criteria for critical habitat (for example, new information indicating that the areas in question lack the PCEs, due to recent timber harvest, stand-replacing fires, or other such events). In others, the Secretary has chosen to exclude lands from the designation. In such cases, exclusion does not signal a determination that these areas are not essential to the conservation of the species, but only that the Secretary has determined that the benefits of exclusion outweigh those of inclusion. All congressionally-reserved natural areas (wilderness areas, national parks), State parks, and private lands have been excluded from this final designation of critical habitat for the northern spotted owl (see Exclusions).

We reduced critical habitat in all four of these counties across all ownerships as we refined our proposal. In response to comments, we used additional information sources to very carefully identify and retain areas that were best suited to meeting the unique conservation needs for northern spotted owl conservation that are associated with the geographic location of these counties.

The Columbia River, which forms the southern boundaries of Skamania and Klickitat counties, presents a formidable obstacle to dispersal of northern spotted owls. Maintaining demographic exchange between northern spotted owl populations in Washington and Oregon requires both maintenance of a robust population of potentially dispersing owls, and quality habitat as near to the Columbia River as possible to increase the likelihood of dispersing owls successfully crossing the river. Critical habitat in Skamania and Klickitat counties plays a key role in preventing the demographic isolation of Washington spotted owls, and preventing isolation is widely recognized as an essential feature of sustaining wildlife populations. The designated lands in Wasco County, Oregon, contribute to this cross-Columbia River connection, as well as providing sites for northern spotted owl reproduction. In Del Norte County, California, designated lands contribute to demographic support to the overall northern spotted owl population, but also function for connectivity across the landscape and for habitat that can be colonized by young owls. In short, the designated lands in all these counties are part of a network that supports northern spotted owl sites for reproduction, habitat available for colonization by young, and habitat that connects populations across the range of the species, all of which are, in concert, essential to provide for the conservation of the species.

Our economic analysis indicated that Del Norte and Skamania counties may be more sensitive to future changes in timber harvests, industry employment, and Federal land payments, due to recent socioeconomic trends. Timber harvest changes related to critical habitat designation are one potential aspect of this sensitivity. Between 1989 and 2009, timber industry employment declined by 70 percent or more in Del Norte and Skamania counties. These counties also experienced the greatest declines in timber harvests and timber industry employment. Skamania County is also highly reliant on Federal payments to counties, with these payments representing between 26 and 50 percent of total revenues. We considered all these factors while evaluating comments from these counties.

The potential impact of the designation of critical habitat on timber harvest levels, and whether that change will be positive or negative, is uncertain. Therefore, how critical habitat designation may impact the timber industry in terms of future harvest levels, employment, and revenue-sharing payments to counties is also uncertain. As outlined in the economic analysis timber harvest may increase, decrease or stay substantially the same as recent timber harvest levels depending on how the Forest Service and BLM decide to manage their lands within the designation. Furthermore, timber industry employment is affected not only by harvest trends but also by fluctuations in national and international markets; changes in land ownership; and increasing mechanization and productivity in the industry. Our economic analysis also indicated the potential for beneficial economic and ancillary effects of spotted owl conservation due to critical habitat designation, but monetizing effects such as improved water quality and aesthetic improvements remains challenging. Finally, our analysis of the incremental impacts of critical habitat designation suggested that the annual administrative costs associated with designation were likely to be relatively low.

Our weighing of the relative benefits of inclusion in critical habitat integrated (1) the relative sensitivity of counties to economic impacts associated with critical habitat designation, (2) uncertainty regarding potential economic effects, (3) our expectation that incremental administrative costs may be minor, and (4) modeling results that indicated essential conservation functions of habitat in these counties. Based on these factors the Secretary has chosen not to exert his discretion to exclude these lands from critical habitat.

Comment (78): Del Norte County, California, requested that the Service exclude all congressionally reserved areas from critical habitat.

Our Response: All congressionally reserved natural areas have been excluded from this final designation of critical habitat, as described in the Exclusions section of this document.

Comment (79): One commenter stated that the O&C Act limits the authority of the Service in designating critical habitat.

Our Response: The O&C Act (pertaining to lands in Oregon and California) does not limit the Service's authority to designate critical habitat for the northern spotted owl. The designation of critical habitat is not a land use allocation and does not impose management prescriptions. Under section 7(a)(2) of the Act, each Federal agency must insure that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of the designated ''critical habitat'' of the species. 16 U.S.C. 1536(a)(2). To help action agencies comply with this provision, section 7 of the Act and the implementing regulations set out a detailed consultation process for determining the impacts of a proposed activity on species listed as threatened or endangered, or its designated ''critical habitat.'' 16 U.S.C. 1536; 50 CFR part 402. In *Seattle Audubon Society* v. *Lyons* (''*Lyons''*), 871 F. Supp. 1291 (W.D. Wash. 1994), the district court held that ''the O&[C Act] does not allow the BLM to avoid its conservation duties under NEPA or the Act * * *'' *Id.* at 1314. The critical habitat designation does not preclude the sustained-yield timber management of O&C lands consistent with the above requirements of the Act.

Comment (80): One commenter stated that the Service failed to explain why revising the designation of critical habitat for the northern spotted owl is ''exempt'' under sections 2 and 3 of the Executive Order 13132 on Federalism.

Our Response: We have complied with E.O. 13132 by explaining why the rule does not have federalism implications, impose substantial direct compliance costs on State and local governments, or preempt State law so that a federalism summary impact statement pursuant to section 6 of the executive order is not required. The designation of critical habitat directly affects only the responsibilities of Federal agencies through section 7(a)(2) of the Act. The Act does not directly impose other duties with respect to critical habitat on either States or local governments and as a result does not have substantial direct effects on the States and local governments, the relationship between the national government and the States, or the distribution of powers and responsibilities among the various levels of government. Sections 2 and 3 of E.O. 13132 set out Fundamental Federalism Principles and Federalism Policymaking Criteria, respectively. Within the framework of the Act, which requires the Service to designate critical habitat to the maximum extent prudent and determinable, we have adhered to the concepts discussed in these sections. For example, even though the rule does not have federalism implications, we strongly urged the States and county governments to provide comments to us and provided them an additional period for comment to ensure they had an opportunity for thorough review. Our economic analysis examined potential indirect impacts of the rule on all who may participate in section 7 consultations, and that was available for comment by the States and counties as well. In addition, we have also taken into account State law protections for northern spotted owl critical habitat in our decisions whether to exclude areas under section 4(b)(2) of the Act.

Comment (81): Several counties, including Del Norte County, California, and Wasco County, Oregon, expressed concerns about the impact of barred owls on the northern spotted owl, and questioned whether recovery can be achieved without addressing the impacts of the barred owl. Some of these commenters believe barred owl management should occur prior to designation of additional critical habitat areas.

Our Response: The survival of northern spotted owls depends in large part on the protection of habitat—this protection remains crucial to the recovery of the northern spotted owl regardless of whether barred owls are present or not. Given that barred owls and northern spotted owls are now occupying similar habitats, it is essential to maintain sufficient habitat that meets the needs of northern spotted owls. The extent to which northern spotted owls persist (sometimes undetected) on areas with high barred owl densities is unclear. With a second species competing for similar habitat, providing more of that habitat may increase the ability for northern spotted owls to persist in the presence of barred owls. If management of barred owls is implemented and assessed, the Service may reconsider this critical habitat designation and revise as appropriate.

In our separate actions investigating possible barred owl management, we can, and are, modeling some approaches with and without barred owl competition effects on the northern spotted owl, and will continue to do so as new information becomes available. Recent research (Wiens 2012) indicates that population performance of both northern spotted owls and barred owls is greatest when high-quality habitat is most abundant, and most peer reviewers supported the approach of conserving more habitat to help offset the impact of the barred owl on the northern spotted owl.

County Comments on Active Management and Fire Management

Comment (82): Several counties including Wasco County, Oregon, and Del Norte County, California, requested that the Service promote active management activities within critical habitat to reduce fire risk and reduce fuels, and raised the concern that critical habitat designation could reduce or delay the ability of land managers to manage fuels and thus increase risks from wildfire.

Our Response: This rule does not establish management prescriptions for lands designated as critical habitat. However, the Service has made considerable effort to discuss, for the benefit of land managers, potential approaches to active forest management in dry forests, including actions that manage fuels and restore ecosystem health. We encourage land managers to consider active management of their forests that balances short-term impacts with long-term beneficial effects that ultimately support long-term conservation of the northern spotted owl. In dry forests, this could include using a landscape assessment approach to improve the estimation of effects of management actions on northern spotted owl habitat and to better identify and prioritize areas for treatments. The assessment may be used to provide support and rationale for treatment, especially in areas where active forest management actions appear to be in conflict with the conservation of high-value northern spotted owl habitat.

The draft economic analysis (DEA) addressed the potential impacts of critical habitat on fire management in Chapters 4 and 8. In Chapter 4, the DEA discussed the fact that ecological fire salvage activities could result in incremental economic effects. Due to data limitations and fire location uncertainty, however, these effects were not quantified. In the benefits discussion in Chapter 8, the DEA recognized that it is possible that the designation could result in increased resiliency of timber stands associated with improved timber management practices, such as thinning, partial cutting, and active adaptive forest management and monitoring. These efforts may reduce the threat of catastrophic events such as wildfire, drought, and insect damage. This in turn may generate benefits in the form of reduced property damage.

Comment (83): Jefferson County, Washington, encouraged the Service to determine adverse modification at a finer scale, such as the owl's home range.

Our Response: The final rule establishes that the scale of the adverse modification determination will be ''the entire designated critical habitat, as described below, with consideration given to the need to conserve viable populations within each of the physiographic provinces identified in the Revised Recovery Plan (USFWS 2011, Recovery Criterion 2).'' The Service believes the entire designated critical habitat is the appropriate scale for this analysis because our determination is whether implementation of the Federal action would preclude the critical habitat from serving its intended conservation function or purpose. That conservation role of critical habitat is to conserve the listed species throughout its range, which is closely aligned with the entire critical habitat designation. Therefore, the entire designation is the most appropriate scale for the adverse modification determination. However, a proposed action that compromises the capability of a subunit or unit to fulfill its intended conservation function or purpose (e.g., demographic, genetic, or distributional support for spotted owl recovery) could represent an appreciable reduction in the conservation value of the entire designated critical habitat.

Comment (84): Wasco County, Oregon, requested that the Service do an Environmental Impact Statement to ensure a full analysis of the effects of the critical habitat designation has been done, including a fuller picture of potential economic and social impacts.

Our Response: The critical habitat proposal was fully compliant with NEPA. Economic and social effects are not intended by themselves to require preparation of an environmental impact statement. 40 CFR 1508.14. We have determined, for the reasons contained in our Finding of No Significance, that an environmental impact statement is not necessary.

Comment (85): Klickitat County, Washington, asserts that the Service has not adequately considered ''forest vulnerabilities'' and potential economic impacts to local communities, and is inconsistent with the Presidential Memorandum to the Secretary of the Interior dated February 28, 2012.

Our Response: We disagree with the assertion that the Service has not adequately considered ''forest vulnerabilities'' in this designation of critical habitat. If we correctly understand ''forest vulnerabilities'' to include all those natural and human induced disturbance processes that have the potential to change the structure and function of forests, these factors played a prominent role in our entire approach to this designation. We believe this rule, along with the Revised Recovery Plan for the Northern Spotted Owl, provides a thorough explanation of how past management and future disturbance can affect habitat quality for spotted owls, and especially how ecological forestry might be used to manage these effects.

The purpose of the economic analysis is to provide the Secretary of the Interior with information to consider potential economic impacts and analyze whether the benefits of excluding a particular area may outweigh the benefits of including that particular area as critical habitat based on potential disproportionate economic impacts. Chapter 6 of the FEA provides a detailed socioeconomic profile of each of the 23 counties (including Klickitat County, Washington) containing proposed critical habitat subunits. The analysis presents data on the percent change in timber production between 1990 and 2010 for each county, and on the percent growth of annual industry employment between 1989 and 2009 for each county. In addition, the analysis presents data on Federal land payments to each of the 23 counties as a percent of the total local government revenue in FY 2009, demonstrating the relative importance of these funds to each County's budget. We find the information provides sufficient context for understanding relative economic circumstances and the potential incremental impacts of the designation to local communities across the designation.

The section ''Consistency with Presidential Directive'' in our Executive Summary describes how we have addressed the points raised in President Obama's Memorandum of February 28, 2012.

Comment (86): Jefferson County, Washington, encouraged the Service to consider the effects of critical habitat designation on ecosystem services, such as drinking water, hunting and fishing, carbon storage, and erosion and flood control.

Our Response: The Service recognizes that much attention has been paid nationally and globally to valuing ecosystem services provided by landscapes. Published, peer-reviewed studies provide information on values of multiple categories of ecosystem services (e.g., agricultural production, water quality regulation, carbon storage and sequestration, recreation, aesthetic values, etc.) across a variety of land use types (e.g., wetlands, forests, etc.). Over the past 20 years, multiple studies have relied on this literature to develop large-scale benefits transfer analyses in order to estimate a total value of a parcel of land, a watershed, a State, or even the planet (e.g., Costanza 1997, as described in the comment letter). We believe that improving native ecosystems is a benefit to the species that rely on them, is consistent with the goal of the Act and will improve all these ecosystem functions.

Public Comments

Active Forest Management

Comment (87): One commenter agreed that the Service is not able to predict the outcome of section 7 consultations, but expressed concern that land management decisions would be made, using the critical habitat rule for justification of these outcomes. A suggestion was made to eliminate or modify portions of the critical habitat rule that encourage active management within critical habitat.

Our Response: The Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) and the NWFP recommends certain types of active forest management within the range of the northern spotted owl to meet various management goals. Our critical habitat rule refers to these recommendations. The Revised Recovery Plan encourages careful consideration and incorporation of specific and appropriate information when deciding which actions, if any, are appropriate for active forest management within critical habitat. However, we are not able to predict where or what types of actions will be proposed within northern spotted owl critical habitat, nor is it within the authority of this rulemaking to prescribe where or what types of actions will take place. The actual management activities that may take place within critical habitat will depend on future management decisions by the land managing agencies consistent with their land use plans and the legal authorities under which they operate, and in consultation with us under section 7 of the Act for those activities involving a Federal nexus.

Comment (88): Several commenters raised concern over the creation of early-seral habitats. The points raised a concern over the removal of current habitat to create early-seral habitat, expressed a need to make use of natural disturbances to achieve early-seral habitat, and questioned the appropriateness of creating early-seral habitat inside critical habitat.

Our Response: Recent research has informed land managers on the biological value of complex early-seral habitats. The Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) suggests that management of early-seral habitats be considered where they are underrepresented and would improve landscape and biological diversity. Within that context, thinning and targeted variable-retention harvest in moist forests could be considered, where the conservation of complex early-seral forest habitat is a management goal. This approach provides a contrast to traditional clear-cutting that does not mimic natural disturbance or create viable early-seral communities that grow into high-quality habitat (Dodson *et al.* 2012, p. 353; Franklin *et al.* 2002, p. 419; Swanson *et al.* 2011, p. 123; Kane *et al.* 2011, pp. 2289–2290; Betts *et al.* 2010, p. 2127, Hagar 2007, pp. 117–118). Swanson (2012, entire) provides a good overview and some management considerations. The Revised Recovery Plan does not suggest that high-quality owl habitat or areas currently on a trajectory to become high-quality owl habitat be removed to create early-seral conditions. The Revised Recovery Plan recommends such treatments, if considered by the land management agencies, be applied in matrix areas consistent with the Standards and Guidelines of the NWFP.

Comment (89): One commenter asked how the Service and managers will evaluate forest management strategies without information on the potential effects of these strategies to determine whether they are positive, neutral, or negative.

Our Response: Commercial thinning has been shown to negatively affect northern spotted owls and their prey, and we have included a more detailed discussion of this issue in the final rule. In areas where active management may be appropriate for consideration, the goal is to conserve and restore ecological function; however, we recognize that management agencies may have multiple management goals. In areas where actions such as commercial thinning may be considered (e.g., the matrix land use allocation), we are not encouraging them in areas of high-quality owl habitat.

Comment (90): One commenter requested consideration of the forest thinning direction contained in *Ecologically Appropriate Restoration Thinning in the Northwest Forest Plan Area* (Kerr 2012) as an option for future critical habitat management.

Our Response: We appreciate this suggestion and have integrated the information in this reference into our discussions of forest thinning.

Comment (91): One commenter requested that special management considerations for the East Cascades emphasize management for well-distributed, large, contiguous blocks habitat across the landscape.

Our Response: Special Management Considerations for the East Cascades are identified that management may be required to address the threats to the essential physical or biological features in this region from past activities. Widespread management of large, fully contiguous blocks of habitat east of the Cascades is not ecologically sustainable in many places, due to the dynamic ecological processes and fire regimes that shape the distribution of forested habitats in this region (Williams 2012, entire). We do, however, recommend land managers consider the conservation of larger blocks of current habitat on areas of landscapes where it is more likely to be resistant or resilient to fire and other natural disturbance. We encourage the use of landscape assessments to identify areas important for ecological process restoration and areas that are valuable for northern spotted owl conservation and recovery (see, e.g., NWFP Standards and Guidelines p. C–13).

Comment (92): One commenter noted that the Service should emphasize protection of mid-seral forests so that they may develop into high-quality habitat.

Our Response: We recommend that habitats with high value to the conservation of the northern spotted owl be conserved. High-value habitat includes mid-seral forests as one component. Mid-seral forests that are generally not occupied by northern spotted owls, however, may be appropriate areas for land management agencies to consider for active forest management that may increase their rate of development into high-quality habitats.

Comment (93): One commenter noted that past active management resulted in excessive logging and road building, which led to the threatened and endangered status of species in the Pacific Northwest. Included in this comment are concerns over active management harming water quality, diminishing recreational activities, and increasing fire risk if followup actions (e.g., removal of slash, removal of burn piles, prescribed fire) are not carried out.

Our Response: We have identified the major threats to owl recovery in this rule, including traditional timber harvest that resulted in the removal of large areas of old forest. Active management, in general, may affect water quality and recreational opportunities, but it may also restore habitat conditions or reduce fire risk if implemented properly. We encourage land managers to be mindful of these concerns and to protect important areas from long-term adverse impacts wherever possible.

Comment (94): Several commenters expressed concern that logging in critical habitat and LSRs would increase the risk of extinction of the northern spotted owl, degrade owl habitat, increase the risk of fire, damage forest health, and damage watershed health. Commenters expressed concern about specific logging prescriptions that appear to remove trees or degrade areas that could function as habitat for northern spotted owl, such as mistletoe removal, post-fire logging, or disease management activities. In addition, several thousand commenters submitted similar comments in general support of protections against logging the mature and old-growth forests of the Pacific Northwest and Northwest California due to economic and environmental benefits.

Our Response: The critical habitat rule identifies habitats with high value to the recovery of the northern spotted owl that are essential and will receive regulatory protections under section 7 of the Act where a Federal nexus exists. We emphasize that careful consideration should be given to any forest management activities occurring within northern spotted owl critical habitat. The Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) indicates that active forest management, when applied at appropriate scales and locations, could be a valuable tool in the recovery of the species and conservation of forest ecosystems. Further, we recommend that the focus of these treatments be outside of high-value habitat for northern spotted owls wherever possible and that high-quality habitats be conserved and recruited. Work inside of LSRs should be in accordance with the NWFP Standards and Guidelines. We again note that, although we encourage land management agencies to follow the recommendations for the Revised Recovery Plan for the Northern Spotted Owl, it is beyond the authority of this rulemaking to mandate specific management activities within critical habitat. The actual management activities that may take place within critical habitat will depend on future management decisions by the land managing agencies consistent with their land use plans and the legal authorities under which they operate.

Comment (95): One commenter suggested our treatment of the effects of forest thinning on owls and of fire was incomplete and biased towards supporting thinning treatments in critical habitat.

Our Response: We recognize that more research would be helpful to better understand how northern spotted owls respond to various vegetation management treatments, especially those implemented to address long-term forest health and increasing risk of wildfire. Thinning and other vegetation management may have either negative or beneficial impacts to northern spotted owl habitat depending on how, when, and where the treatments are implemented.

The existing information about the tradeoffs associated with active and passive management in dry forests indicates that strategic application of active management may offer a higher likelihood of achieving conservation objectives than no management. Although passive management can be viewed as more precautionary, this view is rooted in a perspective that considers risks to northern spotted owl habitat from natural disturbance to be relatively low. However, we believe that the weight of evidence from both tracking of habitat removal due to natural disturbance and results from modeled simulations of fire dynamics suggest that risks of habitat loss due to natural disturbance is high enough to warrant consideration of strategic active management within critical habitat by land managers, especially in forested plant associations that typically have frequent or mixed-severity fire regimes (Buchanan 2009, pp. 114–115; Healey *et al.* 2008, pp. 1117–1118; Roloff *et al.* 2012, pp. 8–9; Ager *et al.* 2007, pp. 53–55; Ager *et al.* 2012, pp. 279–282; Franklin *et al.* 2009, p. 46; Kennedy and Wimberly 2009, pp. 564–565). In the final rule, we have refined and expanded our discussion of ways land managers might implement active management to minimize potential risks to northern spotted owls and their habitat, and provide appropriate safeguards in the face of scientific uncertainties surrounding disturbance dynamics in dry forests and northern spotted owl responses to management. In addition, active adaptive forest management may prove to be an essential tool for reducing uncertainties and increasing the conservation effectiveness of active management for northern spotted owl habitat.

Comment (96): Several commenters expressed concern over the justification of projects that encourage timber harvest in suitable northern spotted owl habitat, including the pilot projects guided by Drs. Johnson and Franklin that are occurring in BLM's pilot projects out of the Roseburg and Coos Bay BLM offices.

Our Response: The Service is working with land managers and scientists to minimize impacts to northern spotted owl's essential habitat, and owl conservation as a consequence of timber harvest and other vegetation management projects. We worked closely with Dr. Norm Johnson, Dr. Jerry Franklin, and the Roseburg and Coos Bay BLM offices to evaluate these pilot projects, which are not in LSRs and are consistent with requirements of the NWFP. The Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) recommends applying ecological forestry techniques as a way of reducing impacts to northern spotted owl habitat in areas proposed for timber harvest. In general, northern spotted owl habitat in moist forests that is on a trajectory for development into late-successional conditions is not in need of active management to enhance its development. The Service recommends that land managers consider thinning and other regular management in critical habitat, when the goal is to improve or maintain northern spotted owl habitat and long-term forest health. Specific conditions vary as will determinations of where, when and how to apply management. The actual management activities that may take place within critical habitat will depend on future management decisions by the land managing agencies consistent with their land use plans and the legal authorities under which they operate, and in consultation with us under section 7 of the Act for those activities involving a Federal nexus.

Comment (97): Several commenters suggested that the Service should include a full analysis of the risks to northern spotted owl habitat from fire, in an effort to support the recommendations for active forest management, and should also include an analysis of the effects to northern spotted owl habitat from post-fire logging activities in the final rule.

Our Response: First, we must clarify that this critical habitat rule does not take any action or adopt any policy, plan, or program in relation to active forest management. The discussion is provided only for consideration by Federal, State, local, and private land managers, as well as the public, as they make decisions on the management of forest land under their jurisdictions and through their normal processes. Second, there is considerable scientific uncertainty over the risk of fire to northern spotted owl habitat. Where data are available, the literature shows that high-severity fire and increased frequency of fire may be a risk to the nesting function of northern spotted owl habitat (e.g., Kennedy and Wimberly 2009, p. 565). The literature so far is unclear, not only on how much high-severity fire may be a risk to northern spotted owls, but also regarding what spatial arrangement and amount of burned and unburned vegetation or different burn severities may be beneficial or detrimental to northern spotted owl occupancy and habitat use. We address this issue in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), in which we also suggested an adaptive management framework to test hypotheses that will help address this uncertainty. Recovery Action 12 in the Revised Recovery Plan summarizes the literature on post-fire logging and recommends that these types of silvicultural activities focus on conserving and restoring those habitat elements that take a long time to develop (e.g., large trees, medium and large snags, downed wood).

Comments on Ecological Forestry

Comment (98): One commenter noted that the Service is promoting timber harvest activities that are compatible with northern spotted owl critical habitat, but regulations prevent this work from occurring.

Our Response: We believe the activities recommended in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) and discussed in this critical habitat rule are compatible with the Standards and Guidelines of the NWFP. We encourage land management agencies to consider active management of forests that balance short-term impacts with long-term beneficial effects that ultimately support long-term conservation of the northern spotted owl.

Comment (99): One commenter noted that ecological forestry practices are not clearly defined and according to the rule will be different in each situation.

Our Response: Land management decisions on when and where to apply ecological forestry practices are context-specific, based on local conditions, and will be made by the appropriate land managers. The prescription of specific management practices is beyond the authority of this rule. This critical habitat rule and the Revised Recovery Plan (USFWS 2011, entire) provide an overview and multiple scientific references on ecological forestry. We are available to work with land managers to provide technical assistance in further defining ecological forestry practices at finer scales, should land managers be interested in applying such techniques.

Comment (100): Several commenters raised concerns that critical habitat designation would reduce or delay the ability of land managers to manage fuels, that more implementation of fuels reduction activities are needed, that fire resiliency needs to be achieved, and that we consider timber and nontimber resources to manage fuels.

Our Response: The Service has made considerable effort to discuss recommendations and descriptions of active forest management in dry forests, including actions that manage fuels and restore ecosystem health, in this critical habitat rule. This rule is different from previous designations of northern spotted owl critical habitat in that we are recommending a ''hands on'' approach to forest management within critical habitat. We encourage land managers to consider active management of forests that balance short-term impacts with long-term beneficial effects, which ultimately supports long-term conservation of the northern spotted owl. In dry forests, we recommend that land managers consider a landscape assessment approach to improve the estimation of effects of management actions on northern spotted owl habitat and to better identify and prioritize areas for treatments. The assessment may be helpful, especially in areas where other landscape or biodiversity management goals may conflict with the conservation of high-value northern spotted owl habitat. We note that this rule can only provide general advice as to those activities that may be consistent with the designation of critical habitat for the northern spotted owl. The actual activities proposed within critical habitat are dependent upon decisions by the land managers themselves, in accordance with their land use plans and legal authorities.

Comments on Exclusions

Comment (101): Several comments questioned why the proposed critical habitat did not include private lands in Oregon but did in Washington or California, and encouraged the Service to exclude private lands in all three States in the final rule, due to concerns around the regulatory burdens of critical habitat and the lack of need for additional protections, in light of existing conservation agreements and State laws.

Our Response: In this designation of critical habitat, we relied on public lands to the maximum extent possible in determining what lands met the definition of critical habitat in that they either contain essential physical or biological features or are themselves essential for the species' conservation. We looked first to Federal lands for critical habitat; however, in areas of limited Federal ownership, some State and private lands provide areas determined to be essential to the northern spotted owl, by contributing to demographic support and connectivity to facilitate dispersal and colonization. State and private lands were included only where essential to achieve conservation of the species, and State lands were prioritized over private lands. In Oregon, Federal and State lands identified were sufficient to meet the conservation needs of the owl; in Washington and California, there were some areas where Federal and State lands were not sufficient to meet the population metrics essential to recovery for the species, and some private lands were identified as essential for contributing to the conservation of the species. These private lands were subsequently excluded from the final designation under section 4(b)(2) of the Act (see Exclusions). As discussed in our response to *Comment (104),* such exclusion does not signal that these lands are not important for the conservation of the northern spotted owl, but only that the Secretary has determined that the benefits of excluding these areas outweighs the benefits of including them.

We received several comments from private landowners expressing concern that their land uses would be restricted by the designation of critical habitat, or that jobs would be lost if critical habitat is designated on private lands. Some landowners were under the false impression that their access to Federal funds would be restricted, or that they would be unable to complete forest health improvement projects on their lands if critical habitat were designated there. We reiterate that the regulatory effect of critical habitat is the requirement for Federal agencies to consult with the Service on actions they carry out, fund, or authorize that may affect the designated critical habitat of endangered or threatened species. Activities can continue on private lands with critical habitat in place; it is only if Federal funding or permits are required that the Federal agency involved would need to consult with the Service to insure that the proposed action does not destroy or adversely modify critical habitat. However, as a consequence of the exclusion of all private lands from this final designation of critical habitat for the northern spotted owl, concerns such as those expressed above should be moot.

Comment (102): One commenter expressed concern about the potential impact of designating critical habitat on private lands related to the California Environmental Quality Act (CEQA) regulations, and cited to the marbled murrelet, California red-legged frog, California tiger salamander, and western snowy plovers as examples of increased regulatory impact resulting from critical habitat designation.

Our Response: Our economic analysis concluded that private lands in California and subject to CEQA must comply with the California Forest Practice Rules already in place, regardless of critical habitat. Further, the economic analysis reports that CALFIRE is unlikely to request additional protective measures for habitat beyond those already required by these regulations. Subsequently, we conclude the incremental costs of the designation would be limited to the potential for additional administrative burden under CEQA (IEC 2012b, p. 5–19).

The only other potential regulatory impact to private landowners which we would foresee from the designation of northern spotted owl critical habitat may occur when a proposed project has a Federal nexus (e.g., Federal funding or authorization) and the project may affect designated critical habitat. However, as all private lands have been excluded from this final designation of critical habitat, this should no longer be a concern.

The Service is unaware that the designation of critical habitat for the marbled murrelet, California red-legged frog, California tiger salamander, or the western snowy plover has led to any increase in regulatory impacts to private landowners. While private landowners may have experienced an increased regulatory burden with the listing of these species under the Endangered Species Act, we are not aware of an increased regulatory impact associated with the designation of critical habitat for these species.

Comment (103): One commenter expressed concern that the regulatory burden imposed by critical habitat designation on private lands in California will be exacerbated, because the Service is no longer providing technical assistance for California forest landowners who wish to prepare State-required timber harvest plans.

Our Response: We believe the commenter was mistaken in stating that the Service is no longer available to assist private landowners in the preparation of timber harvest plans in California, as the Service's technical assistance program is still operational and available to assist private landowners in this regard. The Service does not review every timber harvest plan, but is available for review when requested after the initial review by CALFIRE. In addition, since all private lands have been excluded from this final designation of critical habitat, the concern regarding potential exacerbation of regulatory burden is no longer relevant.

Comment (104): Numerous commenters supported including private lands, and urged the Service not to exclude these areas in the final rule for a variety of reasons, including the conservation value of including all lands identified as suitable habitat, the need for connectivity, existing management flexibility and a lack of additional regulatory burden, the opportunity to build cooperative management agreements, and concerns that exclusion is not supported by the best available science and would signal that these lands are not important to the recovery of the species.

Our Response: The Act specifically requires the Service to designate critical habitat for listed species to the maximum extent prudent and determinable, and does not restrict such designation to particular land ownership. Rather, areas that meet the definition of critical habitat, as determined on the basis of the best scientific data available, are proposed for designation. However, section 4(b)(2) of the Act further provides that the Secretary, in designating critical habitat and making revisions, shall take into consideration the economic impact, the impact on national security, and any other relevant impact of specifying any particular area as critical habitat. The Secretary may then choose to exercise his discretion to exclude any area from critical habitat if he determines that the benefit of exclusion outweighs the benefits of specifying such areas as part of the critical habitat, unless that exclusion would result in the extinction of the species.

Lands excluded under section 4(b)(2) are still considered essential to the conservation of the species. Such areas were identified as critical habitat because they either provide the essential physical or biological features, if occupied, or were otherwise determined to be essential, if unoccupied. Exclusion should never be interpreted as meaning that such areas are unimportant to the conservation of the species. Exclusion is based upon a determination by the Secretary that the benefit of excluding these essential areas outweighs the benefit of including them in critical habitat.

In this case, the Secretary has chosen to exercise his discretion to exclude non-Federal lands from the final designation of critical habitat if an existing conservation agreement or partnership is in place that provides benefits that are greater than the benefits that would be provided by the designation of critical habitat. Such exclusions have only been made following a careful weighing of both the benefits of inclusion and the benefits of exclusion. We wish to emphasize that the exclusion of lands from the critical habitat designation should not be construed as a message that these lands are not important or essential for the conservation of the northern spotted owl, nor should exclusion be interpreted as some indication that these lands are now somehow subject to habitat degradation or destruction because they are not included in critical habitat. Lands excluded on the basis of conservation agreements and the recognition of conservation partnerships are fully expected to continue to make an important contribution to the conservation and recovery of the owl absent the designation of critical habitat. Such lands are excluded only if we have evidence that such expectations for future contributions of the habitat on these lands are well-founded, as evidenced by a conservation easement, habitat conservation plan, safe harbor agreement, or other instrument, or by a proven track record of conservation by the partner in question. The details of our considered analyses of each area under consideration for exclusion are provided in the Exclusions section of this document (above).

Comment (105): Numerous commenters requested that the final rule include lands covered by conservation agreements in the final rule for a variety of reasons, including consistency with existing policy, a need for connectivity, the habitat value of these areas, a lack of explicit population recovery objectives, a need for increased protections and legal safeguards, concerns about the conservation effectiveness and appropriate implementation of these agreements, and a need for additional analysis before they are excluded.

Our Response: As described earlier, the Service carefully evaluated each conservation agreement or partnership under consideration for exclusion on its own merits, and weighed the benefits of exclusion versus inclusion. As described in our response to *Comment (104),* above, we emphasize that the exclusion of such lands does not signal that they are not important to the conservation or recovery of the northern spotted owl, and indeed such exclusions are made only on the basis of our determination that the benefits of exclusion outweigh those of inclusion, and that such exclusion will not result in the extinction of the species.

Comment (106): Several commenters requested that the final rule exclude particular land areas in private ownership (including but not limited to Usal Redwood Forest Company, Hawthorne Timber Company, Mendocino Redwood Company, Rayonier, Sierra Pacific, Pope timberlands, Merrill & Ring's lands, Weyerhaeuser Mineral, SDS Lumber Co., Olympic Resource Management, Green Diamond, and Wauna Lake Club) for a variety of reasons, including economics, additional regulatory burdens and uncertainty, a lack of conservation benefits, mapping errors, effects on existing and future conservation easements and agreements, State protections, ongoing voluntary conservation activities, potential disincentives for preserving habitat, and possible negative impacts to existing partnerships and relationships.

Our Response: No private lands are included in the final designation of critical habitat. Many of these lands were excluded under section 4(b)(2) of the Act; our detailed evaluation of these exclusions is provided in the Exclusions section of this document. In some cases, lands were removed following a review of habitat conditions on the specific parcels identified using 2011 National Agricultural Imagery Program (NAIP) imagery, in response to public comment. Upon review, we determined that lands identified by Rayonier, Pope Resources, Olympic Resource Management, and Weyerhauser Mineral did not meet the definition of critical habitat. Therefore, these lands were removed from the final designation.

Some landowners asked for exclusion from the proposed critical habitat, but were not actually included in the proposed designation in the first place. An example of such a case is Merrill and Ring lands. In other cases, commenters did not submit sufficient location information for us to be certain of the location of the parcel in question; Wauna Lake Club, for example, fell into this category.

In cases where mapping errors may have been made in our proposed critical habitat designation, such that lands that do not meet the definition of critical habitat for the northern spotted owl were inadvertently included within the proposed designation, the mapping in the final rule was corrected, so that those lands are removed from the final designation. Sierra Pacific lands in California, for example, were inadvertently included in the proposed designation due to a mapping error; these lands were removed from the final designation. We similarly made any corrections to area total errors that were identified in comments on the proposed rule, and thank landowners for bringing these corrections to our attention.

All specific requests for exclusion and records of our consideration of those requests are in our record, and available upon request (see **FOR FURTHER INFORMATION CONTACT**).

Comment (107): More than 50 private landowners in Washington State requested individual exclusions for their lands for a variety of reasons, including economics, additional regulatory burdens, a lack of conservation benefits, fire risks, mapping errors, existing conservation agreements, and disincentives for voluntary conservation measures and for preserving habitat.

Our Response: Upon further review, using the underlying aerial photo imagery from the 2011 National Agricultural Imagery Program (NAIP) and Ruraltech's 2007 forestland parcel data, we determined that the vast majority of Small Forest Landowner parcels we examined had either highly fragmented, little, or no northern spotted owl habitat currently present. Based on the combination of parcel size, current habitat conditions, and spatial distribution, we concluded that private lands coded as Small Forest Landowner parcels do not provide the PCEs for northern spotted owls, nor are they essential to the conservation of the species; thus, these areas do not meet the definition of critical habitat, and we have removed them from the final designation of critical habitat for Washington State.

We removed from the final critical habitat designation lands described in 17 comments after confirming that these lands did not contain the PCEs, or that they were too small, fragmented, or isolated to contribute to spotted owl conservation, and therefore did not meet the definition of critical habitat. Lands owned by 19 other commenters that requested removal were not within proposed critical habitat. The land of one commenter was removed to correct a mapping error in the proposed rule. We excluded another commenter's lands due to their completion of a SHA. Finally, 16 commenters did not provide sufficient location information to enable us to unambiguously identify their parcels. Of these 16, we inferred that we likely removed 6 from the final critical habitat designation because the size of the commenters' parcels were very small, making it likely that our process of removing small forest landowners from the final designation included the properties of these commenters. For the remaining 10 commenters, lack of location and parcel size information in the comments we received made it impossible for us to determine or infer whether these parcels were included in our final critical habitat designation. However, as all private lands were excluded from critical habitat under section 4(b)(2) of the Act (see Exclusions), no private lands remain in the final designation.

Public Comments on Critical Habitat Boundaries

Comment (108): One commenter noted that the inclusion of the term ''necessary'' within the definition of ''conserve'' (16 U.S.C. 1532(2)) indicates that Congress intended a ''high threshold'' for designating land as critical habitat, and that land designated must be required to bring the species to the point of no longer needing the protection of the Endangered Species Act. The commenter further asserts that the Service must show that all specific areas proposed as critical habitat are necessary, essential, and required for the continued existence of the species.

Our Response: The use of ''necessary'' in the definition of conservation does not change the requirements related to critical habitat. Furthermore, the Act provides that the Service ''to the maximum extent prudent and determinable * * * shall * * * designate any habitat of [the species] which is then considered to be critical habitat.'' 16 U.S.C. 1533(a)(3)(A); see also *Center for Biological Diversity* v. *FWS,* 450 F.3d 930, 935 (9th Cir. 2006) (noting Congress' use of the word ''shall'' and holding that ''[i]t follows that critical habitat designations are mandatory''). There are only two exceptions to the mandate that critical habitat be designated at the time of listing. First, designation may be temporarily delayed if critical habitat is ''not determinable,'' e.g., it cannot be identified based on current scientific information. 16 U.S.C. 1533(a)(3)(A); 50 CFR 424.12(a). Second, designation is not required if it is ''not prudent,'' see id., but Congress intended that finding to be made ''only rarely.'' S. Rep. 106–126, at 4 (1999); see also H.R. Rep. 95–1625, at 16–17 (1978) (designation required except in ''rare circumstances'').

We agree that the rule should designate either (1) specific areas within the geographical area occupied by the species at the time of listing that contain physical or biological features essential to the conservation of the species and which may require special management considerations or protection, or (2) specific areas outside the geographical area occupied at the time of listing that are essential to the conservation of the species. We have identified the specific areas that were occupied at the time of listing through historical surveys. We have determined that other areas were occupied at the time of listing (based on the presence of suitable habitat as well as the high probability that nonterritorial and dispersing subadult owls were present). In addition, we analyzed all areas as if they were not occupied and applied the standard applicable to unoccupied habitat. We used the methodology described in both the proposed and final rules to determine which unoccupied areas are essential to the conservation of the species, and have explained why unoccupied habitat in each subunit is essential to the conservation of the species.

For occupied areas, the attributes of forest composition and structure, and characteristics of the physical environment associated with nesting, roosting, and foraging habitat—physical or biological features used by the species—were identified based on published research results and expert opinion and incorporated into a predictive habitat model. We determined that, for the most part, the physical or biological features supporting these known sites are essential to the conservation of the species (the exceptions are owl sites that were isolated or in areas of marginal quality). The special management considerations are described by geographic region and in the subunit descriptions. However, large areas within the species' geographical range had not been surveyed at the time of listing, and we have determined that a designation based solely on the locations of those known territories would not be adequate to conserve the species. Therefore, we used habitat information based on habitat selected by those known owl pairs to identify other areas that were likely supporting northern spotted owl territories at the time of listing or that could support the species' recovery in the future. We then determined where these areas are essential to conservation of the species based on a spatially explicit northern spotted owl population model as described in the proposed rule, and again in this final rule.

Comment (109): One commenter stated that one or more of the PCEs are too general in nature and should be more narrowly clarified or defined. In particular, the comment suggested that PCE #1 and #4 seem to be met by all forested lands.

Our Response: PCE 1 (Forest types that may be in early-, mid-, or late-seral stages and that support the northern spotted owl across its geographical range) identifies the specific forest types that support northern spotted owl life-history needs across the species' range, but is more narrowly refined in that it must exist in concert with one of the other PCEs to meet the definition of critical habitat. PCE 4 (habitat to support the transience and colonization phases of dispersal) is described in the preamble of the proposed rule as those forests with at least an average diameter at breast height (DBH) of 11 inches (28 centimeters) and at least a 40 percent canopy cover. We have included these metrics in the regulatory portion of the final rule to more narrowly clarify the forest structure that meets this PCE. In addition, it is only where these PCEs in the appropriate arrangement and quantity are essential to the conservation of the northern spotted owl that they are selected for designation as critical habitat.

Comment (110): Several commenters believe that additional lands beyond those already designated as northern spotted owl critical habitat are not necessary for northern spotted owl recovery, and the increase in total area is not supported by the science. The commenters suggest that including them will reduce or eliminate timber harvest on designated lands.

Our Response: The continued decline of the overall northern spotted owl population demonstrates that the threats to the species are still having a significant impact on northern spotted owl occupancy, reproduction, and survival. As described in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), the main threats to northern spotted owls are the past and continued loss of habitat and the competitive effects of barred owls. The increase in designated critical habitat area to help offset these threats is supported by northern spotted owl experts, researchers, and scientific peer reviewers. The results of our modeling efforts presented in Appendix C of the 2011 Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011, Appendix C) and in the Modeling Supplement for this rule (Dunk *et al.* 2012b) show that the 2008 critical habitat network performed worse (greater population declines over time, higher extinction risk) than the 2012 Revised Critical Habitat this revised designation.

The Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) recommends active management of some forest lands using ecological forestry approaches in appropriate stands such that we believe there are widespread opportunities for continued timber harvest management within the range of the northern spotted owl.

Comment (111): One commenter noted that the Endangered Species Act requires that designated critical habitat only include those areas ''occupied at the time of listing,'' and that any additional areas defined by the Secretary must be essential to conserving the species. The commenter argued that the standards for designating critical habitat for occupied and unoccupied habitat differ, and that Congress did not intend the phrase ''conserve'' to include extending the range of a species. The commenter also asserted that stating that substantially all of the occupied and unoccupied area is necessary does not comply with the statutory requirements.

Our Response: Congress specifically provided for designating unoccupied areas where doing so is essential to the conservation of the species. Congress expressly recognized that ''conservation'' could require designation of areas unoccupied at the time of listing. In this rule, we are designating unoccupied habitat in places where it is essential to the species' recovery; however, we are not designating critical habitat outside the historical range of the species. We are also not designating critical habitat everywhere within the present range of the northern spotted owl.

The proposed rule did not say that ''substantially all of the occupied and unoccupied area is necessary.'' The proposed rule explained how much of each subunit was occupied based on historical survey data, and why the areas of potentially unoccupied habitat in each subunit are essential to the conservation of the species. In addition, the methodology used to determine what is essential was explained in the proposed rule and this final rule.

Comment (112): Several commenters suggested that there was insufficient evidence to determine whether lands proposed as critical habitat were occupied at the time of listing, and questioned the data used for assessing northern spotted owl populations, both at the time of listing and at the present time.

Our Response: Occupancy by individuals of wide-ranging species can be difficult to definitively demonstrate or verify, particularly when different areas are utilized by individuals at different times in their life stages, and when the species responds to survey techniques in a variety of ways. Effectively detecting territorial northern spotted owls in a home range is a well-established technique, but locating nonterritorial or transient northern spotted owls is more difficult, even though they occupy many areas between established home ranges of territorial owls. The Service determined that most of the areas within critical habitat that have the PCEs were occupied at the time of listing by the species. However, as stated in the rule, we have determined all areas within critical habitat to be essential for the conservation of the species. Areas essential to the conservation of the species are not required to be occupied at the time of listing to be included in critical habitat.

For the purpose of developing and evaluating revised critical habitat for the northern spotted owl, we used a definition of ''geographical area occupied by the species'' at the time it was listed consistent with the species' distribution, population ecology, and use of space. We based our identification of ''occupied'' geographical area on: (1) The distribution of verified northern spotted owl locations and (2) scientific information regarding northern spotted owl population structure and habitat associations. While there were approximately 1,500 northern spotted owl pairs identified at the time of listing (1990), subsequent surveys across a larger percentage of the landscape in the mid and late 1990s detected more than 4,000 pairs. Because adult northern spotted owls are long-lived and have high site fidelity, it is reasonable to assume that these sites identified as occupied several years post-listing were also occupied by owls at the time of listing.

In addition, we are not stating that all critical habitat was occupied at the time of listing, but as clearly identified in the proposed rule and this final rule under the section Unoccupied Areas (77 FR 14062, p. 14099), we acknowledge the uncertainty regarding whether some areas were occupied at the time of listing or not (especially those areas used for dispersal or which were likely occupied based on habitat suitability). Therefore, we have evaluated these areas as if they were unoccupied at the time of listing and have found them to be essential to the conservation of the species.

Comment (113): One commenter questioned how some ''occupied'' habitat areas can be considered nonessential while other ''non-occupied'' habitat was considered essential for the conservation of the species.

Our Response: To conserve the northern spotted owl it is essential to have larger, connected areas that are managed for the development of their habitat even though some of those areas may not currently be occupied by the species. As habitat develops over time, both within occupied and unoccupied areas, we anticipate northern spotted owls will colonize the unoccupied habitat and positively contribute to population demographics which contribute to conservation of the species. The closer these currently unoccupied areas are to the improved sites over time the more likely dispersing northern spotted owls will be able to successfully colonize them. By evaluating northern spotted owl population metrics, such as relative population size, population trend, and extinction risk that resulted from each scenario evaluated, we designated only those lands that contain the physical and biological features essential to conserve the northern spotted owl, or that are essential themselves. This network has the potential to support an increasing or stable population trend of northern spotted owls that exhibits relatively low extinction risk, both rangewide and at the recovery unit scale, and achieves adequate connectivity among recovery units. It does not include every known northern spotted owl site. Occupied northern spotted owl sites that are not included are isolated or in small groups with other sites and will provide relatively less demographic contribution to the population than those sites that are in larger, contiguous groups. Therefore, we determined that they did not contain the physical and biological features essential to northern spotted owl conservation.

Comment (114): Numerous commenters requested we maximize the total area included in the designation by including the most area in any of the composites or by including all northern spotted owl habitat across all ownerships.

Our Response: We have designated critical habitat based on the identification of those areas meeting the definition of critical habitat or that are otherwise essential to the conservation of the northern spotted owl. Toward this end, maximizing land area is not the key factor. Our goal was to designate critical habitat that is essential for northern spotted owl recovery but achieves the desired results on as small an area as possible (i.e., it is efficient). This reduces any potential regulatory burdens and land management conflicts, which will increase the likelihood of success at meeting our goals. In addition, designating areas beyond that necessary to achieve the conservation of the species would indicate that we had included areas beyond what is truly essential to the conservation of the species, and exceeded the intent of the statute.

Comment (115): Several commenters suggested revisions to the boundaries of the proposed critical habitat, including several proposed additions (e.g., lands near Cascade-Siskiyou National Monument, Coquille tribal land, Coos Bay Wagon Road lands, the Olympics/ Western Cascade area, etc.) for several reasons, including the conservation value of the habitat, increased connectivity benefits for dispersal and gene flow, the need for additional protections to avoid habitat degradation, and consistency with the best available science and existing policy.

Our Response: When determining what is essential to the conservation of the northern spotted owl, we prioritized Federal, then State, and finally private or Tribal lands. Where Federal and State lands were sufficient to provide for the essential conservation needs of the northern spotted owl as demonstrated through our population modeling in HexSim, no additional lands were added. In addition, in accordance with the provisions of the Act, not all habitat that could be occupied by northern spotted owls was included in the designation. Only areas that meet the definition of critical habitat for the species were designated.

In Washington, we added suggested areas to critical habitat only where updated information about land ownership indicated a change in ownership from private ownership to Federal ownership. This was based on our prioritization of landownerships in the designation, as described above, wherein we looked to Federal lands first for critical habitat, and included State and finally private or Tribal lands only where necessary to achieve the conservation of the species. These areas had not initially been included in the proposal because the ownership information we used had indicated these lands were privately owned, and therefore they were not prioritized for inclusion. These additions occurred in the central Cascade Range of Washington where many sections of industrial timberlands in checkerboard ownership with Federal lands had recently been transferred to Federal ownership. This area of the central Cascades surrounding Snoqualmie Pass has repeatedly been identified as essential to maintaining demographic linkages among spotted owl populations from northern to southern Washington, and from the west slope to the east slope of the Washington Cascades.

Public Comments Regarding the Northwest Forest Plan (NWFP)

Comment (116): Several commenters stated that the rule needs to be more explicit about how it relates to the NWFP, and that the NWFP should direct the management of the critical habitat lands.

Our Response: We have clarified the relationship between the critical habitat rule and the NWFP under the ''Forest Management Activities in Northern Spotted Owl Critical Habitat'' heading. The designation of critical habitat for the northern spotted owl identifies the areas essential for the conservation of the species; it does not supersede the Standards and Guidelines for lands in the NWFP. The Service believes the NWFP has functioned as intended for the retention and development of late-successional forest habitat (Thomas *et al.* 2006; Davis 2012). The NWFP was developed with the expectation that emerging scientific data would be incorporated into the management of Federal forest lands. The discussions of active forest management in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) and this preamble are based on numerous recent scientific study results. We wish to be clear, however, that the inclusion or exclusion of NWFP reserves in the designation of critical habitat changes neither the land allocation nor the Standards and Guidelines for those lands under the NWFP. Nevertheless, we believe that our discussion of active forest management is consistent with the objectives of the NWFP.

Comment (117): One commenter suggested that lands currently managed under the NWFP do not require additional management considerations or protections from designated critical habitat.

Our Response: The Service is not relieved of its statutory obligation to designate critical habitat based on the contention that it will not provide additional conservation benefit. We do not agree with the argument that specific areas and essential features within critical habitat do not require special management considerations or protection because adequate protections are already in place. In Ctr. for Biological Diversity v. Norton, 240 F. Supp. 2d 1090 (D. Ariz. 2003), the court held that the Act does not direct us to designate critical habitat only in those areas where ''additional'' special management considerations or protection is needed. If any area provides the physical or biological features essential to the conservation of the species, even if that area is already well managed or protected, that area still qualifies as critical habitat under the statutory definition if special management is needed.

Comment (118): Numerous commenters asserted the proposed critical habitat rule would result in the weakening of the NWFP, including the dismantling or eradication of the late-successional (and riparian) reserves, and that we should use a variety of approaches explicitly elucidated in the final rule to maintain the LSR network.

Our Response: In designating critical habitat the Service is required to use the best available science to identify specific areas that provide the PCEs or are otherwise essential to the conservation of the species. Our modeling effort and other data identified some nonreserved areas that are high value for the northern spotted owl and essential to the conservation of the species. Additionally, there are portions of reserved allocations that are of relatively low value to the northern spotted owl. As a result of incorporating the best available science, our modeling process demonstrated that the critical habitat network identified here is more effective at conserving the northern spotted owl than the NWFP network of reserves. This is not unexpected, as the LSR network was never intended solely for the benefit of northern spotted owls, but was created to provide for many late-successional species. However, the designation of critical habitat does not change the existing NWFP land use allocations or Standards and Guidelines. The inclusion or exclusion of NWFP reserves as critical habitat changes neither the land allocation nor the Standards and Guidelines for those lands. The Service encourages continued implementation of the NWFP and adherence to the Standards and Guidelines for reserve management.

Comment (119): Several commenters noted the critical habitat rule should adopt the Standards and Guidelines of the NWFP in an effort to protect northern spotted owl habitat, including all late-successional and old-growth forests.

Our Response: In designating critical habitat we are required to identify those lands essential to the conservation of the species through application of the best available science. Our incorporation of state-of-the-art modeling programs, techniques, and data identified those areas, many of which contained late-successional or old-growth forest. However, the purpose of this rule is to designate critical habitat, not to adopt specific standards for its management. The Revised Recovery Plan for the Northern Spotted

Owl (USFWS 2011) recommends the retention of structurally complex forests where they currently exist (Recovery Action 32). We did not find, however, that retaining all northern spotted owl habitat is essential for the conservation of the species, so not all habitat was included.

Public Comments on Competition From Barred Owls

Comment (120): Several commenters recommended that the Service should objectively determine whether the barred owl threat has so overwhelmed the northern spotted owl as to make additions to critical habitat unnecessary, and noted that dealing with the barred owl and habitat threats separately could be detrimental to northern spotted owl recovery.

Our Response: The scientific information available at this time is not adequate to statistically assess the effect of barred owls on any specific conservation strategy or agency action, though these strategies include efforts to address barred owls. The extent to which northern spotted owls remain (sometimes undetected) on areas with high barred owl densities is unclear. However, the threat posed by barred owls does not relieve the Service of its statutory obligation to designate critical habitat for the northern spotted owl under section 4(a)(3)(A) of the Act. Furthermore, suitable habitat is essential for northern spotted owls to persist, with or without barred owls. Our modeling approach for designating critical habitat included barred owl effects on spotted owl population performance. Recent research (Wiens 2012) indicates that population performance of both northern spotted owls and barred owls is greatest when high-quality habitat is most abundant, and most peer reviewers supported the approach of conserving more habitat to help offset the impact of the barred owl on the northern spotted owl.

Public Comments on the Modeling Process

Comment (121): One commenter was critical that the process for combining different models in different modeling regions was unclear, and was also critical that a nonrandom sampling of nesting centers and the approach used to create a contiguous underlying RHS (Relative Habitat Suitability) map using MaxEnt modeling software.

Our Response: Although the RHS values within one modeling region may not be directly comparable to another's, the similarity of each modeling region's strength of selection curves (see Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011)), suggested that the interpretation of RHS values was similar between/among regions. Furthermore, Zonation was run within modeling regions (see Appendix C of the Revised Recovery Plan) to ensure that potential critical habitat units and subunits were well distributed throughout the northern spotted owl's range. We are aware of only one effort to date that has utilized random sampling of a relatively large region within the range of the northern spotted owl (Zabel *et al.* 2003). The demographic study areas were not randomly located, nor were the northern spotted owl location data we used. Thus, the chance exists that it is biased in some way. Nonetheless, given the relatively large sample sizes, and the geographic and habitat variation that exists around northern spotted owl sites in the samples we used, we contend that this is the best data available to use. The Service acknowledges that there is uncertainty in this process, and that this is unavoidable. There exists no perfect rangewide habitat map, no perfect (large) random sample of owl locations, no randomly allocated demographic study areas from which to draw strong range-wide inferences about population trends, nor a perfect understanding of the northern spotted owl's life history. That said, we have used the best data available, thoroughly documented our approach and presented our evaluation of the usefulness of the models we used, and we find they provide a strong foundation using the best available science for informing decisions about critical habitat.

Comment (122): One commenter indicated a need to clarify the basis for the thinning of northern spotted owl location data used in modeling.

Our Response: The basis of the thinning is articulated on pages C–20 and C–21 of Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011).

Comment (123): One commenter indicated that the assumptions for this modeling process were not completely spelled out nor were their validities addressed. For example, the modeling of habitat suitability assumes that core use areas and home ranges of northern spotted owls are relatively constant in size throughout their geographic range, but this assumption is not well supported by the proposed critical habitat, Appendix C of the 2011 recovery plan, or the published literature. Core use areas and home ranges increase in size for northern spotted owls in the northern part of their range versus those in the southern part (Thomas *et al.* 1990). Second, the modeling process for evaluating habitat suitability under MaxEnt assumes that some moderate amount of edge and degree of forest fragmentation is good for demography and fitness of northern spotted owls throughout their geographic range based on Franklin *et al.* (2000), yet this relationship has been shown mainly for northern California and one area in Oregon (Olson *et al.* 2005), not the remainder of the subspecies' range in Oregon and Washington. For example, Dugger *et al.* (2005) found no relationship between the amount of edge and demographic performance of northern spotted owls in southern Oregon; consequently, the validity of this assumption for the entire range of the subspecies is questionable.

Our Response: We did use one spatial scale throughout the northern spotted owl's range for our MaxEnt modeling. We also assumed that territories, in our northern spotted owl HexSim model, were of uniform size (3 hexagons) throughout the northern spotted owl's range. We did not, however, assume home ranges were of equal size throughout the range (see table C–24 in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011)). We also did not assume that edge or forest fragmentation was good for northern spotted owl demographic performance in our MaxEnt models. We did, however, allow for edge metrics to be included in the models where they had clear effects on the MaxEnt models; however, we did not force them in to the models in modeling regions where they had no effect. It is important to note that, unlike studies that have attempted to evaluate competing mechanistic hypotheses regarding northern spotted owl habitat/climate-demographic relationships (e.g., Franklin *et al.* 2000, Dugger *et al.* 2005), in our MaxEnt modeling process, we did not attempt to evaluate competing hypotheses. Instead, we attempted to develop MaxEnt models that had good discrimination ability, were well calibrated, and were robust (see our response to *Comment (20);* additional discussion is provided on pages C–30 to C–32 of the Revised Recovery Plan, USFWS 2011).

Comment (124): One commenter requested more justification for the choice of features in MaxEnt modeling. For example, the threshold feature was used, but the product feature was excluded. They predicted that product features in particular might be relevant to biological hypotheses (e.g., when nesting habitat is low, increases in foraging habitat don't increase occupancy, but when nesting habitat is greater, foraging habitat has a greater impact on occupancy).

Our Response: We could have allowed all MaxEnt feature types to be used in our process. The product (interaction) feature would have resulted in even more complex models. However, we were able to develop models without additional complexity (e.g. interaction terms) that worked well for the purposes for which they were developed. Results from model cross-validation and comparisons with independent data sets (USFWS 2011, Appendix C, Table 19, pp. C–39 to C–41) showed that our models were well calibrated and had good ability to predict spotted owl locations (USFWS 2011, Appendix C, Table 20).

Comment (125): Several commenters requested more detail regarding how the different Zonation scenarios from Phase 1 in Appendix C of the Revised Recovery Plan were selected for inclusion in proposed critical habitat. In particular, the reviewers believed that Zonation 70 and 90 scenarios would have provided better modeled northern spotted owl population performance.

Our Response: We assume that the question is about why the 30, 50, and 70 percent of habitat value were chosen for the initial Zonation networks. They were chosen to provide relatively broad side-boards, particularly in regard to network size. To have started with even more extreme side-boards (e.g., Z10 and Z90) would have been excessive because these configurations would have included either a very large amount of land that doesn't have features that would support owls (Z90) or an area so small (Z10) that viable owl populations could not be sustained. It is true that a Z90 scenario would have provided much more area of potential critical habitat, but the amounts of high RHS (> 0.5) in Z70 are nearly identical to those in Z90. In fact, Z50ALL contained 92%, 98%, 99%, and 100% of RHS bins 0.6–0.7, 0.7–0.8, 0.8–0.9, and > 0.9, respectively. Z90ALL contained 100% of the RHS from each bin, but encompassed a much larger area (i.e., for very little added inclusion of high RHS areas, Z90 included millions of additional acres). In effect, moving from Z70 to Z90 adds a lot more area; however, the additional lands added do not contribute much to spotted owl population performance.

Zonation 70 was considered, and subsequently modified in various composite networks we evaluated. We found that simply increasing the area of potential critical habitat networks did not always result in better performance of simulated owl populations in HexSim (e.g., Composite 7 was 13.9 million ac (5.625 million ha) and had an ending population that did not differ (95 percent confidence intervals overlapped) from composites with from 18.2 to more than 20 million ac (7.4 to more than 8.1 million ha)). In some modeling regions, our modeling results suggest that owl populations are likely to remain relatively low; in part due to the relatively small amount of mid-to-high RHS area in them. The population results for Zonation 40, 60, 80 and 90 are provided in our Modeling Supplement (Dunk *et al.* 2012b).

Comment (126): One commenter indicated there were key assumptions used in the modeling process that should be more clearly documented. The reviewer indicated that the proposed critical habitat document refers the reader to the Dunk *et al.* (2012a) Modeling Supplement for a discussion of these assumptions but they were unable to locate them in this document. Not only should the assumptions of the modeling be included in the proposed critical habitat, but the validity of the assumptions should also be addressed.

Our Response: The key assumptions used in our modeling process are provided in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), and referenced in our proposed rule. Appendix C also provides a thorough discussion of our process of testing and cross-validating our models. We have also clarified this in the final version of our Modeling Supplement (Dunk *et al.* 2012b).

Comment (127): One commenter noted that the modeling of population response and viability under HexSim assumed that recruits into the population become co-owners of their mother's territories, yet most owls are recruited into the population in different areas after extensive dispersal over several months and sometimes years. They asked to what extent are these assumptions valid, and how would lack of validity potentially affect the results of the modeling process?

Our Response: In the northern spotted owl HexSim model we assumed that juvenile birds, prior to dispersal, co-owned their mother's territory. However, juveniles were forced to disperse in the model. The recruits are only co-owners until they fledge, and fledging always takes place in the first year of life. Further, in the modeling two post-fledging females did not share a territory.

Comment (128): One commenter noted that composite 3 performed poorer than composite 1 based on population performance, yet composite 4 was based on the network in composite 3 and composite 5 was based, in part, on that in composite 4. This sequence of models based on the poor performance of composite 3 does not make sense from an ecological or conservation stand point. It is obvious that composites 1–7 do not represent the complete range of habitat networks that might provide for sustainable populations of northern spotted owls in most of the modeling regions. They contend that there should have been more attention paid to increasing habitat for northern spotted owls and providing for sustainable populations in all modeling regions instead of increasing efficiency. They understood the need to make any habitat network efficient but believed that this was a case where efficiency has trumped conservation of habitat for the northern spotted owl and other species associated with old forest ecosystems.

Our Response: Relatively poorer performance (as noted by the reviewer) is not equivalent to ''poor performance.'' In fact, the 95 percent confidence intervals of the mean estimated population sizes at time-step 350 overlapped for composites 1, 3, 4 (highest point estimate), 5, 6, and 7 indicating that the differences may not be statistically significant. Furthermore, although Composite 3 did perform worse than Composite 1 in terms of exceeding pseudo-extinction thresholds, Composite 7's performance was nearly identical to Composite 1's. Thus, we disagree with the assertion that our sequence was based on poorly performing composites. There are an infinite number of possible potential critical habitat networks that could have been evaluated. Efficiency, as used by the Service in this effort, did entail reducing the size of potential critical habitat networks, because our charge under the statutory definition of critical habitat is to designate only those lands occupied at the time of listing that contain essential physical and biological features or unoccupied lands that are essential.

Comment (129): One commenter indicated that the process for comparing GNN (vegetation) data with owl nest sites and foraging areas is unclear. The reviewer asked whether GNN data indicated that nest site centers were characterized by large, old trees with closed canopy forests and stated that this process needs better explanation.

Our Response: The process for developing models of nesting and foraging habitat is described in detail on pages C–14 through C–43 in Appendix C of the 2011 Revised Recovery Plan for the Northern Spotted Owl. Nesting and roosting habitat was characterized by large, old trees with closed canopies; however, the specific vegetation characteristics included in the models varied by region. Our confidence that the GNN layer was sufficiently accurate to support our modeling process was based on several formal and informal evaluations. First, we evaluated northern spotted owl habitat modeling conducted by the Northwest Forest Plan Interagency Monitoring Program (Davis *et al.* 2011), which was also based on the GNN data. This effort used GNN and MaxEnt to predict northern spotted owl nesting habitat, obtaining models quite similar to the NR models in our modeling effort. We also obtained less formal, but very useful, feedback from a number of USFS scientists who had made comparisons between GNN output and their own field-typed northern spotted owl nesting habitat with good results. Finally, as described in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011), we evaluated the reliability of the MaxEnt models' predictions (RHS) and found that the models had good ability to predict northern spotted owl locations. Systematic inaccuracy of the GNN data would be unlikely to result in the accurate predictions we obtained in our modeling. In addition, please see our responses to *Comment (19)* through *Comment (22)* for details on our testing, cross-validation, and use of GNN and MaxEnt.

Comment (130): One commenter stated that more information on the ''independent test data sets'' used for model cross-validation is necessary before they are acceptable as an adequate test. In particular, if these data sets suffer from the same non-random sampling as the training data, then they will not aid in determining whether the RHS and AUC values are biased by the nature of the sampling or not.

Our Response: As described in Appendix C of the Revised Recovery Plan (USFWS 2011, p. C–20), we expended substantial effort on the verification of both the spatial accuracy and territory status of each site center used in our data set. We received high quality data from northern spotted owl demographic study areas (DSAs), and obtained a large set of additional locations from the NWFP Effectiveness Monitoring Program. We also obtained and verified data sets from private timber companies, the USFS Region 5 NRIS database, and a number of research and monitoring projects throughout the range of the northern spotted owl. We are aware of only one effort to date that has utilized random sampling of a relatively large region within the range of the northern spotted owl (Zabel *et al.* 2003). Because of the spatial extent of the range of the northern spotted owl (more than 23 million acres), we do not have the luxury of having equal survey effort throughout the region. The demographic study areas are not randomly located, nor are the northern spotted owl location data we used. Nonetheless, given the relatively large sample sizes, and the geographic and habitat variation that exists around northern spotted owl sites in the samples we used, we consider this information to represent the best available scientific data for our purposes, and are not aware of any alternative data sets.

Comment (131): One commenter expressed concern that the encounter rates of northern spotted owls with barred owls found in Forsman *et al.* (2011) were reduced downward to a maximum rate of 0.375 even though there is strong evidence in Forsman *et al.* (2011) that the rate is higher in some modeling regions, and Wiens *et al.* (2011) has shown that abundance of barred owls (and encounter rates) is much higher in the Coast Ranges of Oregon than initially thought or is documented in Forsman *et al.* (2011). The lower encounter rates of northern spotted owls with barred owls that were used in Phases 2 and 3 of the modeling represent more optimistic performances of northern spotted owls to habitat conditions than is likely to occur in reality. The reviewer contends that it would have been more appropriate to use Zonation 70 or even 90 to a greater extent in some modeling regions, than to arbitrarily reduce the barred owl encounter rate to a maximum of 0.375 in order to provide for sustainable populations in all modeling regions.

Our Response: The modeling we conducted suggested that the larger the barred owl encounter probability was, there was less variation in northern spotted owl population performance among potential critical habitat networks (even when network size varied by more than a factor of 2); effectively all populations did uniformly poorly. However, when barred owl encounter probabilities were lower (e.g., 0.25), considerable variation in northern spotted owl performance among potential critical habitat networks resulted. Thus, under extremely high barred owl encounter probabilities, our modeling suggested that even large amounts of area in potential critical habitat networks did not compensate for those barred owl impacts. Thus, in order to identify potential critical habitat areas for the northern spotted owl, we made assumptions about barred owl encounter probabilities in each of the 11 modeling regions. The assumed changes in encounter probabilities we used in Phases 2 and 3 of our modeling were, in most cases, relatively modest changes from the currently estimated encounter probabilities. In fact, for Phase 2 and 3 modeling, we decreased barred owl encounter probabilities in only 3 of 11 modeling regions, and increased encounter probabilities in 8 of 11 modeling regions. Mean absolute value of change (from currently estimated to what we assumed in Phases 2 and 3) among modeling regions was 0.081 (range = 0.005 (in the KLE) to 0.335 (in the OCR)). For additional detail, please see our response to *Comment (38).*

Comment (132): One commenter suggested that we use an occupancy analysis on the long-term demographic study areas rather than modeling habitat with MaxEnt to better address barred owl effects.

Our Response: Barred owl impacts were included in HexSim. In our response to comments made on Appendix C in the Draft Revised Recovery Plan for the Northern Spotted Owl (75 FR 56131; September 15, 2010), the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) addressed the choice we made to use MaxEnt and the full data set of owl site center locations that was available to us, rather than rely solely on data from the Demographic Study Areas.

Comment (133): One commenter contended that a separate analysis of BLM checker-boarded lands in western Oregon is needed in order to understand the performance of northern spotted owl populations under the different habitat networks and composites on those lands.

Our Response: The number of possible owner/district/region-centric analyses that we could have evaluated was nearly infinite. The BLM's ownership was considered in the same way that other ownerships were. In developing the critical habitat designation, we prioritized public lands over private lands.

Comment (134): One commenter noted that for most of the study areas, the estimates from HexSim compared favorably to the empirical estimates from the field studies except for the South Cascades (CAS) and Klamath (KLA) Study Areas. In one case (CAS), the estimate from HexSim was much larger than that from the field studies, and in the other case (KLA) the estimate from HexSim was significantly smaller than from the field studies. These differences and inconsistencies raise some concerns for the validity of the modeling results from HexSim. The commenter asked for some explanation for these differences and inconsistencies, and whether the input parameters for HexSim need to be revised.

Our Response: We are aware of these differences, as noted in Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011). We evaluated multiple changes to the northern spotted owl HexSim model's settings, but those changes did not result in overall better agreement between HexSim population estimates and empirical estimates from demographic study areas (DSAs). To some extent, this issue is the result of the spatial scale at which we ran the northern spotted owl HexSim model. The overall results, in our view, were quite good—but not in every specific case. Although there were discrepancies at these local areas, we believe that the scale at which we evaluated information for potential critical habitat networks (modeling regions and the entire geographic range of the northern spotted owl in the United States, which is at least an order of magnitude larger than a demographic study area) was appropriate. We provide additional justification in the following paragraphs.

The KLA DSA is quite small, and is distributed across the Klamath East and Klamath West modeling regions. The CAS DSA is large, and is distributed across the Klamath East and East Cascades South modeling regions. There were no simulated northern spotted owl life-history parameters that varied based on demographic study area location. Some demographic data (resource target and home range size) did, however, vary by modeling region.

HexSim simulation data show that the East Cascades South modeling region exchanged owls principally with the Klamath East and West Cascades South modeling regions. The Klamath East modeling region exchanged owls principally with the East Cascades South and Klamath West modeling regions, with relatively small numbers of immigrants coming from the West Cascades South region. The Klamath West modeling region exchanged owls principally with the Klamath East modeling region, with the next highest number of emigrants and immigrants being associated with the Oregon Coast and Redwood Coast regions, respectively.

The simulated CAS DSA population size is roughly 45 owls too large, whereas the KLA DSA population size is about 55 owls too small. These two DSAs are spread across three modeling regions, with both DSAs residing partly in the Klamath East region. Because the Klamath East modeling region exhibits high rates of simulated immigration and emigration with the other two modeling regions in question (see previous paragraph), the discrepancy in simulated DSA population sizes is not a big concern. The sum of the simulated CAS and KLA DSA population sizes is almost exactly equal to the combined field estimates for those two regions. This suggests that HexSim's simulated northern spotted owl population size and distribution is quite accurate at the scale of the DSA for most DSAs, and for these two DSAs in particular, it is similarly accurate, just at a slightly larger spatial scale.

Comment (135): One commenter asked what publication or data set were used for establishing the barred owl influence on northern spotted owl reproduction in the HexSim model.

Our Response: In the northern spotted owl HexSim model we used, barred owls did not have any influence on northern spotted owl reproduction, but did on adult survival. This has been clarified.

Comment (136): Several commenters requested that the Service integrate industry data into the modeling process and that attention be given to the assumptions and limitations of the models and whether or not the assumptions and model outputs have been validated.

Our Response: The modeling process incorporated data sets, expert opinion, and published information from the timber industry. We carefully evaluated the appropriateness of our models, data sets, and assumptions and tested the outputs and products of the modeling effort; we therefore are confident that our process was rigorous and met our objectives. Please see Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) for a discussion of the rigorous testing and cross-validation we conducted on our models, as well as our responses to *Comment (19)* through *Comment (22).*

Comment (137): One commenter raised concerns about leaving out high RHS value habitat on State and private lands in Washington, and provided recommendations of specific areas to include in critical habitat designation.

Our Response: The modeling process that the Service developed to help identify potential critical habitat is most appropriately used to make relative comparisons of alternative scenarios. While we sought to make the models as realistic as possible to achieve meaningful relative comparisons, these modeling tools are not designed to predict specific future outcomes. We are confident in the ability of the modeling routine to rank a set of scenarios from best to worst and provide insights about the degree of difference among them. But population metrics provided by the models are better viewed as relative indices than as predictions. This caution about interpretation of model output is particularly relevant to modeling regions with low amounts of total habitat area, such as in the State of Washington. In the modeling environment, small population sizes tend to lead to high variation in outcomes among iterations. Furthermore, competitive effects of barred owls played a large role in determining population outcomes, especially in Washington where encounter rates between barred owls and northern spotted owls are high.

We used the objectives and criteria in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) to guide our critical habitat proposal. Only after we had a critical habitat network that we considered essential to meet recovery objectives did we impose the secondary criterion of network efficiency. We retested networks after efficiency modifications were made to ensure they were still likely to meet recovery objectives. We included State or private lands only where our modeling results indicated Federal land was insufficient to provide what is essential for recovery.

As described in the section Criteria Used to Identify Critical Habitat, we have included in this designation only those areas occupied at the time of listing that provide the essential physical or biological features, or areas unoccupied at the time of listing that we have determined are otherwise essential to the conservation of the northern spotted owl. We appreciate the commenter's suggestion of additional areas for consideration, and we did evaluate all areas on the basis of RHS throughout the range of the northern spotted owl, including State and private lands in southwest Washington. We have included in this final designation all areas that we have determined are essential to the conservation of the species. A determination that certain areas are not essential should not, however, be interpreted to mean that such areas do not have the potential to contribute to the recovery of the species, and we encourage landowners to participate in other recovery efforts to achieve conservation on their lands (for example, as identified in Recovery Actions 14 and 15 of the Revised Recovery Plan (USFWS 2011)). In addition, we identified some State and private lands in Washington as essential for the conservation of the northern spotted owl, but all of the private lands and some of the State lands were subsequently excluded under section 4(b)(2) of the Act (see Exclusions). As discussed in our response to *Comment (104),* above, exclusion of areas is not the same as a determination that those areas are not essential; it only reflects the Secretary's determination that the benefits of excluding such areas outweighs the benefits of including them in critical habitat.

Comment (138): One commenter claimed that critical habitat includes nearly all suitable habitat—occupied or not—and was driven by the artificial constraints incorporated into the recovery plan—namely the manipulation of the barred owl interaction model. According to the commenter, absent these artificial constraints, the model would have predicted that none of the alternatives will conserve the species in the face of barred owls, therefore none of the lands wherein there is significant barred owl interaction are ''essential'' for the survival of the species. The commenter further stated that given the significant impact on the human environment by restricting management of the lands within this region, the Service needs to clearly provide the public with an estimation of the scientific reliability of their ability to conserve the northern spotted owl, and this information is critical to weighing the social and economic ramifications of the proposed action.

Our Response: The proposed critical habitat rule did not include ''nearly all suitable habitat'' and our evaluation indicated that the large majority of the proposed designation was occupied at the time of listing and contains the physical and biological features essential to conservation of the species. It also identified other areas essential to the species' conservation, which represent only a small portion of the proposed critical habitat. Contrary to the commenter's assertion, the barred owl impacts used in the population modeling process were similar to or slightly higher than those reported in most modeling regions; barred owl effects were reduced in only three of 11 regions (Table 2 in Modeling Supplement). This was done to enable the identification of areas essential to the spotted owl's recovery; threats that are not habitat-based are addressed through implementation of actions in the recovery plan. The current influence of barred owls on occupancy by northern spotted owls does not negate the role of habitat in the recovery of the species. The Service clearly noted in the proposed rule that the areas proposed as critical habitat are essential, but not sufficient absent other management actions, to recover the northern spotted owl.

Comment (139): One commenter was concerned that the proposed rule did not present an effects analysis for the proposed exclusions that indicates how northern spotted owl populations would likely respond if these lands were excluded.

Our Response: Many of the potential exclusions put forth in the proposed critical habitat rule would be unlikely to affect the outcome of our population modeling. This is because those exclusions, if made, would be based on their having some existing habitat protections (e.g., wilderness areas, national parks, HCPs, SHAs) that we would reasonably expect to continue into the future, and thus our treatment of them in the modeling would be the same as if they were included in a critical habitat network. If we were to exclude lands without consideration of continued conservation, we agree that this could change the results of our population modeling. However, since this is not the case, and no such lands were excluded from this final rule, we did not need to conduct such an analysis in this final rule.

Comment (140): One commenter was critical that no analysis was provided as to the relative effectiveness of the new critical habitat network in also capturing habitat for other late-seral/old-growth-associated species of concern, and encouraged an analysis of the effects of the proposed critical habitat network on multi-species conservation goals, by overlaying critical habitat boundaries on data on occurrence and habitat distribution for other species of concern.

Our Response: Analyzing the effects of the proposed critical habitat network on multi-species conservation goals is beyond the scope of the critical habitat designation process for the northern spotted owl. Furthermore, the results of such an analysis would not affect the selection of the final critical habitat designation for the northern spotted owl, as the statutory language defines critical habitat with reference to a particular listed species.

Comment (141): One commenter suggests that the Service fails to explain to the public why, in order to model sustainable northern spotted owl populations, it was required to arbitrarily select an interaction rate with barred owls that was not based on science-based field studies. Rather, the commenter states, it was based on the assumption that barred owls would be addressed through their extirpation from wide swaths of the Pacific Northwest (''Modeling and Analysis Procedures used to Identify and Evaluate Potential Critical Habitat Networks for the Northern Spotted Owl,'' USFWS Feb. 28, 2012, pp. 14–15), an assumption that is neither legally nor scientifically supportable.

Our Response: The Service made no assumption, written or otherwise, that the barred owl would be extirpated from any portion of the northern spotted owl's range. The ''ceiling'' on barred owl encounter rates that was used in the modeling (Phases 2 and 3 from Dunk *et al.* 2012a) was not arbitrary, but based on the results from several scenarios presented and compared during Phase 1 modeling. As explained in both Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) and Dunk *et al.* 2012b, the barred owl encounter rates used in the testing and selection of the proposed critical habitat designation are, in most modeling regions, similar to or even slightly above the currently estimated encounter rates. Only in portions of Washington were encounter rates reduced in order to identify essential habitat absent the undue influence of barred owls, but certainly not to the extent of ''extirpation of wide swaths'' as suggested in this comment. For additional details, please see our response to *Comment (38).*

Comment (142): One commenter stated that the original critical habitat designations were based on forest stand characteristics whereas the new designations are based on computer simulations that are untested and unreliable, and that this is not an improvement on the existing science. The commenter states that northern spotted owl populations have continued to decline as suitable habitat has increased; therefore, there are factors other than habitat that are decimating northern spotted owls, namely barred owls and catastrophic fires, and increasing the size of habitat will do nothing to save them.

Our Response: While it is true that northern spotted owl populations continue to decline, we have no evidence to suggest that suitable habitat has increased rangewide. Furthermore, we recognize that loss or degradation of habitat is not the only threat affecting northern spotted owl populations. However, as we have stated, comprehensive recovery actions for the northern spotted owl are provided in the Revised Recovery Plan (USFWS 2011). The existence of other, non-habitat based threats does not relieve the Service of its statutory obligation to designate critical habitat for the species to the maximum extent prudent and determinable.

We believe the commenter may not have understood that the computer programs that we used were developed, to the extent that it was defensible to do so, with empirically derived information, and thus were also ultimately based on real forest stand characteristics. In cases where this was not possible, a rationale for parameter inputs was provided (see Appendix C of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) and Dunk *et al.* 2012b). For example, actual weather station data are not available across the entire range of the northern spotted owl; however, temperature and precipitation models that provide site-specific climate data across the species' range provide these data. Additional explanation of the extensive degree to which our models were tested and cross-validated is also provided there, as well as in our responses to *Connet (19)* through *Comment (22),* among others.

Comment (143): Several commenters noted that the Service should redo its habitat modeling by including active management as a setback of owl habitat and to determine how long it will take for treated areas to recover to suitable nesting, roosting, and foraging habitat.

Our Response: The analysis suggested in this comment is predicated on the availability of reliable information on the extent to which active management may potentially be implemented within the boundaries of critical habitat, if at all. As we have noted throughout this rule, the discussion of active management provided is for use by Federal, State, local, and private land managers, as well as the public, as they make decisions on the management of forest land under their jurisdictions and through their normal processes. We are attempting to emphasize that critical habitat is not necessarily a ''hands off'' designation, depending on the nature of the habitat and the action under consideration, and we encourage land managers to consider the flexibility of management options available to them consistent with the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) and the Standards and Guidelines of the NWFP (USDA, USDA 1994). However, as noted in our economic analysis of the designation, predicting what land managers may choose to do is an exercise in uncertainty; land managers may choose to refrain from any management actions, may continue to manage lands as they currently do, or make choose to implement alternative active management practices. Given that we do not know whether land managers will even attempt to implement active management, much less how often or on what scale, attempting to model the effects of those actions on RHS would be purely speculative and, for our purposes, uninformative.

Other Public Comments

Comment (144): Two comments were submitted regarding how proposed critical habitat (not specific to a particular land use allocation) will negatively impact future development within counties.

Our Response: The forested areas included in the critical habitat designation are primarily managed for forest products, including timber production. We are not aware of any development projects proposed within the area of this revised designation, and our final economic analysis did not identify any such potential impacts.

Comment (145): Two commenters asserted that the regulatory mechanisms for protecting critical habitat on State and private lands were insufficient to adequately protect northern spotted owl habitat.

Our Response: The statutory authority defining and regulating critical habitat is the Endangered Species Act (Act). Section 7(a)(2) of the Act specifically provides that protections to critical habitat via consultation are triggered by actions authorized, funded, or carried out by Federal agencies (referred to as a ''Federal nexus''). If there is no Federal nexus involved in a proposed action, the law does not require consultation with the Service. The Act does not provide a direct regulatory mechanism for protecting critical habitat on State or private lands absent a Federal nexus.

Comment (146): One commenter requested that the Secretary identify those lands being designated for the purpose of expanding the range or dispersing the northern spotted owl into unoccupied areas.

Our Response: The designated lands are entirely within the range of the northern spotted owl and the vast majority of lands were occupied by northern spotted owls at the time of listing. This designation does not identify any areas for the purpose of expanding the range of the species. We have included some small areas that may have been unoccupied at the time of listing for the purposes of accommodating potential population growth. Each of the subunit descriptions in this rule describes the subset of area, if any, that was identified to assist with northern spotted owl movement across broad landscapes, to provide connectivity between established populations, or to provide for population expansion. Population expansion, as used here, is meant to describe population growth in terms of increased numbers of individuals within an area, not range expansion. In Oregon we have designated two areas specifically to assist in the movement of northern spotted owls between the Oregon coast (ORC) and the western Cascades south (WCS) critical habitat units. In Washington, many historically occupied areas included in critical habitat are currently unoccupied due to reductions in spotted owl populations. Full occupancy of these formerly occupied areas (population growth or expansion) would provide for conservation of the spotted owl without expanding the range. Relative to past critical habitat designations for the spotted owl, we also included additional areas in northern Washington into the current critical habitat designation. These areas may increase the potential for dispersal of owls to and from British Columbia, Canada, in the future. Currently, such exchange is unlikely due to low abundance of spotted owls in this landscape on both sides of the international border. All of this area is within the current geographic range of the northern spotted owl, and does not expand that range beyond its historical boundaries.

Comment (147): One commenter questioned how the Service had applied a ''significant contribution'' standard to occupied and unoccupied areas.

Our Response: We considered a specific area to make a ''significant contribution'' to the conservation of the species if adding or removing that area from the habitat network under consideration resulted in an appreciable change in the population performance in that modeling region.

Comment (148): One commenter requested additional clarification of the terms ''largely occupied'' or ''approximately occupied'' at the time of listing for particular subunit areas.

Our Response: These terms have been clarified in the final rule. For each subunit, the proposed rule explained that the specified percentage ''was covered by verified northern spotted owl home ranges at the time of listing.'' As an example, such subunit descriptions then went on to say: ''[w]hen combined with likely occupancy of suitable habitat and occupancy by nonterritorial owls and dispersing subadults, we consider this subunit to have been largely occupied at the time of listing. In addition, there may be some smaller areas of younger forest within the habitat mosaic of this subunit that were unoccupied at the time of listing. We have determined that all of the unoccupied and likely occupied areas in this subunit are essential for the conservation of the species to meet the recovery criterion that calls for continued maintenance and recruitment of northern spotted owl habitat. The increase and enhancement of northern spotted owl habitat is necessary to provide for viable populations of northern spotted owls over the long-term by providing for population growth, successful dispersal, and buffering from competition with the barred owl.'' Thus, the specified percentage is based on actual surveys. However, as described in Criteria Used to Identify Critical Habitat, we also determined that all areas designated are essential to the conservation of the northern spotted owl, using the more restrictive standard for unoccupied areas, to ensure all areas were appropriately designated even if there was any uncertainty about its occupancy status at the time of listing.

Comment (149): One commenter requested additional clarification about how the ''time of listing'' occupancy analysis relates to information suggesting that old growth and late-successional habitat features may not be optimal for the northern spotted owl in the Oregon Coast Range.

Our Response: Northern spotted owls live in a variety of forest types and rely on forests of varying structure to survive during different parts of their life cycles. The occupancy data from the time of listing reinforces that the northern spotted owl requires older forest structure to maintain viable reproducing populations throughout much of its range. This commenter appeared to be referring to studies that have shown that northern spotted owls will use younger forests in the Oregon Coast Ranges (Glenn *et al.* 2004) and appear to benefit from some degree of younger forest interspersed in older forest in southwest Oregon (Olson *et al.* 2004) and northern California (Franklin *et al.* 2000). However, none of these studies suggest that old growth and late-successional forest are not optimal habitat for northern spotted owls.

Comment (150): One commenter requested that the Service acknowledge the benefits of grazing on public lands as a tool to manage vegetation which provides the northern spotted owl with easier access to prey. The commenter also expressed concern that the expansion of critical habitat would limit grazing.

Our Response: We are not aware of any research or scientific publications on grazing and northern spotted owl foraging use, and the commenter did not provide supporting information. In any case, this rule does not prescribe limitations on grazing.

Comment (151): One commenter requested that regeneration harvest be restored on all Federal forests within the Northwest Forest Plan boundary, in particular on the Olympic Peninsula. The commenter suggested that regeneration harvest would help restore forest health, create jobs, provide revenue from timber harvest, and reduce effects of forest fires on northern spotted owl habitat.

Our Response: This rule is limited to the designation of critical habitat for the northern spotted owl. While the preamble discusses some management techniques for consideration by land managers, specific management prescriptions for Federal lands within the NWFP is beyond the scope of this rulemaking.

Comment (152): Several commenters suggested narrowing the scale at which the Service assesses whether a proposed action destroys or adversely modifies critical habitat to better reflect northern spotted owl biology, to better capture localized negative trends, or to align with the intent of the Endangered Species Act.

Our Response: In accordance with Service policy, the adverse modification determination is made at the scale of the entire designated critical habitat, unless the critical habitat rule identifies another basis for the analysis (USFWS and NMFS 1998). The adverse modification determination for the northern spotted owl will occur at the scale of the entire designated critical habitat, as described above in the section Determinations of Adverse Effects and Application of the ''Adverse Modification'' Standard, with consideration given to the importance of the conservation function of units and subunits within each of the recovery units identified in the Revised Recovery Plan (USFWS 2011, Recovery Criterion 2). The Service believes the entire designated critical habitat is the appropriate scale for this analysis, because our determination is based on whether implementation of the Federal action would preclude the critical habitat as a whole from serving its intended conservation function or purpose. However, a proposed action that compromises the ability of a subunit or unit to fulfill its intended conservation function or purpose could represent an appreciable reduction in the conservation value of the entire designated critical habitat.

Comment (153): Several commenters suggested that the Service cannot legally designate land as critical habitat that does not currently contain primary constituent elements (PCEs), and should not designate lands that may become habitat in the future.

Our Response: In our proposed designation of critical habitat for the northern spotted owl, we identified primarily areas that were occupied at the time of listing as critical habitat; all such areas support the PCEs and subsequently the essential physical or biological features as identified in this rule. In addition, some areas that may not have been occupied at the time of listing are designated as critical habitat, because we determined that such areas are essential to the conservation of the species. These areas make up a relatively small percentage of the total designation. Because the loss or degradation of habitat was one of the primary threats that led to the listing of the species, the restoration of habitat is required to achieve the recovery of the species, as identified in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011). In some areas, the recovery goal of achieving viable populations across the range of the owl cannot be achieved without the development of some areas that are presently younger forest into additional habitat capable of supporting northern spotted owl populations into the future.

We evaluated all areas anticipated to develop into suitable habitat in the future as if they were unoccupied at the time of listing, to determine whether such areas are essential to the conservation of the species. We included such areas in the final designation of critical habitat only if they were essential to the conservation of the species because they provide connectivity between occupied areas, room for population expansion or growth, or the ability to provide sufficient suitable habitat on the landscape for owls in the face of natural disturbance regimes, such as fire. In addition, recent research indicates that northern spotted owls require additional habitat area to persist in the face of competition with barred owls. Finally, in some areas where habitat loss or degradation was historically severe, areas of currently degraded habitat may be in need of restoration to provide the large, contiguous areas of nesting, roosting and foraging habitat required by the species. Section 3(5)(A)(ii) of the Act provides for the designation of critical habitat in specific areas outside the geographical area occupied at listing upon a determination that such areas are essential for the conservation of the species. As the Secretary has determined that these areas of younger forest that may have been unoccupied at the time of listing are essential to the conservation of the species, the law provides for their designation as critical habitat.

Economic Analysis Comments

Comments From States

Comment (154): The California Department of Forestry and Fire Protection (CALFIRE) states that the designation of Jackson Demonstration State Forest land as critical habitat could result in costly section 7 consultations that might prohibit or delay the approval or implementation of environmental restoration projects. It identifies water quality permits under the Clean Water Act for timber harvesting plans as a potential future nexus, while noting that currently, a waiver of waste discharge requirements can be applied to discharges related to timber harvest activities on non-Federal lands in the North Coast Region. It identifies current litigation threatening this exemption.

Our Response: Chapter 5 of the Final Economic Analysis (FEA) provides extensive discussion of the potential Federal nexuses necessitating section 7 consultation on State and private lands (paragraphs 209 through 221). Specifically, it discusses the Clean Water Act (CWA) permitting requirements and a recent ruling by the Ninth Circuit that has the potential to increase permitting requirements for silviculture operations as sources of point-source pollution. *Northwest Environmental Defense Ctr.* v. *Brown,* 640 F.3d 1063 (9th Cir.). However, in light of the fact the United States Supreme Court has granted a *writ of certiorari* to review this ruling, the economic analysis concludes that considerable uncertainty surrounds this litigation and whether it will in fact change the permitting requirements for silvicultural operations within the next 20 years. Due to this uncertainty, we assume for purposes of our economic analysis the current CWA exemption and subsequent lack of a Federal nexus continues, and therefore do not anticipate direct effects on private or State lands associated with Clean Water Act permitting activities, and therefore do not anticipate any significant impacts to the restoration projects resulting from the designation of critical habitat. Please see the discussion of the Jackson Demonstration State Forest in the section Changes from the Proposed Rule for more details.

Comment (155): CALFIRE provides additional information describing the current management of the Jackson Demonstration State Forest and northern spotted owl habitat.

Our Response: We have added additional discussion of baseline practices at Jackson Demonstration State Forest to Chapter 5 of the FEA.

Comments From Federal Land Managers

Comment (156): U.S. Bureau of Land Management (BLM) asked for clarification as to how the DEA used the data provided by their agency.

Our Response: The BLM provided more detailed geospatial data than other agencies; therefore, when BLM data are aligned with the Service data layers and USFS historical and projected timber harvest, the analysis endeavors to utilize a consistent data set across land ownership types. For example, while BLM provided data on 30 years of planned timber harvest, as well as stand age (i.e., over and under 80 years of age), the analysis focuses on timber harvest projections for the first decade to derive a 20-year projection and does not incorporate stand age, because this information was not available for other areas. Specifically, the draft economic analysis (DEA) used a filtering approach to identify those specific areas where incremental timber harvest effects may occur. Further explanatory detail on these methods has been added to Chapter 4 of the final economic analysis (FEA).

Comment (157): The BLM requested further clarification on how the Service considered the effects on long-term, sustained-yield timber production due to the shift in management objectives for the Matrix lands that are proposed to be designated as critical habitat.

Our Response: The DEA and FEA state that the obligation of the agencies is to consult with the Service to ensure that their actions are not likely to destroy or adversely modify critical habitat and may opt from a wide range of management options, consistent with their land use plans and statutory authorities. It is challenging to predict how the land management agencies will respond or on what actions they will consult. Therefore, there is considerable uncertainty regarding long-term effects, if any, on sustained yield timber production due to a potential shift in management objectives within the revised critical habitat designation. A range of potential effects are discussed qualitatively in the analysis.

Comment (158): The U.S. Forest Service questioned the DEA assumption about the distribution of timber harvested from Federal lands, and stated that the average estimated annual yield per acre may understate actual timber harvest, as well as the assumption that USFS harvest projections include only thinning activities and do not anticipate future regeneration harvest activities.

Our Response: In an ideal world, the economic analysis would utilize detailed geospatial data showing when and where Federal timber harvest is projected to occur. However, lacking data on the narrowly defined areas where timber harvest is projected to occur, and where critical habitat may have an incremental effect on these harvests, the analysis broadly applies projected timber harvest across all Federal land acres. Using this approach, the DEA used timber harvest projections ranging from 14 to more than 200 bf per acre per year across critical habitat subunits, as described in Chapter 4 of the DEA (IEC 2012a, p. 4–18). The DEA based FS Region 6 projections on historical timber harvest quantities provided by USFS. Therefore, planned changes to timber harvest were not contemplated. To address this uncertainty in the amount of timber that could potentially be harvested in the future (i.e., if changes to timber harvest should occur), the FEA scales existing baseline projections upward to account for a potential 20-percent increase in timber harvest projection on USFS lands. The FEA also revised the language regarding projected timber activities to clarify that they may include both thinning and regeneration harvest.

Comment (159): The U.S. Forest Service stated that the DEA assumption about the distribution of timber harvested from Federal lands is problematic and that the average estimated yield of 63 BF per acre per year may understate actual timber harvest. In Region 6, the FY 2013 and FY 2013 NWFP timber program is expected to increase by 20 percent in terms of acres and volume. USFS also disagrees with the assumption that ''USFS harvest projections include only thinning activities and do not anticipate future regeneration harvest activities (page 4–18).''

Our Response: In the Final Economic Analysis, we rely on data provided by USFS Region 5 and Region 6 to estimate annual projected timber harvest amounts. Each region provided an annualized projection of future timber harvest (Region 5) or a 5-year historical annual average timber harvest (Region 6) by national forest. Using GIS acreage data for each national forest, we calculate an average annual timber harvest yield in BF/acre/year. We then estimate a baseline average annual timber harvest yield for each critical habitat subunit based on the number of acres and the proportion of the subunit within each national forest.

To estimate potential incremental economic impacts of the proposed critical habitat designation, we focused on matrix lands that are likely to be unoccupied by the northern spotted owl. We did not estimate that there will be incremental economic impacts across the entire proposed critical habitat, so the comparison to the USFS expected harvest for the entire National Forest System across the entire range of the northern spotted owl is inappropriate. There are approximately 9.5 million acres of USFS lands in the proposed critical habitat. Of these, 6.9 million acres are reserves and 2.6 million are matrix lands. Of the matrix lands, approximately 1.1 million acres are predominantly younger forests (considered to be unoccupied) and 1.6 million acres are northern spotted owl habitat. Furthermore, we estimate that approximately 6.5 percent of northern spotted owl habitat is likely to be unoccupied. We find that incremental economic impacts to USFS timber harvest are relatively more likely in unoccupied matrix lands or approximately 1,158,314 acres of 2,629,031 total acres of all USFS matrix lands.

For example, in USFS Region 5, there are approximately 956,000 acres of matrix lands. The data provided by Region 5 suggest that the annualized projected timber harvest in these matrix lands is 105.4 MMBF (as noted in the comment). However, we estimate that incremental economic impacts due to the critical habitat designation would be relatively more likely to occur in unoccupied areas. We presume that there will not be incremental impacts to timber harvest due to critical habitat in occupied areas as these areas are already sufficiently managed for NSO conservation in the baseline. In Region 5, there are approximately 502,500 acres of matrix lands that are likely to be unoccupied (100 percent of predominantly younger forests and 6.5 percent of northern spotted owl habitat). Thus our area of potential impact is smaller than that contemplated in the comment. Our estimate of baseline timber yield within these areas, however, is consistent with those presented in the comment and FS data. Specifically, the annualized projected timber harvest in these unoccupied matrix lands is 55.5 MMBF. Therefore, when we contemplate a 20 percent reduction in timber harvest due to critical habitat in matrix lands that may potentially experience incremental impacts, we calculate a reduction of approximately 11.1 MMBF (20 percent of 55.5 MMBF), versus a reduction of 21.1 MMBF (20 percent of 105.4 MMBF). In sum, our baseline timber yield and harvest projections are consistent with the USFS data cited in the comment; we are simply assessing impacts on a more constrained set of acres where incremental impacts are relatively more likely to occur.

Note also that the DEA based USFS Region 6 projections on historical timber harvest quantities provided by USFS. Therefore, planned changes to timber harvest were not contemplated. To address this uncertainty, the FEA scales existing baseline projections upward to account for a potential 20 percent increase in timber harvest projection on USFS lands. The FEA also revises the language regarding projected timber activities to clarify that they may include both thinning and regeneration harvest. However, this does not materially affect the results of the analysis.

Finally, we note that our estimate of the area of younger forest in the matrix where incremental impacts may occur is most likely an overestimate. As stated above, we estimated that of the matrix lands, approximately 1.1 million acres are predominantly younger forests (considered to be unoccupied). This estimate, however, was based on the total area of younger forest in the matrix within the proposed designation regardless of patch size. As we noted in our incremental effects memorandum (IEC 2012b, p. B–7), it would be unusual for an agency to contemplate a timber sale or other activity on a very small patch of younger forest; based on our experience, we assumed roughly 40 ac (16 ha) as the minimum patch size of younger forest on which we would anticipate potential incremental impacts. As the estimate of younger forest within the matrix used in the economic analysis did not screen out patches less than 40 ac (16 ha) in size, the resulting total of 1.1 million acres is likely an overestimate of the area of younger forest where incremental impacts may occur on matrix lands. In addition, the final designation represents a net reduction of matrix lands where economic impacts are relatively more likely to occur and this reduction was not analyzed in the FEA (see Changes from the Proposed Rule). It is also important to note that, even if there were likely to be higher economic impacts, we would not exclude these lands from designation under section 4(b)(2) because a critical habitat designation in these areas will likely have regulatory benefits in conserving this essential habitat.

Comment (160): The USFS suggested that additional person-hours for consultations to consider critical habitat issues may be higher than described in the DEA.

Our Response: The USFS currently plans projects outside of existing critical habitat that may be included in the revised critical habitat. Therefore, the administrative burden may include additional consultations beyond the additional hours contemplated for consultations that would already occur absent critical habitat. The FEA makes note of this potential incremental increase in administrative burden.

Comments on the Economic Analysis From the Public

Comment (161): One submission noted that the proposed rule does not make clear the specific restrictions imposed on designated private lands. Furthermore, many submissions note that the resulting regulatory uncertainty will likely reduce the market value of designated private lands, contributing to the loss of multiple-use, working forests that provide other valuable types of habitat and jobs, or result in timber management practices designed to ensure private lands do not become northern spotted owl habitat. Potential third-party litigation risk also contributes to this uncertainty.

Our Response: The proposed rule provided a detailed description of the protection provided to areas designated as critical habitat (see 77 FR 14081; March 8, 2012). Specifically, section 7 of the Act requires that Federal agencies ensure, in consultation with the Service, that any action they authorize, fund, or carry out is not likely to result in the destruction or adverse modification of critical habitat. Chapter 5 of the DEA provided explicit discussion of the potential for State and private landowners to request Federal permits, thereby necessitating consultation under section 7. Furthermore, the chapter acknowledged the concerns raised in the comments regarding the potential impact of regulatory uncertainty on the market value of private lands, including potential changes in State regulations in response to the designation and changes in private timber harvest practices resulting from greater perceived investment risk, and discusses the existing data limitations preventing estimation of the monetary value of such impacts (see DEA paragraphs 259 through 281). Additional information provided through public comment and supporting the existing analysis has been added to Chapter 5 of the FEA.

All private lands have been excluded from this final designation of critical habitat for the northern spotted owl (see Exclusions).

Comment (162): One submission states that all private and State lands in Washington are already subject to State and Federal regulations providing protection for the northern spotted owl; therefore, designating these lands results in duplicative regulation that is contrary to Executive Order 13563 and the President's memorandum dated February 28, 2012. An additional submission recommends that the Service rely instead on existing State regulations and cooperative approaches.

Our Response: The Service is required under the Act to designate critical habitat to the maximum extent prudent and determinable for listed species regardless of State laws. This process is separate from and additional to the listing of a species under the Act and is specifically needed for the northern spotted owl because habitat loss is one of the primary threats to its conservation. The requirement to designate critical habitat is not replaced by State regulations or classification of lands. Please note that, as discussed in our section on Exclusions, above, we were able to exclude all private lands proposed as critical habitat in the State of Washington and California.

Comment (163): One submission questions the DEA's estimate that 117,628 ac (47,602 ha) in Washington may be subject to incremental effects, noting that the calculation is unclear. The comment suggests the correct acreage is 133,895 ac (53,558 ha). Furthermore, two submissions express concern that the State could change the definition of suitable habitat to include all designated private lands, implying the potential increased regulatory burden identified in the DEA may be understated.

Our Response: As noted in Exhibit 5–6 of the DEA, area calculations in the DEA were based on the GIS data layers provided by the Service to the economists preparing the DEA on March 1, 2012. The area estimates derived from these data layers differ slightly from those provided in the proposed rule due to minor boundary adjustments under consideration by the Service. A total of 178,147 ac (72,094 ha) of private land in Washington were proposed for designation, of which 60,519 (24,491 ha) were subject to existing or proposed conservation plans, leaving 117,628 ac (47,602 ha) that may be subject to indirect impacts. As discussed in detail in paragraphs 227 through 235 of the DEA, interviews with Washington State regulators revealed that even if all private lands were designated and subsequently defined by the State as suitable habitat, the State would defer to approved habitat conservation plans (HCPs) or Safe Harbor Agreements (SHAs). Thus, indirect incremental impacts for 60,519 ac (24,491 ha) are unlikely. Of the remaining 117,628 ac (47,602 ha), much of this area may already fall within mapped Home Range Circles for the northern spotted owl and thus are already considered to be suitable habitat. Finally, whether the State will make any changes to its regulations is highly uncertain. However, as all private lands in the State of Washington have been excluded under section 4(b)(2) of the Act (see Exclusions), the concerns expressed by the commenter are moot.

Comment (164): One submission states that the DEA does not account for additional, unforeseen regulatory costs and project delays associated with the regulation of critical habitat by California State agencies.

Our Response: Chapter 5 of the DEA provides a detailed account of our discussions with the California Department of Forestry and Fire Protection (CALFIRE) to understand whether the State would regulate harvests on private timberlands differently if those lands are federally designated critical habitat (see paragraphs 246 through 257). Given the extensive baseline protections provided by California's Forest Practice Rules and the California Environmental Quality Act, CALFIRE does not anticipate any changes as a result of the designation.

Comment (165): Two submissions note that private landowners obtain Federal funding for forest health improvements, fire resiliency projects, and watercourse restoration. Access to these funds may be restricted or delayed because of the designation, resulting in decreased incentives for landowners to complete such projects.

Our Response: As all private lands have been excluded from this final designation of critical habitat for the northern spotted owl, the concerns expressed by these commenters are no longer relevant.

Comment (166): One private landowner stated that the economic impacts of the northern spotted owl listing and protection prior to critical habitat designation are relevant considerations in the exclusion process.

Our Response: Section 4(b)(1)(A) of the Act provides that the listing of a species is determined based solely on the basis of the best scientific and commercial data available. However, under section 4(b)(2) of the Act, the Service may consider economic impacts, and other relevant impacts of designating a specific area as critical habitat. Therefore, when designating critical habitat and evaluating specific areas under section 4(b)(2) of the Act for potential exclusion, we consider the incremental impacts of critical habitat designation, above the ''baseline'' conservation measures resulting from listed status. These incremental impacts (economic or other factors) are then evaluated relative to the conservation benefit of including the specific area in the critical habitat designation. If the costs outweigh the benefits, then the Secretary may exercise his discretion to exclude the area, provided that the exclusion does not result in the extinction of the species.

Comment (167): One submission takes issue with the DEA's conclusion that the approval of HCPs and reinitiation of consultations on existing HCPs will result only in minor administrative burden. Interpretive disputes around the adverse modification of critical habitat can readily lead to costly delays, litigation, and pressure to modify existing and proposed HCPs as well as other projects. Critical habitat designations on private lands discourage the development of HCPs and take away stability over long-term investment horizons.

Our Response: The reinitiation of consultation on an existing HCP is the responsibility of the Service and requires the formulation and addition of an adverse modification analysis. Those consultations that already include an effects determination and no jeopardy determination for northern spotted owls will have incorporated an analysis of the effects of the action (the HCP) on northern spotted owl habitat, which will be similar to the adverse modification analysis except that additional analysis could be needed on impacts to the conservation function of the critical habitat subunit. Only where an HCP would be anticipated to cause adverse modification of a newly designated critical habitat network would significant modification likely be necessary, and we have not found any HCPs that fall into this category for this designation. As for HCPs that are under development the need to minimize impacts to northern spotted owl habitat in an effort to minimize impacts to northern spotted owls is likely to suffice to bring the impacts below the threshold of destruction or adverse modification, thereby reducing the time and energy necessary to complete an HCP as indicated in the Economic Analysis. We note that we have excluded all lands covered by an HCP pursuant to section 4(b)(2).

Comment (168): Several comments provided additional information on the relationship between the amount of private forestland available for harvest and employment. The three comment letters refer to the results of a recent study prepared by Forest2Market on the economic contribution of forestry-related industries to Washington State's economy. They state that for every 1,000 ac (400 ha) of private forestland in Washington, there are 5 jobs in forestry-related industries (or 11 to 15 jobs including indirect and induced employment), an associated $224,000 to $233,000 in wages (or $495,000 to $631,000 including indirect and induced employment), and up to $30,000 in taxes and fees annually. The commenters then use these relationships to estimate the total number of jobs supported by private working forestland proposed for critical habitat designation.

They conclude that if private acres in Washington are designated as critical habitat, all of these jobs, and the associated wages, taxes, and fees, will be lost. In other words, a total of 1,650 jobs, $74.3 million in annual wages, and $4.5 million in annual taxes and fees to counties will be lost. If the Washington multipliers are extended to all 1.3 million private acres proposed in Washington and California, more than 19,000 jobs could be affected. A separate comment states that for every 1,000 ac (400 ha) of private working forestland in California taken out of production, 12 jobs are lost. Using the resultant multiplier of 0.012 jobs per acre, the comment states that the 1.27 million ac (514,000 ha) of private land proposed for critical habitat designation in California represents more than 15,000 jobs.

Our Response: The comments assume the designation of critical habitat precludes any timber harvests on private lands (i.e., all employment associated with designated acres will be lost). Chapter 5 of the economic analysis examines the potential for harvests to be precluded on private lands and concludes that existing baseline protections in the form of habitat conservation plans (HCPs) and Safe Harbor Agreements (SHAs) are likely to provide sufficient protection to much of the habitat without additional restrictions (see paragraphs 211 and 212 of the DEA). We note that all private landowners with HCPS or SHAs that were proposed for exclusion from critical habitat in the proposed rule were excluded from the final designation. In addition, private landowners of small woodlots in Washington were removed from critical habitat upon a determination that their lands either do not provide the PCEs or are not essential to the conservation of the species. Finally, the remaining 307,308 ac (124,364 ha) of private lands in the proposed designation in California and Washington, which we identified as possibly subject to incremental changes in harvests as a result of the indirect effects of critical habitat designation should a Federal nexus exist, have been excluded from the final designation (see Exclusions). However, here we explain how we derived our estimates of the relationship between private timberland, harvest levels, and employment in the economic analysis.

On some private lands, uncertainty on the part of landowners over whether the designation will result in future restrictions may create an incentive for those landowners to shorten harvest rotations, cutting timber earlier than is financially optimal (see paragraphs 263 through 269 of the FEA). We did not anticipate that private landowners will be precluded from harvesting timber as a result of the designation; rather, we assumed they may harvest earlier than they would have absent the designation. As a result, the estimates noted in the comment of lost employment and associated wages, fees, and revenues anticipated in the comments are likely overstated.

In Washington, 21,715 ac (8,788 ha) of private land in the proposed designation are identified by the State as suitable habitat for the northern spotted owl, but are not currently designated as ''critical habitat state.'' It is possible that the State may reclassify these areas as ''critical habitat state'' in response to the Federal designation, which would impose significant administrative costs on landowners, such that landowners would likely forego future harvests. However, such a regulatory change on the part of the State is uncertain (see complete discussion in paragraphs 231 through 235, 269, and 276 through 279 of the FEA). These private lands are not included in the final designation, as the result of either refinements to critical habitat (determinations that small private landholdings either do not contain the PCEs, or are not essential to the conservation of the species) or exclusions under section 4(b)(2) of the Act.

Thus, the DEA estimated that at worst, it is possible that 21,715 ac (8,788 ha) in Washington may not be harvested, or approximately 1,086 ac (439 ha) per year over the 20-year timeframe of our analysis. Estimating the impact of such a small change in harvestable acres on employment is difficult and likely to be highly dependent on the location and timing of the foregone harvests. The relationships between acres and jobs, revenues, or fees and taxes presented in the comments may not be applicable to such small, marginal changes in harvestable acres.

For example, the ratio of 5 jobs for every 1,000 ac (400 ha) likely represents the average jobs created per acre when total acres of forestland are divided by total timber employment in the State (the Forest2Market report is not clear about whether its ratios represent average or marginal changes). A marginal estimate, on the other hand, would look at the number of jobs associated with the ''next'' 1,000 acres of harvest given existing employment levels and harvestable acres, as the relationship between jobs and acres may not be perfectly linear. Employment associated with the next 1,000 acres of harvest may be larger or smaller than the average. Furthermore, it is possible that other private acres may be harvested as substitutes for the 21,715 ac (8,788 ha) that could be restricted if the State changes its regulations, diminishing the rule's effect on employment. Thus, even if we knew with certainty that the State of Washington will change its regulations as a result of the designation, forecasting potential changes in employment is challenging given existing data limitations.

Comment (169): One comment states that the SDS Lumber Company is the only remaining mill in Klickitat County, and that designating approximately 29,000 ac (11,700 ha) of private forest in Klickitat and Skamania Counties, including approximately 16,000 ac (6,500 ha) of SDS and Broughton Lumber Company land, will have direct and significant impacts on its 300 employees.

Our Response: SDS and Broughton Lumber Company have developed a Safe Harbor Agreement in collaboration with the Service. As described in the Exclusions section of this document, SDS lands within the proposed critical habitat covered by this SHA have been excluded from the final designation.

Comment (170): One comment states that Rayonier (a forest products company) already protects 100 of the 540 ac (40 of the 220 ha) of its land in Washington proposed for critical habitat, making the remaining 440 ac (180 ha) especially important to Rayonier, local communities, and the people who work in forest industry. A reduction in logging on these 440 ac

(180 ha) would directly reduce logging and trucking jobs and have downstream effects in the community.

Our Response: We determined that the lands owned by Rayonier did not meet our definition of critical habitat, therefore these lands are not included in our final designation (see *Comment (106)).* Therefore, we do not anticipate any potential impact of critical habitat in terms of possible reduced harvests on Rayonier lands or effects on local employment due to this rulemaking.

Comment (171): One comment noted that the ''checkerboard'' and intermingled Federal and private ownership patterns make it difficult, if not impossible, for many timberland owners to haul their timber products without the use of some type of Federal road use permit. Access to existing or new roads may be precluded by critical habitat concerns.

Our Response: This issue is addressed in Chapter 5 (p. 5–6) of the FEA. The report notes that a review of Federal consultations over the last 3 years indicates that no consultations related to the northern spotted owl have resulted from application for this type of permit. Representatives of the USFS and BLM further noted that formal consultation of this type of activity is not prioritized, and that any request for consultation would likely be limited to hauling activity and would not include the timber harvest activity itself. As a result, we do not anticipate any direct effects on State or private lands as a result of this potential nexus.

Comment (172): One comment notes that the DEA does not address potential affects to the U.S. Treasury and Federal job losses.

Our Response: Project modification costs quantified in the DEA result from changes in the quantity of timber harvested on Federal lands. As discussed in detail in Chapter 4 of the DEA, section 7 consultations on the sale of timber from Federal lands may result in an increase, decrease, or no change in harvest levels, based on several plausible assumptions. The direct cost (or benefit) of these section 7 project modifications is a loss (or gain) in Federal revenues collected by the U.S. Forest Service and the U.S. Bureau of Land Management resulting from the associated timber sales. Stumpage values related to these effects are summarized in Exhibit ES–4 of the DEA. With available data, we are unable to discern how these timber harvest changes may affect employment at Federal agencies.

Comment (173): One commenter suggested that the DEA fails to comply with the requirements of Executive Order 12866, which requires the Secretary to base his decision on the best reasonably available economic information, and circular A–4, which provides guidance for complying with Executive Order 12866. The commenter states that the DEA applies different standards of information and analysis in its assessment of the effect of the proposed rule on timber production and its assessment of other important ancillary benefits of the designation, as well as the baseline applied in the analysis.

Our Response: An assessment of ancillary benefits is not possible without first assessing the effect of the proposed rule on timber production; the ancillary benefits derive from changes in timber management practices. Therefore, accurately assessing changes in timber production is critical for multiple facets of the economic analysis. The results of this assessment suggest that incremental changes in annual harvests are likely to be small, less than one percent of total harvests in the 56 counties overlapping the designation. While quantification of the value of foregone timber (or timber brought back into production as a result of the regulation) is relatively straightforward, because market data provide an indication of the value of this resource, estimating the marginal changes in terms of the distributional impacts on communities of these small changes in harvests, or the marginal changes in ecosystem services, is challenging and requires significantly more data and sophisticated modeling tools. Thus, both are discussed qualitatively in the FEA.

Regarding the assessment of ancillary benefits, Circular A–4 states, ''You should begin by considering and perhaps listing the possible ancillary benefits and countervailing risks. However, highly speculative or minor consequences may not be worth further formal analysis. Analytic priority should be given to those ancillary benefits and countervailing risks that are important enough to potentially change the rank ordering of the main alternatives of the analysis'' (Circular A–4, p. 26). This text provides some discretion to the Agency to determine whether the quantification of ancillary benefits is necessary. As described in responses to earlier comments, the application of best available data and tools to estimate the incremental changes in ecosystem services resulting from the designation of critical habitat would require significant effort and some data that do not currently exist. Because the Service has not excluded areas where such benefits are possible (i.e., Federal matrix lands), quantification of ancillary benefits would not change the regulatory outcome.

With regard to baseline definition, the comment suggests the analysis should incorporate potential future changes in timber markets, changes in external factors affecting costs and benefits, changes in future regulations, and likely future compliance with other regulations. With regard to future demand for timber, the analysis relies on the best available data provided by the USFS and BLM regarding baseline harvest levels (see FEA paragraphs 166 through 175). Data to predict future changes in the demand of timber products are highly speculative, given current economic conditions (e.g., demand for timber is largely driven by the housing market). We have no reason to anticipate other regulatory changes that would affect the designation of critical habitat, and the comment provides no additional information on this topic. Finally, we consider the degree of compliance with section 7 of the Act in the absence of critical habitat in determining the likelihood of future consultations (see, for example, the discussion in paragraphs 181 through 186 of the FEA).

Comment (174): One comment claims that the DEA distorts the impacts of the proposed critical habitat designation on Douglas County by including ''metropolitan areas that have little to no critical habitat nor similarities to Douglas County's social and economic environment.''

Our Response: Chapter 6 of the DEA provided a detailed socioeconomic profile of each of the 23 counties (including Douglas County) containing proposed critical habitat subunits with higher proportions of Federal forests that are relatively more likely to experience incremental impacts due to the designation of critical habitat. The analysis presents data on the percent change in timber production between 1990 and 2010 for each county, and on the percent growth of annual industry employment between 1989 and 2009 for each county. In addition, the analysis presents data on Federal land payments to each of the 23 counties as a percent of the total local government revenue in FY 2009, demonstrating the relative importance of these funds to each county's budget. The analysis then concludes that five counties (including Douglas County) may be more sensitive to additional incremental changes in timber harvests, industry employment, and Federal land payments. Such data are not readily available at a sub-county level. We believe, however, the information provides sufficient context for understanding relative economic circumstances across the designation.

Comment (175): One comment states that designating O&C lands as critical habitat is inconsistent and in direct conflict with the statutory provisions of the O&C Act and Sec. 701(b) of FLPMA (Federal Lands Policy management Act). (''O&C lands'' refers to certain areas in western Oregon established under the O&C Act of 1937, and ''O&C'' counties represent those counties containing O&C lands). The Association of O&C Counties asserts that the proposed critical habitat designation will prevent 18 O&C counties from receiving sufficient revenues on a sustainable basis as required by the O&C Act, and will result in employment and income impacts on a local and regional scale.

Our Response: The designation of critical habitat is not a land use allocation. Under section 7(a)(2) of the Act, each Federal agency must insure that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of the designated critical habitat of the species. 16 U.S.C. 1536(a)(2). To help action agencies comply with this provision, section 7 of the Act and the implementing regulations set out a detailed consultation process for determining the impacts of a proposed activity on species listed as threatened or endangered, or its designated critical habitat. 16 U.S.C. 1536; 50 CFR Part 402. In *Seattle Audubon Society* v. *Lyons* (''Lyons''), 871 F. Supp. 1291 (W.D. Wash. 1994), the district court held that ''the O & [C Act] does not allow the BLM to avoid its conservation duties under NEPA or ESA * * *'' Id. at 1314. The critical habitat designation does not preclude the sustained yield timber management of O&C lands consistent with the above requirements of the Act. The economic impact to local counties of this critical habitat designation will be determined by the timber management direction the Federal land managers take within critical habitat lands. We believe the ecological forestry techniques discussed in this designation could allow for timber harvest that is consistent with critical habitat objectives and section 7(a)(2), thereby providing increased revenues to affected counties. The Service encourages land managers to consider use of this type of forest management in critical habitat where appropriate.

As discussed in detail in Chapters 3 and 6 of the FEA, the O&C counties currently elect to receive Secure Rural Schools and Community Self-Determination Act (SRS) rather than revenue-sharing payments from BLM under the O&C Act. These payments are supplemented by Payments in Lieu of Taxes (PILT) (see paragraphs 128 through 130 of the FEA). Even absent the designation of critical habitat, the magnitude of future payments under these programs is highly uncertain given that these Federal programs have not been reauthorized (i.e., SRS) or funded (i.e., PILT) by Congress. If SRS and PILT payments continue, the changes in harvests on BLM lands will have minimal to no effect on payments, because SRS and PILT are not directly linked to harvest levels. However, if Congress decides to reduce or end payments under SRS and PILT, counties will shift back to receiving revenue-sharing payments under the O&C Act, and changes in timber harvests on BLM lands will affect the size of these payments. Importantly, we note that under the third scenario analyzed in the DEA, the potential decrease in harvest from BLM lands represents approximately 2 percent of total harvests from BLM lands in these counties (Based on BLM transaction data over the last four quarters (2011Q4–2012Q3) viewed at *http://www.blm.gov/or/resources/forests/blm-timber-data.php*). Thus, if affected, impacts to revenue payments resulting from the designation are likely to be small.

Comment (176): One commenter states increased timber production often has been associated with deteriorating indicators of socio-economic well-being in nearby rural communities, including income, percent living in poverty, and housing conditions, and noted a positive relationship between the health of local economies and the presence of unlogged Federal forests.

Our Response: The comment cites extensively from a report by the National Resources Council (NRC) (NRC 2000). The committee was asked to evaluate the nature of possible economic and social costs and benefits of alternative forest management practices. The committee wrote, ''[a]lthough the question is easy to ask, it is hard to answer. Few social-impact studies clearly tie social and economic outcomes with specific forest-management practices, such as old-growth harvest rates, the use of clearcutting as a harvest technique, or the relative intensity of silvicultural practices'' (p. 163). The committee went on to review a meta-analysis of the relationship between varying levels of timber dependence and measures of community well-being, which finds for most relationships that ''well-being went up as timber dependency went down'' (p. 163). Furthermore, the committee cited studies suggesting that ''wilderness and amenity protection can have a positive influence on certain measures of community well-being, although in-migration brings its own difficulties'' (NRC 2000, p. 164).

The NRC report concluded, ''[d]iverse economic conditions create diverse opportunities and thus temper the effects of timber industry fluctuations on local communities'' (p. 165). It went on to note that ''[a]s the importance of extractive industry declines, the Pacific Northwest communities are looking toward tourism as a way to bolster their economies * * * However, tourism by itself is not a substitute for timber industry jobs'' (NRC 2000, p. 167).

In summary, the NRC report suggests that economically diverse communities are better off than communities that are highly dependent on the timber industry, and preserving wilderness can attract new economic activity to communities. We have added text summarizing the NRC findings in the FEA. However, the designation of critical habitat does not preserve wilderness. Furthermore reducing timber harvests does not guarantee that other sources of economic activity, such as tourism or in-migration by wealthy, highly educated individuals, will generate enough new economic activity to replace lost timber-related jobs and wages. Finally, the designation is likely to reduce or increase annual timber harvests from Federal lands by less than one percent. Thus, any changes in economic diversity resulting from the rule are likely to be difficult to measure.

Comment (177): One comment suggests that the proposed critical habitat designation will create a regulatory hurdle that will impede the construction of vital infrastructure projects (roads, bridges, power lines, and other utilities).

Our Response: Chapter 7 of the DEA discusses the potential economic impacts to road and bridge construction and maintenance, and installation and maintenance of power transmission lines and other utility pipelines. The analysis concludes that all potential conservation efforts associated with linear projects are expected to result from the presence of the northern spotted owl, not the designation of critical habitat, and are thus considered baseline impacts (see paragraphs 315 through 320 of the DEA). Incremental costs attributable to critical habitat are limited to the administrative costs of additional hours spent by Federal agency staff and the Service to consider critical habitat during section 7 consultation on these projects.

Comment (178): Many comments describe the adverse impacts that changes in the timber industry have had on local and regional employment levels, government revenues, and overall socioeconomic conditions. Several of these comments request that these impacts be taken into consideration in the economic analysis.

Our Response: Chapter 3 of the DEA describes how, over the past 20 years, the Pacific Northwest timber industry has undergone significant changes that have manifested in reduced timber-related jobs and revenues. The analysis provides detailed data on the changes in timber production levels between 1990 and 2010, and on the changes in industry employment and payroll between 1989, 1999, and 2009 in each of the 56 counties where critical habitat was proposed. This information is intended to provide context for the analysis and illustrate the importance of the timber industry to local economies. In addition, Chapter 6 of the DEA provides a detailed socioeconomic profile of the 23 counties containing proposed critical habitat subunits that contain a higher proportion of Federal lands that are relatively more likely to experience incremental impacts due to the designation of critical habitat. The chapter examines trends in timber harvests, industry employment, and Federal land payments in these counties, and concludes that certain counties may be more sensitive to additional incremental changes in timber harvests, industry employment, and Federal land payments.

Comment (179): The Small Business Administration (SBA) expressed concern that the Service does not have an adequate factual basis for certifying that the rule will not have a significant economic impact on a substantial number of small businesses. It disagrees with the Service's assertion that small businesses are not directly regulated by the proposed rule and states that the Service incorrectly analyzes the universe of affected small businesses by counting the number of consultations required by the designation, as opposed to the number of all small businesses affected by these consultations. SBA also notes that the DEA states private landowners may be affected if they have federally funded or permitted activities on Federal or private land, such as participation in timber sales or timber management projects or application for a section 10 permit.

Our Response: The Service agrees with SBA's statement that small entities (businesses, governments) may be affected by the designation of critical habitat as third parties involved with consultation under section 7 of the Act with Federal action agencies. However, we disagree that these entities are directly regulated. This position is supported by existing case law regarding the certification requirements under the Regulatory Flexibility Act (RFA), the Small Business Regulatory Enforcement Fairness Act (SBREFA) (see paragraphs 378 through 381 of the DEA), and SBA's handbook, ''A guide for Government Agencies: How To Comply With the Regulatory Flexibility Act (2003). However, we believe it is good policy to assess these indirect impacts to third parties if we have sufficient available data to complete the necessary analysis, whether or not this analysis is strictly required by the RFA. Therefore, where third parties are anticipated to participate in consultations under section 7 of the Act with Federal action agencies, these entities are included in the screening analysis (see paragraphs 383 through 392 of the DEA). Please refer to the discussion under Regulatory Flexibility Act later in this final rule and the FEA for a more complete discussion of our factual basis for certification under RFA that this rule will not result in a significant impact to a substantial number of small entities.

Comment (180): An additional entity asserts that the Service is incorrect in stating that only Federal agencies will be ''directly regulated'' by critical habitat designation. It contends that private sector entities relying directly or indirectly on Federal timber sales are also directly regulated. The entity cites case law, stating, ''The RFA requires consideration of *'the small entities which will be subject to the proposed regulation—that is, those small entities to which the proposed rule will apply.' Cement Kiln Recycling Coalition v. E.P.A.,* 225 F. 3d 855, 869 (DC Cir. 2001).'' A critical habitat designation ''applies to'' private parties as much as Federal agencies; a private party seeking a Federal permit that may affect designated critical habitat cannot obtain the permit until a consultation is completed under section 7 of the Act, and has the statutory right to participate in that consultation. Thus, such entities must be considered under the RFA.

Our Response: The Service's current understanding of recent case law, including the *Cement Kiln* case, is that Federal agencies are only required to evaluate the potential incremental impacts of rulemaking on those entities directly regulated by the rulemaking; therefore, they are not required to evaluate the potential impacts to those entities not directly regulated. The language from the *Cement Kiln* case quoted by the commenter merely restates the language of the RFA itself. Several court decisions, including the *Cement Kiln* decision, have interpreted that language to require Federal agencies to analyze the rule's effects on any small entities that are subject to—that is, directly regulated by—the rule, rather than requiring Federal agencies to consider every potential impact that a regulation may have on indirectly affected small entities. *See also Am. Trucking Ass'ns* v. *Envtl. Prot. Agency,* 175 F.3d. 1027 (D.C. Cir. 1999); *Mid-Tex Elec. Coop.* v. *Fed. Energy Regulatory Comm'n,* 773 F.3d 327 (D.C. Cir. 1985); *et al.*

The regulatory mechanism through which critical habitat protections are realized is section 7 of the Act, which requires Federal agencies, in consultation with the Service, to insure that any action authorized, funded, or carried out by the Agency is not likely to adversely modify critical habitat. The designation of critical habitat for an endangered or threatened species only has a regulatory effect where a Federal action agency is involved in a particular action that may affect the designated critical habitat. Under these circumstances, only the Federal action agency is directly regulated by the designation, and, therefore, consistent with the Service's current interpretation of RFA and recent case law, the Service may limit its evaluation of the potential impacts to those identified for Federal action agencies. Under this interpretation, there is no requirement under the RFA to evaluate the potential impacts to entities not directly regulated, such as small businesses. However, EO's 12866 and 13563 direct Federal agencies to assess costs and benefits of available regulatory alternatives in quantitative (to the extent feasible) and qualitative terms. Consequently, it is the current practice of the Service to assess to the extent practicable these potential impacts if sufficient data are available, whether or not this analysis is believed by the Service to be strictly required by the RFA. In other words, while the effects analysis required under the RFA is limited to entities directly regulated by the rulemaking, the effects analysis under the Act, consistent with the EO regulatory analysis requirements, can take into consideration impacts to both directly and indirectly impacted entities, where practicable and reasonable.

Therefore, as discussed in the previous response, where third parties are anticipated to participate in section 7 consultations, these entities are still included in the screening analysis if sufficient data is available to complete the necessary analysis. The direct compliance costs of section 7 consultations concerning timber sales are the administrative costs of conducting the consultation, which are primarily borne by the Service and the Federal Action Agency, and potential changes in revenues to Federal agencies from timber sales.

Potential impacts to the profitability of timber industry entities resulting from changes in the price or availability of timber represent an indirect effect of the regulation. In this case, we note that potential changes in timber harvests are anticipated to be less than one percent of average annual harvests in the region subject to the designation.

Comment (181): The SBA states that the Service underestimates the economic impact of the rule on the timber industry and private landowners because, in its screening analysis, it only considers administrative costs of section 7 consultations, rather than quantifying the costs of project modifications resulting from those consultations.

Our Response: Project modification costs quantified in the DEA result from changes in the quantity of timber harvested on Federal lands. As discussed in detail in Chapter 4 of the DEA, section 7 consultations on the sale of timber from Federal lands may result in an increase, decrease, or no change in harvest levels, based on several plausible assumptions. We note that if future harvests are restricted, total annual harvests could decrease by 24.56 million board feet (MMBF). This decrease represents less than one percent of 2010 total harvest and the average annual harvests between 2006 and 2010 across the 56-county area overlapping proposed critical habitat. The designation may also result in an increase in annual harvests of 12.28 MMBF, or less than half a percent of total annual harvests in the 56-county area. Finally, it is possible that harvest levels will not change a result of the designation. In summary, the proposed rule is anticipated to have a minor impact on future harvest levels. Although the Service has estimated these potential impact scenarios relative to the total harvest, the agency acknowledges that the designation of critical habitat may have indirect impacts on industry subsectors and/or related sectors with high concentrations of small businesses. However, a more detailed analysis capturing these impacts is not available to the agency at this time.

The direct cost (or benefit) of these section 7 project modifications is a loss (or gain) in Federal revenues collected by the U.S. Forest Service and the U.S. Bureau of Land Management resulting from the associated timber sales. Stumpage values related to these effects are summarized in Exhibit ES–4 of the DEA. In the FEA, we include additional information in the RFA/SBREFA screening analysis (Appendix A) describing these project modification costs, which are borne entirely by Federal agencies.

The potential indirect effects of these lost Federal revenues, in terms of implications for County revenue sharing programs, are discussed in Chapter 6 of the DEA (see paragraphs 293 through 299). In addition, Chapter 6 also identifies the counties with Federal lands more likely to experience changes in harvest levels as a result of the designation and provides background information on harvest and employment trends in these counties.

Comment (182): Several commenters stated that the DEA misrepresented the baseline or underestimates timber harvest impacts on Federal lands. One commenter in particular asserts that the true baseline is best represented by the land management plans that have been adopted by BLM and FS, in which planned annual harvest volumes may total 840 MMBF across all lands encompassed by the NWFP.

Our Response: The baseline projection should represent the best estimate of the world absent critical habitat, given the best available data. Relying on this criterion, the baseline projection first focuses on areas of the proposed designation where incremental impacts to Federal timber harvest are relatively more likely to occur as a result of critical habitat. As identified in the Incremental Effects Memorandum, these areas include matrix lands that are likely to be unoccupied by the northern spotted owl, representing approximately 1.4 million acres of matrix lands out of approximately 12 million Federal acres in the proposed designation. Given that incremental impacts, if any, are likely to occur primarily in these more discrete areas, a projection utilizing the range-wide planned harvest levels contemplated under the NWFP would overstate baseline conditions.

Second, based on historical experience, projected actual timber harvest in the baseline on USFS and BLM lands is likely to be less than that in the formally-approved land management plans under the NWFP. Federal land managers have not achieved this level of timber harvest over the past several years, and do not anticipate this level of harvest in the future, providing further confirmation that the identified long-term sustained yield of 840 MMBF associated with these plans would overstate the baseline.

For those matrix areas where incremental effects may be relatively more likely to occur, the FEA utilizes a variety of planned, historical actual, and projected actual timber harvest data provided by BLM and FS to derive the annual baseline projection, which totals approximately 123 MMBF. This projection is then appropriately caveated, with the FEA noting that within the discrete areas of each subunit where incremental effects may occur, the subunit level projection could vary materially from future actual timber harvest in these areas.

We note further, however, that based on comments received from Federal land managers, we have added an additional sensitivity analysis to Chapter 4 of the FEA. Specifically, the sensitivity analysis tests alternative assumptions concerning: (a) The percentage of northern spotted owl habitat on BLM matrix lands that is likely to be unoccupied, which increases the acreage where incremental timber harvest impacts may occur and thus the baseline projection; and (b) the baseline harvest projection for USFS Region 6, where we assume a 20 percent increase in baseline timber harvest relative to historical yields.

Comment (183): Several commenters questioned whether the DEA was meaningful, because it displays results as a menu of choices, including a potential increase in timber harvest on Federal lands. In addition, one commenter contemplated a potential reduction in annual planned harvest volumes of 500 MMBF as a result of critical habitat designation.

Our Response: The DEA presented alternative scenarios due to considerable uncertainty regarding the specific projects that may be proposed or management options that Federal land managers may consider. These scenarios are intended to present a range of estimates for the potential incremental impacts of various options for complying with section 7 available to Federal agencies. Based on the best available data and information, these decisions, including the adoption of ecological forestry practices, may result in harvest levels being maintained (as described in Scenario #1), increased (Scenario #2), or decreased (Scenario #3). This range of estimates is not meant to be interpreted as ''over 100 potential outcomes.'' Statistical analyses frequently account for uncertainty by presenting a range of estimates in which each individual data point is not considered an independent outcome. One purpose of this analysis was to aid the Secretary in determining if any lands should be excluded due to the financial burden associated with the designation, and this analysis does so by identifying the subunits and relevant landowners for whom incremental impacts are relatively more likely to occur, as demonstrated through these scenarios.

With respect to the representation of the potential 500 MMBF reduction in annual timber harvest, this figure overstates any possible effect of critical habitat. This volume is roughly equivalent to the total harvest on the National Forest System and BLM lands in the NWFP area in recent years, and is roughly five times the baseline harvest projection for potentially-affected areas. The figure implies that the designation will largely preclude any timber harvest whatsoever on Federal lands operated under the NWFP. Based on the historical record of actual timber harvest volumes and the best available information concerning potential future harvest activity under the designation, we reject this representation.

Comment (184): One comment suggested that the DEA underestimated the administrative costs associated with consultations.

Our Response: The additional burden of 4 to 6 hours described in the FEA reflects an incremental impact to consultations that would already occur due to the listing of the species. These costs do not reflect the total cost of consultations that would occur absent the critical habitat designation. The FEA discusses additional consultations that would not have occurred but for the critical habitat designation.

Comment (185): One commenter stated that the high-impact economic estimate based on a $250/mbf stumpage value underestimates the true economic costs of the proposed designation, and that a stumpage rate of $350/mbf is more realistic.

Our Response: The stumpage values in the economic analysis ($100 to $250/mbf) reflect a wide range of historical values for timber harvest from Federal lands for the years 2000 to 2011 (the most recent estimates that were available). Average stumpage prices vary by forest, species, product, and year, reflecting, among other things, shifts in economic demand. Exhibit 4–11 presents a weighted average of stumpage values across USFS National Forests and BLM districts within the proposed critical habitat designation for each Federal land manager. These values best represent the average price of timber sold in areas of concern where incremental effects are relatively more likely to occur. Please see chapter 4.4.3 of the FEA for further explanation of how we arrived at these values. However, even if we apply the $350/mbf figure, the annual high-impact result would increase by $2.5 to $2.9 million, which is still a relatively small incremental impact.

Comment (186): One submission noted that a number of Pacific Northwest Ski Areas Association (PNSAA) member ski areas operate on National Forest System (NFS) land potentially within the range of the northern spotted owl. The primary request of the comment is that areas covered by special use permits (SUPs) under which the ski areas operate be excluded from the final designation. The comment goes on to note potential burdens critical habitat designation may entail for these areas and their economic impact. This economic activity and any related regulatory impacts are not addressed in the draft economic analysis.

Our Response: While ski areas are found on a very small proportion of the forested lands in the Pacific northwest, our analysis found these lands provide essential high-value northern spotted owl habitat to the critical habitat network. Currently, impacts to northern spotted owl habitat in these areas are subject to the section 7 consultation process for effects to northern spotted owls. Our experience shows that ski area development actions generally tend not to conflict with northern spotted owl and critical habitat conservation needs, so we do not anticipate any significant regulatory burden associated with the designation of these lands as critical habitat. Removing lands managed under ski area special use permits would increase fragmentation of the critical habitat network and potentially continuous tracts of northern spotted owl habitat. Therefore, there is a greater benefit to the species associated with retaining ski areas in the critical habitat designation. In situations involving the imminent loss of human life or property the managing agency should implement emergency section 7 measures to avoid compromising public safety. A note regarding ski area activities and their economic impact has been added to Chapter 1 of the FEA.

Comment (187): Several submissions commented upon how critical habitat may affect wildfire risks and related coverage of this issue in the draft economic analysis. One comment asserts that critical habitat makes fuel management more difficult, resulting in the destruction of habitat. Another comment notes the prospect of reduced fire risk under critical habitat due to restoration of riparian forests or road closure.

Our Response: The FEA addresses the potential impacts of critical habitat on fire management in Chapters 4 and 8. In Chapter 4, the FEA discusses the fact that ecological fire salvage activities contemplated as part of proposed critical habitat designation on both reserved and nonreserved lands may result in incremental economic effects. Due to data limitations and fire location uncertainty, however, these effects are not quantified. In the benefits discussion in Chapter 8, the FEA recognizes that it is possible that the designation could result in increased resiliency of timber stands associated with improved timber management practices, such as thinning, partial cutting, and adaptive management and monitoring. These efforts may reduce the threat of catastrophic events such as wildfire, drought, and insect damage. This in turn may generate benefits in the form of reduced property damage.

Comment (188): One comment noted that the DEA only considers impacts related to logging, and limits its coverage of many other economic purposes that critical habitat may negatively affect.

Our Response: Based on a review of the consultation record, recognized threats to the species, and other related information, the FEA focuses on those economic activities that could be materially affected by the designation. These activities include timber harvest on public and private lands, fire management activities, and linear projects (roads, gas pipelines, utility lines, etc.). We are not aware of other economic activities that will be materially affected by the designation. In addition, the FEA qualitatively considers potential benefits from the designation on certain activities, including recreation.

Comment (189): Multiple submissions assert that the DEA does not sufficiently consider the cumulative economic impacts of northern spotted owl conservation efforts since the time of its listing, instead focusing primarily on the potential incremental impacts of the proposed critical habitat designation prospectively.

Our Response: The U.S. Office of Management and Budget's (OMB) guidelines for best practices concerning the conduct of economic analysis of

Federal regulations direct agencies to measure the costs of a regulatory action against a baseline, which it defines as the ''best assessment of the way the world would look absent the proposed action.'' (OMB, ''Circular A–4,'' September 17, 2003, available at *http://www.whitehouse.gov/omb/circulars/a004/a-4.pdf.*) The baseline utilized in the DEA is the existing state of regulation, prior to the designation of critical habitat, which provides protection to the species under the Act, as well as under other Federal, State, and local laws and guidelines. To characterize the ''world without critical habitat,'' the DEA also endeavors to forecast these conditions into the future over the timeframe of the analysis, recognizing that such projections are subject to uncertainty. This baseline projection recognizes that the northern spotted owl is already subject to a variety of Federal, State, and local protections throughout most of its range, due to its threatened status under the Act and regardless of the designation of critical habitat.

Significant debate has occurred regarding whether assessing the impact of critical habitat designations using this baseline approach is appropriate, with several courts issuing divergent opinions. Courts in several parts of the country, including the 9th Circuit Court of Appeals, which has jurisdiction in Washington, Oregon, and California, have ruled that the consideration of economic impacts in the designation of critical habitat should be based on the incremental impacts of the designation. See, e.g., *Home Builders Association of Northern California* v. *United States Fish and Wildlife Service,* 616 F.3d 983 (9th Cir. 2010), cert. denied, 179 L. Ed. 2d 301; *Arizona Cattle Growers* v. *Salazar,* 606 F.3d 1160 (9th Cir. 2010), cert. denied, 179 L. Ed. 2d 300.

Chapter 3 of the FEA provides extensive discussion of the historical and current economic conditions against which critical habitat is designated. Specifically, the document provides data, by each of the 56 counties overlapping the proposed rule, on changes in timber harvests, timber industry employment, and timber industry payroll since 1989. It also provides a detailed discussion of the existing revenue-sharing programs related to timber harvests and the data describing which counties are most reliant on these programs.

Comment (190): One comment states that, while accepted in the academic literature, existence values, contingent values, recreational hedonic values, and other nonmarket values that might be assigned to critical habitat designation are unreliable and irrelevant where the only benefit of relevance to the decisionmaker is the conservation of a listed species. The Act calls for a cost-effectiveness approach where the Service should seek to minimize the economic costs and burdens that must be incurred to designate only that habitat that is essential for species conservation. Other benefits are irrelevant and should not be offset against the costs.

Our Response: The valuation of nonmarket goods as part of the evaluation of the benefits of proposed Federal regulations is a widely accepted and regularly applied practice. The U.S. Office of Management and Budget (OMB) explicitly recommends the use of revealed preference (recreational demand models, hedonics) and stated preference methods (contingent valuation) in its guidance to Federal agencies (Circular A–4) on best practices for preparing regulatory analysis required by Executive Order 12866. Circular A–4 includes criteria for conducting and applying stated preference studies, which are commonly used to measure existence values. Chapter 8 of the FEA describes the data limitations preventing the Service from quantifying or estimating the value of these benefits. Thus, the direct benefits of the designation are described qualitatively.

In weighing the benefits of including an area in critical habitat as opposed to excluding it, ancillary benefits may be considered, although we agree with the comment that the most relevant benefit of designating critical habitat for the northern spotted owl are the benefits to the species' conservation and recovery. However, ancillary benefits are relevant only to a decision whether to exclude an area under section 4(b)(2) of the Act, not to the threshold determination that an area meets the definition of critical habitat. We agree that only lands that meet the definition of critical habitat (areas occupied at the time of listing containing features essential to the species' conservation or unoccupied areas that are themselves essential to the species' conservation) should be designated.

Comment (191): One comment states that most of the economic benefits (e.g., existence value, wildlife viewing, ecosystem services) derive from the listing; the incremental benefit of critical habitat is negligible to nonexistent.

Our Response: As discussed in detail in the DEA, particularly Chapter 4, the designation of critical habitat may result in changes in timber management practices. These physical changes are likely to support the conservation and recovery of the northern spotted owl. As described in Chapter 8 of the DEA (paragraphs 342 through 343), the benefits of the regulation in terms of improved probability of northern spotted owl conservation and recovery are difficult to quantify due to existing data limitations.

Comment (192): Several commenters asserted that in not attempting to quantify environmental and ecosystem services benefits, the Service is not employing the best available science regarding the benefits that endangered species and their critical habitat provide, and is undervaluing the economic benefits of the designation. The comment asserts that multiple global efforts have been developed to quantify ecosystem services in order to inform policy, promote incorporating ecosystem services into decision making, and provide guidelines to assess costs and benefits of policies and better account for ecosystem service effects. Commenters encourage the Service to make a credible (if rapid) attempt to value ecosystem service benefits and consider ecosystem services.

Our Response: The Service recognizes that much attention has been paid nationally and globally to valuing ecosystem services provided by landscapes. Published, peer-reviewed studies provide information on values of multiple categories of ecosystem services (e.g., agricultural production, water quality regulation, carbon storage and sequestration, recreation, aesthetic values, etc.) across a variety of land use types (e.g., wetlands, forests, etc.). Over the past 20 years, multiple studies have relied on this literature to develop large-scale benefits transfer analyses in order to estimate a total value of a parcel of land, a watershed, a State, or even the planet (e.g., Costanza 1997, as described in the comment letter).

The first comment focuses in particular on the potential relevance to the DEA of a large-scale benefits transfer estimate developed for the Skykomish watershed. This study is characterized as a ''rapid ecosystem service valuation.'' In general, the authors first identified land cover types present in the watershed, identified the categories of ecosystem services relevant to those types, and then researched existing studies valuing those categories of ecosystem service benefits. From the available literature, the authors estimated a range of values for each category of ecosystem service by relying on the low end and high end estimates identified. The authors then summed across relevant ecosystem service values to estimate a value range for each land cover type, and summed across the land cover types within the watershed to estimate a value range for the entire Skykomish watershed of $245 million to $3.3 billion per year.

While case- and site-specific modeling to value ecological benefits is preferable, the Service agrees that benefits transfer methods may be useful in the absence of resources for intensive primary research. To use these methods in support of Federal rulemakings, OMB has developed guidelines for conducting credible benefits transfer. A rapid assessment of ecosystem services, such as that developed for the Skykomish, is unlikely to meet the criteria specified by OMB. Multiple responses to similar large-scale benefits transfer studies have highlighted the theoretical and practical problems associated with estimating and extrapolating per-acre estimates of values taken from other studies of ecosystem services (e.g., Bockstael *et al.,* 2000).

First, this approach ignores site-specific factors affecting the production of services by not accounting for variations in the condition or quality of an ecosystem. For example, a less dense or degraded forest area stores less carbon than a dense, healthy forest. The extent to which a given acre of land delivers ecosystem services also depends on the surrounding land uses. For example, a wetland downslope of cropland may provide a valuable service by filtering nitrogen runoff and decreasing the total amount of the nutrient reaching a water supply, whereas a wetland surrounded by forest is unlikely to intercept such runoff to begin with and, therefore, would not provide this service. By relying on site-specific studies valuing these types of services in other areas—the Skykomish study relies on a variety of studies of ecosystems all across the country—these differences are not taken into account. In addition, benefits transfer for rapid assessments, such as the Skykomish study, fail to account for differences in values associated with differences in socioeconomic context between sites. For example, the recreational value of a forest depends on multiple site-specific socioeconomic factors such as accessibility (landownership and proximity to roads and towns). In transferring values of ecosystem services from other studies, the Skykomish study fails to account for such ecological and socioeconomic context affecting these values. This represents one reason we do not rely on the values presented in this study in the DEA.

Second, rapid assessments do not provide information on the effects of changes in the condition or quality of an ecosystem on the associated service values. The Skykomish study assigns an equal value to all ‘‘forest’’ acres and therefore does not provide any information to support an analysis of the ecosystem service benefits of changes in the management of a forest. It is the incremental change in the value of a service provided that is relevant to the DEA. For example, the DEA concludes critical habitat designation for the northern spotted owl may result in the harvest of fewer board feet of timber in a portion of the forests. Decreased harvest of trees may not change the land cover type (forest) as characterized in the rapid assessment; it simply affects the density of the trees in given areas. The rapid assessment approach does not address such differences across areas within a land use type (i.e., forests); rather, it is more useful in comparing the ecosystem services provided across different land use types (i.e., deserts, prairie, forests, marshes) and is therefore of limited use in evaluating tradeoffs associated with changes in the condition of a given ecosystem.

Consequently, absent a full-scale change from one ecosystem type to another, the rapid assessment approach to valuing benefits of critical habitat designation does not provide a valid approach to quantifying the ecological benefits of critical habitat designation for the northern spotted owl. While the DEA provides information on the types of services associated with the ecosystems types potentially affected by the designation, it does not attempt to perform a rapid assessment of the values of these services, for the reasons stated.

Comment (193): One commenter suggested that the Service could employ any of three approaches to value ecosystem service benefits of critical habitat designation: (1) The Integrated Valuation of Ecosystem Services and Tradeoffs (InVEST) model; (2) the Ecosystem Services Review Method; and (3) the Wildlife Habitat Benefits Estimation Toolkit. The comment states that all three are available and ready for immediate, widespread use. A second comment states that the Service is far behind the ecosystem services valuation curve.

Our Response: The Service recognizes that multiple tools exist that focus on evaluating ecosystem service benefits of land management changes. The authors of the DEA have experience with a number of these methods, including the InVEST tool and the Wildlife Habitat Benefits Estimation Toolkit. As a practical matter, the InVEST tool could be used to evaluate potential ancillary benefits of critical habitat for the northern spotted owl. The tool comprises a series of biophysical and economic models that aim to translate changes in a given landscape into changes in the delivery of multiple ecosystem services. These models are data-intensive and require site-specific information.

For each ecosystem service, InVEST relies on two separate models: One that estimates the biophysical change in the delivery of a service and, for some services, a second economic model that monetizes that change. For example, to estimate the change in water quality resulting from changes in the management of a given forest, the following types of detailed, on-the-ground, data would be required as inputs to the biophysical model: A digital elevation model, soil depth, plant available water content (the fraction of water that can be stored in the soil profile for plants' use), root depth of vegetative cover, evapotranspiration, nutrient or sediment loading for each land use type across the landscape, the vegetation filtering capacity of the land cover (as a function of the type and density of vegetation), and pre-existing water quality conditions for model calibration (e.g., nitrogen, phosphorus, or sediment concentrations). While some of these data are available; some would need to be generated at a relatively fine level of resolution in order to model the incremental changes in the ability of the landscape to filter pollutants likely to result from the designation. The InVEST tool values this service in terms of changes in treatment costs for nutrients or sediment. These costs are likewise site-specific.

This effort is particularly significant in light of the conclusion of the DEA that the critical habitat designation is most likely to generate only minor incremental changes in the management of land uses within the designation. The key change is a potential increase or decrease in timber harvest of less than one percent in the region. While the analysis describes qualitatively that this change potentially could generate some marginal improvements in services such as water quality regulation, these benefits are expected to be relatively minor, ancillary benefits of the rule. The same is true of application of other models to evaluate benefits, such as the Multiscale Integrated Model of Ecosystem Services (MIMES), also described in the comment. Finally, the areas most likely to produce these ancillary benefits (e.g., Federal matrix lands) are included in the final designation; thus additional analysis of the ancillary benefits of including these areas would not change the final regulatory decision. The DEA therefore provides qualitative information to the Service regarding potential ancillary benefits.

The objective of the Ecosystem Services Review (ESR) Method is to provide companies with information on how their business depends on ecosystem services, whether their business affects their (or others') ability to access these services, and opportunities to capitalize on and minimize effects on these services. The ESR is not a quantitative tool but a series of steps embedded in a spreadsheet model to help users incorporate consideration of ecosystem services into business decisionmaking. While useful to corporations, it is unclear how this tool may be used to improve the benefits discussion in the DEA. Section 8.2 of the DEA describes potential categories of ancillary ecosystem service benefits that may result from the designation and where (in which units) these benefits may occur. This information is provided for the Service to consider alongside the costs. The ESR does not provide a means to value these services.

The Wildlife Habitat Benefits Estimation Toolkit is a benefits transfer tool developed by the Defenders of Wildlife and Colorado State University for the purposes of valuing ecosystem services associated with species and habitat conservation, such as property values, recreation, and existence values. The benefits transfers facilitated by this toolkit suffer from some of the same issues as the rapid assessment described above. The policy context or sites subject to analysis are most often not transferable to the issue being evaluated: In this case, the land management changes resulting from the critical habitat designation for the northern spotted owl.

Comment (194): One organization stated the DEA is incomplete, in part because it focuses too narrowly on impacts to the timber industry, while the final designation will also affect the economies of the region in other ways. Specifically, two comments stressed that the analysis should consider the total value of the goods and services provided by forests in this region, including reduced wildfire threats, reduced impacts of droughts, reduced threat of insect damage, reduced property damage due to these risk reductions, increased quality or quantity of recreational activities, aesthetic improvements for people passing on nearby roads, carbon sequestration, and improved water quality.

Our Response: The economic analysis's focus on changes in timber harvest practices is appropriate because this activity is the conduit for all other ''on-the-ground'' changes, positive or negative, resulting from the designation. Increases or decreases in timber harvests could positively or negatively affect regional socioeconomic conditions. Thus, Chapter 3 of the DEA provides context explaining historical and current conditions, and Chapter 6 identifies counties that may experience the greatest impacts. The same changes in timber harvests could affect the northern spotted owl's conservation and recovery, discussed in Chapter 8 of the DEA. Finally, these changes in timber harvests are the driver of the potential changes in other ecosystem services, including recreational opportunities, described in the comment. These ancillary benefits are also described in Chapter 8 of the DEA.

Responses provided to earlier comments review the best available modeling tools for quantifying and valuing ecosystem services and describe why these tools were not employed in this instance. In the FEA, we expand our qualitative discussion of potential ancillary benefits to include the broader set of ecosystem service categories discussed in the comment.

Comment (195): One organization states that OMB's Circular A–4 is fundamentally flawed in excluding the flow of ecosystem services from the baseline and recommending discounting practices that are inconsistent with ecosystem service valuation. The comment further states that Circular A–4 is insufficient because it provides the Service with a rationale to avoid quantifying the benefits of critical habitat designation by allowing for a qualitative assessment where benefits are ''difficult to quantify.''

Our Response: The conceptual framework of the FEA is to evaluate impacts by comparing the world without critical habitat (baseline) to the world with critical habitat. The difference between these two states represents the incremental impacts of the rule. Thus, the FEA does not exclude the flow of ecosystem services from the baseline. To understand how the flow of ecosystem services may change, one must first understand the categories and magnitude of existing services. In this way, while not explicitly quantified in the analysis, the current flow of ecosystem services is implicitly captured in our characterization of the baseline condition.

Put another way, the organization appears to be asking us to first present the total value of all services provided by forests included in proposed designation. Then, our analysis would estimate the value of the incremental change in quality and quantity of these services as a result of the designation. Such an effort would be equivalent, on the cost side of the analysis, to first presenting the total value (in terms of stumpage prices) of all the timber found in proposed critical habitat, and then presenting the value of the change in the amount of timber harvested as a result of the regulation. On both sides of the equation, providing a monetized estimate of the value of the baseline resources is not a necessary step to understanding the value or the change in services resulting from the designation. Correctly *characterizing* the baseline conditions is necessary, but valuation efforts appropriately focus on what will change, rather than what exists today.

Substantial debate surrounds the selection of appropriate discount rates for ecosystem services. While Circular A–4 recommends applying discount rates of 7 and 3 percent for regulatory analyses, it does not preclude the application of alternative discount rates for comparison. The comment recommends assessing ecosystem services benefits using discount rates of zero and one percent, in addition to three and seven percent. Because ecosystem services are not quantified in the economic analysis, we do not consider additional sensitivity analysis around the discount rate assumption.

Further, such an effort would require some data that are not currently available.

Comment (196): One comment states that the cost of avoiding carbon emissions is less than the cost of climate mitigation, and several studies have shown that changing forest practices is one of the more efficient and economical ways to store carbon and reduce emissions. Given that carbon storage is just one of the many important ecological services provided by mature and old forest, every effort should be made to avoid as much warming as possible by protecting mature forests.

Our Response: We have added discussion of the potential for increased carbon sequestration to Chapter 8 of the FEA.

Comment (197): A comment asserts that the Presidential Memorandum to the Secretary of the Interior on the northern spotted owl is not consistent with the Endangered Species Act because it states that ''the benefits of excluding private lands and State lands may be greater than the benefits of including those areas in critical habitat.'' The commenter is concerned that this statement is made in the Presidential Memorandum without an attempt to quantify ecosystem services benefits of the designation on these lands, and these benefits are therefore given an effective price of zero.

Our Response: We do not believe that the directive in the Presidential memorandum is inconsistent with section 4(b)(2) of the Act, which states that the Secretary may exclude areas from critical habitat if the benefits of exclusion outweigh the benefits of inclusion, as long as failure to designate such areas will not result in extinction of the species. The purpose of the economic analysis is to provide the Secretary of the Interior with information to support analysis of where the benefits of excluding a particular area may outweigh the benefits of including that particular area as critical habitat. In providing the qualitative discussion of benefits, the FEA does not assign zero values to these potential benefits; this discussion is provided for the Secretary to consider alongside the quantitative information provided.

Comment (198): One commenter stated that the DEA estimates the benefits of increased timber production in terms of the market value of the logs, but ignores the costs to Federal agencies of producing the logs (i.e., costs of managing the land for timber production and executing the timber sales), and that the total cost to taxpayers may exceed the logs' market value.

Our Response: In support of its comment that the costs to Federal agencies (and ultimately taxpayers) of timber sales exceeds the revenues from the sales, the commenting organization cites several studies from the early 1980s, as well as a more recent report published by the Congressional Research Service (CRS) in 2004 (Gorte, R.W. 2004, Below Cost Timber Sales: An Overview, CRS, Order Code RL32485).

We agree that whether the net benefit of timber sales in terms of costs and revenues is positive has been the subject of much debate. CRS summarizes this debate and notes ''the estimates of financial results of [USFS] timber sales vary widely. This disparity is due to differences in basic approach—profit-and-loss, cash flow, or other approach—and in assumptions about relevant costs'' (Gorte, R.W. 2004, summary page). In particular, CRS notes differing assumptions regarding which Agency costs are relevant and how to allocate those costs to specific sales may result in different answers using the same basic accounting approach.

CRS also notes that the USFS sells timber for many reasons, such as ''to generate receipts, to supply wood for manufacturers, to provide employment, to expand access for motorized vehicles, to alter the composition and distribution of vegetation in the area, and more'' (p. 5). The ''value'' of all of these positive attributes of the sales may not be captured in the stumpage price paid by the loggers or mills purchasing the timber, as many of these attributes represent market externalities. Furthermore, ''the multiple outputs, environmental impacts, and differing time scales of timber sales and related activities make identifying relevant costs and comparing them with relevant revenues problematic. Two decades of debate have not resolved the dilemma, and further debate seems unlikely to result in widespread agreement'' (Gorte, R.W. 2004, p. 7).

Thus, whether the Federal agency costs of baseline timber sales anticipated in the absence of critical habitat, or new sales potential generated by the designation, exceed revenues is unknown. However, the fact that these sales are often conducted for multiple purposes, such as improved ecosystem services or regional employment, and those purposes may have value that is not captured in stumpage prices, suggests that our assumption that the benefits of the sales exceed costs is not unreasonable.

Comments on the Economic Analysis From Counties

Comment (199): Several counties including Wasco, Del Norte, Klickitat, and Skamania Counties expressed criticism of the Draft Economic Analysis, including concerns about the incremental analysis approach and the negative economic impact of reducing or restricting commercial timber harvest on local communities (employment, tax base, quality of life, and other socioeconomic impacts).

Our Response: The economic impact to local counties of this critical habitat designation will be determined in large part by the timber management direction the Federal land managers take within critical habitat lands. Project modification costs quantified in the FEA primarily result from changes in the quantity of timber harvested on Federal lands. As discussed in detail in Chapter 4 of the DEA, section 7 consultations on the sale of timber from Federal lands may result in an increase, decrease, or no change in harvest levels, based on several plausible assumptions. We note that if future harvests are restricted, total annual harvests could decrease by 24.56 million board feet (MMBF). This decrease represents less than one percent of 2010 total harvest and the average annual harvests between 2006 and 2010 across the 56-county area overlapping proposed critical habitat. The designation may also result in an increase in annual harvests of 12.28 MMBF, or less than half a percent of total annual harvests in the 56-county area. Finally, it is possible that harvest levels will not change as a result of the designation. In summary, the designation is anticipated to have a minor impact on future harvest levels.

The DEA used a filtering approach to identify those specific areas where incremental timber harvest effects may occur. Further explanatory detail on these methods has been added to Chapter 4 of the FEA. In addition, the chapter also notes the potential effects to the baseline timber projection related to increasing the percentage of matrix lands with northern spotted owl habitat that are likely to be unoccupied.

Comment (200): Two small county governments submitted comment stating the proposed rule would have disproportionate impacts on local employment, payroll, and county services funded by revenues-sharing programs and taxes. They provide data describing economic conditions in the 1970s and 1980s, and describe the economic decline experienced since the owl was listed in 1991.

Our Response: We recognize that many small governments have experienced significant changes in employment, payroll, and county revenues as a result of the decline in the timber industry over the last 21 years. Chapter 3 of the DEA provides detailed data by county describing these changes and providing context for the analysis. Chapter 6 provides information specific to the counties where changes in Federal timber harvests are relatively more likely. We note that these counties are not directly regulated by the designation of critical habitat for the northern spotted owl; rather, potential impacts result from changes in harvest practices on Federal lands or where other Federal actions may be involved.

Given the numerous factors affecting the future of the industry, including changes in the availability of Federal timber, mechanization, transfer of capital investment away from the region, closure of less efficient mills, and fluctuating demand for wood products, we are unable to provide quantitative projections of future timber-related employment. Furthermore, as discussed in Chapters 3 and 6 of the DEA, uncertainty regarding the future of existing county revenue-sharing programs, such as PILT and SRS, confound our ability to predict potential changes in county revenues. However, we note that reasonable assumptions suggest overall changes in harvest levels resulting from the designation are likely to be less than one percent of current levels. Chapter 6 of the DEA discusses the counties most likely to see the largest changes. In addition, most of the costs cited by the commenter, if not all, are attributable to the listed status of the northern spotted owl, rather than the incremental effects of critical habitat.

Comment (201): Several county governments reference a report prepared by the Sierra Institute for Community and Environment and Spatial Informatics Group, titled ''Response to the Economic Analysis of Critical Habitat Designation for the Northern Spotted Owl by Industrial Economics,'' and submitted as a public comment. Funding for the report was provided by the National Forest Counties and Schools Coalition. The report states that the DEA's assessment is insufficient in its documentation of cumulative socioeconomic impacts and current socioeconomic conditions. It provides detailed discussion and data concerning a variety of characteristics for communities potentially affected by the designation, including: Number of mills and mill closures; employment patterns; revenue-sharing payments to counties; family income; poverty levels; home ownership; health outcomes and factors; and enrollment in programs such as School Free and Reduced-Price Meals (FRPM).

Our Response: Chapter 3 of the DEA is intended to provide context to the decision maker regarding historical changes in the timber industry in the Pacific Northwest in terms of production, employment, income, and county revenues. It also discusses multiple possible causes contributing to these changes, including protection of the northern spotted owl. The Sierra Institute for Community and Environment report provides additional socioeconomic information supplementing the background information provided in Chapter 3. Text summarizing the contents and availability of this report has been added to the FEA. We note that verification of the data provided by the Sierra Institute for Community and Environment is complicated by the fact that citations are not provided for the majority of the report's figures and data.

Comment (202): The Sierra Institute for Community and Environment states in several places in its report that the DEA argues the loss of 30,000 jobs in the timber industry between 1990 and 2010 was offset by regional gains in population and employment of 15 percent and 18 percent, respectively. They state that the DEA errs by assuming that job gains in one time period offset losses in another, and that job gains (and losses) are equally distributed across the region. In addition, they claim that the DEA does not analyze or sufficiently discuss the issue of disparity and does not discuss how areas with a proportionally greater amount of employment in the timber industry are affected by the proposed critical habitat designation.

Our Response: The authors are referring to information provided in paragraphs 14 and 106 of the DEA, which present regional job loss figures and changes in regional population and employment. The DEA simply presents these facts; it makes no assumptions, and draws no conclusions, about whether lost timber jobs are offset by overall employment gains in the region or how job losses and gains are distributed across the region. Detailed analysis of rate and nature of reemployment of former timber industry employees is complex and beyond the scope of the DEA.

Chapter 6 of the DEA attempts to address potential disparity in the distribution of regional impacts of the designation. It combines background information on timber industry harvest and employment trends (presented in Chapter 3), and county dependency on revenue-sharing payments, with information about subunits where changes in timber harvest are possible (Chapter 4). It highlights the counties most likely to be affected by the rule based on proximity to affected subunits, and identifies which of these counties have already experienced the most significant declines in the industry over the last 20 years. The report notes that these counties may be more sensitive to future changes in timber harvests.

Definitely linking changes in timber harvests to timber-related jobs in certain communities is challenging. Timber industry jobs are not necessarily closely correlated with the amount of timber being harvested in that specific county; some mills or related manufacturers (e.g., wood product manufacturers) may rely on resources harvested from outside their immediate community. In its presentation of historical data on regional mill closures, the Sierra Institute for Community and Environment acknowledges, ''Other reasons for mill closure also include, but are not limited to, industry closing older, less efficient mills, closure of mills that handled only larger trees coupled with less old-growth timber available, and shipping raw logs and cants out of the region for processing elsewhere. Additional study is needed'' (page 31).

Teasing out the precise location of potential regional impacts resulting from critical habitat designation is particularly challenging due to the relatively small overall change in harvest anticipated to result from the final rule (at worst, a less than one percent decline in annual harvest). This marginal change in available Federal timber is unlikely to cause large-scale changes in the regional industry. Identification of who will experience impacts requires better understanding of potential substitutes and the degree of flexibility in the current production system, as well as proprietary information about the financial characteristics and operations of individual mills. Such data are not available to us and are not provided in the Sierra Institute for Community and Environment's report.

Comment (203): The Sierra Institute for Community and Environment report states that the DEA fails to link job losses to socioeconomic conditions and that this is required by the February 2012 Presidential Memo.

Our Response: The Presidential Memorandum directs the Secretary of the Interior to: (1) Publish, within 90 days of the date of this memorandum, a full analysis of the economic impacts of the proposed rule, including job impacts, and make the analysis available for public comment. The DEA satisfied this direction. It estimates the incremental change in social costs and benefits that may result from the proposed rule, as required by Executive Order 12866, following OMB's guidance on best practices as defined in *Circular A–4,* and consistent with existing case law; and, it provides a separate analysis of potential job impacts in Chapter 6.

The memorandum did not require the Secretary to take the additional step of developing complex models to link changes in timber industry employment to changes in socioeconomic conditions, such as poverty rates, homeownership, and participation in food assistance programs, as suggested by the report authors. Furthermore, the authors of the Sierra Institute for Community and Environment report acknowledge that linking changes in socioeconomic factors to changes in land management, and specifically to critical habitat designation, is challenging due to time constraints and complex data requirements (see, for example, pages 94, 105, 168 of the Sierra Institute for

Community and Environment report). As a result, the organization does not estimate these changes in its report.

Comment (204): The Sierra Institute for Community and Environment report states that an unintended consequence of critical habitat designation is that private landowners ''do nothing'' due to the increased cost of compliance, and that this has real social and environmental costs, such as reducing job availability and revenues and increasing fire risk.

Our Response: As described in Chapter 5 of the DEA, there is a potential for increased compliance costs, such as preparing environmental impact statements. In Washington, the DEA indicated that this may occur only in the event that the State Forest Practices Board redefines all suitable habitat overlapping Federal critical habitat within SOSEAs as ''critical habitat state'' (see paragraphs 227 through 232 of the DEA). The likelihood of such an outcome is uncertain. If it occurs, we estimated that at most 21,715 ac (8,788 ha) of proposed private lands could be incrementally affected. The remaining lands are already considered ''critical habitat state'' or are protected by existing or proposed HCPs and SHAs. The potential social and environmental costs of not harvesting these 21,715 ac (8,788) over the 20-year timeframe of the analysis are too small to measure.

In California, the FEA states that one stakeholder noted that landowners may be required to provide additional documentation under CEQA to demonstrate that their management plan timber harvest plan will mitigate impacts to critical habitat. Since CALFIRE has stated that it is unlikely to require additional protective measures for designated critical habitat beyond those already required by State regulation, any incremental costs would be limited to the possibility for additional CEQA review.

The FEA also identifies possible changes to timber harvest practices suggested by private parties as potentially occurring due to regulatory uncertainty, ranging from harvesting existing trees as early as feasible to discontinuing use of the property for timber production. However, due to the high degree of uncertainty over whether these impacts may occur, we were not able to quantify the potential effects.

We note that all private lands were excluded from critical habitat for the northern spotted owl under section 4(b)(2) of the Act (see Exclusions), therefore none of the potential scenarios considered by the DEA are germane to the final designation.

Comment (205): The Sierra Institute for Community and Environment report states that the DEA is insufficient because it does not adequately characterize cumulative socioeconomic impacts. The authors state that ''understanding current condition requires an understanding of what has transpired in recent years and trend [sic], which are, for the most part, not factors in the analysis.'' They also question why the Entrix report and the 2012 analysis ''ended up in inconsistent places with respect to baseline and included incremental impacts.''

Our Response: The DEA provides data on historical changes in timber industry production, employment, and income (see Chapter 3). It also provides information about trends in county revenue-sharing payments. This information is included in order to provide the Secretary with context for the incremental impacts of the analysis.

The OMB guidelines for best practices (*Circular A–4*) concerning the conduct of economic analysis of Federal regulations direct agencies to measure the costs of a regulatory action against a baseline, which it defines as the ''best assessment of the way the world would look absent the proposed action.'' The baseline utilized in the DEA is the existing state of regulation, prior to the designation of critical habitat, which provides protection to the species under the Act, as well as under other Federal, State, and local laws and guidelines. To characterize the ''world without critical habitat,'' the DEA also endeavors to forecast these conditions into the future over the timeframe of the analysis, recognizing that such projections are subject to uncertainty. This baseline projection recognizes that the northern spotted owl is already subject to a variety of Federal, State, and local protections throughout most of its range, due to its threatened status under the Act, and regardless of the designation of critical habitat.

Significant debate has occurred regarding whether assessing the impact of critical habitat designations using this baseline approach is appropriate, with several courts issuing divergent opinions. In 2010 and 2011, courts in several parts of the country, including the Ninth Circuit Court of Appeals, which has jurisdiction in Washington, Oregon, and California, ruled that decisions concerning designation of critical habitat should be based on the incremental impacts of the rule. The 9th Circuit cases were appealed to the Supreme Court, which declined to hear them.

The Entrix report analyzing the 2008 designation was prepared under subcontract to Industrial Economics, Incorporated (IEC), the authors of the 2012 analysis, and project managers from IEC worked closely on both efforts. The difference in the two analyses regarding whether to quantify impacts resulting from baseline regulatory protections is due to the change in case law described in the previous paragraph.

Comment (206): The Sierra Institute for Community and Environment report questions why the background data provided on timber industry employment and harvests do not factor into the overall assessment and analysis of impacts. The report states that the analysis does not address localized and community-level impacts.

Our Response: As described above, Chapter 6 of the DEA combines data from Chapters 3 and 4 of the analysis to identify counties that may be particularly susceptible to changes in timber harvests resulting from the designation. Employment and harvest trend data are generally available at the county level through publicly available sources, such as State natural resource agencies, the U.S. Census, and the U.S. Bureau of Labor Statistics. Assessing distributional impacts as a finer level of resolution is challenging given a lack of data. In addition, linking changes in community outcomes to the designation would require complex modeling that is beyond the scope of this analysis given the numerous other confounding factors and the relatively small changes in annual harvest that could result from the designation.

Comment (207): The Sierra Institute for Community and Environment report states that counties, municipalities, and schools were ''given short shrift'' in the DEA and that there was no substantive exchange about the conditions of counties or municipalities for the analysis. In addition, other economist commenters also said that they were not consulted for the DEA.

Our Response: During preparation of the draft, IEC contacted many stakeholders, including Federal agencies, State governments, and representatives of the timber industry, and sought to obtain economic and other relevant information from publicly available sources. They collected and analyzed data on historical changes in timber harvests and timber industry employment and payroll for each of the 56 counties overlapping the proposed designation and reviewed literature related to impacts to regional communities, including counties. IEC conducted research on county revenue sharing programs and presented data on the proportion of total county revenues derived from these programs. Two of the eight report chapters in the FEA focus exclusively on historical and current conditions in the counties, identifying those that are most likely to experience incremental impact and those that are likely to be more sensitive to changes in in harvests resulting from the proposed regulation.

IEC also reached out directly to County representatives. On June 6, 2012, IEC emailed representatives of Siskiyou, Skamania, and Douglas Counties, as well as the Association of O & C Counties, the Association of Oregon Counties, and the Washington State Association of Counties, and offered to meet with them via conference call. On June 25, 2012, IEC received a letter from representatives of Skamania, Douglas, and Siskiyou Counties requesting a meeting with all of the counties that may be affected by the designation. Since the comment period closed on July 6, 2012, the Service determined that there was not time to arrange a meeting with all 56 counties. However, on July 20, 2012, per section 4(b)(5) of the Act, we again invited all State agencies and affected jurisdictions to submit their comments on the proposed critical habitat revision.

Comment (208): The Sierra Institute for Community and Environment report questions the DEA's statement that employment in California, Oregon, and Washington increased only three percent between 2000 and 2010. The report states that reliance on Bureau of the Census and Bureau of Labor Statistics for employment data, such as the data presented in Exhibits 3.6 and 3.7 of the DEA, will result in an undercount of employment. Lastly, the authors state that they were unable to replicate the numbers in the tables because the methodology is inadequately specified.

Our Response: In both the Executive Summary and Chapter 3, the DEA reported that total employment in California, Oregon, and Washington increased by three percent between 2000 and 2010. IEC has added the source for this data, which is the Bureau of Economic Analysis (BEA), to the FEA. The BEA provides data on total annual State employment, which IEC used to determine the tri-State area employment increase between 2000 and 2010. The data is publically available and can be found online at BEA's Interactive Data Web site at *http://www.bea.gov/itable/*.

The data source for Exhibits 3.6 through 3.8 of the DEA, which present historical timber industry employment and payroll data for each county that contains proposed critical habitat (as well as for each State and for the entire study area), is the U.S. Census Bureau's County Business Patterns. Data for the County Business Patterns excludes data on self-employed individuals, employees of private households, railroad employees, agricultural production employees, and most government employees. More information on these exclusions can be found at *http://www.census.gov/econ/cbp/methodology.htm.* While a certain amount of undercoverage may occur, we believe the data provide the best available information from a reliable source. The exhibits list the SIC and NAICS codes that were used to estimate industry employment, as well as the Web site where the data can be found (*http://censtats.census.gov*).

Comment (209): The Sierra Institute for Community and Environment report states active forest management occurs on National Park Service lands in Shasta County.

Our Response: We make note of this representation in the FEA.

Comment (210): The Sierra Institute for Community and Environment report disagrees with the results of Scenario 3 of the Federal lands analysis (described in Section 4.4.2.3 of the DEA). The authors state that the DEA bases its analysis of incremental changes in timber harvests on a period in which there is a severe downturn in the economy and wood products industry and that this results in an undercount of likely impacts. They state that the analysis ''relies on 5 years (2006 to 2010) of harvest data to base future timber harvests.'' In addition, they state that estimates of harvest totals are generalized and not linked to subunit timber harvest totals.

Our Response: The DEA and FEA rely on historical actual harvest data for USFS Region 6 because it represented the best available data for purposes of the analysis. For USFS Region 5, the analysis relies on projected actual timber harvests by forest, provided by USFS. For BLM lands, the FEA utilizes BLM-provided data on timber harvest projections by critical habitat subunit for three decades of incremental impact estimates, by land allocation type, forest conditions, and harvest type. To conduct the analysis, these various timber projections needed to be converted to board feet, per-acre, per-year measurements, by critical habitat subunit. In an ideal world, the FEA would utilize detailed geospatial data showing when and where Federal timber harvest is projected to occur. However, lacking data on the narrowly defined areas where timber harvest is projected to occur, and where critical habitat may have an incremental effect on these harvests, the analysis broadly applies projected timber harvest across all Federal lands. Using this approach, the FEA uses timber harvest projections ranging from 14 to more than 200 BF-per-acre per-year across critical habitat subunits, as described in Chapter 4. In sum, the FEA does not rely exclusively on historical data, and variable projected harvests are linked to specific subunits to the extent possible.

Comment (211): The Sierra Institute for Community and Environment questions the baseline timber harvest projection used in the DEA, stating that it fails to draw a distinction between dry and wet forests and those that are commercially viable and those that are not.

Our Response: As noted in the prior response, the economic analysis endeavors to distinguish potential future harvest levels by forest type and characterization, and by areas within each subunit, to the extent possible given the best available information.

Comment (212): The Sierra Institute for Community and Environment report claims that the DEA does not provide sufficient analysis of indirect incremental effects of the critical habitat designation on private landowners. To assess the effects of potential changes in Washington State regulations resulting from critical habitat designation, the authors suggest, ''There may not be adequate estimates of the probability or the total number of acres that could be included, but probabilistic models coupled with a sensitivity analysis could offer insight into the impact and are possible to develop'' (Sierra Report 2012, p. 13).

Our Response: Chapter 5 of the FEA provides a detailed discussion of the sources of the data required to quantify the potential indirect effects of the designation on private lands (see paragraphs 279 through 287), including the number of acres where landowners are likely to alter current timber management practices; the characteristics of the stands (type of tree, age, etc.) subject to changes in the timing of harvests; current and revised harvest schedules; financial models of the change in the present value of existing lands that incorporate information about stumpage prices, stand growth curves, and the opportunity cost of capital to private timber managers; and information regarding the probability that the Washington Forest Practices Board will undertake regulatory changes. Basic data are not available for most of these elements, and thus, information necessary to create distributions describing these data elements and assumptions, which are required for probabilistic models, are scarce. Any distributions would likely be vague (for example, the probability of the Washington Forest Practices Board changing its regulations would range from zero to 100%, with an equal probability of any point in between these two endpoints). While it is technically possible to build a Monte Carlo-type probabilistic model using such vague probability distributions, the lack of data for meaningful inputs would render the results uninformative. We also note that private lands have been excluded from the final rule pursuant to section 4(b)(2) of the Act.

Comment (213): The Sierra Institute for Community and Environment report states that it is important for the DEA to quantify potential impacts of critical habitat designation on SRS and PILT payment programs. The authors state that it is not difficult to quantify the effects that future changes in timber harvests from Federal lands resulting from critical habitat designation would have on these payment programs. The authors also state that the analysis does not make clear that the revenue-sharing programs for Federal lands only continues if SRS is reauthorized after 2013.

Our Response: The Sierra Institute for Community and Environment is mistaken in its statement on page 14 of its report that the revenue-sharing programs for Federal lands only continue if SRS is reauthorized after 2013. It is true that if SRS is not reauthorized, the payments received by counties could be substantially different. However, as described in paragraphs 128 through 129 of the FEA, the U.S. Forest Service (USFS) 25% Fund and the Bureau of Land Management Oregon and California Land Grant (BLM O&C) Revenue-Sharing Payments (50 percent of commercial receipts) are permanently authorized by Congress and have dedicated funding sources in the form of commodity receipts. States and counties currently elect to receive SRS payments instead of revenue-sharing payments from the USFS 25% Fund and the BLM O&C Revenue-Sharing Program. In the absence of SRS (and possibly a second program called Payments in Lieu of Taxes, or PILT), the older programs would still be available and would serve as the sources of revenue-sharing payments.

Exhibit 3–9 in the FEA illustrates the relative magnitude of historical payments under all four programs, and Exhibit 3–10 provides information on percent of local government revenue that is made up of payments from these programs. Current SRS and PILT payments are based on historical revenue payments under preexisting programs and are allocated based on formulas considering a variety of factors. If these programs are re-authorized and funded, changes in revenues from Federal lands designated as critical habitat would first filter through the national allocation scheme and then through the State formulas, making it difficult to predict changes in payments. If these programs are not reauthorized and funded, then the payments would change each year based on a 7-year rolling average of receipts for USFS lands and the prior year's receipts for BLM O&C lands, and would also be filtered through the State's allocation formulas. Given the uncertainty associated with the future of SRS and PILT, the varying allocation schemes associated with the programs, and the relatively small change in anticipated harvests, the potential change in revenue-sharing payments is difficult to predict. Importantly, we note that the reauthorization and funding of SRS and PILT is unrelated to the decision to designate critical habitat for the northern spotted owl.

Environmental Analysis Comments

Comment (214): One commenter believed that the Secretary has not met the NEPA standard of full cooperation with State and county agencies in two different ways: (1) By setting a public comment timeframe that limits the agencies' ability to fully and knowingly provide comments; and (2) by denying the county the opportunity to be a cooperating agency under CEQ regulations and DOI policy.

Our Response: We believe the 30-day public comment period is adequate for review and comment on the draft environmental analysis and is consistent with the public comment period on many NEPA documents. In addition, we provided counties with an extended opportunity to comment, as described in Previous Federal Actions, above. With regard to cooperating agencies, neither CEQ nor DOI regulations discuss cooperating agencies in the context of environmental assessments because they are generally concise documents prepared to determine whether the proposed action will significantly affect the quality of the human environment and whether an environmental impact statement (EIS) is needed. Thus, environmental assessments normally do not warrant use of formally designated cooperating agencies. Because we initiated the NEPA analysis with an environmental assessment, we did not formally appoint any agency as a cooperating agency.

Comment (215): Several commenters requested the Service complete an environmental impact statement to address the effects of thinning, ecological forestry, and other active management activities on northern spotted owl populations. Commenters believe an EIS needs to be done for the critical habitat rule for a number of reasons, including that effects are significant; critical habitat designation could harm, rather than recover, the northern spotted owl; there is a need to accurately identify relevant environmental concerns and to take a ''hard look'' at these concerns; and the analysis in the draft environmental assessment is insufficient to prove effects are not significant (i.e., presents no information to justify a finding of no significant impact (FONSI)).

Our Response: This rulemaking is limited to the designation of critical habitat for the northern spotted owl. This final rule does not mandate or prescribe specific management activities, and the implementation of thinning, ecological forestry, or other types of activities is not required by this rulemaking. Should any such activities be proposed by the land management agencies when implementing specific projects on their managed lands, the only effect of this critical habitat rule is that Federal agencies will have to consult with the Service on their activities that may affect designated northern spotted owl critical habitat and ensure that their actions are not likely to destroy or adversely modify critical habitat, as those terms are used in section 7 of the Act. Our critical habitat proposal was fully compliant with NEPA, although we note that we elected to develop an environmental assessment pursuant to NEPA in this case entirely at our discretion, and not as a legal requirement. The proposal presented an overview of the state of the science on active management for consideration by land managers. It does not require any specific management actions. Any plans or project-level decisions concerning active forest management are appropriately made by land managers in accordance with their normal planning and project implementation procedures, and are beyond the authority of this rulemaking. Actions proposed on Federal lands must be consistent with the requirements of the NWFP and associated plans, and these plans have already undergone NEPA compliance. Step-down implementation of specific actions such as thinning projects on USFS or BLM lands also require NEPA compliance on a case-by-case basis.

Comment (216): One commenter stated that the barred owl EIS should not be a separate analysis document from the NEPA analysis done for the critical habitat rule, but that a single EIS should be prepared to address the entire proposal.

Our Response: The barred owl EIS represents an action entirely separate from the present critical habitat rulemaking, and is an evaluation of an experiment stemming from the recommendations of the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011). The Federal action requiring NEPA for the barred owl EIS is the issuance of a permit under the Migratory Bird Treaty Act for the scientific collection of barred owls, as well as additional permits that may be required for the experiment. In contrast, the designation of critical habitat is a statutory requirement under the Act, and is an entirely separate action from the issuance of necessary permits for research, take, or special use. We have addressed the barred owl EIS as an ongoing action in the cumulative effects analysis section of the environmental assessment of this rulemaking.

Comment (217): Commenters believed that the Draft Environmental Assessment is predecisional because it has committed to completing the NEPA process in a preordained timeline that does not allow sufficient time to meet the NEPA requirements of an EIS.

Our Response: An EIS is required only when an action is determined to have likelihood of significant impact on the human environment. Completion of an environmental assessment is a step in the NEPA process to determine whether or not impacts of the Federal action are significant and thus require an EIS. We have not predetermined the outcome of our environmental assessment. Rather, we have used the environmental assessment to establish whether or not impacts of the designation of critical habitat for the northern spotted owl are significant. Although there is a court-ordered schedule for completion of this critical habitat rule, if our environmental assessment had determined that impacts were significant, we would have sought an extension of time to complete our NEPA analysis. Our environmental analysis was consistent with the spirit and intent of NEPA, and was not predecisional. Further, our experience of evaluating the possible effects of critical habitat under NEPA suggested that an environmental assessment was the appropriate place to start.

Comment (218): One commenter described errors in public scoping in that we did not disclose our purpose and need during the scoping process.

Our Response: Public scoping is not required for the development of an environmental assessment. As stated in the environmental assessment, we used internal scoping (internal discussions among Service divisions regionally and nationally, and among staff with long-term experience with land-use activities conducted within critical habitat on Federal and non-Federal lands) to identify concerns, potential impacts, relevant effects of past actions, and possible alternative actions (October 15, 2008; FR 73 61292).

Comment (219): One commenter described several errors and inaccuracies in defining the purpose and need. Specifically: (1) The stated purpose of achieving the greatest conservation and recovery for the northern spotted owl is erroneous and more than required to meet the Act, and is also too narrow, overly restricting the range of reasonable alternatives; (2) the court-ordered due date of November 15 does not drive the need but rather the need is whatever was the Service's motivation in arranging the date with the court; and (3) the purpose of complying with the Act is not a purpose but an agency duty.

Our Response: Regarding item number 1, the commenter only partially described the purpose. The full purpose stated in the draft environmental assessment was to ''achieve the greatest relative conservation and recovery goals for the northern spotted owl but simultaneously minimize effects to other land and resources uses.'' We disagree that the purpose, as a whole, is more than required to meet the Act. Rather, our intent is to designate lands meeting the definition of critical habitat (i.e., areas occupied at the time of listing that contain the features essential to the species' conservation or unoccupied areas that are themselves essential to the species' conservation), determining what is essential in a way that minimizes effects on resource uses to the extent possible, and then using the exclusion process provided by section 4(b)(2) of the Act to weigh the benefits of inclusion versus the benefits of exclusion. This is what we mean by using the term ''relative.'' This balance does not result in more action than is required to meet the provisions of the Act, and we have clarified this in the environmental assessment. Regarding item number 2, we did not mean to imply that the court deadline drives the need. The need is to revise critical habitat pursuant to a court-ordered remand of the 2008 designation (Carpenters' Industrial Council (CIC) v. Salazar, 734 F. Supp. 2d126 (D.D.C. 2010) * * *); we have clarified this point in the final environmental assessment, available at *http://www.regulations.gov* and at *http://www.fws.gov/oregonfwo/Species/Data/NorthernSpottedOwl/CriticalHabitat/default.asp.* Regarding item number 3, the purpose of an action proposed by the Service or any other Federal agency, based on common NEPA practice and Federal NEPA guidance includes but is not limited to statutory authority. The Service cannot carry out an action that is inconsistent with our authorities, hence our purpose explicitly included reference to those authorities.

Comment (220): One commenter believed there was an inadequate range of alternatives. Furthermore, they believed that the alternatives the Service noted in the draft environmental assessment as considered but not fully developed were not fully considered because there was no environmental review of these alternatives.

Our Response: NEPA requires that we must analyze those alternatives necessary to permit a reasoned choice (40 CFR 1502.14). When there are potentially a very large number of alternatives, NEPA requires that we analyze only a reasonable number to cover the full spectrum of alternatives that are consistent with the purpose and need. We did consider but excluded some modeling outcomes from further analysis. NEPA allows the elimination of an action alternative from detailed analysis for a variety of reasons including ineffectiveness, technical or economic infeasibility, inconsistency with management objectives of the area, remote or speculative implementation, and substantial similarity in design and effects of an alternative that has been analyzed. We disagree with the commenter in that NEPA does not require an ''environmental review'' of alternatives eliminated from detailed study, but rather, a brief discussion of the reasons for their having been eliminated (40 CFR 1502.16(a)). We have further clarified our reasons for eliminating these alternatives from further analysis in the final NEPA document.

Comment (221): One commenter believed we did not adequately identify the range of issues that could be affected by critical habitat designation. They further pointed out that limiting our analysis to threatened and endangered species and stating in the environmental assessment that it is not possible to analyze effects on the other 1,200 species is wrong because it is possible and has been done for such actions as the NWFP.

Our Response: Only potentially significant issues must be the focus of the environmental analysis. Issues that are not significant (i.e., related to potentially significant effects) can be eliminated from detailed study, ''narrowing the discussion of these issues in the statement to a brief presentation of why they will not have a significant effect on the human environment.'' (40 CFR 1501.7(a)(2), 40 CFR 1501.7(a)(3)). We have further elaborated in the final environmental assessment (available at *www.regulations.gov* and at *http://www.fws.gov/oregonfwo/Species/Data/NorthernSpottedOwl/CriticalHabitat/default.asp*) why we found that these issues will not have a significant effect on the human environment. Regarding our statement that it is not possible to analyze effects on 1,200 species given that such an analysis was done in the NWFP, we agree this was in error and will remove that language from the final environmental assessment. However, we do not find that this impels us to analyze effects on all 1,200 late-successional species. In the case of the NWFP, the intent of the revision to USFS and BLM land management plans was to provide comprehensive management of habitat for late-successional and old-growth forest species. Thus, it was prudent to examine those species as part of the NWFP analysis. We do not believe that such a level of analysis is necessary for this purpose and have thus limited our analysis to effects on listed species to ensure critical habitat designation does not reduce their potential for recovery.

Comment (222): Three commenters believed the analysis failed to disclose that current habitat set-asides have not produced measurable success in northern spotted owl recovery, and that expanding critical habitat will also fail because barred owls are the primary causal factor in the northern spotted owl decline. On a related topic, one commenter felt the environmental assessment failed to describe how the proposed action would lead to recovery and why other alternatives would not.

Our Response: Threats to northern spotted owls are described in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) as habitat loss and competition from the barred owl. We acknowledge in this rule and the final environmental assessment that we need to address both of these threats if we are to recover the northern spotted owl. As to the need to describe how the proposed action would lead to recovery while other alternatives would not, we do not need to show that alternatives not chosen would not lead to recovery; we merely need to disclose the effects of each alternative on the relevant issues, in this case, primarily northern spotted owl populations, to provide information to decisionmakers. Recovery of northern spotted owls will require addressing multiple issues, of which habitat loss is only one and will be partly addressed through critical habitat designation.

Comment (223): One commenter noted we did not analyze the effects of eliminating LSRs as part of the critical habitat designation.

Our Response: This comment is based on a misunderstanding of the critical habitat designation, which does not eliminate the Late-Successional Reserve Network of the Northwest Forest Plan.

Comment (224): One commenter believed we failed to fully disclose the existing regulatory structure, and also failed to fully disclose the disincentives to landowners to retain habitat, resulting in the potential elimination of northern spotted owl habitat.

Our Response: We noted in the draft environmental assessment the potential for landowners to prematurely harvest existing habitat, maintain shorter harvest rotations, or change from forest management to development. We received several comments from landowners indicating their intention to deforest their property if designated as critical habitat. We acknowledge that possibility for some landowners in the final environmental assessment (available at *www.regulations.gov* and at *http://www.fws.gov/oregonfwo/Species/Data/NorthernSpottedOwl/CriticalHabitat/default.asp*) based on these comments, but cannot describe the extent or degree of these effects based on the comments we received. We also note that, in our preferred alternative, all private lands were excluded from this designation.

Comment (225): One commenter disagreed with what effects we considered speculative and not reasonably foreseeable, and believed we are obligated to display environmental consequences of potential effects even if actual outcomes are unknown.

Our Response: DOI NEPA regulations define reasonably foreseeable future action as, ''activities not yet undertaken, but sufficiently likely to occur, that a Responsible Official of ordinary prudence would take such activities into account in reaching a decision. These Federal and non-Federal activities that must be taken into account include, but are not limited to, activities for which there are existing decisions, funding, or proposals identified by the bureau. Reasonably foreseeable future actions do not include those actions that are highly speculative or indefinite.'' 43 CFR 46.30. We contend that the actions we consider not reasonably foreseeable meet this definition.

Comment (226): Two commenters indicated we failed to examine cumulative and connected actions in an economic and social context.

Our Response: We have completed an economic analysis that addresses economic and social aspects of the designation of critical habitat. In addition, the Council on Environmental Quality's implementing regulations indicate that economic and social effects are not by themselves intended to require preparation of an EIS, but should be considered if an EIS is prepared (40 CFR 1508.14). Our purpose in preparing an environmental assessment was to determine whether an EIS should be prepared. Because we determined that the critical habitat revision resulted in a finding of no significant impact (FONSI), it was determined that an EIS was not necessary to evaluate social and economic impacts.

Comment (227): One commenter noted we failed to analyze the economic effects of the northern spotted owl listing decision as a cumulative and connected action of critical habitat designation.

Our Response: We agree that the environmental assessment should consider all relevant cumulative effects, which may include the effects of past actions, as necessary to determine whether a finding of no significant impact is warranted. One element of that determination is ''[w]hether the action is related to other actions with individually insignificant but cumulatively significant impacts. Significance exists if it is reasonable to anticipate a cumulatively significant impact on the environment. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts.'' 40 CFR 1508.27(b)(7). As discussed in the previous comment, ''human environment'' is defined to include the natural and physical environment and the relationship of people with that environment except that economic or social effects are not intended by themselves to require preparation of an environmental impact statement. 40 CFR 1508.14. In this environmental assessment we have considered the potential effects of the designation added to other past, present, and reasonably foreseeable future actions that would affect the identified resources of concern to determine whether this would result in significant impacts to the human environment as defined for purposes of an environmental assessment. We have added the past action of listing the northern spotted owl to our cumulative effects analysis and considered those effects on the resources of concern identified in the environmental assessment.

Comment (228): One commenter contended that just because future action will undergo NEPA analysis does not relieve the Service of its NEPA duty to analyze the effects of the critical habitat proposal.

Our Response: We can analyze the indirect effects of the critical habitat designation only to the degree that we are reasonably certain of the actions that may occur within critical habitat, how they might be modified as a result of the section 7 process, and what the environmental impacts of those modifications might be. To that end, we have met our NEPA obligation. As individual Federal actions are developed with more information on location, activity type, magnitude, duration, and intensity, all things we cannot assess at this point in time, those actions will be subject to NEPA and analyzed in further detail.

Comment (229): One commenter believed it was incorrect for the Service to assume agencies will implement 100% of actions in the recovery plan [Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011)] and that we must assume agencies will implement NWFP requirements without further matrix restrictions.

Our Response: We have included as part of our range of possible outcomes the possibility that agencies will implement only the NWFP requirements, without implementing any additional recovery plan actions that may restrict actions in the matrix. However, we believe that is not the only possible scenario, given that we have examples of agencies implementing discretionary actions from the northern spotted owl recovery actions that are in addition to the Standards and Guidelines of the NWFP.

XIII. Required Determinations

Regulatory Planning and Review (Executive Orders 12866 and 13563)

Executive Order 12866 provides that the Office of Information and Regulatory Affairs (OIRA) will review all significant rules. The Office of Information and Regulatory Affairs has determined that this rule is significant because it will raise novel legal or policy issues.

Executive Order 13563 reaffirms the principles of E.O. 12866 while calling for improvements in the nation's regulatory system to promote predictability, to reduce uncertainty, and to use the best, most innovative, and least burdensome tools for achieving regulatory ends. The executive order directs agencies to consider regulatory approaches that reduce burdens and maintain flexibility and freedom of choice for the public where these approaches are relevant, feasible, and consistent with regulatory objectives. E.O. 13563 emphasizes further that regulations must be based on the best available science and that the rulemaking process must allow for public participation and an open exchange of ideas. We have developed this rule in a manner consistent with these requirements.

Regulatory Flexibility Act (5 U.S.C. 601 et seq.)

Under the Regulatory Flexibility Act (RFA; 5 U.S.C. 601 *et seq.*) as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA) of 1996 (5 U.S.C. 801 *et seq.*), whenever an agency must publish a notice of rulemaking for any proposed or final rule, it must prepare and make available for public comment a regulatory flexibility analysis that describes the effects of the rule on small entities (small businesses, small organizations, and small government jurisdictions). However, no regulatory flexibility analysis is required if the head of the agency certifies the rule will not have a significant economic impact on a substantial number of small entities. The SBREFA amended the RFA to require Federal agencies to provide a certification statement of the factual basis for certifying that the rule will not have a significant economic impact on a substantial number of small entities.

According to the Small Business Administration, small entities include small organizations such as independent nonprofit organizations; small governmental jurisdictions, including school boards and city and town governments that serve fewer than 50,000 residents; and small businesses (13 CFR 121.201). Small businesses include manufacturing and mining concerns with fewer than 500 employees, wholesale trade entities with fewer than 100 employees, retail and service businesses with less than $5 million in annual sales, general and heavy construction businesses with less than $27.5 million in annual business, special trade contractors doing less than $11.5 million in annual business, and forestry and logging operations with fewer than 500 employees and annual business less than $7 million. To determine if potential economic impacts to small entities may result from this designation, and whether these potential impacts may be significant, we considered the types of activities that might trigger regulatory impacts under this designation as well as types of project modifications that may result. In general, the term ''significant economic impact'' is meant to apply to a typical small business firm's business operations.

The Service's current understanding of recent case law is that Federal agencies are only required to evaluate the potential impacts of rulemaking on those entities directly regulated by the rulemaking; therefore, they are not required to evaluate the potential impacts to those entities not directly regulated. The designation of critical habitat for an endangered or threatened species only has a regulatory effect where a Federal action agency is involved in a particular action that may affect the designated critical habitat. Under these circumstances, only the Federal action agency is directly regulated by the designation, and, therefore, consistent with the Service's current interpretation of RFA and recent case law, the Service may limit its evaluation of the potential impacts to those identified for Federal action agencies. Under this interpretation, there is no requirement under the RFA to evaluate the potential impacts to entities not directly regulated, such as small businesses. However, E.O.'s 12866 and 13563 direct Federal agencies to assess costs and benefits of available regulatory alternatives in quantitative (to the extent feasible) and qualitative terms. Consequently, it is the current practice of the Service to assess to the extent practicable these potential impacts if sufficient data are available, whether or not this analysis is believed by the Service to be strictly required by the RFA. In other words, while the effects analysis required under the RFA is limited to entities directly regulated by the rulemaking, the effects analysis under the Act, consistent with the E.O. regulatory analysis requirements, can take into consideration impacts to both directly and indirectly impacted entities, where practicable and reasonable.

We acknowledge that in some cases, third-party proponents of the action subject to permitting or funding, though not directly regulated, may participate in a section 7 consultation with the Federal action agency. Moreover, E.O.'s 12866 and 13563 direct Federal agencies to assess all costs and benefits of available regulatory alternatives in quantitative (to the extent feasible) and qualitative terms. We believe it is good policy to assess these impacts if we have sufficient data before us to complete the necessary analysis, whether or not this analysis is strictly required by the RFA. While the Service does not consider this regulation to directly regulate these entities, in our draft economic analysis, we have conducted an evaluation of the potential number of third parties participating in consultations on an annual basis in order to ensure a more complete examination of the potential incremental effects of this rule in the context of the RFA. As discussed earlier in our March 8, 2012, proposed rule (77 FR 14062), our notice of availability of the draft economic analysis (77FR 32483; June 1, 2012), and in the draft economic analysis itself, we determined that the incremental effects of this revised designation are relatively small due to the extensive conservation measures already in place for the species, due to its being listed under the Act, and because of measures provided under the NWFP and other conservation programs. The FEA affirms these conclusions, and we have determined that these conclusions are applicable to this final revised designation of critical habitat for the northern spotted owl. Thus, even taking into account those entities not directly regulated, we certify that the revised designation of critical habitat for the northern spotted owl will not have a significant economic impact on a substantial number of small entities.

Importantly, the incremental regulatory and economic impacts of the rule must be *both* significant and substantial to prevent certification of the rule under the RFA and to require the preparation of a regulatory flexibility analysis. If a substantial number of small entities are affected by the critical habitat designation, but the per-entity economic impact is not significant, the Service may certify. Likewise, if the per-entity economic impact is likely to be significant, but the number of affected entities is not substantial, the Service may also certify. Because per-entity impacts are currently uncertain, our evaluation focused on the number of small entities potentially affected as third parties to consultation with Federal agencies that may be directly regulated by the designation

While developing our draft economic analysis (DEA), we determined that there may be third-party participants to consultations involved with timber harvest and linear projects. In estimating the potential number of entities involved with consultations on timber harvest, we used the projection of 1,000 consultations over the 20-year time horizon of the DEA related to timber harvest management, providing an assumption of 50 consultations per year. We predict that many of these consultations will not involve third parties, but data is lacking about third-party participation rates. For the sake of our evaluation, we took a more inclusive approach and assumed that third parties are involved with these consultations and that each party is a small entity, providing an annual estimate of 50 small entities that may be involved over the 20-year time horizon of the study. This is likely an overestimate of the number of third parties involved with timber management consultations and therefore an even greater overestimate of the number of small entities involved because many of those third parties will not be small entities. The DEA further explored the projection of small businesses in timber-related sectors in the geographic areas overlapping the critical habitat designation, which differed depending on the specific data sets used, either 7,140 entities or 2,616 entities. Using our conservative estimate of 50 small entities involved annually, the proportion of entities in the timber harvest management sector potentially impacted by the designation would be 0.70 percent and 1.9 percent, respectively, over the 20-year time horizon of the study.

The RFA does not explicitly define the specific proportion of any given sector that would represent a substantial number, but leave that determination to the discretion of the agency issuing the regulation. While the Service or the Department of Interior does not have a specific policy concerning what proportion of any given sector impacted would represent a substantial number, the Service, as a matter of practice, uses a value of 3% to evaluate whether the regulation may impact a substantial number. In other words, if a regulation is determined to have an impact on less than 3% of entities in a given sector, then the agency makes a determination that a substantial number is not affected. Whereas, if it is determined that the proportion of entities impacted by a given regulation is equal to or greater than 3%, then the agency further evaluates available data to make a specific determination for that regulation.

Applying the aforementioned criteria to the specific proportion of the timber harvest management sector, we have concluded that these proportions do not represent a substantial number of small business entities potentially affected in the timber harvest management sector. Please refer to Appendix A of the FEA for further details of our evaluation.

Next, we explored the potential impact to third parties that may be involved with consultations related to linear projects (i.e., roads, pipelines, and powerlines). On the basis of similar conservative assumptions explained in the DEA, we concluded that there may be a total of 11 projects in a given year that may involve third parties. If we similarly assume that each of these parties represent small entities, then we estimate that 11 small entities in a given year could be impacted by the designation. While there is greater uncertainty as to the number of small entities involved with linear projects, we believe that the relative proportion these 11 entities represent is unlikely to constitute a substantial number. Further, the projected impacts to third parties resulting from the consultations on linear projects are anticipated to be solely administrative in nature. Thus, even with the uncertainty as to whether the proportion of entities potentially effected is may be substantial (although we think that it is not), we have determined that the potential impacts to these entities would not be significant as they would only be the result of additional administrative costs, which are relatively minor. Therefore, based on our conservative estimates in identifying third parties in this sector that potentially may be impacted, the projected number of entities and types of impacts, we concluded that the designation would not result in a significant impact to a substantial number of small business entities in this sector.

These conclusions were reaffirmed in our FEA. Please refer to Appendix A of the FEA for further details of our evaluation. In development of the final economic analysis (FEA) and taking into consideration all information and comments received, and based on our conservative evaluation of the number of entities in the timber management and linear project sectors potentially impacted, the proportion of the affected entities to those representing the sector in the study area, and the types of impacts, we again determined that the revised critical habitat designation will not have a significant economic impact on a substantial number of small business entities. In Appendix A of the FEA, we acknowledge that the primary economic impact of the project modifications resulting from the consultations described above is a change in Federal revenues generated by timber sales. In other words, if harvests are increased or decreased as a result of the designation, the USFS and BLM will receive more or less revenues, respectively, from the sale of this timber. However, these Federal agencies are not, as noted, small businesses. Furthermore, entities bidding for new timber sales on Federal lands would not incur costs as a result of this critical habitat designation because they will only pay for the value of the sale after any modifications are made as part of the section 7 consultation process. In other words, any impact of this regulation on those entities would be indirect.

In the FEA, we evaluated the potential indirect economic effects on small business entities resulting from conservation actions related to the listing of the northern spotted owl and the designation of critical habitat. The analysis is based on the estimated impacts associated with the rulemaking, as described in Chapters 4 through 8 and Appendix A of the analysis, and evaluates the potential for economic impacts related to: (1) Timber management, (2) barred owl management, (3) northern spotted owl surveys and monitoring, (4) fire management, (5) linear projects (i.e., roads, pipelines, and powerlines), (6) restoration, (7) recreation, and (8) administrative costs associated with consultations under section 7 of the Act.

With respect to Federal lands, consultations with Federal land managers, the Service, and other experts indicate varying opinions regarding potential critical habitat effects on timber management practices, and noted the difficulty and limitations of deriving precise measures of positive or negative incremental change. Therefore, the FEA considered three alternative scenarios, which are described in Chapter 4 and summarized in Exhibit ES–4 of the FEA. These scenarios include: (1) Administrative costs only; (2) potential positive incremental impacts to timber harvest on Federal lands; and (3) potential negative incremental impacts to timber harvest on Federal lands. Furthermore, the economic analysis presents a potential low impact and high impact outcome for each of the three scenarios. Thus under the positive impact scenario, the estimated annualized *increase* in timber harvest revenue on Federal lands range from $1,230,000 to $3,070,000. Under the negative impact scenario, the annualized *decrease* in timber harvest revenue on Federal lands ranges $2,460,000 to $614,000,000. In all three scenarios, the estimated annualized administrative costs on Federal lands are from $185,000 to $316,000.

In response to public comment, a sensitivity analysis was performed on the baseline timber harvest projections, to better inform the alternative impact scenarios in the FEA. The economic analysis uses a baseline harvest projection of approximately 122.80 million board feet (MMBF) per year. In the sensitivity analyses, the baseline timber harvest projection increases by up to an additional 27.99 MMBF per year. Therefore, the range of incremental impacts to Federal timber harvest widens from a potential increase in stumpage value of $3,580,000 (under the increased timber harvest scenario) to a potential decrease of $7,860,000 (under the decreased timber harvest scenario) per year.

In addition, Exhibit ES–4 of the FEA presents our qualitative conclusions concerning potential timber harvest impacts to private lands, and notes that there may be possible negative impacts associated with regulatory uncertainty, and new regulation in the State of Washington, and concludes that zero timber harvest impacts are likely to occur on State lands. Finally, Exhibit ES–4 notes the potential incremental administrative costs related to linear projects, which are estimated to be between $10,800 on the low end and $19,500 on the high end.

The FEA also confirms our conclusion that between less than one percent and two percent of potentially effected small entities in the 56 county study area may participate as third parties in section 7 consultations related to timber harvests on an annual basis. In addition, approximately 11 electricity transmission or natural gas pipeline companies may participate in section 7 consultations in a given year. While we believe that this number does not represent a significant proportion of entities in this sector, the impacts to these entities are expected not to be significant as they are anticipated to be solely administrative in nature.

The FEA also explains that these estimates almost certainly overstate rather than understate the number of affected entities, perhaps to a significant degree, because: (1) Not all section 7 consultations will involve a third party; (2) not all third parties will be small entities; and (3) the same entity may consult more than once in a single year. We have also constrained the population of potentially affected entities to those found in counties overlapping critical habitat, as opposed to including others within the States of Washington, Oregon, and California. In addition, as described elsewhere in this rule, the greatest impact of section 7 will likely occur in unoccupied habitat, due to the fact that consultation would already occur in occupied habitat due to the presence of the listed species. We estimate that the vast majority of the areas being designated in this rule were occupied at the time of listing.

Finally, our analysis of potential impacts to small entities is overestimated because it was based on the proposed designation, which has been reduced by 4,197,484 ac (1,697,903 ha) in this final rule. Designated Federal lands are reduced by 2,849,745 ac (1,151,297 ha) due to the elimination of lands that we have determined do not meet the definition of critical habitat, the exemption of DOD lands under section 4(a)(3) of the Act, and the exclusion of Congressionally-reserved lands under section 4(b)(2) of the Act. Designated State and private lands are reduced by 1,647,170 ac (665,843 ha) due to the elimination of some lands that do not meet the definition of critical habitat and the exclusion of State parks and private lands under section 4(b)(2) of the Act.

In summary, we considered whether this designation would result in a significant economic impact on a substantial number of small entities. Based on the above reasoning, relevant case law, and currently available information, we concluded that this rule will not result in a significant economic impact on a substantial number of small entities. We are reaffirming our certification that this revised designation of critical habitat for the northern spotted owl will not have a significant economic impact on a substantial number of small entities, and a regulatory flexibility analysis is not required.

Energy Supply, Distribution, or Use (Executive Order 13211)

Executive Order 13211 (Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use) requires agencies to prepare Statements of Energy Effects when undertaking certain actions. While this final rule to designate revised critical habitat for the northern spotted owl is a significant regulatory action under Executive Order 12866, it is not expected to significantly affect energy supplies, distribution, or use. Therefore, this action is not a significant energy action, and no Statement of Energy Effects is required.

Unfunded Mandates Reform Act (2 U.S.C. 1501 et seq.)

In accordance with the Unfunded Mandates Reform Act (2 U.S.C. 1501 *et seq.*), we make the following findings:

(1) This rule will not produce a Federal mandate. In general, a Federal mandate is a provision in legislation,

statute, or regulation that would impose an enforceable duty upon State, local, or Indian governments, or the private sector, and includes both ''Federal intergovernmental mandates'' and ''Federal private sector mandates.'' These terms are defined in 2 U.S.C. 658(5)–(7). ''Federal intergovernmental mandate'' includes a regulation that ''would impose an enforceable duty upon State, local, or Indian governments'' with two exceptions. It excludes ''a condition of Federal assistance.'' It also excludes ''a duty arising from participation in a voluntary Federal program,'' unless the regulation ''relates to a then-existing Federal program under which $500,000,000 or more is provided annually to State, local, and Indian governments under entitlement authority,'' if the provision would ''increase the stringency of conditions of assistance'' or ''place caps upon, or otherwise decrease, the Federal Government's responsibility to provide funding,'' and the State, local, or Indian governments ''lack authority'' to adjust accordingly. At the time of enactment, these entitlement programs were: Medicaid; Aid to Families with Dependent Children work programs; Child Nutrition; Food Stamps; Social Services Block Grants; Vocational Rehabilitation State Grants; Foster Care, Adoption Assistance, and Independent Living; Family Support Welfare Services; and Child Support Enforcement. ''Federal private sector mandate'' includes a regulation that ''would impose an enforceable duty upon the private sector, except (i) a condition of Federal assistance or (ii) a duty arising from participation in a voluntary Federal program.''

The designation of critical habitat does not impose a legally binding duty on non-Federal Government entities or private parties. Under the Act, the only regulatory effect is that Federal agencies must ensure that their actions do not destroy or adversely modify critical habitat under section 7. While non-Federal entities that receive Federal funding, assistance, or permits, or that otherwise require approval or authorization from a Federal agency for an action, may be indirectly impacted by the designation of critical habitat, the legally binding duty to avoid destruction or adverse modification of critical habitat rests squarely on the Federal agency. Furthermore, to the extent that non-Federal entities are indirectly impacted because they receive Federal assistance or participate in a voluntary Federal aid program, the Unfunded Mandates Reform Act would not apply, nor would critical habitat shift the costs of the large entitlement programs listed above onto State governments.

(2) We have determined that this rule will not significantly or uniquely affect small governments because the designation of critical habitat imposes no obligations on State or local governments. By definition, Federal agencies are not considered small entities, although the activities they fund or permit may be proposed or carried out by small entities. Consequently, we do not believe that the critical habitat designation would significantly or uniquely affect small government entities. As such, a Small Government Agency Plan is not required. Further, it will not produce a Federal mandate of $100 million or greater in any year, that is, it is not a ''significant regulatory action'' under the Unfunded Mandates Reform Act.

Takings (Executive Order 12630)

In accordance with Executive Order 12630 (Government Actions and Interference with Constitutionally Protected Private Property Rights), we have analyzed the potential takings implications of designating critical habitat for the northern spotted owl in a takings implications assessment. As discussed above, the designation of critical habitat affects only Federal actions. Although private parties that receive Federal funding or assistance or require approval or authorization from a Federal agency for an action may be indirectly impacted by the designation of critical habitat, the legally binding duty to avoid destruction or adverse modification of critical habitat rests squarely on the Federal agency. The takings implications assessment concludes that this designation of critical habitat for the northern spotted owl does not pose significant takings implications for lands within or affected by the designation.

Federalism (Executive Order 13132)

In accordance with Executive Order 13132 (Federalism), we have determined that this rule does not have direct federalism implications that would require a federalism summary impact statement; however, we are aware of the State-level interest in this rule, and we both summarize below and explain in more detail in other parts of this package activities and responsibilities on Federal, State, and private lands.

From a federalism perspective, the designation of critical habitat directly affects only the responsibilities of Federal agencies. As explained in detail earlier, section 7(a)(2) of the Act requires Federal agencies—and only Federal agencies—to ensure that the actions they authorize, fund, or carry out are not likely to destroy or adversely modify critical habitat. The Act imposes no other duties with respect to critical habitat, either for States and local governments, or for anyone else. As a result, the rule does not have substantial direct effects either on the States, or on the relationship between the national government and the States, or on the distribution of powers and responsibilities among the various levels of government. However, in keeping with Department of the Interior and Department of Commerce policy and the federalism principles set forth in Executive Order 13132, we requested information from, and coordinated development of, this revised critical habitat designation with appropriate State resource agencies in Washington, Oregon, and California, on the effects of revised designation of critical habitat. We received comments from the Washington State Department of Natural Resources, Washington Department of Fish and Wildlife, Oregon Department of Forestry, the State of Oregon, and California Department of Forestry and Fire Protection (CALFIRE), as discussed in the Summary of Comments and Responses section of the rule, above. In addition, we received comments from the following counties:

- Washington: Jefferson County, Klickitat County, Skamania County, and Skagit County;
- Oregon: Hood River County, Jackson County, Linn County, Douglas County, and the Association of O&C Counties; and
- California: Del Norte County, Tehama County, Regional Council of Rural Counties, Siskiyou County, and Trinity County.

We used this information to more thoroughly evaluate the probable economic and regulatory effects of the proposed designation in our final economic analysis, to inform the development of our final rule, and to consider the appropriateness of excluding specific areas from the final rule. We found that the revised designation of critical habitat for the northern spotted owl has little incremental impact on State and local governments and their activities.

The revision of critical habitat also is not expected to have substantial indirect impacts. As explained in more detail above, activities within the areas proposed to be designated as critical habitat are already subject to a broad range of requirements, including: (1) The various requirements of the Northwest Forest Plan, including those applicable to its Late-successional Reserves, Riparian Reserves, and ''survey and manage'' restrictions; (2) the prohibition against ''taking'' northern spotted owls under sections 4(d) and 9 of the Act; (3) the prohibition against Federal agency actions that jeopardize the continued existence of the northern spotted owl under section 7(a)(2) of the Act; (4) the prohibition against taking other federally listed species that occur in the area of the designated critical habitat (e.g., salmon, bull trout, and marbled murrelets); and (5) the prohibition against Federal agency actions that jeopardize the continued existence of such other listed species. All of these requirements are currently in effect and will remain in effect after the final revision of critical habitat.

Some indirect impacts of the rule on States are, of course, possible. Section 7(a)(2) of the Act requires Federal agencies (action agencies) to consult with the Service whenever activities that they undertake, authorize, permit, or fund may affect a listed species or designated critical habitat. States or local governments may be indirectly affected if they require Federal funds or formal approval or authorization from a Federal agency as a prerequisite to conducting an action. In such instances, while the primary consulting parties are the Service and the Federal action agency, State and local governments may also participate in section 7 consultation as an applicant. It is therefore possible that States may be required to change project designs, operation, or management of activities taking place within the boundaries of the designation in order to receive Federal funding, assistance, permits, approval, or authorization from a Federal agency. Also, to the extent that the designation of critical habitat affects timber harvest amounts on Federal land, county governments that receive a share of the receipts from such harvests may be affected. However, while non-Federal entities that receive Federal funding, assistance, or permits, or that otherwise require approval or authorization from a Federal agency for an action, may be indirectly impacted by the designation of critical habitat, the legally binding duty to avoid destruction or adverse modification of critical habitat rests squarely on the Federal agency.

On the other hand, the designation of critical habitat will likely have some benefit to State and local governments because the areas that contain the physical or biological features essential to the conservation of the species are more clearly defined, and the elements of the features of the habitat necessary to the conservation of the species are specifically identified. It may also assist local governments in long-range planning (rather than having them wait for case-by-case section 7 consultations to occur).

Civil Justice Reform (Executive Order 12988)

In accordance with Executive Order 12988 (Civil Justice Reform), the Office of the Solicitor has determined that the rule does not unduly burden the judicial system and that it meets the requirements of sections 3(a) and 3(b)(2) of the Order. We have revised critical habitat in accordance with the provisions of the Act. To assist the public in understanding the habitat needs of the species, the rule identifies the elements of physical or biological features essential to the conservation of the species. The designated areas of critical habitat are presented on maps, and the rule provides several options for the interested public to obtain more detailed location information, if desired.

Paperwork Reduction Act of 1995 (44 U.S.C. 3501 et seq.)

This rule does not contain any new collections of information that require approval by OMB under the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 *et seq.*). This rule will not impose recordkeeping or reporting requirements on State or local governments, individuals, businesses, or organizations. An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number.

National Environmental Policy Act (42 U.S.C. 4321 et seq.)

It is our position that, outside the jurisdiction of the U.S. Court of Appeals for the Tenth Circuit, we do not need to prepare environmental analyses pursuant to the National Environmental Policy Act (NEPA), 42 U.S.C. 4321 *et seq.,* in connection with designating critical habitat under the Act for the reasons outlined in a notice published in the **Federal Register** on October 25, 1983 (48 FR 49244). This position was upheld by the U.S. Court of Appeals for the Ninth Circuit (in a challenge to the first rulemaking designating critical habitat for the northern spotted owl. *Douglas County* v. *Babbitt,* 48 F.3d 1495 (9th Cir. 1995), cert. denied 516 U.S. 1042 (1996)).

However, at our discretion, we undertook an environmental assessment for this revised critical habitat designation, and notified the public of the availability of the draft environmental assessment for the proposed rule, for review and comment. We took all substantive comments into consideration, both to make revisions or corrections in the environmental assessment, and in the decisionmaking process made in finalizing the determination. In our final environmental assessment, we were able to make a finding of no significant impact (FONSI) from this rulemaking action. The final environmental assessment is available at *www.regulations.gov* and at *http://www.fws.gov/oregonfwo/Species/Data/NorthernSpottedOwl/CriticalHabitat/default.asp.*

Government-to-Government Relationship With Tribes

In accordance with the President's memorandum of April 29, 1994 (Government-to-Government Relations with Native American Tribal Governments; 59 FR 22951), Executive Order 13175, ''Consultation and Coordination with Indian Tribal Governments'' (November 6, 2000, and as reaffirmed November 5, 2009), and the Department of the Interior's manual at 512 DM 2, we readily acknowledge our responsibility to communicate meaningfully with recognized Federal Tribes on a government-to-government basis. The United States recognizes the right of Indian tribes to self-government and supports tribal sovereignty and self-determination, and recognizes the need to consult with tribal officials when developing regulations that have tribal implications. In accordance with Secretarial Order 3206 of June 5, 1997 (American Indian Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act), we readily acknowledge our responsibilities to work directly with tribes in developing programs for healthy ecosystems, to acknowledge that Indian lands are not subject to the same controls as Federal public lands, to remain sensitive to Indian culture, and to make information available to tribes. Even though we have determined that there are no Indian lands that meet the definition of critical habitat for the northern spotted owl, and therefore no Indian lands are included in this designation, we will continue to coordinate and consult with tribes regarding resources within the revised designation that are of cultural significance to them.

XIV. References Cited

A complete list of references cited in this rulemaking is available on the Internet at *http://www.regulations.gov* and upon request from the Oregon Fish and Wildlife Office (see **FOR FURTHER INFORMATION CONTACT**).

Regulation Promulgation

Accordingly, we amend part 17, subchapter B of chapter I, title 50 of the Code of Federal Regulations, as set forth below:

PART 17—ENDANGERED AND THREATENED WILDLIFE AND PLANTS

■ 1. The authority citation for part 17 continues to read as follows:

Authority: 16 U.S.C. 1361–1407; 16 U.S.C. 1531–1544; 16 U.S.C. 4201–4245; Pub. L. 99–625, 100 Stat. 3500; unless otherwise noted.

■ 2. Amend § 17.95(b) by revising the critical habitat entry for ''Northern Spotted Owl *(Strix occidentalis caurina)*'' to read as follows:

§ 17.95 Critical habitat—fish and wildlife.

* * * * *

(b) *Birds.*

* * * * *

Northern Spotted Owl *(Strix occidentalis caurina)*

(1) Critical habitat units are depicted for the States of Washington, Oregon, and California on the maps below.

(2) Critical habitat for the northern spotted owl includes the following four primary constituent elements set forth in paragraph (2)(i) (primary constituent element 1) through paragraph (2)(iv) (primary constituent element 4) of this entry. Each critical habitat unit must include primary constituent element 1 and primary constituent element 2, 3, or 4:

(i) Primary constituent element 1: Forest types that may be in early-, mid-, or late-seral stages and that support the northern spotted owl across its geographical range. These forest types are primarily:

(A) Sitka spruce;

(B) Western hemlock;

(C) Mixed conifer and mixed evergreen;

(D) Grand fir;

(E) Pacific silver fir;

(F) Douglas-fir;

(G) White fir;

(H) Shasta red fir;

(I) Redwood/Douglas-fir (in coastal California and southwestern Oregon); and

(J) The moist end of the ponderosa pine coniferous forest zones at elevations up to approximately 3,000 ft (900 m) near the northern edge of the range and up to approximately 6,000 ft (1,800 m) at the southern edge.

(ii) Primary constituent element 2: Habitat that provides for nesting and roosting. In many cases the same habitat also provides for foraging (primary constituent element (3)). Nesting and roosting habitat provides structural features for nesting, protection from adverse weather conditions, and cover to reduce predation risks for adults and young. This primary constituent element is found throughout the geographical range of the northern spotted owl, because stand structures at nest sites tend to vary little across the northern spotted owl's range. These habitats must provide:

(A) Sufficient foraging habitat to meet the home range needs of territorial pairs of northern spotted owls throughout the year; and

(B) Stands for nesting and roosting that are generally characterized by:

(1) Moderate to high canopy cover (60 to over 80 percent).

(2) Multilayered, multispecies canopies with large (20–30 inches (in) (51–76 centimeters (cm)) or greater diameter at breast height (dbh)) overstory trees.

(3) High basal area (greater than 240 ft^2/acre; 55 m^2/ha).

(4) High diversity of different diameters of trees.

(5) High incidence of large live trees with various deformities (e.g., large cavities, broken tops, mistletoe infections, and other evidence of decadence).

(6) Large snags and large accumulations of fallen trees and other woody debris on the ground.

(7) Sufficient open space below the canopy for northern spotted owls to fly.

(iii) Primary constituent element 3: Habitat that provides for foraging, which varies widely across the northern spotted owl's range, in accordance with ecological conditions and disturbance regimes that influence vegetation structure and prey species distributions. Across most of the owl's range, nesting and roosting habitat is also foraging habitat, but in some regions northern spotted owls may additionally use other habitat types for foraging as well. The foraging habitat PCEs for the four ecological zones within the geographical range of the northern spotted owl are generally the following:

(A) *West Cascades/Coast Ranges of Oregon and Washington.*

(1) Stands of nesting and roosting habitat; additionally, owls may use younger forests with some structural characteristics (legacy features) of old forests, hardwood forest patches, and edges between old forest and hardwoods.

(2) Moderate to high canopy cover (60 to over 80 percent).

(3) A diversity of tree diameters and heights.

(4) Increasing density of trees greater than or equal to 31 in (80 cm) dbh increases foraging habitat quality (especially above 12 trees per ac (30 trees per ha)).

(5) Increasing density of trees 20 to 31 in (51 to 80 cm) dbh increases foraging habitat quality (especially above 24 trees per ac (60 trees per ha)).

(6) Increasing snag basal area, snag volume (the product of snag diameter, height, estimated top diameter, and including a taper function), and density of snags greater than 20 in (50 cm) dbh all contribute to increasing foraging habitat quality, especially above 10 snags/ha.

(7) Large accumulations of fallen trees and other woody debris on the ground.

(8) Sufficient open space below the canopy for northern spotted owls to fly.

(B) *East Cascades.*

(1) Stands of nesting and roosting habitat.

(2) Stands composed of Douglas-fir and white fir/Douglas-fir mix.

(3) Mean tree size (quadratic mean diameter greater than 16.5 in (42 cm)).

(4) Increasing density of large trees (greater than 26 in (66 cm)) and increasing basal area (the cross-sectional area of tree boles measured at breast height), which increases foraging habitat quality.

(5) Large accumulations of fallen trees and other woody debris on the ground.

(6) Sufficient open space below the canopy for northern spotted owls to fly.

(C) *Klamath and Northern California Interior Coast Ranges.*

(1) Stands of nesting and roosting habitat; in addition, other forest types with mature and old-forest characteristics.

(2) Presence of conifer species such as incense-cedar, sugar pine, and Douglas-fir and hardwood species such as bigleaf maple, black oak, live oaks, and madrone, as well as shrubs.

(3) Forest patches within riparian zones of low-order streams and edges between conifer and hardwood forest stands.

(4) Brushy openings and dense young stands or low-density forest patches within a mosaic of mature and older forest habitat.

(5) High canopy cover (87 percent at frequently used sites).

(6) Multiple canopy layers.

(7) Mean stand diameter greater than 21 in (52.5 cm).

(8) Increasing mean stand diameter and densities of trees greater than 26 in (66 cm) increases foraging habitat quality.

(9) Large accumulations of fallen trees and other woody debris on the ground.

(10) Sufficient open space below the canopy for northern spotted owls to fly.

(D) *Redwood Coast.*

(1) Nesting and roosting habitat; in addition, stands composed of hardwood tree species, particularly tanoak.

(2) Early-seral habitats 6 to 20 years old with dense shrub and hardwood cover and abundant woody debris; these habitats produce prey, and must occur in conjunction with nesting, roosting, or foraging habitat.

(3) Increasing density of small-to-medium sized trees (10 to 22 in; 25 to 56 cm), which increases foraging habitat quality.

(4) Trees greater than 26 in (66 cm) in diameter or greater than 41 years of age.

(5) Sufficient open space below the canopy for northern spotted owls to fly.

(iv) Primary constituent element 4: Habitat to support the transience and colonization phases of dispersal, which in all cases would optimally be composed of nesting, roosting, or foraging habitat (PCEs 2 or 3), but which may also be composed of other forest types that occur between larger blocks of nesting, roosting, and foraging habitat. In cases where nesting, roosting, or foraging habitats are insufficient to provide for dispersing or nonbreeding owls, the specific dispersal habitat PCEs for the northern spotted owl may be provided by the following:

(A) Habitat supporting the transience phase of dispersal, which includes:

(1) Stands with adequate tree size and canopy cover to provide protection from avian predators and minimal foraging opportunities; in general this may include, but is not limited to, trees with at least 11 in (28 cm) dbh and a minimum 40 percent canopy cover; and

(2) Younger and less diverse forest stands than foraging habitat, such as even-aged, pole-sized stands, if such stands contain some roosting structures and foraging habitat to allow for temporary resting and feeding during the transience phase.

(B) Habitat supporting the colonization phase of dispersal, which is generally equivalent to nesting, roosting and foraging habitat as described in PCEs 2 and 3, but may be smaller in area than that needed to support nesting pairs.

(3) Critical habitat does not include:

(i) manmade structures (such as buildings, aqueducts, runways, roads, other paved areas, or surface mine sites) and the land on which they are located; and

(ii) meadows, grasslands, oak woodlands, or aspen woodlands as described below existing on January 3, 2013 and not containing primary constituent elements 1 and 2, 3, or 4 as described in paragraph (2) of this entry.

(A) Meadows and grasslands include: dry, upland prairies and savannas in valleys and foothills of western Washington, Oregon, and northwest California; subalpine meadows; and grass and forb dominated cliffs, bluffs and grass balds found throughout these same areas. These areas are dominated by native grasses and diverse forbs, and may include a minor savanna component of Oregon white oak, Douglas-fir, or Ponderosa pine.

(B) Oak woodlands are characterized by an open canopy dominated by Oregon white oak. These areas may also include ponderosa pine, California black oak, Douglas-fir, or canyon live oak. The understory is relatively open with shrubs, grasses and wildflowers. Oak woodlands are typically found in drier landscapes and on south-facing slopes. This exception for oak woodlands does not include tanoak (*Notholithocarpus densiflorus*) stands, closed-canopy live oak (*Quercus agrifolia*) woodlands and open-canopied valley oak (*Quercus lobata*) and mixed-oak woodlands in subunits ICC–6 and RDC–5 in Napa, Sonoma, and Marin Counties, California.

(C) Aspen (*Populus* spp.) woodlands are dominated by aspen trees with a forb, grass or shrub understory and are typically found on mountain slopes, rock outcrops and talus slopes, canyon walls, and some seeps and stream corridors. This forest type also can occur in riparian areas or in moist microsites within drier landscapes.

(4) We have determined that the physical and biological features in habitat occupied by the species at the time it was listed, as represented by the primary constituent elements, may require special management considerations or protection as required by 16 U.S.C. 1532(5)(A). However, nothing in this rule requires land managers to implement, or precludes land managers from implementing, special management or protection measures.

(5) *Critical habitat map units.* The designated critical habitat units for the northern spotted owl are depicted on the maps below. The coordinates or plot points or both on which each map is based are available at the field office Internet site (*http://www.fws.gov/oregonfwo*), *http://www.regulations.gov* at Docket No. FWS–R1–ES–2011–0112, and at the Service's Oregon Fish and Wildlife Office. You may obtain field office location information by contacting one of the Service regional offices, the addresses of which are listed at 50 CFR 2.2.

Revised Recovery Plan for the Northern Spotted Owl (*Strix occidentalis caurina*)

Cover photo:

Revised Recovery Plan for the Northern Spotted Owl (*Strix occidentalis caurina*)

Region 1
U.S. Fish and Wildlife Service
Portland, Oregon

Approved: Robyn Thorson
Regional Director, U.S. Fish and Wildlife Service

Date: JUN 2 8 2011

Disclaimer

Recovery plans describe reasonable actions and criteria that are considered necessary to recover listed species. Recovery plans are approved and published by the U.S. Fish and Wildlife Service ("Service" or "we" in narrative, (except as otherwise indicated) "USFWS" in citations, "FWS" in tables) and are sometimes prepared with the assistance of recovery teams, contractors, State agencies, and others. The 2011 Revised Recovery Plan for the Northern Spotted Owl (Revised Recovery Plan) does not necessarily represent the view or official position of any individual or organization—other than that of the Service—involved in its development. Although the northern spotted owl is a subspecies of spotted owl, we sometimes refer to it as a species when discussing it in the context of the ESA or other laws and regulations.

Approved recovery plans are subject to modification as dictated by new findings, changes in species status, and the completion of recovery actions. The objectives in this Revised Recovery Plan will be achieved subject to availability of funding and the capability of the involved parties to participate while addressing other priorities. This Revised Recovery Plan replaces, in its entirety, the 2008 Recovery Plan.

Acknowledgments

The Service gratefully acknowledges the effort and commitment of the many individuals involved in the conservation and recovery of the northern spotted owl who participated in the preparation of both the 2008 Recovery Plan and this Revised Recovery Plan. Without their individual expertise and support, this Revised Recovery Plan would not have been possible as it is the culmination of many years of labor. This Revised Recovery Plan is the culmination of many hours of discussion, research and analysis by a large number of scientific experts and managers over several years.

This revision to the 2008 Recovery Plan has been led by the Service and builds upon the efforts of numerous individuals from several different agencies, academia, State governments and private organizations; their names and affiliations are listed in Appendix H. The Service is indebted to all of these individuals for the information provided during the preparation of this Revised Recovery Plan. Their names, affiliations, and roles are listed below. Their participation in the revision process does not imply these contributors or their sponsoring agencies agree with the recommendations and conclusions of this Revised Recovery Plan.

Recovery Plan Revision Lead

EXECUTIVE SUMMARY

Current Status

The northern spotted owl (*Strix occidentalis caurina*) (spotted owl) inhabits structurally complex forests from southwest British Columbia through the Cascade Mountains and coastal ranges in Washington, Oregon, and California, as far south as Marin County (Appendix A). After a status review (USFWS 1990a), the spotted owl was listed under the Endangered Species Act (ESA) as threatened on June 26, 1990 (USFWS 1990b) because of widespread loss of spotted owl habitat across the spotted owl's range and the inadequacy of existing regulatory mechanisms to conserve the spotted owl. Past habitat loss and current habitat loss are also threats to the spotted owl, even though loss of habitat due to timber harvest has been greatly reduced on Federal lands over the past two decades. Many populations of spotted owls continue to decline, especially in the northern parts of the subspecies' range, even with extensive maintenance and restoration of spotted owl habitat in recent years. Managing sufficient habitat for the spotted owl now and into the future is important for its recovery. However, it is becoming more evident that securing habitat alone will not recover the spotted owl. Based on the best available scientific information, competition from the barred owl (*S. varia*) poses a significant and complex threat to the spotted owl.

Based on the best available scientific information, competition from the barred owl (*S. varia*) poses a significant threat to the spotted owl.

Habitat Requirements

Scientific research and monitoring indicate spotted owls generally rely on mature and old-growth forests because these habitats contain the structures and characteristics required for nesting, roosting, and foraging. Although spotted owls can disperse through highly fragmented forested areas, the stand-level and landscape-level attributes of forests needed to facilitate successful dispersal have not been thoroughly evaluated or described.

Delisting

In order to consider a species recovered, analysis of five listing factors must be conducted and the threats from those factors reduced or eliminated. The five listing factors are:

A. The present or threatened destruction, modification, or curtailment of the species' habitat or range;
B. Overutilization for commercial, scientific, or educational purposes;
C. Disease or predation;
D. Inadequacy of existing regulatory mechanisms;
E. Other natural or manmade factors affecting its continued existence.

Recovery Strategy

Currently, the most important range-wide threats to the spotted owl are competition with barred owls, ongoing loss of spotted owl habitat as a result of timber harvest, habitat loss or degradation from stand replacing wildfire and other disturbances, and loss of amount and distribution of spotted owl habitat as a result of past activities and disturbances. To address these threats, this recovery strategy includes four basic steps:

1. Completion of a rangewide habitat modeling tool;
2. Habitat conservation and active forest restoration;
3. Barred owl management; and
4. Research and monitoring.

In addition to describing specific actions to address the barred owl threat, this Revised Recovery Plan continues to recognize the importance of maintaining habitat for the recovery and long-term survival of the spotted owl.

The U.S. Fish and Wildlife Service (Service) recognizes the barred owl constitutes a significantly greater threat to spotted owl recovery than was envisioned when the spotted owl was listed in 1990. As a result, the Service recommended in the 2008 Recovery Plan that specific actions to address the barred owl threat begin immediately. These actions are currently underway, and this Revised Recovery Plan builds on these actions.

In addition to describing specific actions to address the barred owl threat, this Revised Recovery Plan continues to recognize the importance of maintaining and restoring high value habitat for the recovery and long-term survival of the spotted owl.

Maintaining and restoring sufficient habitat is important to address the threats the spotted owl faces from a loss of habitat due to harvest, loss or alteration of habitat from stand replacing fire, loss of genetic diversity, and barred owls (Forsman *et al.* 2011). The 2008 Recovery Plan established a network of Managed Owl Conservation Areas (MOCAs) across the range of the species. Based on scientific peer review comments the Service is not incorporating the previously recommended MOCA network into this Revised Recovery Plan. We will update spotted owl critical habitat; in the interim, we recommend land managers continue to implement the standards and guidelines of the Northwest Forest Plan (NWFP) throughout the range of the species, as well as fully consider other recommendations in this Revised Recovery Plan. We also support the updating of existing land management plans.

The estimated time to delist the species is 30 years if all actions are implemented and effective. While the 2008 Recovery Plan identified an interim 10-year timeframe, this revision identifies several actions that will take many years to implement effectively. Therefore, the Service believes that this Revised Recovery Plan can be fully implemented in a 30-year timeframe. A longer time to delisting would be required if these assumptions are not met. Total cost for delisting over these 30 years is $127.1 million (see Section IV; Implementation Schedule and Cost Estimates for specific costs).

Due to the uncertainties associated with the effects of barred owl interactions with the spotted owl and habitat changes that may occur as a result of climate change, the Service intends to implement this Revised Recovery Plan aggressively and will use the 5-year review process to evaluate recovery implementation and success. The Service and other implementers of this Revised Recovery Plan will have to employ an active adaptive management strategy to achieve results and focus on the most important actions for recovery. Adaptive management is a systematic approach for improving resource management by learning from the results of explicit management policies and practices and applying that learning to future management decisions.

After the 2008 Recovery Plan was finalized, an inter-organizational Northern Spotted Owl Recovery Plan implementation structure was established that included multiple interagency recovery implementation teams. This implementation structure will be reevaluated and updated in accordance with this Revised Recovery Plan.

Recovery Goal

The goal of every Recovery Plan is to improve the status of the species so it can be removed from protection under the ESA. The long-term goal for the spotted owl is the same.

Recovery Objectives

The objectives of this Revised Recovery Plan are:

1. Spotted owl populations are sufficiently large and distributed such that the species no longer requires listing under the ESA;
2. Adequate habitat is available for spotted owls and will continue to exist to allow the species to persist without the protection of the ESA; and
3. The effects of threats have been reduced or eliminated such that spotted owl populations are stable or increasing and spotted owls are unlikely to become threatened again in the foreseeable future.

Recovery Criteria

There are four Recovery Criteria in this Revised Recovery Plan. Recovery Criteria are measurable, achievable goals that we believe will result from implementation of the recovery actions in this Revised Recovery Plan. Achievement of these criteria will take time and is intended to be measured over the life of the plan, not on a short-term basis and should not be considered near-term recommendations. Not all recovery actions necessarily need to be implemented for the Service to consider initiating the delisting process based on the statutory criteria for determining whether a species should be listed (16 U.S.C. § 1533(a)(1)).

Recovery Criterion 1 – Stable Population Trend: The overall population trend of spotted owls throughout the range is stable or increasing over 10 years, as measured by a statistically reliable monitoring effort.

Recovery Criterion 2 – Adequate Population Distribution: Spotted owl subpopulations within each province (*i.e.*, recovery unit) (excluding the Willamette Valley Province) achieve viability, as informed by the HexSim population model or some other appropriate quantitative measure.

Recovery Criterion 3 – Continued Maintenance and Recruitment of Spotted Owl Habitat: The future range-wide trend in spotted owl nesting/roosting and foraging habitat is stable or increasing throughout the range, from the date of Revised Recovery Plan approval, as measured by effectiveness monitoring efforts or other reliable habitat monitoring programs.

Recovery Criterion 4 – Post-delisting Monitoring: To monitor the continued stability of the recovered spotted owl, a post-delisting monitoring plan has been developed and is ready for implementation within the States of Washington, Oregon, and California, as required in section 4(g)(1) of the ESA.

Recovery Actions

Recovery actions are near-term recommendations to guide the activities needed to accomplish the recovery objectives and achieve the recovery criteria. This Revised Recovery Plan presents 33 actions that address overall recovery through maintenance and restoration of spotted owl habitat, monitoring of avian diseases, development and implementation of a delisting monitoring plan, and management of the barred owl. These actions are organized following the five listing factors described earlier.

Organization of Revised Recovery Plan

This Revised Recovery Plan is organized into four main sections with supporting appendices and retains the structure of the 2008 Plan. After Section I the Introduction, Section II gives a summary of recovery goals, objectives, and strategy. This section also gives an overview of how this recovery strategy for spotted owls fits within a broader ecosystem management approach. Section III describes recovery units, criteria, and the actions that are necessary to recover the species. These recovery actions are organized according to the five factors considered when a species is listed under section 4(a)(1) of the ESA. Section IV outlines the Plan's implementation schedule and cost estimates.

This Revised Recovery Plan also includes several appendices. These appendices provide background information, literature cited, a description of the spotted owl habitat modeling tool, and other important supporting information.

I. INTRODUCTION

Development of This Revised Recovery Plan

This Revised Recovery Plan builds extensively on the 1992 Draft Recovery Plan for the Northern Spotted Owl (USFWS 1992b), the 1994 NWFP (USDA and USDI 1994a, b), and the 2008 Recovery Plan for the Northern Spotted Owl (USFWS 2008b).

In 1993, President Clinton announced the NWFP which was intended to serve three roles: (1) a program to manage forests to achieve both sustainable timber production and protection of biological diversity; (2) a system for coordinating Federal agency implementation of the forest management efforts and receiving advice from non-federal interests; and (3) an initiative for providing economic assistance for those individuals and communities who were adversely affected by the reduction in the timber program. The 1994 NWFP signaled a unique approach to Federal land management in that it sought to embody (Pipkin 1998):

1. A shift to an ecosystem approach that crosses jurisdictional boundaries;
2. Active and meaningful public participation;
3. A balancing of commodity production and ecosystem viability;
4. Increased adaptive management efforts that support reevaluation and adjustments based on science;
5. A commitment to improved interagency processes; and
6. Federal agencies sharing responsibility for the implementation of a set of standards and guidelines for managing a common resource.

Due to its broad, over-arching nature and comprehensive scientific information, the 1994 NWFP was widely viewed as the Federal government's contribution to the recovery of the spotted owl since it contained the information used to develop the draft 1992 Northern Spotted Owl Recovery Plan. The NWFP was directly incorporated into 4 National Forest land and resource management plans (LRMPs) and amended the LRMPs or resource management plans (RMPs) that guide the management of each of the 15 National Forests and 6 Bureau of Land Management (BLM) Districts across the range of the spotted owl. These plans adopted a series of reserves and management guidelines that were intended to protect spotted owls and their habitat as well as other species.

As time passed, the public and land managers expressed a desire for a spotted owl recovery plan that explicitly outlined and described the management actions and habitat needs of the species. The U.S. Fish and Wildlife Service (Service) responded by publishing in May, 2008, the Recovery Plan for the Northern Spotted Owl, which was created after 2 years of scientific meetings, peer review, input from a wide variety of experts and more than 70,000 public comments.

The 2008 Recovery Plan identified two predominant threats: increasing competition from barred owls, and habitat loss from timber harvest and fire. The main elements of the 2008 Recovery Plan included: (1) a network of conservation areas on Federal lands west of the Cascade Crest; (2) a new approach to habitat management on Federal lands east of the Cascade Crest that maintains spotted owl habitat in a fire-prone landscape; (3) barred owl removal experiments; and (4) maintenance of substantially all older forests on Federal lands west of the Cascade Crest to reduce spotted owl and barred owl competitive interactions as we evaluate barred owl management options.

In June 2008, the Service received reviews of the 2008 Recovery Plan from the American Ornithologists' Union, Society for Conservation Biology and The Wildlife Society. These scientific peer reviews were consistent in their comments, noting that the recovery plan provided a "solid conceptual framework for recovery." However, the comments were critical of several key aspects of the 2008 Recovery Plan, particularly addressing threats posed by habitat loss from fire and concerns regarding the adequacy of reserves and their management.

Both the 2008 Recovery Plan and the 2008 revised critical habitat designation for the northern spotted owl, which is based on the 2008 Recovery Plan, were challenged in court, *Carpenters' Industrial Council v. Salazar*, 1:08-cv-01409-EGS (D.D.C.). In addition, on December 15, 2008, the Inspector General of the Department of the Interior issued a report entitled "Investigative Report of the Endangered Species Act and the Conflict between Science and Policy," which concluded that the integrity of the agency decision-making process for the 2008 Recovery Plan was potentially jeopardized by improper political influence. As a result, the Federal government filed a motion in the lawsuit for remand of the 2008 Recovery Plan and the 2008 critical habitat designation. On September 1, 2010, the Court issued an opinion remanding the 2008 Recovery Plan to the Service for issuance of a revised recovery plan within nine months. On May 6, 2011, the Court granted our request for a 30-day extension to allow time to consider the comments we received on Appendix C, which describes the modeling process, during an additional 30-day comment period. This Revised Recovery Plan is the result of the process to consider revisions to the 2008 Recovery Plan.

This Revised Recovery Plan is based on the best scientific information available, addressing the scientific peer reviewers' comments and including more recent scientific information involving climate change and habitat modeling. This Revised Recovery Plan focuses largely on five topics:

1. Conservation of spotted owl sites and high value spotted owl habitat;
2. Ecological forestry and active forest restoration to meet the challenges of climate change and altered ecological processes;
3. The threat posed by barred owls and management options to address it;
4. The potential need for State and private lands to contribute to spotted owl recovery in certain areas; and

5. Completion of a habitat modeling framework as an informational tool to better enable future land management decisions.

While this document retains some aspects of the 2008 Recovery Plan such as the strategy to assess and address threats from the barred owl and support for forest restoration treatments, it presents the most comprehensive, up-to-date evaluation of spotted owl science, conservation needs and management alternatives. With it, the Service seeks to engage Federal, State and private landowners in developing a comprehensive, landscape-level approach that furthers the recovery of the spotted owl.

The following is a chronology of the process involved in writing this Revised Recovery Plan.

- September 2010: 2010 Draft Revised Recovery Plan released for public comment and scientific peer review.
- Fall, 2010: Service holds eight stakeholder briefings and workshops regarding development of the habitat modeling tool.
- October 2010: Service posts to website a map depicting the results of the first two steps of the modeling tool.
- December 2010: Service posts summary results of the third step of the modeling tool.
- November 15, 2010: public comment period closes, but is extended until December 15, 2010.
- April 22, 2011: 30-day public comment period opened for review of and comment on updated spotted owl habitat modeling information contained in draft Appendix C.

Recovery Planning and Timeframes

The Endangered Species Act of 1973, as amended (16 USC 1531 *et seq*.)(ESA), establishes policies and procedures for identifying and conserving species of plants and wildlife that are endangered or threatened with extinction. To help identify and guide species recovery efforts, section 4(f) of the ESA directs the Secretary of the Interior to develop and implement recovery plans for listed species. These plans are to include:

1. A description of site-specific management actions necessary for conservation and survival of the species;
2. Objective, measurable criteria that, when met, will allow the species to be delisted; and
3. Estimates of the time and funding required to achieve the plan’s goals and intermediate steps.

Recovery plans are not regulatory documents; rather, they are created by the Service as guidance to bring about recovery and establish criteria to be used in evaluating when recovery has been achieved. There may be many paths to recover a species. Recovering a wide-ranging species takes time and significant effort from a multitude of entities. Recovering a species is a dynamic process, and judging when a species is recovered requires an adaptive management approach that is sensitive to the best available information and risk tolerances. Given the adaptive nature of this iterative process, recovery may be achieved without fully following the guidance provided in this Revised Recovery Plan.

Recovery Plan Objectives, Criteria, and Actions

The ultimate goal of this Revised Recovery Plan is to recover the spotted owl so that protections afforded by the ESA are no longer necessary, allowing us to delist the species. Its objectives describe a scenario in which the spotted owl's population is stable or increasing, well-distributed, and affected by manageable threats. To meet this goal and these objectives, interim expectations are defined to guide us as we learn more about the multiple uncertainties surrounding this species.

This Revised Recovery Plan was developed using the best scientific information available and a "step-down" approach of objectives, criteria and actions. Recovery objectives are broad statements that describe the conditions under which the Service would consider the spotted owl to be recovered. Recovery criteria serve as objective, measurable guidelines to assist in determining when an endangered species has recovered to the point that it may be downlisted to threatened, or that the protections afforded by the ESA are no longer necessary and the species may be delisted. Recovery actions are the Service's recommendations to guide the activities needed to accomplish the recovery criteria. Recovery actions are recommended throughout the U.S. range of the spotted owl and are designed to address the specific threats identified in this Revised Recovery Plan. Implementation of the full suite of recovery actions will involve participation from the States, Federal agencies, non-federal landowners and the public.

The recovery criteria and actions are described at the beginning of this Revised Recovery Plan. Information concerning the spotted owl's biology is in Appendix A, and a description of the threats to the spotted owl is presented in Appendix B.

Five-year Status Reviews

A 5-year review of a listed species is required by section 4(c)(2) of the ESA, and considers all new available information concerning the population status of the species and the threats that affect it. This process can serve as an integral component of tracking recovery implementation, updating scientific understanding and evaluating status of the species. The Service conducts these periodic reviews to ensure the listing classification of a species as threatened or endangered is accurate. A 5-year status review considers the best scientific and commercial information that has become available since the original listing determination or last review such as: species biology, habitat conditions, conservation measures, threat status and trends, and any other new information. The Service publishes a notice in the Federal Register announcing the initiation of these reviews and provides the public an opportunity to submit relevant information regarding the species and its threats.

A 5-year review is intended to indicate whether a change in a species listing classification is warranted. Changes in classification recommended in a 5-year review could include delisting, reclassification from threatened to endangered (*i.e.*, uplisting), reclassification from endangered to threatened (*i.e.*, downlisting), or no change is warranted at this time. The 5-year review does not involve rule-making, so no change to a species classification is made at the time a review is completed. If a change is recommended in the completed review, the Service would need to initiate a separate rule-making process to propose the change.

Delisting Process

When sufficient progress toward recovery has been made, a separate effort will assess the spotted owl's status in relation to the five listing factors found in section 4(a)(1) of the ESA to determine whether delisting is appropriate (see Executive Summary). A change in status (downlisting or delisting) requires a separate rule-making process based on an analysis of the same five factors (referred to as the listing factors) considered in the listing of a species, as described in section 4(a)(1) of the ESA. These include:

A. The present or threatened destruction, modification, or curtailment of its habitat or range;
B. Overutilization for commercial, recreational, scientific, or educational purposes;
C. Disease or predation;
D. The inadequacy of existing regulatory mechanisms;
E. Other natural or manmade factors affecting its continued existence.

This subsequent review may be initiated without all of the recovery criteria in this Revised Recovery Plan having been fully met. For example, one or more criteria may have been exceeded, while other criteria may not have been fully accomplished. In this instance, the Service may judge that, overall, the threats have been minimized sufficiently and the species' population health is robust enough to be considered for delisting. If sufficient progress toward recovery has not been made, the spotted owl may retain its current status. If the spotted owl's condition deteriorates, it may be necessary to change its status to "endangered."

New recovery opportunities or scientific information may arise that were unknown at the time this Revised Recovery Plan was created. New opportunities may encompass more effective means of achieving recovery or measuring recovery. In addition, new information may alter the extent to which criteria need to be met for recognizing recovery of the species. Conversely, new information may result in new challenges, and achieving recovery may be more difficult than we now believe.

Assumptions Made in Drafting the Revised Recovery Plan

There are numerous land management plans and strategies being implemented to help recover the spotted owl. This Revised Recovery Plan is not meant to negate or supplant these other plans. However, these plans may be subject to change, so this Revised Recovery Plan is meant to be a stand-alone document that describes steps necessary to recover the spotted owl. The recommendations described in the Revised Recovery Plan are meant to be successful on their own; that is, they are not dependent on the continuance of any other conservation or management plan to be successful, unless specifically noted.

Implementation of the full suite of recovery actions will involve participation from the States, Federal agencies, non-federal landowners and the public.

Listing History and Recovery Priority

The spotted owl was listed as threatened on June 26, 1990. On a scale of 1C (highest) to 18 (lowest) (USFWS 1983a, b), the Service recovery priority number for the spotted owl is 12C. We assigned this number per our guidelines for the following reasons: the spotted owl faces a "moderate" degree of threat which equates to a continual population decline and threat to its habitat, although extinction is not imminent. It received a "low recovery potential" because there is uncertainty regarding our ability to alleviate the barred owl impacts to spotted owls and the techniques are still experimental; and because of the spotted owl's taxonomic status as a subspecies and inherent conflicts with development, construction, or other economic activity given the economic value of older forest spotted owl habitat (USFWS 1983a, b). Despite the definitions that led us to a 12C Recovery priority number, the Service is optimistic regarding the spotted owl's potential for recovery if immediate challenges such as barred owls are managed.

The spotted owl was listed in 1990 as a result of widespread loss and adverse modification of spotted owl habitat across its entire range and the inadequacy of existing regulatory mechanisms to conserve the spotted owl.

Reasons for Listing and Assessment of Threats

The spotted owl was listed as threatened throughout its range "due to loss and adverse modification of spotted owl habitat as a result of timber harvesting and exacerbated by catastrophic events such as fire, volcanic eruption, and wind storms" (USFWS 1990b:26114). More specifically, threats to the spotted owl included low populations, declining populations, limited habitat, declining habitat, inadequate distribution of habitat or populations, isolation of populations within physiographic provinces, predation and competition, lack of coordinated conservation measures, inadequacy of regulatory mechanisms and vulnerability to natural disturbance (USFWS 1992b). These threats were characterized for each province as severe, moderate, low or unknown (USFWS 1992b). The range of the spotted owl is divided into 12 physiographic provinces from Canada to northern California and from the Pacific Coast to the eastern Cascades (see Appendix A, Figure A-1). Declining habitat was recognized as a severe or moderate threat to the spotted owl throughout its range, isolation of populations was identified as a severe or moderate threat in 11 provinces, and a decline in population was a severe or moderate threat in 10 provinces. Together, these three factors represented the greatest concerns about range-wide conservation of the spotted owl. Limited habitat was considered a severe or moderate threat in nine provinces, and low populations was a severe or moderate concern in eight provinces, suggesting that these factors were also a concern throughout the majority of the spotted owl's range. Vulnerability to natural disturbances was rated as low in five provinces.

The Service conducted a 5-year review of the spotted owl in 2004 (USFWS 2004b), based in part on the content of an independent scientific evaluation of the status of the spotted owl (Courtney *et al.* 2004) performed under contract with the Service. For that evaluation, an assessment was conducted of how the threats described in 1990 might have changed by 2004. Some of the key ideas relative to threats identified in 2004 were: (1) "Although we are certain that current harvest effects are reduced, and that past harvest is also probably having a reduced effect now as compared to 1990, we are still unable to fully evaluate the current levels of threat posed by harvest because of the potential for lag effects" (Courtney and Gutiérrez 2004:11-7); (2) "Currently the primary source of habitat loss is catastrophic wildfire, although the total amount of habitat affected by wildfires has been small" (Courtney and Gutiérrez 2004:11-8); and (3) "We are convinced that Barred Owls are having a negative impact on Spotted Owls at least in some areas" (Gutiérrez *et al.* 2004:7-43) and "there are no grounds for optimistic views suggesting that Barred Owl impacts on Northern Spotted Owls have been already fully realized" (Gutiérrez *et al.* 2004:7-38).

On June 1, 2006, we convened a meeting of seven experts to help identify the most current threats facing the species. Six of the seven were experts on the biology of the spotted owl, and a seventh was an expert on fire ecology. The workshop was conducted as a modified Delphi expert panel in which the seven experts scored the severity of threat categories. The baseline assumption of this meeting was that existing habitat conservation strategies (*e.g.,* the NWFP) would be in place. With that assumption, the experts identified and ranked threats to the spotted owl. The 2007 Recovery Team then had an opportunity to interact with them to discuss their individual rankings and thoughts on spotted owl threats. The experts re-ranked the threats if they felt this was relevant given the substance of the discussion.

These experts identified past habitat loss, current habitat loss, and competition from barred owls as the most pressing threats to the spotted owl, even though timber harvest recently has been greatly reduced on Federal lands. They noted that evidence of these three threats is presented in the scientific literature. The range of threat scores made by the individual experts was narrowest for barred owl competition and slightly greater for habitat threats, indicating that there was more agreement about the threat from barred owls. The experts identified disease and the effect of climate change on vegetation as potential and more uncertain future threats.

The experts also ranked the threats by importance in each province. Among the 12 physiographic provinces, the more fire-prone provinces (Eastern Washington Cascades and Eastern Oregon Cascades, California Cascades, Oregon and California Klamath) scored high on threats from ongoing habitat loss as a result of wildfire and the effects of fire exclusion on vegetation change. West-side provinces (Western Washington Cascades and Western Oregon Cascades, Western Washington Lowlands, Olympic Peninsula, and Oregon Coast Range) generally scored high on threats from the negative effects of habitat fragmentation and ongoing habitat loss as a result of timber harvest. The province with the fewest number of threats was Western Oregon Cascades, and the provinces with the greatest number of threats were the Oregon Klamath and the Willamette Valley. For a more complete description of the threats, see Appendix B.

Barred Owls

It is the Service's position that the threat from barred owls is extremely pressing and complex, requiring immediate consideration. Barred owls have been found in all areas where surveys have been conducted for spotted owls. In addition, barred owls inhabit all forested areas throughout Washington, Oregon, and northern California where nesting opportunities exist, including areas outside of the specific range of the spotted owl (Kelly and Forsman 2003, Buchanan 2005, Gutiérrez *et al.* 1995, 2007, Livezey 2009a). Consequently, the Service assumes barred owls now occur at some level in all areas used now or in the past by spotted owls.

The workshop panel unanimously identified past habitat loss, current habitat loss, and competition from barred owls as the most-pressing threats to the spotted owl, even though timber harvest recently has been greatly reduced on Federal lands.

Addressing the threats associated with past and current habitat loss must be conducted simultaneously with addressing the threats from barred owls. Addressing the threat from habitat loss is relatively straightforward with predictable results. However, addressing a large-scale threat of one raptor on another, closely related raptor has many uncertainties.

At this time, the long-term removal of significant numbers of barred owls, along with a suite of other recovery actions, will be assessed as a possible approach to recover the spotted owl. Before considering whether to fund and fully implement such an action, however, the Service needs to be confident this removal would benefit spotted owls. The Service is currently developing a draft Environmental Impact Statement to assess the effects of barred owl removal experiments proposed in this Revised Recovery Plan.

Because barred owls compete with spotted owls for habitat and resources for breeding, feeding and sheltering, ongoing loss of habitat has the potential to intensify the competition by reducing the total amount of these resources available to the spotted owl and bringing barred owls into closer proximity with the spotted owl. In order to reduce or not increase this potential competitive pressure while the threat from barred owls is being addressed, this Revised Recovery Plan now recommends conserving and restoring older, multi-layered forests across the range of the spotted owl.

Habitat Management

In addition to addressing the barred owl threat, the Service agrees with scientific experts that it is necessary to conserve the highest value spotted owl habitat to address the key threats. The 2008 Recovery Plan recommended establishing Managed Owl Conservation Areas (MOCAs) on Federal lands to provide the important habitat needed for the species to recover over the long-term. The Service is not making this recommendation in this Revised Recovery Plan. Instead, we rely on the habitat conservation network of the NWFP, in addition to other habitat conservation recommendations contained within this Revised Recovery Plan. In addition, we have completed a range-wide, multi-step habitat modeling tool, described in Appendix C, that will help evaluate and inform the Service's designation of critical habitat, and the development of future land management plans by Federal land managers, and the consideration of management options by State, Tribal, or private landowners as recommended by this Revised Recovery Plan.

In addition, given the continued decline of the species, the apparent increase in severity of the threat from barred owls, and information indicating a recent loss of genetic diversity for the species, this Revised Recovery Plan also recommends retaining more occupied spotted owl sites and unoccupied, high value spotted owl habitat on all lands. Vegetation management actions that may have short-term impacts but are potentially beneficial to occupied spotted owl sites in the long-term meet the goals of ecosystem conservation. Such actions may include silvicultural treatments that promote ecological restoration and are expected to reduce future losses of spotted owl habitat and improve overall forest ecosystem resilience to climate change, which should result in more habitat retained on the landscape for longer periods of time.

In the more disturbance-prone provinces on the east side of the Cascade Mountains and in the Klamath Province, the Dry Forest Landscape and Klamath Province Work Groups (these are recovery implementation teams established as recommended by the 2008 Recovery Plan) are working to develop strategies that incorporate the dynamic natural disturbance regime in a manner that provides for long-term ecological sustainability through the restoration of ecological processes while conserving spotted owl habitat over the long-term. Some land management units, such as the Okanagan-Wenatchee National Forest, have published such strategies (USDA 2010).

II. RECOVERY GOAL, OBJECTIVES, CRITERIA, AND STRATEGY

Recovery Goal

The long-term goal of this recovery plan is to improve the status of the spotted owl so it can be removed from protection under the ESA.

Recovery Objectives

The objectives of this Revised Recovery Plan are:

1. Spotted owl populations are sufficiently large and distributed such that the species no longer requires listing under the ESA;
2. Adequate habitat is available for spotted owls and will continue to exist to allow the species to survive without the protection of the ESA; and
3. The effects of threats have been reduced or eliminated such that spotted owl populations are stable or increasing and spotted owls are unlikely to become threatened again in the foreseeable future.

Recovery Criteria

There are four recovery criteria in this Revised Recovery Plan. Recovery criteria are measurable, achievable goals that we believe will result from implementation of the recovery actions in this Revised Recovery Plan. Achievement of these criteria will take time and is intended to be measured over the life of the plan, not on a short-term basis and should not be considered near-term recommendations. This plan is designed to meet these criteria at which time the Service will make a decision about whether to propose delisting the spotted owl. Not all recovery actions need to be implemented and not all recovery criteria need to be fully achieved for the Service to consider delisting.

Recovery Criterion 1 - Stable Population Trend: The overall population trend of spotted owls throughout the range is stable or increasing over 10 years, as measured by a statistically-reliable monitoring effort.

Recovery Criterion 2 – Adequate Population Distribution: Spotted owl subpopulations within each province (*i.e.*, recovery unit) (excluding the Willamette Valley Province) achieve viability, as informed by the HexSim population model or some other appropriate quantitative measure.

Recovery Criterion 3 – Continued Maintenance and Recruitment of Spotted Owl Habitat: The future range-wide trend in spotted owl nesting/roosting and foraging (NRF) habitat is stable or increasing throughout the range, from the date of Revised Recovery Plan approval, as measured by effectiveness monitoring efforts or other reliable habitat monitoring programs.

Recovery Criterion 4 – Post-delisting Monitoring: To monitor the continued stability of the recovered spotted owl, a post-delisting monitoring plan has been developed and is ready for implementation within the States of Washington, Oregon, and California (as required by section 4(g)(1) of the ESA).

Recovery Strategy

Currently, the most important range-wide threats to the spotted owl are competition with barred owls, ongoing loss of spotted owl habitat as a result of timber harvest, loss or modification of habitat from uncharacteristic wildfire, and loss of amount and distribution of spotted owl habitat as a result of past activities and disturbances. To address these threats, this recovery strategy includes five basic steps:

1. Development of a range-wide habitat modeling framework;
2. Barred owl management;
3. Monitoring and research;
4. Adaptive management; and
5. Habitat conservation and active forest restoration.

These five steps are described in detail below.

Development of Range-wide Habitat Modeling Framework

The first step in this recovery strategy is to develop a state-of-the-science modeling framework for evaluating spotted owl habitat and populations. Scientific peer reviewers were critical of the 2008 Recovery Plan's MOCA reserve strategy and the general lack of updated habitat modeling capacity. The Service agreed with this concern; the MOCA recommendation is not contained in this Revised Recovery Plan.

When listed as threatened in 1990 (USFWS 1990), habitat loss and fragmentation of old-growth forest were identified as major factors contributing to declines in spotted owl populations. As older forest became reduced to smaller and more isolated patches, the ability of spotted owls to successfully disperse and establish territories was reduced (Lamberson *et al.* 1992). Lamberson *et al.* (1992) identified that there appeared to be a sharp threshold in the amount of habitat below which spotted owl population viability plummeted. In order to promote spotted owl recovery, earlier plans including the 1992 Draft Recovery Plan for the Northern Spotted Owl (USFWS 1992) and the Northwest Forest Plan (USDA and USDI 1994) established spotted owl habitat reserve networks to promote species recovery. The goal of these conservation reserves was to achieve a high likelihood of long-term persistence while minimizing impacts on resources with economic value. For territorial species such as the spotted owl, Lamberson *et al.* (1994) concluded that size, spacing and shape of reserved areas all had strong influence on population persistence, and reserves that could support a minimum of 20 spotted owl territories were more likely to maintain spotted owl populations than smaller reserves. They also found that juvenile dispersal was facilitated in areas large enough to support at least 20 spotted owl territories. In addition to size, spacing between reserves had a strong influence on successful dispersal (Lamberson *et al.* 1992). Forsman *et al.* (2002) reported dispersal distances of 1,475 spotted owls in Oregon and Washington for 1985–1996. Median maximum dispersal distance (the straight-line distance between the natal site and the farthest location) for radio-marked juvenile male spotted owls was 12.7 miles, and that of female spotted owls was 17.2 miles (Forsman *et al.* 2002: Table 2). Dispersal data and other studies on the amount and configuration of habitat necessary to sustain spotted owls provided the foundation for developing previous spotted owl habitat reserve systems.

Although we are not recommending a new habitat conservation network, we recommend utilizing the best available information, including modeling data, to evaluate and refine such a network that will continue to support the recovery of the spotted owl. The NWFP currently provides a network of reserve land use allocations that protects habitat for late-successional forest species, including the demographic and dispersal needs of the spotted owl. Anthony *et al.* (2006) and Forsman *et al.* (2011) have reported that demographic rates for spotted owls on long-term Federal monitoring areas that contained late-successional reserves were higher than those from other long-term study areas. We believe a habitat conservation network designed using the best available science is necessary to recover the spotted owl. The NWFP reserve network, in addition to other habitat conservation recommendations in this Revised Recovery Plan (*e.g.*, Recovery Actions 10, 32 and 6), meets that need in the near term until the Forest Service and BLM revise their respective management plans. We recommend that any future revisions in Federal land management plans take into account the need for appropriately spaced, large habitat conservation areas for spotted owls. The upcoming critical habitat revision process will help identify whether any additional areas or adjustments to that network are warranted.

Therefore, we recommend continued application of the reserve network of the NWFP until the 2008 designated spotted owl critical habitat is revised and/or the land management agencies amend their land management plans taking into account the guidance in this Revised Recovery Plan. We have developed a modeling framework that can provide information for numerous spotted owl recovery actions and management decisions, including revisions to the spotted owl critical habitat designation. This spatially-explicit modeling effort is designed to allow for a more in-depth evaluation of various habitat features that affect the distribution of spotted owl territories and the factors influencing spotted owl populations. Different land management scenarios can then be evaluated for their relative potential contribution to spotted owl recovery. This modeling effort is described in detail in Appendix C. The Service hopes this modeling framework or similar approaches will be used by Federal, State, and private scientists to make better informed decisions concerning what areas should be conserved for spotted owls.

Barred Owl Management

The second step in this recovery strategy is to move forward with a scientific evaluation of potential management options to reduce the impact of barred owls on spotted owls. Barred owls pose perhaps the most significant short-term threat to spotted owl recovery. This threat is better understood now than when the spotted owl was listed. Barred owls have reduced spotted owl site occupancy, reproduction, and survival. Because the abundance of barred owls continues to increase, effectively addressing this threat depends on initiating action as soon as possible. The recovery actions address research involving the competition between spotted and barred owls, experimental control of barred owls and, if recommended by research, management of barred owls. Discussion of the barred owl threat occurs throughout this document, especially in Listing Factor E and Appendix B.

Monitoring and Research

The third step in this recovery strategy is to continue implementing a robust monitoring and research program for the spotted owl. This Revised Recovery Plan recommends activities be implemented to track progress toward recovery, to inform changes in recovery actions by a process of adaptive management, and ultimately to help determine when delisting is appropriate. The following primary elements of this strategy will provide information required to evaluate progress toward the Recovery Criteria. The monitoring and research results can be considered within the 5-year review process which is required under the ESA.

Monitoring of Spotted Owl Population Trend

Currently, this monitoring is done within a network of demographic study areas, but it may be possible to monitor trends using other reliable methods. Recognizing that the demographic monitoring efforts are costly, it is recommended that, in the absence of another method that would provide reliable trend data at an improved cost-effectiveness, these existing studies should be continued while other methods are piloted and tested. The current demographic studies provide region-specific demographic data that provide the basis for many of the current and proposed studies of spotted owl ecology. Also, because monitoring in the demographic study areas has been ongoing for approximately two decades, the data from these efforts allow trend estimates in the near-term that would not be available for a considerable length of time if new methods were implemented.

A Comprehensive Effort of Barred Owl Research and Monitoring

This is needed to experimentally determine the effects of barred owls on spotted owls and to incorporate this information into management to reduce negative effects to a level that would promote spotted owl recovery.

Given the immediacy of the barred owl threat, the continuation of monitoring in the demographic study areas provides a timely opportunity to integrate barred owl removal experiments to assess any demographic response of spotted owls to removal of barred owls. Assessing the demographic response will help the Service determine whether the effects of this threat could be reduced or eliminated by a larger-scale control program.

Continued Habitat Monitoring

The Effectiveness Monitoring program initiated by the NWFP includes tracking the status and trends of spotted owl habitat (Davis and Lint 2005). This monitoring program will allow us to assess progress towards meeting **Recovery Criterion 3: Continued Maintenance and Recruitment of Spotted Owl Habitat** and help the Service determine whether the threat of habitat loss has been reduced or eliminated such that spotted owls are unlikely to become threatened again in the foreseeable future.

Inventory of Spotted Owl Distribution

The recovery of the spotted owl is predicated on maintaining the current rangewide distribution of the species within each of the 12 provinces (see Recovery Unit discussion). When trend data indicate that populations are stable or increasing in the provinces as specified in Recovery Criterion 1, sampling should also be considered to evaluate spotted owl distribution in all provinces.

Explicit Consideration for Climate Change Mitigation Goals Consistent with Spotted Owl Recovery Actions

There is significant overlap between many of the spotted owl recovery goals described in this Revised Recovery Plan and opportunities to mitigate impacts due to climate change. The Service is applying Secretarial Order No. 3289: *Addressing the Impacts of Climate Change on America's Water, Land, and Other Natural and Cultural Resources* into our forest management activities. This Secretarial Order directs DOI agencies to analyze potential climate change impacts when undertaking long-range planning exercises, developing multi-year management plans, and making major decisions regarding potential use of resources under the Service's purview. This direction applies to this Revised

Recovery Plan, which includes a detailed treatment of climate change and its potential impact on spotted owl recovery.

Adaptive Management

Risk, Uncertainty and Changing Management

When writing a recovery plan, the Service must use the best scientific information available. However, the information available rarely addresses all of the questions at hand, meaning there is usually some degree of uncertainty. Hence, recovery plans include an element of risk management (especially for wide-ranging species which face a multitude of threats) because the Service must make recommendations and decisions in the face of incomplete information and uncertainty.

In the face of significant scientific uncertainty, we propose aggressive strategies to address the threats from habitat loss, barred owls and climate change. It is understood that this Revised Recovery Plan's expression of risk, as embodied by the recovery strategy and actions, may not match the risk tolerance of every interested party. However, it is the conclusion of the Service that the actions in this Revised Recovery Plan are necessary to achieve the plan's goal for the conservation and survival of the species.

In order to deal with uncertainty and risk the Service will employ an active program of adaptive management. Adaptive management includes identifying areas of uncertainty and risk, implementing a research and monitoring approach to clarify these areas, and making decisions to change management direction that is not working while still maintaining management flexibility (see Thomas *et al.* 1990, USFWS 1992b). Where possible, the implementation of the recovery actions included within this Revised Recovery Plan should be designed in a manner that provides feedback on the efficacy of management actions such that the design of future actions can be improved.

What is Adaptive Management?

Adaptive management is a systematic approach for improving resource management by learning from the results of explicit management policies and practices and applying that learning to future management decisions (Holling 1978, Walters 1986, Gregory *et al*. 2006). This tool is useful when there is substantial uncertainty about appropriate strategies for managing natural resources. Although adaptive management is a form of "learning by doing," its purposefulness and systematic approach distinguish it from learning by trial and error where management direction changes in the face of failed policies and actions (Stankey *et al*. 2005, Gregory *et al.* 2006). Bormann *et al.* (2007:187) provide a practical description of and purpose for adaptive management:

> "Adaptive management requires exploring alternative ways to meet management objectives, predicting the outcomes of alternatives based on what is known, implementing one—or if possible, more than one—of these alternatives, monitoring to learn which alternative best meets the management objectives, and then using results to update knowledge and adjust management actions. Adaptive management is not an end in itself, but a means to more effective decisions and enhanced benefits; thus, its true measure is in how well it helps meet environmental, social, and economic goals, adds to scientific knowledge, and reduces tensions among stakeholders."

Key components of adaptive management include: (1) treating management actions and policies as formal experiments that yield new information; (2) embracing risk and uncertainty as opportunities for learning; and (3) applying the knowledge gained from management experiments to subsequent actions (Holling 1978, Stankey *et al*. 2003, Stankey *et al.* 2005). We elaborate on each of these components below.

Treating management actions as experiments is a fundamental component of the adaptive management process. Key to this is clearly articulating questions about the effects of implementing management actions, formally re-casting these questions as testable hypotheses, implementing them as experiments to be tested, and monitoring the results. Yet this is often where the process fails. For example, in a critique of the NWFP adaptive management program, Stankey *et al*. (2003) found a major fault to be a predominant reliance on decision-making approaches that were informal and incremental, yet widely accepted as an adaptive management approach. Articulating measurable management objectives and forming them into explicit hypotheses that can be tested is what ultimately separates adaptive management from learning by trial and error.

The second key component in successfully implementing adaptive management, as identified above, requires embracing risk and uncertainty as opportunities for learning. The need for adaptive management is driven by the existing uncertainty surrounding appropriate management treatments and how ecosystems may respond to those treatments. A risk-averse mentality of not acting until more information is known may ultimately result in implementing ongoing, ineffectual policies that may not only further threaten resources of concern, but also suppress experimental actions that could provide learning to inform and improve future management. While there are costs and risks in applying experimental treatments, failing to experiment also carries costs and risks (Wildavsky 1988, as cited in Stankey *et al*. 2003). As Stankey *et al*. (2003:45) noted, "The irony here is that while continuation of policies that have not worked seems to ensure continued failure, undertaking actions where outcomes are uncertain is resisted because of the inability to ensure that unwanted effects will not result." Testing clearly formed hypotheses in a systematic manner under identifiable, bounded settings and monitoring the outcomes will go far in improving future management and developing more resilient policies while minimizing risk to resources.

The knowledge gained from testing hypotheses must be documented and applied to future actions if learning is to happen and if the policy or decision-making process is to be informed and improved. Thus, it is vital that the question asked as part of the experiment is relevant to managers. To speed the pace of learning, Williams *et al.* (2009) recommend that alternative management options be applied and tested, and that these options are sufficiently different to produce observable responses that can be detected by monitoring.

Goals and Steps in an Adaptive Management Process for the Spotted Owl

The overarching purpose of implementing adaptive management for spotted owl recovery is to reduce key scientific uncertainties with respect to spotted owl management and recovery and apply that knowledge to future spotted owl management decisions. An adaptive management program must deliver biological and ecological information relevant to spotted owl recovery; key objectives to facilitate this need are:

1. Identify and fill key gaps in our knowledge base
2. Improve our understanding of ecosystem responses, thresholds and dynamics
3. Learn about the effectiveness of alternate management policies and activities
4. Document and disseminate the knowledge gained so that it is available in future management

Several sources of information are available that outline steps in designing and implementing adaptive management programs (Williams *et al.* 2009, BCMFR undated). Typical steps in adaptive management include:

1. Assess and define the problem – including defining measurable management objectives and potential management treatments, along with key indicators and projected responses for each objective.

2. Design the management treatment and monitoring plan – including clarifying response thresholds that will trigger management adjustments, and identifying which management adjustments are needed.

3. Implement the management treatment and monitoring program – including documenting any deviation from the plan.

4. Monitor treatment implementation and results following the protocol designed in Step 2.

5. Evaluate results – including comparing outcomes to forecasts made in Step 1, as well as communicating results to others facing similar management issues.

6. Adjust or revise hypothesis and management as necessary – including identifying where uncertainties have been reduced and where they remain unresolved, as well as adjusting the model used to predict outcomes developed in Step 1 so that it reflects the hypothesis supported by the results.

The Service encourages existing recovery plan work groups to develop Steps 1 and 2 in the above adaptive management steps for problems relevant to their chartered tasks. Developing a clearly articulated problem and objective statement, combined with an implementation and monitoring plan, will provide an adaptive management framework that allows us to learn from future management activities. Work groups will forward frameworks to the Service for presentation to the Regional Interagency Executive Committee for consideration at the executive level under the existing Northwest Forest Plan process. The Service will work with these agencies to look for opportunities to implement Steps 3 through 6 of the above adaptive management steps consistent with the framework developed under Steps 1 and 2.

Below is a list of potential questions that may drive development of an adaptive management framework. It is not meant to be comprehensive, nor is it necessarily a prioritized list. Further articulation of these questions may be needed to develop frameworks that will be most informative. Additional questions are expected to arise as the Revised Recovery Plan is implemented. For example, results gleaned from Recovery Action 8, as well as implementation of the modeling process described in Appendix C, are expected to provide additional questions for adaptive management.

Questions that may for consideration under adaptive management include:

- What vegetation management treatments best accelerate the development of forest structure associated with spotted owl habitat functions while maintaining or restoring natural disturbance and provide greater ecosystem resiliency? What are the effects of these vegetation management treatments on spotted owl occupancy, demography, and habitat use immediately following treatment and at specified time periods after treatment? What are the effects of these treatments on spotted owl prey abundance and availability immediately following treatments and at specified time periods after treatment? What are the effects of the above vegetation management treatments on the habitat components that spotted owls and their prey use? How effective are these vegetation management treatments in developing desired forest structure and how long does this development take?
- What are the effects of wildland and prescribed fire on the structural elements of spotted owl habitat (compare burned and unburned areas, as well as different fire severities)? What are the effects on spotted owl habitat use? What are the effects of these fires on abundance of spotted owl prey? How does the scale of high severity burn patches affect foraging use by spotted owls? How does the

pattern and distribution of burned and unburned patches, or patches of differing burn severities, affect spotted owl use for foraging, roosting, and nesting?

- Can strategically-placed restoration treatments be used to reduce the risk of spotted owl habitat being burned by high severity fire within dry forest ecosystems?
- What are the effects of epidemic forest insect outbreaks on spotted owl occupancy and habitat use immediately following the event and at specified time periods after treatment?
- What is the nature of the competitive interaction between spotted and barred owls, and how might those interactions be managed in terms of direct intervention (*e.g.,* barred owl control) or indirectly through habitat management (*e.g.,* vegetation management treatments)?

Habitat Conservation and Active Forest Restoration

The fifth component of this recovery strategy is derived from the stated purpose of the ESA: "to provide a means whereby the ecosystems upon which endangered species and threatened species depend may be conserved." Consistent with this purpose, it is the Service's goal that this spotted owl recovery strategy be embedded within -- and be consistent with -- a broader framework of conservation of forest ecosystems for the Pacific Northwest. This approach will provide more resilient forested habitat in the face of climate change and other stressors, thereby conserving more spotted owl habitat on the landscape for longer periods of time. Species-specific needs of the spotted owl should not be the sole determinant of landscape management decisions. Rather, spotted owl recovery objectives should fit within a broader strategy whose goals include the conservation of the full assemblage of species and ecological processes in that landscape so that it will be more resilient to future losses of spotted owl habitat or ecosystem change resulting from climate change and other disturbances.

The NWFP was developed to meet this goal for spotted owls and many other late-successional forest species. It continues to provide the basic landscape conservation framework for Federal lands in the range of the spotted owl (Noon and Blakesley 2006, Strittholt *et al.* 2006, Spies *et al.* 2010a,b), and the recommendations in this Revised Recovery Plan affirm and build upon the scientific principles of the NWFP. These principles include managing for the maintenance of ecological processes and applying adaptive management strategies to gain new scientific insight (FEMAT 1993, pg. VIII-5).

Although spotted owl recovery still relies heavily upon the principles of the NWFP as its foundation, there have been several significant developments that affect spotted owl recovery since the NWFP was first implemented 17 years ago. These include:

- *The continued decline of the spotted owl populations and low occupancy rates in large habitat reserves, and the growing negative impact from barred owl invasions of spotted owl habitats* (Forsman *et al.* 2011, Dugger *et al.* in press), *which is greater than anticipated in the NWFP*. We recommend increased conservation and restoration of spotted owl sites and high-value spotted owl habitat to help ameliorate this impact.
- *Climate change combined with effects of past management practices are exacerbating changes in forest ecosystem processes and dynamics, including patterns of wildfires, insect outbreaks and disease, to a degree greater than anticipated in the NWFP* (Perry *et al*. 2011). Land managers need to consider this uncertainty and how best to integrate knowledge of management-induced landscape pattern and disturbance regime changes with climate change when making spotted owl management decisions.
- *Scientific principles of forest management continue to evolve since implementation of the NWFP. "Ecological forestry," "natural disturbance-based management," "resilience management" and other related perspectives have emerged as accepted forest management approaches* (Long 2009, Moritz *et al.* 2011). We recommend spotted owl management decisions be implemented within a broader landscape approach based on the conservation of natural ecological patterns and processes.

These issues are not mutually exclusive, and spotted owl recovery depends on the integration of all three. Extant, high-quality spotted owl habitat must be managed, restored, and conserved in the face of a declining population and the potential threats from barred owls. Active, restoration-focused management to address climate change and dynamic ecosystem processes is also necessary in many areas, with the goal of maintaining or restoring forest ecosystem structure, composition and processes so they are sustainable and resilient under current and future climate conditions. Each of these issues is described in more detail below, and site-specific recommendations addressing these issues are contained in various recovery actions later in this Revised Recovery Plan.

This Recovery Strategy requires action in the face of uncertainty. We agree with Carey (2007, pg. 345, 349): "(A)ctive management for ecological values trades short-term negative effects for long-term gains…Collaborative management must be willing to accept short-term impacts and short-term risks to achieve long-term benefits and long-term risk reduction; overly zealous application of the precautionary principle often is a deliberate, conscious management decision to forego long-term increases in forest health and resilience to avoid short-term responsibility or controversy."

In other words, land managers should not be so conservative that, to avoid risk, they forego actions that are necessary to conserve the forest ecosystems that are necessary to the long-term conservation of the spotted owl. But they should also not be so aggressive that they subject spotted owls and their habitat to treatments where the long-term benefits do not clearly outweigh the short-term risks. Finding the appropriate balance to this dichotomy will remain an ongoing challenge for all who are engaged in spotted owl conservation. All Federal actions will be subject to section 7 consultation allowing for site-specific analyses of the effect on spotted owls.

If carefully applied, we believe this Recovery Strategy and the recommendations in this Revised Recovery Plan will recover the spotted owl and sustain its recovery in the long-term by conserving the ecosystem upon which it relies. We also believe this approach is a land management perspective that is embraced by most forest ecologists and biologists and is well published in the scientific literature. It builds on what is already occurring in parts of the Pacific Northwest (see USDA 2010 and Gaines *et al.* 2010) and is consistent with the basic tenets of the NWFP. It provides opportunities for land managers to address multiple management goals in an integrated fashion, including recovery of the spotted owl, conservation of other fish and wildlife species, habitat restoration, fuels management, and timber production. It may also provide a common ground where adversarial stakeholders in the forest management debate can find some agreement and move forward.

III. Recovery Units, Criteria, and Actions

Recovery Units

Unlike previous versions of the spotted owl recovery plan, this Revised Recovery Plan identifies discrete recovery units throughout the entire range of the spotted owl such that each unit provides an essential survival and recovery function for the species. Recovery units defined on this basis are useful for purposes of managing the species and for applying the jeopardy standard under section 7 of the ESA to proposed Federal actions (USFWS and NMFS 1998, NMFS and USFWS 2010). When a proposed Federal action is likely to impair or preclude the capacity of a recovery unit to provide both the survival and recovery function it provides, that action may represent jeopardy to the species, provided the analysis describes not only how the action affects the recovery unit's capability but also the relationship of the recovery unit to both the survival and recovery of the listed species as a whole (NMFS and USFWS 2010).

In this Revised Recovery Plan, recovery units differ from management units, and are also not synonymous with critical habitat units; the former is a unit of the listed species, the latter is a unit of the species' habitat.

The recovery units defined in this Revised Recovery Plan are intended to assist managers in re-establishing or maintaining: (1) historical or current genetic flow between spotted owl populations; (2) current and historic spotted owl population and habitat distribution; and (3) spotted owl meta-population dynamics. Because the recovery units are defined on a biological basis, the recovery criteria for the spotted owl address each identified recovery unit.

In 1990, the Interagency Scientific Committee decided to subdivide the range of the spotted owl into "smaller areas for practical and analytical purposes" and used the physiographic provinces as a basis for their analysis (Thomas *et al.* 1990: 61). The physiographic provinces (also referred to as "provinces") incorporate physical, biological and environmental factors that shape broad-scale landscapes. The provinces reflect differences in geology (*e.g.*, uplift rates, recent volcanism, tectonic disruption) and climate (*e.g.*, precipitation, temperature, glaciation). In turn, these factors result in broad-scale differences in soil development, natural plant communities and ultimately, forest zones. Studies have demonstrated biological differences in the numbers, distribution, habitat use patterns, and prey of spotted owls relative to the different forest zones that occur within its range (Thomas *et al.* 1990). The Northern Spotted Owl Recovery Team (USFWS 1992b) divided the range of the spotted owl into 12 provinces based on differences in vegetation, soils, geologic history, climate, land ownership and political boundaries.

Given the above definitions and background information, the physiographic provinces meet the criteria for use as recovery units (see Figure A-1 in Appendix

A). The provinces collectively cover the range of the species, and each is essential for the conservation of the spotted owl (Thomas *et al.* 1990). The provinces are based on physical, biological and environmental factors that affect spotted owl numbers, distribution, habitat use patterns, habitat conditions, and prey species abundance. These provinces have been scientifically accepted, have been in use since 1990, and are integrated into management regimes and administrative purposes. In addition, most of the physiographic provinces contain long-term monitoring areas for the spotted owl, which yield robust scientific information to assess population dynamics and trends within each area and provide a good basis for analysis at recovery-unit and range-wide scales. Their long-standing monitoring information, biological basis and accepted use by managers should lead to an efficient transition to their adoption as recovery units. Using this rationale, we are proposing to adopt the physiographic province designations in place since 1990 as recovery units, with the exception of the Willamette Valley province, which is comprised largely of non-habitat for the spotted owl.

Recovery Criteria

Recovery criteria serve as objective, measurable guidelines to assist in determining when an endangered species has recovered to the point that it may be downlisted to threatened, or that the protections afforded by the ESA are no longer necessary and the species may be delisted. However, meeting all or most of the recovery criteria does not automatically result in delisting, and does not meeting all criteria preclude delisting. A change in status (downlisting or delisting) requires a separate rule-making process based on an analysis of the same five factors (referred to as the listing factors) considered in the listing of a species, as described in section 4(a)(1) of the ESA. These include:

A. The present or threatened destruction, modification, or curtailment of its habitat or range;
B. Overutilization for commercial, recreational, scientific, or educational purposes;
C. Disease or predation;
D. The inadequacy of existing regulatory mechanisms; and
E. Other natural or manmade factors affecting its continued existence.

Recovery criteria in this Revised Recovery Plan represent our best assessment of the conditions that may result in a determination in a 5-year review that delisting the spotted owl is warranted, which we would follow by a formal regulatory rule-making process to delist the species. Recovery actions are the Service's recommendations to guide the activities needed to accomplish the recovery criteria. Ultimately, a positive response by spotted owl populations to the recovery actions will mean recovery is occurring. Such a positive response will be measured in accordance with the population-related recovery criterion.

When the Service listed the spotted owl, we identified population decline, small population size, and related demographic conditions as threats. In the current assessment, these conditions were viewed as results of other threats and not threats *per se*. However, recovery actions are identified here that are intended to address and ameliorate such demographic conditions and address the key threats to the species. Recovery criteria are measurable and achievable goals that we believe will result from implementation of the recovery actions in this Revised Recovery Plan. Achievement of these criteria will take time and is intended to be measured over the life of the plan, not on a short-term basis.

Recovery Criterion 1 - Stable Population Trend: The overall population trend of spotted owls throughout the range is stable or increasing over 10 years, as measured by a statistically-reliable monitoring effort.

Recovery Criterion 2 – Adequate Population Distribution: Spotted owl subpopulations within each province (*i.e.*, recovery unit) (excluding the Willamette Valley Province) achieve viability, as measured by the HexSim population model or some other appropriate quantitative measure.

Recovery Criterion 3 – Continued Maintenance and Recruitment of Spotted Owl Habitat: The future range-wide trend in spotted owl nesting, roosting, foraging habitat is stable or increasing throughout the range, from the date of Revised Recovery Plan approval, as measured by effectiveness monitoring efforts or other reliable habitat-monitoring programs.

Recovery Criterion 4 – Post-delisting Monitoring: To monitor the continued stability of the recovered spotted owl, a post-delisting monitoring plan has been developed and is ready for implementation within the States of Washington, Oregon, and California (as required by section 4(g)(1) of the ESA).

Recovery Actions

In this Revised Recovery Plan, we have retained some of the original recovery actions from the 2008 Recovery Plan, introduced some new recovery actions, and revised some from the 2008 Recovery Plan to reflect new information, and updated status, in order to clarify our intent or respond to public comments. Generally, recovery actions follow the order of the listing factors. However, the first recovery action pertaining to implementation of this Revised Recovery Plan and Recovery Actions 2-4, which address Recovery Criterion 1, do not fit into any of the listing factors and so are presented first. The first recovery criterion assesses the spotted owl's population status. The Service believes this criterion is the best way to assess whether the five listing factors—that is, the threats facing the spotted owl—are addressed. For a more complete description of the threats to the spotted owl addressed by these recovery actions, see Appendix B.

Northern Spotted Owl Recovery Implementation Oversight

This Recovery Action pertains to all listing factors.

- ***Recovery Action 1: For each State, the FWS will designate offices that will coordinate implementation of the spotted owl recovery plan. These offices will work with local and regional partners to best ensure actions taken within that management jurisdiction are meeting the intention of the recovery plan while taking local context and variation into account. The Oregon Fish and Wildlife Office will remain the overall lead for the species and provide technical assistance and oversight to the other FWS offices as needed.*** We have established and lead an interagency and inter-organizational Northern Spotted Owl Implementation Team (NSOIT) designed to help coordinate implementation of this Revised Recovery Plan throughout the range of the species.

Monitoring and Inventory

These Recovery Actions also pertain to all listing factors.

- ***Recovery Action 2: Continue annual monitoring of the population trend of spotted owls to determine if the population is decreasing, stationary or increasing.*** Monitoring in demographic study areas is currently the primary method to assess the status of populations of spotted owls. Other statistically valid monitoring methods (*i.e.*, analytically robust and representative of the entire province and range) may be possible and could potentially fulfill this recovery action.

- ***Recovery Action 3: Conduct occupancy inventory or predictive modeling needed to determine if Recovery Criteria 1 and 2 have been met.*** It is expected this inventory will begin when it appears the spotted owl is close to meeting Recovery Criterion 1. Modeling techniques have improved recently, so predictive modeling may be part of the methodology for estimating spotted owl occupancy across the range.

LISTING FACTOR A: THE PRESENT OR THREATENED DESTRUCTION, MODIFICATION, OR CURTAILMENT OF THE SPECIES' HABITAT OR RANGE.

The key threats identified that relate to this listing factor are: (1) loss of habitat and changes in distribution of habitat as a result of past activities and disturbances, due especially to timber harvest and permanent conversion of habitat; and (2) ongoing habitat loss from natural disturbance (especially fire), timber harvest, and permanent conversion of habitat (see Appendix B).

Therefore, this Revised Recovery Plan recommends two basic strategies to address these threats: (1) conserve more occupied habitat and unoccupied high-value habitat; and (2) encourage and initiate active management actions that restore, enhance, and promote development of high value habitat, consistent with broader ecological restoration goals.

- ***Recovery Action 4: Use the habitat modeling process described above and in Appendix C to identify and implement recovery actions and conservation measures that would contribute to spotted owl recovery, including testing the efficacy of various habitat conservation network scenarios at conserving spotted owl habitat. Use the results from this effort to inform decisions concerning the possible development of habitat conservation networks.***

The following discussion provides the background and justification for the various recovery actions that address Listing Factor A. First, it is important to understand the potential changes in spotted owl habitat conditions and landscape ecological processes due to ongoing climate change. These changes are occurring throughout the spotted owl's range but are currently most serious in the drier portions of the range, and they affect both the species' habitat and its distribution. Second, we address emerging scientific principles of forestry science and "ecological forestry," and how forest scientists are trying to manage spotted owl habitat for resiliency and uncertainty in the face of climate change. And third, we discuss how the science of spotted owl recovery can fit within and be compatible with the broader forest ecosystem science and strategies that land managers are applying in order to be make spotted owl conservation efforts sustainable into the future. These strategies differ from moist forests to dry forest, and on Federal land versus private lands. Specific recovery actions are presented in the context of the relevant sections where management issues are discussed.

Climate Change and Forest Ecosystems

Climate change, combined with effects from past management practices, is exacerbating changes in forest ecosystem processes and dynamics to a greater degree than originally anticipated in the NWFP. This includes patterns of wildfire, insect outbreaks, drought, and disease. Many researchers believe there is a need to manage forests within an increasingly dynamic and unpredictable future that is driven by climate change (Perera *et al.* 2004, Millar *et al.* 2007, Kurz *et al.* 2008, Heyerdahl *et al.* 2008, Blate *et al.* 2009, Kennedy and Wimberly 2009, Krawchuk *et al.* 2009, Littell *et al.* 2008, 2009, 2010, Reinhardt *et al.* 2008, Johnson and Franklin 2009, Mitchell *et al.* 2009, Spies *et al.* 2010a,b). The preponderance of recent scientific research and opinion on climate change has coalesced around several key points concerning temperature, precipitation, wildfire, and insect and disease outbreaks.

Temperature and Precipitation

In the Pacific Northwest, mean annual temperatures rose 0.8° C (1.5° F) in the 20th century and are expected to continue to warm from 0.1° to 0.6° C (0.2 ° to 1 ° F) per decade (Mote and Salathe 2010). Global climate models project an increase of 1 to 2 percent in annual average precipitation, with some predicting wetter autumns and winters with drier summers (Mote and Salathe 2010). University of Washington researchers (Salathe *et al.* 2009) have developed finer-resolution, regional, predictive climate models that account for local terrain and other factors that affect weather (*e.g.*, snow cover, cloudiness, soil moisture, and circulation patterns) in the Pacific Northwest. These models agree with the global climate models in projecting warmer, drier summers and warmer, wetter autumns and winters for the Pacific Northwest, which will result in diminished snowpack, earlier snowmelt, and an increase in extreme heat waves and precipitation events.

On the cooler, moister west side of the Cascades, the summer water deficit is projected to increase two- to three-fold over current conditions (Littell 2009). East of the Cascade Crest, summer soil deficits may not change as much or may even moderate slightly over current conditions (Elsner *et al.* 2009). Researchers expect some ecosystems to become more water-limited, more sensitive to variability in temperature, and more prone to disturbance (McKenzie *et al.* 2009). There is evidence that the productivity of many high-elevation forests, where low summer temperature and winter snowpack limits the length of the growing season, is increasing in the Pacific Northwest as temperatures rise, potentially increasing the elevation of the tree line (Graumlich *et al.* 1989, Case and Peterson 2009). Conversely, productivity and tree growth in many low-elevation Pacific Northwest forests is likely to decrease due to the longer, warmer summers (Case and Peterson 2009). This may result in a change in species composition or reduction in the acreage of existing low-elevation forests.

Wildfire

Wildfire size and frequency have been increasing in the dry, fire prone forests of the western U.S. as a result of changing climatic conditions and past management activities (Westerling *et al.* 2006, Heyerdahl *et al.* 2008, Reinhardt *et al.* 2008, Wiedinmyer and Hurteau 2010, Spies *et al.* 2010a), although some researchers have suggested finer scale exceptions to this general pattern (Odion *et al.* 2004, Heyerdahl *et al.* 2008, Krawchuk *et al.* 2009, Hanson *et al.* 2009, 2010). According to Schafer *et al.* (2010), "An increase in fire activity is expected for *all* major forest types in Oregon" (emphasis original), and areas burned by fire in the Pacific Northwest are likely to increase substantially in the coming century (Hessburg *et al.* 2005, 2007, Kennedy and Wimberly 2009, Littell *et al.* 2009, 2010, Shafer *et al.* 2010).

Natural landscape resilience mechanisms have been decoupled by fire exclusion and wildfire suppression activities (Hessburg *et al.* 2005, Moritz *et al.* 2011).

Before the era of management, patchworks of burned and recovering vegetation, caused by mostly small and medium-sized fires, reduced the likelihood of the largest fires, which usually resulted from extreme weather events. Twentieth-century fire suppression eliminated most of these fires, and forest landscapes are now susceptible to large wildfires.

Stand-replacing events and disturbances will speed up ecological "conversions" (*e.g.*, forests to shrublands) (Joyce *et al.* 2008, Blate *et al.* 2009, Littell *et al.* 2010). Dry forests are at greater risk to large scale disturbances (Agee and Skinner 2005, Mitchell *et al.* 2009), but recent research suggests "that large disturbances are likely in west-side forests that have not traditionally been thought of as fire prone," and "it is therefore reasonable to expect increased fire activity" in such forests (Littell *et al.* 2010). Dry forests are treated in greater detail later in this section.

Older forests in the range of the spotted owl are being lost due to fire (Spies *et al.* 2006, 2010b, Ager *et al.* 2007a, Clark 2007, Healey *et al.* 2008, Kennedy and Wimberly 2009, Hanson *et al.* 2009, 2010), especially east of the Cascades and in the Klamath Province. However, some patches of habitat may be more resistant to climate change effects than others. A study on the east side of the Cascade Mountains found that areas of high soil and fuel moisture had historically created fire refugia where late-successional forest persisted longer (Camp *et al.* 1997). These patches were often near streams or valley bottoms, had perched water tables, or were near headwalls where soil moisture was higher. They were also often at higher elevations where total precipitation was higher or on northern aspects of mountains where terrain was shaded longer. Daley *et al.* (2009) found that cold air pooling in some mountain valleys may decouple or shelter the local microclimate from regional climate conditions. These studies imply that some areas on the landscape may resist climate-driven disturbances that may affect spotted owls and their habitat.

Insect and Disease Outbreaks

Climate change is affecting the location, size and intensity of insect outbreaks, which in turn affect fire and other forest processes (Joyce *et al.* 2008, Kurz *et al.* 2008, Littell *et al.* 2009, 2010, Latta *et al.* 2010, Spies *et al.* 2010a). Warming temperatures have led to mountain pine beetle outbreaks, with large-scale effects in some western forests, including in the eastern Cascades. In warmer winters more mountain pine beetles survive and shorten their generation time, resulting in larger and more severe outbreaks. Drought can heighten the susceptibility of host trees to attack (Littell *et al.* 2010). Littell *et al.* (2010) suggest that the greatest likelihood of mountain pine beetle attack is when conditions are hot and dry combined with a fairly short period of extreme vapor pressure deficit, when trees are most vulnerable. In the future, outbreaks are projected to increase at higher elevations and decrease at lower elevations (Littell *et al.* 2010), with uncertain implications for spotted owls. Littell *et al.* (2010) have projected that the combination of increased tree susceptibility and mountain pine beetle outbreaks could lead to the loss of pine species in the eastern Cascades as early as the 2040s.

Mixed conifer stands in the eastern Cascades, which include pine species, provide den sites and food resources for bushy-tailed woodrats, an important prey species of spotted owls (Lehmkuhl *et al.* 2006a). Warmer winters have also been shown to increase the incidence of Swiss needle cast, a fungal disease in Douglas-fir on the Oregon coast (Manter *et al.* 2005) inhibiting tree growth, and causing severe chlorosis and defoliation. We are uncertain how significantly this will affect spotted owl habitat.

Effects of Weather and Climate on Spotted Owl Demography

The influence of weather and climate on spotted owl populations was evidenced in northern California (Franklin *et al.* 2000), Oregon, and Washington (Glenn 2009). Climate accounted for 84 and 78 percent of the temporal variation in population change of spotted owls in the Tyee and Oregon Coast Range study areas, respectively (Glenn 2009). Climate and barred owls together accounted for nearly all (~100 percent) of the changes in spotted owl survival in the Oregon Coast Range (Glenn 2009).

Wet, cold weather during the winter or nesting season, particularly the early nesting season, has been shown to negatively affect spotted owl reproduction (Olson *et al.* 2004, Dugger *et al.* 2005), survival (Franklin *et al.* 2000, Olson *et al.* 2004, Glenn 2009), and recruitment (Franklin *et al.* 2000). Cold, wet weather may reduce reproduction and/or survival during the breeding season due to declines or decreased activity in small mammal populations so that less food is available during reproduction when metabolic demands are high (Glenn 2009). Wet, cold springs or intense storms during this time may reduce the time it takes for an adult bird to starve (Franklin *et al.* 2000). Cold, wet weather may also inhibit the male spotted owl's ability to bring food to incubating females or nestlings (Franklin *et al.* 2000). Cold, wet nesting seasons may increase the mortality of nestlings due to chilling (Franklin *et al.* 2000) and reduce the number of young fledged per pair per year (Franklin *et al.* 2000, Glenn 2009). Wet, cold weather may decrease survival of dispersing juveniles during their first winter thereby reducing recruitment (Franklin *et al.* 2000).

Drought or hot temperatures during the previous summer have also reduced spotted owl recruitment and survival (Franklin *et al.* 2000, Glenn 2009). Drier, warmer summers and drought conditions during the growing season strongly influence primary production in forests, food availability, and the population sizes of small mammals (Glenn 2009). Northern flying squirrels, for example, forage primarily on ectomycorrhizal fungi (truffles), many of which grow better under mesic, or moist, conditions (Lehmkuhl *et al.* 2004). Drier, warmer summers, or the high-intensity fires, which such conditions support, may change the range or availability of these fungi, affecting northern flying squirrels and the spotted owls that prey on them. Periods of drought are associated with declines in annual survival rates for other raptors due to a presumed decrease in prey availability (Glenn 2009).

Survival, recruitment, and reproduction increased with precipitation in the late spring or summer (Olson *et al.* 2004, Glenn 2009). Olson *et al.* (2004) found that while survival decreased with early-nesting season precipitation, it increased with late-nesting season precipitation. This is probably due to reducing the potential for drought to occur.

In addition to effects on habitat, the heat itself may have physiological effects on spotted owls. Weathers *et al.* (2001) suggest California spotted owls (*Strix occidentalis occidentalis*) are less heat-tolerant than other owls responding to temperatures of 30 to 34 ^{o} C (86 ^{o}– 93 ^{o} F) with increased breathing rates, fluffing of feathers, and wing drooping. Northern spotted owls in an earlier study (Barrows 1981) showed signs of heat stress at even more modest temperatures of 27 to 31 ^{o} C (81 ^{o}–88 ^{o} F). We have no current information on how this affects survival or reproduction.

The presence of high-quality habitat appears to buffer the negative effects of cold, wet springs and winters on survival of spotted owls as well as ameliorate the effects of heat. High-quality spotted owl habitat was defined in a northern California study area as a mature or old growth core within a mosaic of different seral stages (Franklin *et al.* 2000). The high-quality habitat might help maintain a stable prey base, thereby reducing the cost of foraging during the early breeding season when energetic needs are high (Carey *et al.* 1992, Franklin *et al.* 2000).

Barred Owls, Spotted Owls, and Climate Change

Although the scientific literature has explored the link between climate change and the invasion by barred owls, changing climate alone is unlikely to have caused the invasion (Livezey 2009b). In general, climate change can increase the success of introduced or invasive species in colonizing new territory (Dale *et al.* 2001). Invasive animal species are more likely to be generalists, such as the barred owl, than specialists, such as the spotted owl and adapt more successfully to a new climate than natives (Dukes and Mooney 1999).

Implications for Spotted Owl Conservation

While a change in forest composition or extent is likely as the result of climate change, the rate of that change is uncertain. In forests with long-lived dominant tree species, mature individuals can survive these stresses, so direct effects of climate on forest composition and structure would most likely occur over a longer time scale (100 to 500 years) in some areas than disturbances such as wildfire or insect outbreaks (25 to 100 years)(McKenzie *et al.* 2009). Some changes appear to be already occurring. Regional warming and consequent drought stress appear to be the most likely drivers of an increase in the mortality rate of trees in recent decades in the western United States. The increase was evident across regions (Pacific Northwest, California), elevations (*i.e.*, topography), tree size, type of trees, and fire-return-intervals (van Mantgem *et al.* 2009).

As summarized above, it is clear that ecosystem-level changes are occurring within the spotted owl's forest habitat. Therefore, many of the recovery actions proposed for spotted owls must take into account the uncertainty associated with climate change predictions. There are short-term risks and tradeoffs for long-term benefits when assessing the relative merits of active management (Roloff *et al.* 2005, Spies *et al.* 2006, Carey 2007, Millar *et al.* 2007, Blate *et al.* 2009). As discussed below, landscape-level adaptive management strategies that include active management of forest habitat should be encouraged (Wright and Agee 2004, Lee and Irwin 2005, Carey 2007, Keeton *et al.* 2007, Littell *et al.* 2008). Millar *et al.* (2007) suggest a conceptual framework for managing forested ecosystems in a way that helps ecosystems accommodate changes adaptively. These "adaptation" strategies include: (1) resistance options (to forestall impacts and protect highly valued resources), (2) resilience options (to improve the capacity of ecosystems to return to desired conditions after disturbance), and (3) response options (to facilitate transition of ecosystems from current to new conditions). This framework has value in planning actions to help spotted owls accommodate future climate changes and is discussed in more detail below.

Part of the Service-wide priority for responding to climate change is to conduct species and habitat vulnerability assessments, an analytical tool for determining how climate change will affect a species, habitat, or ecosystem and for developing strategies to safeguard these resources (USFWS 2009). Methodologies have been developed in recent years to conduct vulnerability assessments, some of which may be useful for determining appropriate recovery actions, given the climate change effects on the spotted owl and its habitat (Stein 2010).

Recovery implementation for spotted owls should also, wherever feasible, look for opportunities where managing for spotted owl habitat also meets other societal priorities concerning climate change. For example, the highest densities of forest biomass carbon storage in North America occur in the conifer forests of the Pacific Northwest (Sundquist *et al.* 2009, Keith *et al.* 2010). Older forests with longer rotations may be more effective at sequestering carbon than younger, more intensively managed tree plantations (Schulze *et al.* 2000, Luyssaert 2008), but all forest lands may have value for the purpose of carbon sequestration. Effectiveness in this goal may depend on very specific prescriptions and locales. Preliminary research funded by the Service indicates that forests in Oregon have tremendous potential for carbon sequestration on State forest lands in the Coast Range (Davies *et al*. 2011), and nearby lands likely have similar potential. Likewise, managing for carbon sequestration means it is also necessary to manage forest biomass and the risks of stand replacing wildfire (Canadell and Raupach 2008). As of this writing it is unclear what role, if any, Federal and State forest lands will ultimately play in mitigating climate change, but some policy analysts have begun to frame this issue (see Depro *et al.* 2008).

Therefore, to be consistent with the Secretarial Order as well as other Service initiatives (*e.g.*, Landscape Conservation Cooperatives), we are recommending researchers emphasize ecological and economic overlap between recovery actions for spotted owls and action to mitigation climate change. For example, more research should be conducted on the relative compatibility or conflict between thinning a forest to reduce fire risk, its impact on long-term spotted owl habitat quality, and the action's mitigation of climate change impacts. Although thinning activity removes carbon from the forest system in the short-term, it may reduce the risk of a subsequent carbon release through fire or disease outbreak, and it also encourages carbon being concentrated in fewer, larger trees that approximate old-growth structure of pre-fire suppression forests (Hurteau *et al.* 2008). The validity of such a concept is not in dispute among mainstream scientists but, as discussed elsewhere in this document, there is significant disagreement regarding where, when, and how to implement such management measures to optimize the potential for positive outcomes.

- ***Recovery Action 5 – Consistent with Executive Order 3226, as amended, the Service will consider, analyze and incorporate as appropriate potential climate change impacts in long-range planning, setting priorities for scientific research and investigations, and/or when making major decisions affecting the spotted owl.***

Spotted Owls and Ecological Forestry

As documented above, there is a strong scientific consensus that Pacific Northwest forests will be – and already are – undergoing significant changes from current conditions due to past management practices, shifting disturbance patterns, and changing climate influences. There is a variety of scientific opinion regarding the extent to which land managers can manage or positively influence these changes (Millar *et al.* 2007, Reinhardt *et al.* 2008), and how such shifts may affect spotted owls (see, *e.g.*, Hanson *et al.* 2009, 2010 and Spies *et al.* 2010b). To address this uncertainty, we propose applying "active forest management" as part of a spotted owl recovery strategy that includes "ecological forestry and restoration" as described by Franklin *et al.* (2007), Carey (2007), Johnson and Franklin (2009), Long (2009), and Spies *et al.* (2010a), among others. We recommend that land managers consider implementing forest restoration activities where the best available science suggests ecosystems and spotted owls would benefit in the long-term.

We recognize that this recommendation may be controversial. As described below, some forest areas need or would benefit from restoration treatments, whereas others are at less risk or the science is less clear about how to treat certain areas. We make this recommendation to apply ecological forestry and restoration in many parts of the spotted owl's range because:

- Climate change is rapidly altering forest ecosystems within the range of the spotted owl with some unpredictable or potentially undesirable outcomes (Lenihan *et al.* 2008, Littell *et al.* 2010, Shafer *et al.* 2010, Spies *et al.* 2010a);
- The Service, forest managers, and policy makers must take reasonable but proactive steps to conserve forest ecosystems and spotted owls in the face

of past management and future uncertainty (Agee 2002, Carey 2007, Gaines *et al.* 2010); and

- There is a scientific and social consensus emerging that land managers must restore more sustainable (resistant and resilient) ecological processes to forests at various landscape scales (Hessburg *et al.* 2004, Millar *et al.* 2007, Long 2009, Moritz *et al.* 2011).

First, it is worth noting that this recommendation is consistent with a primary goal of the NWFP – the conservation of ecological processes (FEMAT 1993, App. VIII) – and thus should be addressed within the existing planning and adaptive management framework currently in place for Federal lands in the range of the spotted owl. The concept of "conservation of ecological processes" has long been an underlying principle of "ecosystem management" and should be familiar to most land managers in the Pacific Northwest. Ricklefs *et al.* (1984) proposed this concept to include basic ecological cycles on large landscapes, such as the soil formation cycle and the hydrological cycle, with the understanding that fish and wildlife resources are integral to these cycles. That is, conserve the ecological processes and you conserve fish and wildlife. In the 1980s and 1990s, ecosystem management emerged as a dominant theme in managing large landscapes across varied ownerships. Some examples include management of the Greater Yellowstone Ecosystem, the Florida Everglades, the coastal sage scrub of Southern California and the forests of the Pacific Northwest with the NWFP. The NWFP explicitly includes this goal of conserving natural processes (FEMAT 1993, App. VIII).

Natural disturbance processes – wildfire, disease, insect outbreaks and windthrow – are important forces that influence spotted owl habitat. The scientific study and emulation of these processes has emerged as a "dominant paradigm in North American forest management" (Long 2009). Much of this work has occurred in the Pacific Northwest and has direct applicability to forest management in the range of the spotted owl (*e.g.*, Franklin *et al.* 2002, Perera *et al.* 2004, Hessburg *et al.* 2004, Wright and Agee 2004, Nitschke 2005, Drever *et al.* 2006, Noss *et al.* 2006, Carey 2007, Franklin *et al.* 2007, O'Hara 2009, Johnson and Franklin 2009, Long 2009, Odion *et al.* 2010, Swanson *et al.* 2010). A good synopsis of disturbance-based management for forested systems is provided by North and Keeton (2008:366):

> "Disturbance-based forest management is a conceptual approach where the central premise might be summarized as 'manipulation of forest ecosystems should work within the limits established by natural disturbance patterns prior to extensive human alteration of the landscape' (Seymour and Hunter 1999). Although such an objective seems like a simple extension of traditional silviculture, it fundamentally differs from past fine-filter approaches that have manipulated forests for specific objectives such as timber production, water yield, or endangered species habitat. Some critics have argued that this approach leaves managers without clear guidelines because the scale and processes of ecosystems are poorly defined, making it difficult to directly emulate the ecological effects of natural disturbances.

> Disturbance-based management, however, readily acknowledges these uncertainties. It emphasizes a cautious approach, targeted at those specific management objectives, such as provision of complex habitat structures, reduced harvesting impacts, and landscape connectivity that can be achieved. Although this approach will require changes in how management success is evaluated, disturbance-based management is likely to minimize adverse impacts on complex ecological processes that knit together the forest landscape."

The Service continues to recommend that active forest management and disturbance-based principles be applied throughout the range of the spotted owl with the goal of maintaining or restoring forest ecosystem structure, composition and processes so they are sustainable and resilient under current and future climate conditions in order to provide for long-term conservation of the species. The majority of published studies support this general approach for Pacific Northwest forests, although there is some disagreement regarding how best to achieve it. We received widely varying recommendations for meeting this goal from knowledgeable scientists. Most of this variance in opinion is due to the scientific uncertainty in: (1) accurately describing the ecological "reference condition" or the "natural range of variability" in historical ecological processes, such as fire and insect outbreaks across the varied forest landscape within the range of the spotted owl (*e.g.*, see Hessburg *et al.* 2005, and Keane *et al.* 2002, 2009); and (2) confidently predicting future ecological outcomes on this landscape due to rapid, climate-driven changes in these natural processes, with little precedent in the historical (or prehistoric) record (Drever *et al.* 2006, Millar *et al.* 2007, Long 2009, Littell *et al.* 2010).

These are very real problems that should be addressed with more research (Strittholt *et al.* 2006, Kennedy and Wimberly 2009). In the meantime, addressing this uncertainty in a careful but active manner is the challenge of this Revised Recovery Plan and of forest management in general. The Service agrees with those climate scientists and forest researchers who propose that decision makers must deploy a suite of reactive and proactive approaches to cope with the impacts of climate change on forest lands, while taking into account both short- and long-term timeframes and differing landscape scales (Millar *et al.* 2007, Joyce *et al.* 2008, Reinhardt *et al.* 2008, Blate *et al.* 2009, Gaines *et al.* 2010, Spies *et al.* 2010a, Moritz *et al.* 2011). This strategy should incorporate the concept of "adaptation" into forest management decisions (Drever *et al.* 2006, Joyce *et al.* 2008, Long 2009, Littell *et al.* 2010). Adaptation options include: (1) resisting change; (2) promoting resilience to change; and (3) allowing forest ecosystems to respond to change (Millar *et al.* 2007, Joyce *et al.* 2008, Blate *et al.* 2009, Littell *et al.* 2010).

Resistance strategies are usually deployed to protect high-value resources, such as human structures or very rare habitats. They can be expensive and labor intensive, and include actions such as fire suppression across large and rugged landscapes. Resilience-enhancing adaptations include managing within the bounds of natural disturbance processes by emulating these processes through prescriptive actions (Peterson *et al.* 1998, Franklin *et al.* 2002, Drever *et al.* 2006, Joyce *et al.* 2008). This approach will likely lead to the restoration and maintenance of forest ecosystems which are resilient to a wide range of environmental challenges or scenarios (Long 2009). Allowing forest ecosystems to change as resilience thresholds are crossed means minimizing dramatic and abrupt transitions from one ecosystem condition to another (*e.g.*, forest to shrubland), thereby also minimizing disruptions to important ecological processes (*e.g.*, species dispersal, hydrological cycle, etc.) (Hessburg *et al.* 2005, Blate *et al.* 2009).

Maintaining or improving ecosystem resilience in the face of climate change should be a fundamental goal of forest land managers (Hessburg *et al.* 2005, Reinhardt *et al.* 2008, Lawler 2009, Littell *et al.* 2010). "Resilient forests are those that not only accommodate gradual changes related to climate but tend to return toward a prior condition after disturbance either naturally or with management assistance" (Millar *et al.* 2007). Managing for resilient forests should also be considered a fundamental recovery goal for spotted owls. Federal land managers should apply ecological forestry principles where long-term spotted owl recovery will benefit, even if short-term impacts to spotted owls may occur (Franklin *et al.* 2006) to improve the resiliency of the landscape in light of threats to spotted owl habitat from climate change and other disturbances. For example, managers should promote spatial heterogeneity within patches and local and regional landscapes, restore lost species and structural diversity (including hardwoods) within the historical range of variability, and restore ecological processes to historical levels and intensities (Franklin *et al.* 2002, 2007, Drever *et al.* 2006, Long 2009). This includes early-successional ecosystems on some forest sites (Swanson *et al.* 2010, Perry *et al.* 2011). Some of these management actions may degrade spotted owl habitat in local areas in the short-term (Franklin *et al.* 2006, Spies *et al.* 2006, 2010a), but may be beneficial to spotted owls in the long-term if they reduce future losses of ecosystem structure or better incorporate future disturbance events to improve overall forest ecosystem resilience to climate change (Roloff *et al.* 2005, Ager *et al.* 2007a, Spies *et al.* 2010a).

Of course, trade-offs that affect spotted owl recovery will need to be assessed on the ground, on a case-by-case basis with careful consideration given to the specific geographical and temporal context of a proposed action. There is no "one right prescription." Specific patch-level prescriptions are impossible to make in this Revised Recovery Plan given the tremendous variety in conditions and land management goals across the species' range. Each forest is unique (Agee 2002), and landscape and site-specific assessments need to be made (Lee and Irwin 2005). Prescriptive management goals to address climate change concerns vary across the spectrum of forest types, landscapes, and ownership (Millar *et al.* 2007). When considering a potential restoration treatment project, it will be necessary for land managers working with the Service and other interested stakeholders to weigh the potential tradeoffs between short-term impacts to spotted owl habitat versus longer-term ecosystem restoration outcomes. While our understanding of short- and long-term effects of ecosystem restoration actions on spotted owls is limited at this time, research on effects of more traditional forest management practices on spotted owls and their prey has been conducted and is discussed below. These studies provide data that should inform development of restoration projects to develop desired future conditions while best maintaining existing spotted owls on the landscape. In addition, projects with these types of effects on Federal land will undergo section 7 consultation to assess the impact to the spotted owl.

Effects of Forest Management Practices on Spotted Owls

Before applying ecological forestry principles and implementing the recommendations in this Plan, it is necessary to summarize the scientific understanding of how various forest management practices affect spotted owls. Historically, many of the timber management practices used in the Pacific Northwest have had detrimental consequences for spotted owls. Clearcuts, shelterwoods and heavy commercial thinning operations have typically converted spotted owl habitat to non-habitat. Several peer-reviewed publications (Forsman *et al.* 1984, Zabel *et al.* 1992, Buchanan *et al.*1995, Hicks *et al.* 1999, Meiman *et al.* 2003), three master's theses (Solis 1983, Sisco 1990, King 1993) and a number of reports (Anthony and Wagner 1999, Irwin *et al.* 2005, Irwin *et al.* 2008, Irwin *et al.* 2010) specifically addressed effects of timber harvest (primarily thinning operations) on spotted owls, and results of these studies were summarized by Hansen and Mazurek (2010). In most of these studies, one to two spotted owls were affected by thinning projects, and data on thinning effects were collected incidental to larger research objectives. Furthermore, timber harvest activities in these studies were generally not designed or intended to develop future spotted owl habitat.

Among those studies that reported spotted owl responses to thinning or other timber harvest activities, four studies (Forsman *et al.* 1984, King 1993, Hicks *et al.* 1999, Meiman *et al.* 2003) found spotted owls were displaced by contemporary harvest near the nest or activity center. Based on observations of nine spotted owl territories where harvest occurred during the study, Forsman *et al.* (1984) suggested that negative effects (decreased reproduction, site abandonment) of thinning or selective harvest were most likely associated with higher-intensity thinning, timber harvest close to the nest area and when the affected owl site had low amounts of alternative habitat available. Similarly, Meiman *et al.* (2003) reported that a male spotted owl expanded his home range and shifted foraging and roosting away from a thinning operation located close to the nest tree. Consequently, they recommended harvest operations not be conducted near spotted owl nest sites. While harvest activities tend to decrease use by spotted owls during and immediately following the action, spotted owl use of previously logged forest (selectively logged or thinned) was demonstrated in a number of cases: four of these 12 studies reported nesting attempts, five reported roosting, and nine described foraging activities in stands that had been thinned or selectively logged one to five decades earlier (Hansen and Mazurek 2010). Given the small number of spotted owls studied, the information provided in these studies is insufficient for drawing firm conclusions about the effects of thinning prescriptions on spotted owls.

Another important consideration is the effect of vegetation management on spotted owl prey species, including northern flying squirrels, dusky-footed woodrats, bushy-tailed woodrats and other small mammals. The northern flying squirrel's relationships with forest seral stages, forest structure and land management have been a topic of considerable research and debate. Some studies have found that densities of flying squirrels are highest in old forests (Carey *et al.* 1992, Carey 1995), whereas others have suggested that the species is a generalist with respect to seral stage or stand age (Rosenberg and Anthony 1992, Waters and Zabel 1995, Ransome and Sullivan 1997). Studies of the effects of timber harvest on northern flying squirrels have generally found negative responses to thinning, although results have varied across studies. Several studies have suggested that forest thinning can temporarily (*e.g.*, up to 20 years) reduce the availability of truffles, which are a key food resource for northern flying squirrels and other small mammals on which spotted owls depend (Waters *et al.* 1994, Colgan *et al.* 1999, Luoma *et al.* 2003, Meyer *et al.* 2005). However, studies in British Columbia did not find any significant short-term differences in densities, movements or reproduction of flying squirrels in young, commercially-thinned stands versus unthinned young stands (Ransome and Sullivan 2002, Ransome *et al.* 2004). Carey (2000) found lower abundances of flying squirrels in recently-thinned (within 10 years) stands in Washington than in stands that were clear-cut 50 years prior to the study, with retention of both live and dead trees. He attributed his results to the apparently negative effects of commercial thinning on canopy connectivity, downed wood and truffle communities in the area. Wilson (2010) also reported most thinning is likely to suppress flying squirrel populations for several decades, but the long-term benefits of variable-density thinning for squirrels are likely to be positive. He emphasized that developing the next layer of trees is critical if the goal is to accelerate late-seral conditions and promote prey for spotted owl, and complex structure favorable to squirrels may be achieved sooner in younger stands where there is a shorter vertical distance between the ground and the bottom of the canopy.

Mixed results have also been reported in studies that examined effects of thinning on woodrats. Dusky-footed woodrats occur in a variety of conditions, including both old, structurally complex forests and younger seral stages, and are often associated with streams (Raphael 1987, Carey *et al.* 1992, 1999, Williams *et al.* 1992, Sakai and Noon 1993, Anthony *et al.* 2003, Hamm and Diller 2009). Research has suggested that thinning or associated practices (*e.g.*, burning slash piles) could be detrimental to dusky-footed woodrats if it reduces hardwoods, shrubs or downed wood, yet treatments could ultimately benefit woodrats if they result in growth of shrubs or hardwoods (Williams *et al.* 1992, Innes *et al.* 2007). Bushy-tailed woodrats may be more limited by abiotic features, such as the availability of suitable rocky areas for den sites (Smith 1997) or the presence of streams (Carey *et al.* 1992, 1999). Similar to dusky-footed woodrats, forms of thinning that reduce availability of snags, downed wood or mistletoe could negatively impact bushy-tailed woodrat populations (Lehmkuhl *et al.* 2006a). A study of dusky-footed woodrats in the redwood region of California, however, did not find an association between abundances of woodrats and different intensities of commercial thinning (Hamm and Diller 2009).

Results from these studies suggest that active management projects should explicitly evaluate the short-term impacts to spotted owls and their prey while considering the long-term ecological benefits of such projects, especially in spotted owl core-use areas. Spotted owl home ranges generally have a greater proportion of older forest within the core-use area and more diverse forest conditions on the periphery of their ranges (Swindle *et al.* 1999). The studies referenced above primarily described effects of commercial timber harvest; management designed under an ecological forestry framework should avoid existing high value habitat, if possible, while meeting long-term restoration goals. Within provincial home ranges but outside core-use areas, opportunities exist to conduct vegetation management to enhance development of late-successional characteristics or meet other restoration goals in a manner compatible with retaining resident spotted owls. Restoration activities conducted near spotted owl sites should first focus on areas of younger forest less likely to be used by spotted owls and less likely to develop late-successional forest characteristics without vegetation management. Vegetation management should be designed to include a mix of disturbed and undisturbed areas, retention of woody debris and development of understory structural diversity to maintain small mammal populations across the landscape.

At regional landscape scales, managers should consider how spotted owls fit into a larger ecological framework. Additional factors including historical disturbance regimes and different forest vegetation communities need to be considered. The following section addresses these regional differences in more detail. As ecological forestry is considered and applied in the Pacific Northwest, forest ecosystem management goals will differ between moist and dry forests, and between northern interior portions of the range versus coastal areas in California (Spies *et al.* 2006, Strittholt *et al.* 2006, Mitchell *et al.* 2009). The following sections provide some principles for land managers to consider in these differing forests within the spotted owl's range.

Habitat Management in Moist Forests

A primary spotted owl recovery goal of this Revised Recovery Plan for moist forests is to conserve older stands that are either occupied or contain high-value spotted owl habitat; this recovery goal is discussed in greater detail later under Recovery Action 10 and Recovery Action 32. On Federal lands these recommendations apply to reserved and non-reserved land allocations.

Managers of the moist forest landscapes recognize that emulating natural disturbance patterns at large landscape levels will be very difficult (Wimberly *et al.* 2004). In contrast to dry forests, short-term fire risk is generally lower in the moist forests that are the dominant condition on the west side of the Cascade Range, and disturbance-based management for forests and spotted owls here should be different. Silvicultural treatments are generally not needed to maintain existing old-growth forests on moist sites (Wimberly *et al.* 2004, Johnson and Franklin 2009). Efforts to alter either fuel loading or potential fire behavior in these sites could have undesirable ecological consequences (Johnson and Franklin 2009, Mitchell *et al.* 2009). Potential management in older forests, either for climate-related management or spotted owl recovery, must explicitly weigh the relative pros and cons of such activities.

However, this recommendation should be reassessed regularly as new scientific information emerges regarding climate change. For example, Littell *et al.* (2010) suggest climate-driven fire risk may increase on the west-side in moist forests, and Shafer *et al.* (2010) conclude that fire activity is expected to increases in all forest types in Oregon. Although these model predictions are still highly variable, the recommendations of mainstream climate scientists (Littell *et al.* 2010, Shafer *et al.* 2010) should be incorporated into longer-term planning. Wimberly *et al.* (2004) give some recommendations to consider in the Oregon Coast Range that address historical fire regimes and disturbance patterns.

Even with uncertain model predictions, there are younger or less diverse moist forest areas outside of old-growth stands where active management could promote ecological goals, including spotted owl recovery. The most current evaluations suggest climate change in the Pacific Northwest is affecting processes in addition to wildfire, including insect and disease outbreaks and changes in species composition (Latta *et al.* 2010, Littell *et al.* 2010, Spies *et al.* 2010a). Therefore, ecological forestry and active management in the range of the spotted owl should address issues in addition to wildfire dynamics. For example, where past management practices have decreased age-class diversity and altered the structure of forest patches, targeted vegetation treatments could simultaneously reduce fuel loads and increase canopy and age-class diversity (Franklin *et al.* 2002, 2006, Wimberly *et al.* 2004, Littell *et al.* 2010). Likewise, there may be post-disturbance opportunities to restore more natural, early successional forest conditions that provide more ecological benefits to spotted owls (and other native forest species) than do traditional clearcuts and young, even-aged stands (Swanson *et al.* 2010).

Long-term spotted owl recovery could benefit from forest management where the basic goals are to restore or maintain ecological processes and resilience. Therefore, we recommend application of disturbance-based principles to such decisions (Franklin *et al.* 2002, 2006, 2007, Drever *et al.* 2006, Noon and Blakesley 2006, Carey 2007, Long 2009, Swanson *et al.* 2010). For example, some treatments may accelerate the development of spotted owl nesting habitat (Wimberly *et al.* 2004, Andrews *et al.* 2005), even if it temporarily degrades existing dispersal habitat (Franklin *et al.* 2006). This issue needs more applied research, and land management experiments should target this need. There are areas in moist LSRs where stands average 50 years or older that are uniform and not likely to achieve desired complexity or resilience on their own, yet may develop structural complexity more quickly with treatment (Bailey and Tappeiner 1998, Latham and Tappeiner 2002, Carey 2003). These areas should be considered for restoration treatments designed to encourage development of late-successional structural complexity and promote resilience in the face of expected climate-driven changes (Johnson and Franklin 2009). Much of this activity can, and should, be carried out in all Federal land classifications consistent with the NWFP Standards and Guidelines. In some cases, it may be appropriate to seek exemptions to the 80-year old threshold for silvicultural activities in LSRs if a clear conclusion can be reached that spotted owl recovery and/or ecosystem restoration goals would be met. Research and monitoring on the specific effects of such treatments on spotted owls and their prey is needed and should evaluate effects on both spotted owl recovery as well as broader forest management goals.

In general, to advance long-term spotted owl recovery and ecosystem restoration in moist forests in the face of climate change and past management practices, we recommend the following principles be applied by land managers:

1. Conserve older stands that have occupied or high-value spotted owl habitat as described in Recovery Actions 10 and 32. On Federal lands this recommendation applies to all land-use allocations outside of Congressionally Reserved Areas.
2. Management emphasis needs to be placed on meeting spotted owl recovery goals and long-term ecosystem restoration and conservation. When there is a conflict between these goals, (*e.g.*, short-term adverse impact but expected long-term benefit), managers should make tradeoffs explicit and seek Service input if necessary. Use a sliding scale to prioritize landscapes (*e.g.*, watersheds, stands, etc.) for treatment.
3. Continue to manage for large, continuous blocks of late-successional forest.
4. Regeneration harvest, if carried out, should apply ecological forestry principles as recommended by Franklin *et al.* (2002, 2007), Drever *et al.* (2006), Johnson and Franklin (2009), Swanson *et al.* (2010), and others cited above.
5. Use pilot projects and applied management to test or demonstrate techniques and principles (Noon and Blakesley 2006). In the near term, to reduce conflict and potential inconsistencies with existing Federal land management plans, locate such pilot projects wherever possible in Matrix and Adaptive Management Areas. However, we continue to recommend that such actions be considered in LSRs if a determination is made that treatments would meet broader ecosystem restoration goals.

- ***Recovery Action 6: In moist forests managed for spotted owl habitat, land managers should implement silvicultural techniques in plantations, overstocked stands and modified younger stands to accelerate the development of structural complexity and biological diversity that will benefit spotted owl recovery.***

Implement LSR treatments per the Standards and Guides of the NWFP. In addition, LSR thinning in plantations older than 80 years of age should occur in cases where long-term beneficial effects to spotted owls will be realized from enhancing within-stand structural diversity. The treatment should emphasize the retention of the oldest and largest trees in the stands or any trees with characteristics that create stand diversity (*e.g.*, bole and limb deformities) and should focus on structural diversity in the mid- to upper- story layers, but not at the expense of large snags or existing species diversity. Cases where facilitating a thinning operation necessitates felling existing remnant trees over 120 years old should be rare. We recommend the use of fungal inoculation, mechanical methods, or other tools as needed to create snags. The Service is available to participate in local or regional efforts to provide guidance on these sorts of prescriptions. Any LSR thinning in plantations greater than 80 years old, if appropriate, should occur where nesting and roosting habitat is needed within LSRs to bolster spotted owl populations and should be considered within the interagency structure of the Level 1 teams.

Likewise, in areas with regeneration harvest in moist forest Matrix lands, any harvest should be designed using ecological forestry principles that emphasize retention of larger and older trees, snags and downed wood of varying size and decay classes, and live trees with decay and deformities (see Swanson *et al.* 2010). Unlike traditional regeneration harvests, applying these measures retain important habitat features while also encouraging eventual development of late-successional conditions.

Habitat Management in Dry Forests

Although the dry forest portion of the spotted owl's range hosts a minority of the overall population, management of spotted owl habitat in these drier areas is an extremely complex undertaking. Changing climate conditions, dynamic ecological processes, and a variety of past and current management practices render broad management generalizations impractical. Recommendations for spotted owl recovery in this area also need to be considered alongside other land management goals – sometimes competing, sometimes complimentary – such as fuels management and invasive species control. In some cases, failure to intervene or restore forest conditions may lead to dense stands heavy with fuels and in danger of stand-replacing fires and insect and disease outbreaks. As a consequence, the dry forest discussion below provides substantial detail on spotted owl ecology in such areas, including a more specific treatment of the effects of climate, fire, and insect and disease outbreaks on spotted owl habitat.

In general, we recommend that dynamic, disturbance-prone forests of the eastern Cascades, California Cascades and Klamath Provinces should be actively managed in a way that reconciles the overlapping goals of spotted owl conservation, responding to climate change and restoring dry forest ecological structure, composition and processes, including wildfire and other disturbances (Noss *et al.* 2006, Spies *et al.* 2006, 2010a, Agee and Skinner 2005, Healey *et al.* 2008, Mitchell *et al.* 2009). Vegetation management of fire-prone forests can retain spotted owl habitat on the landscape by altering fire behavior and severity (Reinhardt *et al.* 2008, Haugo *et al.* 2010, Wiedinmyer and Hurteau 2010) and, if carefully and strategically applied, it could be part of a larger disturbance management regime for landscapes that attempts to reintegrate the relationship between forest vegetation and disturbance regimes, while also anticipating likely shifts in future ecosystem processes due to climate (Gartner *et al.* 2008, Noss *et al.* 2006, Lawler 2009, Mitchell *et al.* 2009, Littell *et al.* 2010, Swanson *et al.* 2010, Moritz *et al.* 2011). Such an approach is more likely to achieve ecologically and socially acceptable outcomes, and could enable transitions to more acceptable disturbance regimes, even if it includes more frequent but less severe wildfires (Allen *et al.* 2002, Wright and Agee 2004, Hessburg *et al.* 2005, 2007, Strittholt *et al.* 2006, Reinhardt *et al.* 2008). Some areas, such as dry portions of the Klamath Province, have a different fire ecology than areas in the East Cascades and may not be subject to the same generalizations (Odion *et al.* 2004, 2010, Skinner *et al.* 2006, Hanson *et al.* 2009, 2010); this should be evaluated at a finer scale by recovery implementation teams and interested land managers.

Specific silvicultural practices that promote forest resilience and that can be applied to various forest types are given by Franklin *et al.* (2002, 2006, 2007), Hessburg *et al.* (2004, 2005, 2007), and Drever *et al.* (2006). Short-term decisions to increase forest ecosystem adaptations to climate-driven drought stresses may include vegetation management around older individual trees to reduce competition for moisture (Wright and Agee 2004, Agee and Skinner 2005, Reinhardt *et al.* 2008, Johnson and Franklin 2009, Haugo *et al.* 2010, Littell *et al.* 2010). Longer-term strategies may include protecting or restoring multiple examples of ecosystems and promoting heterogeneity among and within forest stands with the potential for natural adaptation to future (and unpredictable) climate changes (Hessburg *et al.* 2005, Kennedy and Wimberly 2009, Blate *et al.* 2009). In many areas, fire could be encouraged to perform its ecological role of introducing and maintaining landscape diversity (DellaSala *et al.* 2004, Reinhardt *et al.* 2008, Odion *et al.* 2010), although it may be desirable to manage fire severity or return intervals through vegetation management at various temporal and landscape scales (Agee and Skinner 2005, Haugo *et al.* 2010, Littell *et al.* 2010, Spies *et al.* 2010a, Moritz *et al.* 2011).

There is an ongoing debate, as captured in Hanson *et al.* (2009, 2010) and Spies *et al.* (2010b), regarding the relative merits of active management in dry forest landscapes and the potential positive and negative impacts to spotted owls (Spies *et al.* 2006). This debate focuses on uncertainty and seems to be one of degree rather than fundamental difference in long-term conservation goals. We would like to build on areas of agreement for spotted owl recovery, but we recognize that many of these recommendations are controversial due to political and socio-economic reasons (*e.g.*, see Spies *et al.* 2010a). However, given the need for action in the face of uncertainty (Agee 2002, Roloff *et al.* 2005, Carey 2007, Millar *et al.* 2007, Reinhardt *et al.* 2008, Littel *et al.* 2010, Mote *et al.* 2010, Shafer *et al.* 2010), we continue to recommend that land managers implement a program of landscape-scale, science-based adaptive restoration treatments in disturbance-prone forests that will reconcile the goals of conserving and encouraging spotted owl habitat while better enabling forests to: (1) recover from past management measures, and (2) respond positively to climate change with resilience (Spies *et al.* 2006, 2010a,b, Millar *et al.* 2007, Reinhardt *et al.* 2008, Haugo *et al.* 2010, Keane *et al.* 2009, North *et al.* 2010, Littell *et al.* 2010, Stephens *et al.* 2010). This should provide more high quality spotted owl habitat sooner and for longer into the future which will greatly benefit spotted owl recovery in the long-term. Several authors provide clear recommendations for how to consider reconciling spotted owl habitat management with vegetation management in the eastern Cascades (Lehmkuhl *et al.* 2007, Buchanan 2009, Gaines *et al.* 2010, USDA 2010).

Disturbance Regimes of Dry Forests Within the Range of the Spotted Owl

Ecological disturbance regimes derive from complex interactions among vegetation, climate, topography, and other biotic and abiotic factors that vary over space and time. Fire and other disturbances have been fundamentally important to shaping landscape patterns and processes in the dry forest systems (Hessburg *et al.* 2000a, 2005, 2007, Dale *et al.* 2001, Hessburg and Agee 2003, Skinner *et al.* 2006, Skinner and Taylor 2006, Perry *et al.* 2011). Fire regimes have been described for the Eastern Washington Cascades, Eastern Oregon Cascades, California Cascades, and Klamath Provinces (Hessburg *et al.* 2000a, 2005, 2007, Hessburg and Agee 2003, SEI 2008, Skinner *et al.* 2006, Skinner and Taylor 2006, Perry *et al.* 2011), though there is not agreement on some regime descriptions (Hanson *et al.* 2009, 2010, Spies *et al.* 2010b).

Additional research has advanced our understanding of the occurrence of low, mixed, and high-severity fires in dry forest fire regimes typically considered as low severity only (*e.g.,* see Baker *et al.* 2007, Hessburg *et al.* 2007, Beaty and Taylor 2008, Brown *et al.* 2008, Collins and Stephens 2010, Perry *et al.* 2011). In dry forests of the eastern Cascades of Washington, for example, surface-fire dominated mixed severity fires were found to be more prominent historically than previously thought (Hessburg *et al.* 2007), rendering more spatial and temporal variability in landscape patterns of disturbed and recovering vegetation. Kennedy and Wimberly (2009) found similar results for the Deschutes National Forest in the eastern Cascades of Oregon. Consequently, dry forest landscapes historically comprised a complex arrangement of fire regimes and patch sizes (Hessburg *et al.* 2005, 2007, Skinner *et al.* 2006, Skinner and Taylor 2006, Perry *et al.* 2011), creating spatial and temporal patterns and variability in vegetation and fuels that reinforced self-similar patterns (Turner and Romme 1994, Peterson 2002, Hessburg and Agee 2003, Bigler *et al.* 2005, Skinner *et al.* 2006, North and Keeton 2008, Moritz *et al.* 2011). This temporal and spatial variability in vegetation and fuels has been substantially altered by human activities and are key features that must be included in restoring dry forest ecosystems.

Past Management Actions

Over the past two centuries, Euro-American settlement has substantially transformed the inland northwest of the U.S. Anthropogenic activities that have altered the landscape include timber harvesting, mining, livestock grazing, fur trapping, constructing roads and rail lines, development of towns and settlements, agricultural conversion, fire suppression and fire exclusion. These activities have so altered the patterns of vegetation and fuels, and subsequent disturbance regimes, that contemporary landscapes no longer function as they did historically (Hessburg *et al.* 2000a, 2005, Hessburg and Agee 2003, Skinner *et al.* 2006, Skinner and Taylor 2006).

Fire exclusion, combined with the removal of fire-tolerant structures (*e.g.,* large, fire-tolerant tree species such as ponderosa pine, western larch, and Douglas-fir), have reduced the resiliency of the landscape to fire and other disturbances, at least in those forest types outside of the wetter, higher severity fire regime types (Agee 1993, Hessburg *et al.* 2000a, Hessburg and Agee 2003). In the eastern Cascades of Washington and Oregon, forest types that historically had understories of grass and shrubs have shifted to shade-tolerant conifer understories which are denser and less tolerant of fire than historic understories. This has resulted in an overall increase in the area of fire-intolerant forest-types at the expense of fire-tolerant forest types (Hessburg *et al.* 2000a, Hessburg and Agee 2003). Additionally, these understories compete with fire-tolerant tree species for limited water, thus exacerbating drought stress on the structural components that will be important in restoring dry forest ecosystems. These understories result in an altered fuel bed that exhibits increased flame length, fireline intensity and rate of spread over historic understories, putting any remnant fire-tolerant structural features at greater risk of loss to fire (Hessburg *et al.* 2000a).

In addition to the stand structure, the spatial distribution of these stands also influences fire activity across the landscape. The spatial distribution of fire intolerant-stands among the fire-tolerant stands has been fundamentally altered through past management. Past management has homogenized the patchy vegetative network and reduced the complexity that was more prevalent during the pre-settlement era (Skinner 1995, Hessburg and Agee 2003, Hessburg *et al.* 2007, Kennedy and Wimberly 2009). Therefore, rather than existing as patches of fire-intolerant vegetation types being spatially separated, they have become more contiguous, and are more prone to conducting fire, insects, and diseases across large swaths of the landscape (Hessburg *et al.* 2005). This homogenized landscape may be altering the size and intensity of today's fires and further altering landscape functionality (*e.g.,* Everett *et al.* 2000). This alteration in the disturbance regime further affects forest structure and composition. Not only do these landscapes not exhibit the structure or function that they historically had (Hessburg and Agee 2003, Naficy *et al.* 2010), the shift from fire and drought-tolerant species to shade-tolerant species is a shift in the opposite direction in terms of forest types that will be most resilient to projected future climates (Haugo *et al.* 2010).

Projected Effects of Climate Change in Dry Forest Ecosystems

The implications of climate change on dry forest ecosystems are multi-faceted. The effects and interrelationships are complex and not fully understood. A comprehensive treatment of this topic is beyond the scope of the recovery plan.

Instead, we lay out some of the possible implications of climate change on ecosystem structures and processes that are relevant to dry forest management, and restoration and spotted owl recovery.

Mean temperatures have increased in the Pacific Northwest and northern California. Models project an even more substantial increase than what occurred over the twentieth century (Cayan *et al.* 2008, Mote and Salathe 2010). Seasonally, most models predict the greatest increases during the summer rather than winter months (Cayan *et al.* 2008, Mote *et al.* 2010). Regional models that further consider local geographical features show an increased warming above global model predictions. For example, the loss of snowpack in the Cascades is projected to increase temperatures above those projected in the global models, likely due to the increased heat absorption caused by snowpack loss. This results in many areas of the Cascade Range showing greater rates of winter and spring warming, which is expected to hasten the loss of snowpack and further increase drought stress on trees (Salathe *et al.* 2008), as well as lengthen the fire season (Westerling *et al.* 2006).

The magnitude and direction of changes in mean annual precipitation in the Pacific Northwest and northern California are less clear than for temperature (Cayan *et al.* 2008, Westerling and Bryant 2008, Mote and Salathe 2010). This region is located in a transition zone between projected increased precipitation in the southern portion of North America and projected decreased precipitation in the northern part of the continent (Mote and Salathe 2010). Model projections for northern California range from slight increases in precipitation to decreases of 10-20 percent, with no noticeable change in seasonal precipitation (Cayan *et al.* 2008). In the Pacific Northwest, models are ambiguous in their projections of annual precipitation trends. Seasonal predictions are less ambiguous, however, with most predicting increased winter precipitation and decreased summer precipitation (Mote and Salathe 2010), though regional models project local differences (Salathe *et al.* 2008). Even if increases in annual precipitation should occur, summer water deficits in the Pacific Northwest are projected to increase by 2-3 times due to increased temperatures and decreased summer precipitation (Littell *et al.* 2010). Some projections call for decreases in the amount, frequency, and intensity of precipitation in drier parts of the world, including the western U.S., potentially increasing the vulnerability to drought (Sun *et al.* 2007), while in northern California, some models call for a slight increase in the number and magnitude of large precipitation events (Cayan *et al.* 2008). Due to increasing temperatures throughout the west, more precipitation is expected to fall as rain rather than snow, reducing snow accumulation. Snowpacks are already declining (Stewart *et al.* 2005) and showing decreased water content throughout western North America (Mote *et al.* 2005). Warmer temperatures are expected to result in snow continuing to melt earlier than in the past (Mote *et al.* 2005, Cayan *et al.* 2008), further increasing drought stress on dry forests.

Changes to the range and composition of current vegetation species are expected as local climates transform and become more favorable for some species and less favorable for others (van Mantgem *et al.* 2009, Allen *et al.* 2010, Haugo *et al.* 2010, Littell *et al.* 2010, Shafer *et al.* 2010). For example, Littell *et al.* (2010) predict a 32 percent increase in the area of forests in Washington that will be severely water-limited by the 2020s, with further increases of 12 percent by 2040 and another 12 percent by 2080. Specific to the range of the spotted owl, this effect is most likely to occur in the eastern Cascades in the northern part of the state. As a result, shifts in the range of Douglas-fir and several pine species are expected (Littell *et al.* 2010). A statewide analysis of forests in California indicates evergreen forests will decline while mixed evergreen forests will increase under all climate scenarios modeled (Lenihan *et al.* 2008). Total forest cover is expected to increase by 23 percent statewide in California under the cooler and wetter climate scenarios, whereas forest cover is projected to decrease by 3 and 25 percent under the warmer and drier models used (Lenihan *et al.* 2008). Where climate becomes less suitable for tree species, particularly in areas that become drier, these tree species are likely to decline in growth and become more vulnerable to mortality agents such as fire or insects that may result in large-scale mortality (Littell *et al.* 2010).

Increased mortality rates of trees have already been attributed to drought and heat stress caused by increasing temperatures (van Mantgem *et al.* 2009, Allen *et al.* 2010). Mortality is expected to increase further as temperatures warm and drought stress increases, even in systems that are not water limited (Allen *et al.* 2010). Water limitation is expected to increase across a significant portion of the eastern Cascades of Washington (Littell *et al.* 2010). The degree to which trees may succumb to drought stress is not entirely clear, however, when one considers other effects brought on by climate change. The increase in atmospheric CO_2 is expected to have a fertilization effect on tree growth, allowing them to more efficiently use water and reduce their susceptibility to drought stress (Huang *et al.* 2007). However, this efficiency may not be sustainable in the long-term (Huang *et al.* 2007, Lindroth 2010). For example, CO_2-enhanced growth may diminish over time as other nutrients become limited; specifically, as nitrogen demand and its subsequent storage in plant biomass increase, its availability to plant growth is expected to decrease, resulting in systems becoming nitrogen limited (Huang *et al.* 2007, Lindroth 2010). Others project that warmer temperatures will eventually increase water stress and evaporative demand, regardless of precipitation amount or water use efficiency (Nielson *et al.* 2006, Barber *et al.* 2000).

The effect of changing disturbance regimes such as fire and insects will likely be more abrupt and rapid than the changes in vegetation composition, distribution, and productivity in response to climate change (Littell *et al.* 2010). Interactions among these disturbances can alter forest structure and function more rapidly than what is predicted to occur through modeling of vegetation redistribution or disturbance alone. In periods of rapid climate change during the Holocene, fire was often the catalyst for changing vegetation (Whitlock *et al.* 2003). How climate change affects fire regimes will vary with the energy or water limitations of the varying ecosystems (Littell *et al.* 2009). In energy-limited wildfire regimes (*e.g.,* ecosystems with abundant fuels, such as productive forests), increasing temperatures are likely to substantially increase fire risk, regardless of precipitation; conversely, in moisture-limited regimes (*e.g.,* particularly dry ecosystems with limited fuels such as grass and shrublands), changes in both temperature and precipitation will influence their fire risk (Westerling and Bryant 2008). Predicting specifics of disturbance processes is difficult not only because of the uncertainties in the climate models, but also the synergistic interactions among disturbance agents (*e.g.,* Simard *et al.* 2011). In addition, there are other variables not easily modeled that will likely affect disturbance processes under future climate scenarios (Fried *et al.* 2004, Spracklen *et al.* 2009, Littell *et al.* 2010). These include changes in vegetation composition and distribution, as well as changes in ignitions caused by changing climate or by human activity. For example, while mountain pine beetle attacks are projected to be more successful, it is not known how changes in the range of beetles and host trees may affect this success. If vegetation range changes occur rapidly as a result of increased fire, a subsequent spatial heterogeneity across the landscape could substantially reduce the risk of beetle outbreaks (Littell *et al.* 2010).

Multi-year climatic patterns tied to sea surface temperatures in the Pacific Ocean have been linked to fire activity within the Pacific Northwest. Specifically, the El Niño-Southern Oscillation (ENSO) results in an alteration of temperature and precipitation patterns that cycle, on average, every four years, though annual cycles occur (Mote *et al.* 2010). The Pacific Decadal Oscillation (PDO) is a manifestation of ENSO which cycles between cool and warm phases every 20-30 years (Mantua *et al.* 1997). Prior to the onset of fire exclusion in the 20th century, increased fire activity has been associated with warm phases of the PDO (Hessl *et al.* 2004, Heyerdahl *et al.* 2008). Gedalof *et al.* (2005), however, found no difference in fire activity in the latter half of the 20th century between warm and cool phases of the PDO, but they did find a relationship with smaller scale annual and inter-annual variability in the PDO. The PDO entered a warm phase in 1977 (Mantua *et al.* 1997), and it may now be reversing into a cooler phase (JPL 2008), or it may be losing its decadal persistence (Mote *et al.* 2010, NOAA 2011). Given past associations between fire activity and PDO, it could be argued that the next several decades will result in a decrease in fire activity in the Pacific Northwest. However, making such an inference of cause and effect should be done with caution (Hessl *et al.* 2004). The onset of fire exclusion in the 20th century may confound associations of fire activity with PDO (Mote *et al.* 1999). Furthermore, our understanding of how ENSO and PDO will respond to climate change and our ability to extrapolate their influence on disturbance regimes is poor (McKenzie *et al.* 2004).

Though there is uncertainty with how climate change may specifically alter fire regimes, McKenzie *et al.* (2004) proposed several inferences that can be made given our understanding of fire-climate interactions and our understanding of vegetation response to fire. The first inference is that warmer and drier summers will produce more frequent and extensive fires. Second is that reduced snowpack and earlier snowmelt will likely extend the time span of moisture deficits in water-limited systems. Finally, drought stress on plants will increase as a result of the drier conditions and longer moisture deficits, increasing their vulnerability to other multiple disturbances such as fire and insects; these disturbances often have a synergistic effect.

Evidence is already accumulating to support some of the inferences made by McKenzie *et al.* (2004). The frequency of large (>400 hectares) wildfires and the total area burned by these fires has substantially increased in the western U.S. (Westerling *et al.* 2006), despite active fire suppression. Westerling *et al.* (2006) links this trend to an increase in spring and summer temperatures and earlier spring snowmelts, both of which can result in earlier and longer fire seasons. Given the link between climate and wildfire activity, the authors underscore the urgency to ecologically restore forests that have undergone substantial alterations from past land uses. Specific to California and the Pacific Northwest, an analysis of wildland fires between 1984-2005 showed a significant trend of increasing average fire size, and what appears to be a trend towards an increasing proportion of area burned as a result of large fires (Schwind 2008). Trends in burn severity were less conclusive.

Various authors have projected increases in fire potential in response to projected climate changes, both globally (*e.g.,* Liu *et al.* 2010) as well as in areas encompassing parts or all of the spotted owl range. Littell *et al.* (2010) predicted for Washington that by the 2080s, there will be two to three times as much area burned as what burned between 1916 and 2006; specific to the forested ecosystems of the eastern Cascades, Littell *et al.* (2010) predict a near doubling by the 2080s of the mean area burned between 1980 and 2006 (from 63,000 to 124,000 ha). Westerling and Bryant (2008) projected a 15-90 percent increase in fire in northern California by 2070-2099. Though unquantified, an increase in fire activity is expected in all forest types in Oregon (Shafer *et al.* 2010). Spracklen *et al.* (2009) projected that Pacific Northwest forests will experience some of the greatest increases in mean annual area burned in the western U.S., with a projected increase of 78% by 2050 over that burned between 1996-2005. Whitlock *et al.* (2003) suggest that fire frequency or severity may increase under climate projections. However, in areas where changing climate is expected to reduce combustible vegetation, fire activity could decrease (Westerling and Bryant 2008, Krawchuk *et al.* 2009).

Frequent and extensive outbreaks of native forest insects, such as bark beetles and spruce budworm, have occurred historically in the western U.S. (*e.g.*, Amman and Cole 1983, Brookes *et al.* 1987, Swetnam and Lynch 1989, Hessburg *et al.* 1994). However, anthropogenic influences through past management and fire suppression have altered the landscape vegetation patterns, subsequently altering the timing, duration and magnitude of outbreaks (Swetnam and Lynch 1989, Hessburg *et al.* 1994). Climate change is predicted to further exacerbate the situation by redistributing forest insects as well as intensifying all aspects of forest insect outbreak behavior (Logan *et al.* 2003). Temperatures drive the life history of insects and determine their geographic range. As highly mobile species living in a warmer world, insects are expected to readily expand their range and invade new habitats (Logan *et al.* 2003). Increased CO2 levels may further favor sap-feeding insect species such as bark beetles (Whittaker 1999). Yet predicting specific responses is difficult because climate relationships with some forest insect outbreaks are poorly understood (*e.g.*, see Swetnam and Lynch 1993 regarding spruce budworm).

Recent bark beetle outbreaks have exceeded the magnitude of outbreaks documented during the prior 125 years in parts of the U.S. (Raffa *et al.* 2008). It appears that human activities have influenced recent increases in bark beetle activity (Logan and Powell 2001, Logan *et al.* 2003). Changing climate, particularly increased temperature and drought, combined with management that has favored continuous, uninterrupted distributions of host tree species (*e.g.,* Douglas-fir and true fir species), tend to foster outbreaks (Hicke and Jenkins 2008, Raffa *et al.* 2008). Unusually hot and dry weather is already responsible for increased insect outbreaks in forests in several North American localities, from pinyon pine in the southwest U.S. (Breshears *et al.* 2005) to lodgepole pine forests in British Columbia where the beetle outbreak is larger than any recorded in Canada (Carroll *et al.* 2004 as cited in Whitehead *et al.* 2006, Taylor *et al.* 2006). In addition, increased stand densities of lodgepole pine have increased their susceptibility to bark beetle outbreaks throughout the western U.S. (Hicke and Jenkins 2008). There is evidence of irruptive thresholds being crossed by insects in Alaska and British Columbia, whereby the outbreak continues in a self-sustaining mode even after the extreme drought conditions that initiated the attack have subsided (Raffa *et al.* 2008). However, not all outbreaks appear to be exceeding known historical magnitudes. In Colorado for example, mountain pine beetle activity does not exceed historical activity levels, although the insects are moving outside of their known historical range and into higher elevation (Romme *et al.* 2006); the authors, however, point out that it is difficult to know if this movement is truly outside of their historical range given the lack of historical data on beetle distributions.

With respect to forest pathogens, Kliejunas *et al.* (2009) summarize the literature on the relationship between climate change and tree diseases in western North America. They note that while there is great uncertainty with how specific pathogens will respond to climate change, general inferences can be made, all of which can vary by ecosystem and specific climate conditions. Similar to forest insects, pathogen distributions are expected to change, including invasion of new areas by nonnative pathogens. The epidemiology of plant diseases is also expected to change, complicating the prediction of disease outbreaks. The rate that pathogens evolve and overcome host resistance may increase in a rapidly changing climate. With increasing temperatures, we should expect an increase in overwintering survival of pathogens, as well as an increase in disease severity. Predicted drought stress on many host species will increase their vulnerability to, and exacerbate the effect of, many pathogens. Finally, with the exception of extremely dry conditions, climate change may alter fungal pathogens that could have a profound change on rates of wood decay, shortening the length of time valuable legacies like down wood can be retained in the ecosystem (Yin 1999).

Interactions between disturbance processes also need to be considered, but are not well understood. For example, the fuel composition created by mountain pine beetle outbreaks in lodgepole pine is thought to facilitate the stand-replacing fires favorable to lodgepole reproduction (Logan and Powell 2001). However, the evidence is mixed as to whether insect mortality increases the risk or severity of fire (Fleming *et al.* 2002, Bebi *et al.* 2003, Hummel and Agee 2003, Lynch *et al.* 2006, Parker *et al.* 2006, Romme *et al.* 2006, Kulakowski and Veblen 2007, Jenkins *et al.* 2008, Simard *et al.* 2011). Some studies recorded situations where probability or severity of burns was higher in beetle-killed stands than in control stands (Bigler *et al.* 2005, Lynch *et al.* 2006). Others found no difference in severity or probability of fires occurring in beetle-killed stands compared to control stands (Bebi *et al.* 2003, Lynch *et al.* 2006, Kulakowski and Veblen 2007). Furthermore, high-severity fires that did occur were consistent with the typical fire regime of affected forests, even without the insect outbreaks (see Romme *et al.* 2006). Still other research has found that the likelihood of active crown fire was actually reduced in beetle killed stands than in control stands, potentially due to decreases in the canopy fuels caused by beetle mortality (Simard *et al.* 2011). Finally, Bigler *et al.* (2005) observed that while beetle outbreaks may have contributed to fire severity, other contributors such as pre-fire stand structure and composition were more of an influence.

At a minimum, insect outbreaks substantially alter the fuel complex and ultimate vegetative composition within a stand (Jenkins *et al.* 2008), and such alteration can potentially affect fire activity. Insect mortality does more to affect fire behavior than just increase the dead fuel load. The removal of overstory canopy can decrease the surface fuel moistures, alter understories, and allow for greater wind speeds through the stand, which can affect fire behavior. These changes in stand structure and composition may be more influential drivers of fire risk and severity than the actual direct increase in fuels caused by beetle outbreaks (Bigler *et al.* 2005, Lynch *et al.* 2006). These factors change through time and will influence the behavior of fires that enter the stand at any given time. In short, the relationships between insects and fire are complex with no simple, single conclusion that can be drawn (Romme *et al.* 2006).

In summary, the implications of climate change on dry forest ecosystems are broad and multi-faceted. Though models are not all in agreement, it appears likely that there will be at least some level of summer water deficit, even if overall precipitation increases. This increase in water limitation increases the risk of fire activity and creates drought stress on trees, making them more susceptible to insect attacks. Interactions among these disturbances can have synergistic effects. The existing condition of increased stand densities and decreased landscape heterogeneity further exacerbates the vulnerability of these systems to disturbance, as well the potential magnitude and intensity of the event itself, particularly in those fire regimes that were predominately of mixed- and low-severity (Schoennagel *et al.* 2004, Keeton *et al.* 2007). Ecosystem functions that are already altered due to past management will be further altered with projected climate change.

Effects of Fire on Spotted Owl Habitat

Research on all three spotted owl subspecies indicates variability in the degree to which spotted owls use post-fire sites, depending on fire severity and the function of the site for spotted owls (*i.e.*, nesting, roosting, or foraging). A few studies have looked at spotted owl occupancy of nesting territories and survival rates in burned areas. In southwest Oregon, lower occupancy and survival rates of northern spotted owls were found in burned areas compared to unburned areas, but the results were confounded by prior management of the area and harvest after the fire (Clark 2007, Clark *et al.* 2011). Jenness *et al.* (2004) found decreased occupancy of Mexican spotted owls in burned areas compared to unburned areas, although the authors considered the relationship statistically weak. Roberts *et al.* (2011) found no difference in occupancy of California spotted owls between burned and unburned areas, although their burned areas were predominately of low and moderate severity. Bond *et al.* (2002) compared survival rates of all three subspecies of spotted owls in burned sites with overall survival estimates recorded in the literature and found them to be similar.

Spotted owl reproduction and nesting have been observed in burned landscapes and in core areas in which some portion was burned by high-severity fire (*i.e.,* fires with typically 70-100% overstory mortality). It is not known whether there is a maximum amount of high severity fire within a nesting core that would preclude nesting of spotted owls, and there have been no long-term studies to determine how long spotted owls may remain in a burned-over area. Specific to the actual nest tree, Bond *et al.* (2009) did not find any of their four nest trees located in a high severity burn. Nest trees, however, have been observed in patches with low to moderate severity burn (Gaines *et al.* 1997, Clark 2007, Bond *et al.* 2009). For spotted owls nesting in burned areas, reproductive rates are generally similar to unburned areas (Gaines *et al.* 1997, Bond *et al.* 2002, Clark 2007).

While spotted owls have been observed roosting in forests experiencing the full range of fire severity, most roosting owls were associated with low or moderate severity burns (Clark 2007, Bond *et al.* 2009). Specifically, Bond *et al.* (2009) found spotted owls selecting low severity burns for roosting and avoiding high severity burns. In addition, roost sites from which stand measurements were taken had high levels of canopy closure (*i.e.,* greater than 60 percent) and a large tree component, regardless of burn severity (Clark 2007, Bond *et al.* 2009). Spotted owls have been observed foraging in forest areas that experienced fire events of all severities, and seemed especially attracted to edges where burned forest met unburned stands (Clark 2007, Bond *et al.* 2009). This is consistent with other observations of spotted owl habitat use in the Klamath Province, where increased edge between old-growth forest and other vegetation types were important habitat components (Franklin *et al.* 2000). Clark (2007) found that spotted owls did not use large patches of high severity burns, and Bevis *et al.* (1997) found spotted owls shifting their use away from areas burned at a higher severity to those burned at a lower severity; however, the results in both studies may be confounded due to post-fire logging that occurred in the burn areas. Bond *et al.* (2009) found owls selecting burned areas, including high-severity burns, over unburned areas for foraging when those areas were within 1.5 kilometers of a nest or roost site. Bond *et al.* (2009) postulated that selecting burned patches over unburned patches for foraging may be due to increased presence of prey, such as the dusky-footed woodrat, a species associated with open stands and increased shrub and herbaceous cover.

It is unknown whether spotted owl selection of high-severity burns for foraging would prevail in that portion of its range where dusky-footed woodrats are not available (eastern Washington Cascades and most of eastern Oregon Cascades). In these areas, northern flying squirrels are the principle prey species (Forsman *et al.* 2001, 2004, Sztukowski and Courtney 2004) and are more closely tied to closed canopy forest (Lehmkuhl *et al.* 2006a, b). It is difficult to tease out the relationship between prey abundance and prey selection by spotted owls, but studies suggest that variability in diet among spotted owls may be due to spatial variation in prey abundance (Forsman *et al.* 2001, 2004, Roberts and van Wagtendonk 2006). The degree that other prey species are available to spotted owls in post-burn areas outside of the range of the dusky-footed woodrat may affect their use of post-fire landscapes in this area.

There is evidence of spotted owls occupying territories that have been burned by fires of all severities. The limited data on spotted owl use of burned areas seems to indicate that different fire severities may provide for different functions. For example, spotted owls appear to select high severity burns for foraging, but avoid roosting or nesting in these sites. However, there are multiple confounding factors and uncertainties in the data on this topic which limit the strength of the conclusions that can be drawn. Few studies occur in areas where post-fire logging has not taken place, which confounds conclusions regarding non-use of burned areas. Studies that looked at habitat use by radio-marked spotted owls either have low sample sizes or suffer from other confounding effects. For example, Clark (2007) had the largest sample size of radio-marked spotted owls (n=26), but interpretation is confounded by prior management history as well as logging that occurred in the burned area post-fire. The largest sample size of radio-marked spotted owls monitored in burned areas that were not harvested post-fire was seven (Bond *et al.* 2009).

There are no long-term studies to look at how spotted owl habitat use of these sites changes through time since the burn; so far, habitat use studies have all occurred within four years of the fire. Survey information on spotted owls is not always adequate to allow rigorous comparison of spotted owl occupancy in the burn area before and after fire. Likewise, when adequate occupancy data is available pre-fire, the fate of spotted owls tied to sites that are deemed unoccupied after fire are often unknown; whether these spotted owls died in the fire, abandoned the area, or shifted their use to alternate sites within or adjacent to the burned area is rarely known. It is not clear whether spotted owls outside the range of the dusky-footed woodrat, a species tied to habitats consistent with the early seral conditions created by fire, would show similar use of burned areas as those spotted owls in areas where this prey species is available. Finally, we have a poor understanding of how spotted owl occupancy and habitat use are affected by the geographic scale of the disturbance, as well as the spatial arrangement and amount of unburned patches and patches exhibiting different burn severities within a home range. We can conclude that fires are a change agent for spotted owl habitat, but there are still many unknowns regarding how much fire benefits or adversely affects spotted owl habitat.

Restoring Dry Forest Ecosystems

Dry forest ecosystems exhibit tremendous complexity in structure and process, as well as in the relationships among and within biotic and abiotic components. Historically it was topography and disturbance regimes such as insects and fire that shaped the distribution and composition of vegetation across the landscape, with patches of shade-tolerant and fire-intolerant conifers spatially isolated from one another in the drier forest types. The disturbance regimes, along with the vegetation structure, composition and distribution have been substantially altered since Euro-American settlement. As a consequence, dry forest systems no longer function as they once did (Hessburg *et al.* 2005). There is not agreement on some regime descriptions within the range of the spotted owl (*e.g.,* Hanson *et al.* 2009, 2010, Spies *et al.* 2010b), and our understanding of fire regimes in certain dry forest types is changing (*e.g.,* Hessburg *et al.* 2007, Perry *et al.* 2011). Complicating the matter is the ongoing climate change that will likely increase the stressors on these systems. We may accurately predict some ecosystem changes and not others, but we can be confident that dry forest ecosystems will change in the face of projected climate change. Consequently, there are risks in any management decision we make, whether it be action or no action, active or passive management (Agee and Skinner 2005). Any actions we take should move dry forest systems on a path that will develop and retain the resiliency in the ecosystem to adequately respond to whatever changes do occur. The key to developing that resiliency is to restore the inherent forest structure and composition and to reintegrate the relationship between forest vegetation and the disturbance regimes.

As noted earlier in this document, our intent in this Revised Recovery Plan is to embed spotted owl conservation and recovery within broader dry forest ecosystem restoration efforts to increase the likelihood spotted owl habitat will remain on the landscape longer and develop as part of this fire adapted community instead of being consumed by uncharacteristic wildfires. Herein we borrow from original objectives described in SEI (2008). Our first objective is to develop and maintain adequate spotted owl habitat in the near term to allow spotted owls to persist in the face of threats from barred owl expansion and habitat alterations from fire and other disturbances. The second objective is to restore landscapes that are resilient to fire and other disturbances in the near term, and more resilient to alterations projected to occur with ongoing climate change. The final objective is to restore function of a variety of ecological services provided by late-successional and old forests. It is not our intent, nor do we believe it would be consistent with the above objectives, to do landscape-wide treatments for the purpose of excluding disturbance events such as fires, including high-severity fires. On the contrary, we are looking to support the disturbance regimes inherent to these systems and believe our management should be consistent with the counsel of Hessburg *et al.* (2007:21):

> "Restoring resilient forest ecosystems will necessitate managing for more natural patterns and patch size distributions of forest structure, composition, fuels, and fire regime area, not simply a

> reduction of fuels and thinning of trees to favor low severity fires."

We define resiliency as the "ability of a system to absorb change and variation without flipping into a different state where the variables and processes controlling structure and behavior suddenly change (Holling 1996:734-735)." Key to managing systems for resilience are to keep options open, view events in a regional rather than local context, and to manage for heterogeneity (Holling 1973). Furthermore, managers need to acknowledge our limited understanding and assume that unexpected events will happen. Therefore, managing for resilience does not require the need for precision in predicting future events, "but only a qualitative capacity to devise systems that can absorb and accommodate future events in whatever unexpected form they may take" (Holling 1973:21).

To accommodate future disturbances and restore ecosystem resiliency, we believe it is essential to restore ecosystem structure, composition and processes. Restoring ecosystem structures that provide resiliency will necessitate maintaining and restoring the biological legacies that typically persist through disturbance events and influence the recovery process in the post-disturbance landscape (Franklin *et al.* 2000). With respect to the dry forest landscapes, structural legacies include not only the large trees that tend to be fire tolerant, but the snags and downed wood that were created as a result of the disturbance event. Structural legacies serve valuable functions such as reproductive structures that facilitate plant propagation, modifying microclimates, or improving connectivity through the disturbed area (Franklin *et al.* 2007).

Restoring ecosystem composition that provides resiliency will necessitate managing for vegetative heterogeneity both within and among stands. Compositional, as well as structural heterogeneity, are influenced by tree growth and decline, competition among plants and the resulting mortality, as well as small-scale disturbances (Franklin *et al.* 2002, 2007). Heterogeneity in the patterns of vegetation composition and structure are key features of resilient forests (*e.g.,* Stephens *et al.* 2008). Complex arrangements and spatial patterns of vegetation produce a similar variability in fire behavior and effect, maintaining ecosystem heterogeneity (Stephens *et al.* 2010).

Restoring ecosystem processes that provide resiliency will aid in developing the vegetation structures, composition, patterns, and distributions advocated above. This would include managing for high-severity disturbance events in the appropriate landscape context. High severity fires, for example, provide valuable habitat for fire-dependent species (*e.g.,* Hutto 2008), as well as important seral conditions that contribute to biodiversity (Swanson *et al.* 2010). Conversely, specific locations on the landscape may be identified where it is desirable to manage the vegetation so that fire severity is reduced (*e.g.,* in wildland urban interface or in areas where human activities have increased available fuel (see Odion *et al.* 2004), or in areas where it is desirable to reduce the risk to valued structural legacies).

We believe restoring ecosystem processes will contribute to developing and maintaining ecosystem structure and heterogeneity, increasing the resiliency to disturbance events and ongoing climate change (Schoennagel *et al.* 2004, Fettig *et al.* 2007, Hessburg *et al.* 2007, Klenner *et al.* 2008, Stephens *et al.* 2008, 2010). Restoring these features would further allow the disturbance processes to play their inherent role in maintaining these features (Noss *et al.* 2006). The following treatment principles were derived from multiple sources (SEI 2008, Gaines *et al.* 2010, Hanson *et al.* 2010). We believe them to be consistent with the stated objectives above, and will be important to accommodating future disturbances and restoring ecosystem resiliency. These principles should be part of any dry forest restoration treatment:

1. Emphasize vegetation management treatments outside of spotted owl core areas or high value habitat where consistent with overall landscape project goals. The proportion of Federal land in the dry forest provinces that is currently spotted owl habitat ranges from 18 percent in the Eastern Washington Cascades to 42 percent in the Oregon Klamath Province (Davis and Lint 2005, Davis and Dugger in press). Thus, there are many opportunities to restore ecosystem components in areas that will have little direct effects on spotted owls. Where treatments will occur within spotted owl core areas or high value habitat, we recommend monitoring owl response to treatments or apply treatments as part of an adaptive management process to improve our understanding of how these activities affect spotted owls.

2. Design and implement restoration treatments at the landscape level. Treatments need to be placed in context with the surrounding landscape to be most effective and to accommodate the inherent disturbance regime (see USDA 2010).

3. Retain and restore key structural components, including large and old trees, large snags and downed logs. Retaining these structural features will conserve habitat, legacy, seed stock, and genetic values. In addition, vegetation management to reduce moisture competition and improve the vigor of these older trees will also be necessary. An emphasis should also be placed on retaining tree species that are fire and drought tolerant in those vegetation types that exhibit fire regimes typically of low or mixed severity or typically dominated by predominately a surface -fires regime. However, older trees likely present before fire exclusion should also be retained, regardless of their fire tolerance.

4. Retain and restore heterogeneity within stands (*i.e.,* manage for fine-scale mosaic within stands). This includes both vertical and horizontal diversity.

5. Retain and restore heterogeneity among stands (*i.e.,* manage for meso-scale mosaics across a landscape). Retain patches of denser, moister forests that are good quality spotted owl habitat, as appropriate, within the landscapes where fire may be more frequent but less severe, consistent with historic variability or modeled future variability, and

where its occurrence maintains and provides for desired levels of species and structural diversity.

6. Manage roads to address fire risk.
7. Use wildfires to meet vegetation management objectives where appropriate.

Some form of vegetation management will be necessary to address many of the restoration principles described above. This can be done through a variety of methods, including mechanical removal such as thinning, prescribed burning, or using naturally ignited fires burning within a specified prescription to meet ecological objectives (*i.e.*, wildland fire for resource use). There are risks associated with these treatments in their potential to disturb soils, affect long-term productivity, and increase the risk of exotic plant invasions. Managers need to account for and minimize these risks as they plan and implement restoration treatments. There is also limited information on the effects of these types of treatments on spotted owls; the few studies that have looked at effects of thinning on spotted owls were limited to prescriptions designed to increase stand productivity and decrease stand complexity rather than improve stand structure for spotted owl. To fill this knowledge gap, restoration treatments implemented inside spotted owl core areas or high value habitat should be initiated under a monitoring or adaptive management study to test their effects on spotted owl occupancy, demographic performance and habitat use.

Restoring the large and old fire-tolerant trees and structure requires more than simply retaining them where they are found. In places where fire exclusion or past management has increased the density of surrounding trees, the densities of these smaller trees will need to be reduced to decrease the competition for water and resultant susceptibility to drought stress and insect attack (Thomas *et al.* 2006). Reducing the stand basal area around residual target trees, including large trees present prior to settlement, can be effective in improving the vigor of several tree species (Larsson *et al.* 1983, Feeney *et al.* 1998, Kolb *et al.* 1998, Latham and Tappeiner 2002). This increased vigor helps individual trees to withstand drought stress and better ward off attacks from sap-feeding insects such as bark beetles (Amman and Logan 1998, Schmid and Mata 2005, Fettig *et al.* 2007), but only if done before an outbreak begins (Shore *et al.* 2006, Romme *et al.* 2006). Thinning to improve tree vigor may not be as effective in reducing a stand's susceptibility to defoliating insects, such as western spruce budworm (Muzika and Liebhold 2000), but it may reduce insect densities and ultimate stand damage if the treatment is focused on reducing the tree host species within the stand (Swetnam and Lynch 1993, Su *et al.* 1996).

Mountain pine beetles, at least in lodgepole pine stands, tend to prefer larger trees (Safranyik and Carroll 2006). Their preference for tree size is less clear in ponderosa pine stands (Olsen *et al.* 1996, Negron and Popp 2004). Thus, while thinning lodgepole stands may improve tree vigor and resistance, the larger remnant trees may increase the likelihood of beetle colonization in the stand, particularly once an outbreak begins (Mitchell and Preisler 1991, Preisler and Mitchell 1993). This risk needs to be considered when managing vegetation to reduce risk of insect attack. Finally, when treating vegetation to reduce susceptibility to insect attack, care needs to be taken to ensure treatments do not increase risk of attack through injury (Jenkins *et al.* 2008).

Vegetation management for the purpose of altering fuels to modify fire behavior at specific locations can be effective (Omi and Martinson 2002, Pollet and Omi 2002, Martinson *et al.* 2003). This assumes, however, that surface fuels generated from the stand treatment were reduced or removed. Otherwise, severities can actually be higher with treatment (Weatherspoon and Skinner 1995, Raymond and Peterson 2005, Prichard *et al.* 2010). In addition, retaining structures that are fire resistant (*e.g.*, retaining the largest trees) will improve effectiveness (Omi and Martinson 2002, Agee and Skinner 2005). Fire severity, however, results from a complex interaction of fuels (including composition and moisture), topography (including slope percent , elevation, and aspect), and fire weather (including wind and temperature). Variations in each of these components and interactions among them will influence fire behavior and its resultant burn severity. Understanding how these components interact within local fire regimes is important to implementing effective restoration treatments. For example, thinning and underburning have resulted in lower fire severities than those observed in untreated stands across a variety of geographical areas and vegetation types (*e.g.,* Pollet and Omi 2002). However, the mixed evergreen forests of the Klamath Province may exhibit stand development pathways that result in different fire susceptibilities (see Perry *et al.* 2011). For example, lower fire severities were observed in stands with longer fire-free periods as well as in untreated stands with closed canopies or with larger, more mature forest conditions, when compared to treated stands (Weatherspoon and Skinner 1995, Odion *et al.* 2004, Alexander *et al.* 2006, Thompson and Spies 2009). Severities of past fires may be a major determinant of future fire severity; for example, in the Klamath Province, stands burned by high severity fires in the previous one or two decades have been observed to reburn at high severity (Odion *et al.* 2010, Thompson *et al.* 2007, Thompson and Spies 2010). Aspect and slope have been tied to fire severity is some areas (*e.g.*, Alexander *et al.* 2006) but not others (*e.g.*, Turner *et al.* 1999). Fire severity within a given patch may be affected by the surrounding landscape (*e.g.* Weatherspoon and Skinner 1995). Finally, extreme fire weather events can overwhelm a stand's resistance to fire, resulting in high severity burns regardless of the topography, fuel condition or prior management (Martinson *et al.* 2003, Skinner *et al.* 2006). Thus, treatments to reduce fire severity need to be strategically located and designed with specific objectives and a clear understanding of how the local landscape responds to the many variables that influence fire severity.

Fuel treatments have other limitations that need to be considered in their application. Treatments require maintenance if they are to remain effective (Agee and Skinner 2005, Reinhardt *et al.* 2008). In addition, treatments that are not maintained may actually result in fire behavior that is more deleterious than expected without treatment (Ager *et al.* 2007b). Finally, given the stochastic nature of fires, without extremely large-scale treatments that may be neither economically nor socially feasible, there is a low probability of fires intercepting fuel breaks (Rhodes and Baker 2008). However, modeling indicates that strategic placement can improve treatment leverage (*i.e.,* increase the ratio of acres experiencing reduced fire severity to acres treated) (*e.g.,* Loehle 2004, Schmidt *et al.* 2008). Fuel treatments need to be strategically located with clear objectives. They should not be used for the purpose of "fireproofing" the forest. Rather, they should be designed to increase the acceptability of wildfire through reducing fire behavior and severity in local areas, rather than simply to reduce fire occurrence, size, or amount of burned area per se (Reinhardt *et al.* 2008).

Vegetation management treatments that are strategically located in a landscape context are encouraged to restore structural elements, restore heterogeneity within and among stands, and which increase resiliency to future fires and other disturbance events. A necessity of any vegetation management treatment, regardless of its purpose, is to ensure that slash and other residual fuels generated as part of the project are adequately treated so as not to increase fire severity or risk (Agee and Skinner 2005). Treatments should allow us to incorporate future disturbance events as a means to restore and maintain desired ecosystem components and heterogeneity (Noss *et al.* 2006, Reinhardt *et al.* 2008). Prescribed fire may be a means to reintroduce fire as an ecosystem process, but will likely need to be implemented at scales much greater than what has been done in the past to be effective (Baker 1994, Taylor 2000); such a scale may not be socially or politically acceptable at this time (Stephens and Ruth 2005, Schulte *et al.* 2006). Developing wildfire management plans to allow the use of wildfires to meet vegetation management objectives is another tool that the Service encourages.

Need for Active Management

The characterization of fire risk in the dry forest provinces within the range of the spotted owl has recently been argued in the scientific literature (Hanson *et al.* 2009, 2010, Spies *et al.* 2010b). In short, Hanson *et al.* (2009) concluded that, given the low risk of high-severity fire in these provinces, there is time to conduct needed research to fill key information gaps before committing to a large-scale strategy of active management. We acknowledge the value that some high-severity fires may provide to spotted owls in areas where these effects have been studied, though there are many limitations with the existing data to make strong conclusions. We also agree with the authors that an adaptive management framework should be in place so that we can learn from our management efforts as we go forth, and have included an adaptive management discussion in this plan. However, given the highly altered condition of the existing dry forest ecosystem and the effects of ongoing climate change on the currently compromised functions, we believe restoration of dry forest ecosystem structures and processes must begin now and cannot wait for all key information gaps to be filled.

As an example, the Gotchen Risk Reduction and Restoration Project was designed to reduce fire risk and promote forest health in the Gotchen LSR and the surrounding landscape of the Eastern Washington Cascades on the Gifford

Pinchot National Forest. Forest health in the area had declined dramatically due to a history of selective timber harvest, fire suppression, and widespread tree mortality caused by insects and diseases (USFS 2003). The project included over 2,200 acres of strategic thinning and fuels treatments to reduce the risk of catastrophic wildfire including some degradation of spotted owl habitat deemed necessary to achieve the objectives of the project. Treatment areas included over 1,000 acres of suitable spotted owl habitat, but direct impacts to spotted owls were minimized by avoiding treatments near known spotted owl nest sites.

There are some questions under adaptive management that may be answered within the next several years, the results of which can be applied to future management decisions (*e.g.,* how do spotted owls use areas treated with specific vegetation management prescriptions intended to promote structural features conducive to spotted owl habitat?). Other questions, particularly population-based questions such as how spotted owls respond to disturbance processes, may take decades before clear conclusions can be drawn from those studies. The risk in waiting this long before pursuing restoration activities is a continued loss of valued ecological structures (*e.g.,* large, fire-tolerant trees) to increased drought stress that is projected with future climate change, as well as continued decoupling of vegetation patterns from disturbance processes. In the immediate future, we need to pursue restoration activities that are strategic and that focus on restoring and maintaining ecosystem structure, composition, patterns and processes with an eye towards maintaining resiliency in the face of future climate change.

We also stress this cannot be done successfully without an aggressive adaptive management framework to learn from treatments. Land managers should use pilot projects and active management to test or demonstrate techniques and principles (Noon and Blakesley 2006). In the near term, to reduce conflict and potential inconsistencies with existing Federal land management plans, we recommend locating such projects wherever possible in Matrix and Adaptive Management Areas. However, we continue to recommend that such actions be considered in LSRs as well (Gaines *et al.* 2010). An example of a site-specific plan that could be emulated in other areas is the Okanogan-Wenatchee National Forest Restoration Strategy (USDA 2010). This strategy applies many of the concepts described in this Plan to meet the overlapping goals of spotted owl recovery and ecosystem management.

Conclusions Regarding Dry Forest Management

Given the complexity of the disturbance regimes in dry forest systems, response of spotted owls to these disturbances, and the projected influence that climate change will play on these regimes, this Revised Recovery Plan recognizes that active management of vegetation within the dry forest landscape is needed to restore ecosystem resiliency consistent with spotted owl conservation objectives. Restoration of forest ecosystems that are resilient to the endemic disturbance regimes and adaptive to impending climate change is a primary goal of any dry forest recovery strategy and needs to include some form of active management to achieve that objective. Our knowledge is far from complete, and management to restore these systems will be challenging. These knowledge gaps need to be addressed through a well-defined adaptive management approach that reduces biological risk to the spotted owl and provides information to inform future management decisions.

The 2008 Plan called for establishing an interagency, science-based Dry forest Landscape Work Group (DFLWG) as a recovery implementation team to assist the Service in designing a strategy for managing the Klamath Provinces, the Eastern Washington Cascades, Eastern Oregon Cascades, and California Cascades Provinces. Shortly after publication of the 2008 Plan, the Service created another recovery implementation team, the Klamath Province Work Group to address dry forest issues in the Klamath Provinces, leaving the DFLWG to cover the Cascades portion of the dry forest landscape (To more clearly identify the geographic responsibility of the DFLWG, we are renaming it the Dry Cascades Work Group as part of this recovery plan). Both of these work groups were tasked with helping identify landscape-scale approaches to managing these areas based on the restoration of ecosystem processes.

- ***Recovery Action 7: Create an interagency Dry Cascades Work Group that is available to assist land managers in developing and evaluating landscape-level recovery strategies for the Eastern Washington, Eastern Oregon, and California Cascades Provinces, including monitoring and adaptive management actions.***

The DFLWG has been working to evaluate and develop landscape approaches to restoring forest ecosystem structure and processes in support of spotted owl recovery. The work group members represented a broad array of expertise in different technical fields from different geographical areas. Researchers and practitioners comprised the work group, and members brought forward different interpretations of the research in dry forest systems. After this plan is finalized, the Service will appoint a new recovery implementation team, the Dry Cascades Work Group, using a similar diverse array of expertise to continue this work and find areas of agreement upon which a strategy for the dry Cascades provinces can be developed.

This implementation team will be available to help local land management units with the design and development of new prescriptions and treatments for fuel reduction and other dry forest management strategies through training, workshops or other information transfer methods. It may also be asked to develop an integrated strategy for all the Eastern Washington, Eastern Oregon, and California Cascades Provinces. This may include:

1. Recommending relevant research.
2. Standardizing, to the extent possible, new recommendations for prescriptions and treatments for fuel reduction and other dry forest management to facilitate regional comparisons by meta-analysis and to maximize the scientific and management value of studies.

3. Standardizing, to the extent possible, experimental designs to assist with comparability across the region and to ensure statistically valid results.
4. Assisting in the development or evaluation of plans that include landscape specific habitat objectives, treatment strategies, and projected outcomes.
5. Developing monitoring techniques and coordinating effort. Given the uncertainties concerning sustaining spotted owl habitat in dry forest landscapes, monitoring is imperative. Characteristics that may be important to monitor in any dry forest landscape managed for spotted owl habitat include:
   - Total spotted owl habitat area and condition;
   - Dispersal habitat and condition;
   - Effectiveness of spatial isolation on spotted owl habitat clusters;
   - Pattern, amount, and timing of management activities and natural disturbances;
   - Preferred timing of follow-up treatments by area;
   - Patch recruitment potential and timing as replacement spotted owl habitat relative to fledging success; interactions with barred owls; and stand-level prey response to treatments, including habitat elements that support prey (mistletoe, snags, downed wood, forage lichens, truffle abundance);
   - Spotted owl response to habitat and dispersal areas; and
   - Occupancy breeding pairs or single spotted owls

- ***Recovery Action 8: In Eastern Washington, Eastern Oregon and California Cascades Provinces, analyze existing data on spotted owl occupancy pre- and post-fire and establish a consistent database to track owl occupancy response to fires across the dry Cascades provinces.***

Data currently exist that may aid our understanding of spotted owl occupancy of sites after a fire. Most National Forest units in these provinces annually monitor known spotted owl sites for occupancy, and they have accumulated occupancy data sets in burned and unburned areas. Members of the DFLWG have begun compiling and analyzing existing data on occupancy rates of spotted owls in burned and unburned sites, as well as fire extent and severity in the burned sites, to determine how fire influences occupancy rates of spotted owls. We anticipate the DCWG will continue this effort. Existing data on pre- and post-fire vegetation structure is also being analyzed to determine possible connections between pre-fire estimates of fuel loads, fire severity, and subsequent spotted owl occupancy to inform risk analysis efforts. These data should be entered into a database to track future data on spotted owl occupancy and fires. Data collection standards should be established to aid comparison of data among the provinces to aid in comparison across the provinces, though these standards will be subject to change if methodology improvements become available. This synthesis and analysis will inform land managers about how fuel loads in and adjacent to spotted owl habitats can be managed.

- ***Recovery Action 9: Create an interagency Klamath Province Work Group that is available to assist land managers in developing and evaluating landscape-level recovery strategies for the Oregon and California Klamath physiographic province, which include monitoring and adaptive management actions.***

The KPWG was formed as a recovery implementation team as a result of Recovery Action 8 in the 2008 Recovery Plan, and has been operating since 2008. During the course of several meetings and workshops in 2008 and 2009, the KPWG established a multi-step approach for evaluation of potential alternative conservation strategies for spotted owls in the Klamath Province, a combined view of the Oregon and California Klamath Provinces. The primary steps included: (1) conduct a thorough review of the literature, spotted owl data sets, and spatial information and synthesize into a report describing spotted owl habitat in the Klamath Province, and the role of fire in developing, maintaining, modifying, and removing spotted owl habitat at multiple scales; (2) use spatially-explicit predictive models, developed and validated using current spotted owl location data from the Klamath Province, to identify areas of high-value spotted owl habitat based on forest composition and structure, climate variables, and topographic features; and (3) integrate spotted owl habitat models with models of fire occurrence and severity patterns to identify and prioritize areas for habitat protection, habitat restoration, and fuels treatment. This implementation team will be available to help land management units with the design and development of new prescriptions and treatments for fuel reduction and other dry forest management strategies through training, workshops or other information transfer methods.

Spotted Owl Habitat Conservation on All Landscapes

This Revised Recovery Plan recommends building on the principles established in the NWFP to conserve and restore more occupied and high-value spotted owl habitat, including increased conservation of habitat on some Federal "Matrix" lands and the evaluation of potential contributions from State and private lands.

This Plan does not propose a new or revised mapped habitat reserve network and continues to recommend reliance upon the LSRs of the NWFP throughout the range of the spotted owl. In addition, the Service sought remand of the 2008 spotted owl critical habitat designation in a recent court case and will consider revisions to the designation, with a final rule to be published by the end of 2012. Critical habitat designation defines and maps those geographical areas essential to the conservation of the species. Particularly in light of the fact that a revised designation based on the latest and best available information is imminent, the

Service believes it is appropriate to use the critical habitat rulemaking process to identify any essential habitat areas for the spotted owl in addition to the LSR system.

Because of the value to spotted owls, it is likely that much of the LSR network that was originally established in the NWFP process will continue to serve as the foundation for the spotted owl recovery on Federal lands. We expect that recommendations made in this Revised Recovery Plan concerning active management of spotted owl habitat, if applied by land managers, will be beneficial to spotted owl conservation and thus may not be considered as having a significant adverse effect on the spotted owl or its critical habitat in the long-term. Final decisions concerning these and other issues will be made as part of the critical habitat revision and section 7 consultation processes.

Conserving Occupied and High Value Spotted Owl Habitat

The three main threats to the spotted owl are competition from barred owls, past habitat loss, and current habitat loss (USFWS 2008b). Despite the habitat protections of the NWFP, the most recent demographic analysis (Forsman *et al.* 2011) indicates that spotted owl populations are declining on 7 of the 11 active demographic study areas at about 3 percent annually range-wide. Scientific peer reviewers and Forsman *et al*. (2011) recommended that we address this downward demographic trend by protecting known spotted owl sites in addition to the retention of structurally-complex forest habitat.

The Service recommends conserving occupied spotted owl sites throughout the range, especially those containing the habitat conditions to support successful reproduction. This recommendation is especially important in the short-term, until spotted owl population trends improve (Forsman *et al.* 2011).

Conservation of important spotted owl habitat depends on the application of a two-tiered approach to forest land management decisions as follows:

1. Conserve spotted owl sites and high-value spotted owl habitat where possible in addition to Federal conservation blocks to provide additional demographic support to the spotted owl population (see Recovery Action 10, below).
    a. This recommendation includes currently occupied as well as historically occupied sites (collectively “spotted owl sites,” see Appendix G: Glossary of Terms).
    b. Work with land managers and spotted owl field scientists to develop prescriptions and approaches to implement this recommendation. At a minimum, this prescription should retain sufficient NRF habitat within the provincial core-use area and within the provincial home range to support breeding, feeding and sheltering.

2. Maintain and restore the older and more structurally complex multi-layered conifer forests on all lands (see Recovery Action 32 under Listing factor E).

It is clear that these two recommendations overlap. It is our hope that their application on Federal, State, and private lands will more effectively address the threats of competition with and displacement by barred owls, as well as the impacts of past and current habitat loss.

This recommendation can be justified at several scales. At the scale of a spotted owl territory, several studies have shown a positive association between spotted owl fitness and spotted owl habitat or a mosaic of habitat types (Franklin *et al.* 2000, Dugger *et al.* 2005, Olson *et al.* 2004). Additionally, Dugger *et al.* (in press) found an inverse relationship between the amount of old forest within the core area and spotted owl extinction rates from territories. At the population scale, Forsman *et al.* (2011) found a positive relationship between recruitment of spotted owls into the overall population and the percent cover of spotted owl NRF habitat within study areas. This multi-scale research suggests retention of spotted owl habitat within spotted owl territories positively affects demographic rates. Because spotted owls on established territories are likely to be more successful if they remain in those locations (Franklin *et al.* 2000), managing to retain spotted owls at existing sites should be the most effective approach to bolstering the demographic contribution of a habitat conservation network and the highest priority for land managers. Retention of long-term occupancy and reproduction at established spotted owl sites will require a coordinated and cooperative effort to craft management approaches tailored to regional, provincial or local conditions.

- ***Recovery Action 10 - Conserve spotted owl sites and high value spotted owl habitat to provide additional demographic support to the spotted owl population.***

For Federal lands, create an interagency scientific team to use the latest and best available habitat modeling information and other data to identify these high value areas. This recovery implementation team will make recommendations for areas to conserve and manage based upon the following criteria and considerations:

- Use of habitat modeling to better identify high value habitat, including consideration of abiotic factors that influence spotted owl usage.

- Use of demographic monitoring and survey data, if available, to inform other measures of value, such as maintaining population distribution in underrepresented areas or to reflect the most current habitat conditions.

- How retention of specific areas may affect probability of persistence of the spotted owl population at the province scale. Use this evaluation to establish "thresholds" for recommendations of which areas to conserve or not.

- Consideration of related barred owl impacts, influence, and management decisions and the likely success of such management actions in those areas.

The intent of this recovery action is to protect, enhance and develop habitat in the quantity and distribution necessary to provide for the long-term recovery of spotted owls. The Service will use the results of this effort to inform subsequent recommendations or decisions regarding the quantity and spatial configuration of habitat necessary to support the recovery of spotted owls. The spatial depiction informed by the habitat modeling efforts will better identify areas where land managers should consider protecting, enhancing and developing habitat to support recovery of spotted owls and, where appropriate, will seek additional public review and comment (*e.g.*, as part of proposed critical habitat). Where the modeling output and/or examination on the ground indicate that forest stands could and should be enhanced or developed through vegetation management activities to improve long-term habitat conditions, or to create improved habitat for spotted owls, larger habitat patches, or increased connectivity between patches, they should generally be encouraged even if they result in short-term impacts to existing spotted owls. However, such a process should occur where a determination is made that these longer term goals outweigh short-term impacts.

Interim Guidance

In the interim time period while the above team process is formalized and carried out, we recommend the following process be followed.

When planning management activities, Federal and non-federal land managers should work with the Service to prioritize known and historic spotted owl sites for conservation and/or maintenance of existing levels of habitat. The prioritization factors to consider are reproductive status and site condition.

The site conservation priorities for reproductive status are:

- Known sites with reproductive pairs;
- Known sites with pairs;
- Known sites with resident singles; and
- Historic sites with reproductive pairs, pairs, and resident singles, respectively.

The priority for site condition is sites currently with $\geq$40% in the provincial home range (*e.g.*, 1.3 mile radius) and $\geq$50% habitat within the core home range (*e.g.*, 0.5 mile radius). This prioritization provides a guide to evaluate the relative impacts of management actions, and conservation of sites that provide the most support to spotted owl demography.

When implementing this interim process, land managers and the Service should utilize professional judgment as to the best available site-specific data (collectively across years, if appropriate). These data may be contained in agency databases, land manager files, or other sources. Managers can also decide to conduct surveys to document current status.

Land managers should prioritize vegetation management and silvicultural treatments intended to enhance habitat conditions based on:

- Status as follows:
  - Unoccupied stands
  - Miscellaneous observations sites
  - Historic sites and;
  - Known sites – resident singles;
  - Known sites – resident pairs.
- Known sites with ≤40% in the provincial home range and ≤50% habitat within the core home range
- Ability to affect meaningful structural change in ≤30 years. Land managers should generally avoid activities that would reduce nesting, roosting and foraging habitat within provincial home ranges (*e.g.*, 1.3 mile radius) of reproductive pairs. Activities which address threats from stochastic disturbance (*e.g.*, insect, disease, wildfire, etc.) by restoration action will generally be consistent with the intent of RA 10 even if short-term effects to spotted owls would occur.

In unsurveyed spotted owl habitat, the agencies and the Service should work cooperatively through the Endangered Species Act consultation process to minimize impacts to potential spotted owl sites. It is likely to be most beneficial to address these areas as early in the planning process as possible. Non-federal land managers should seek technical assistance from the FWS as appropriate.

It is not uncommon for an occupied spotted owl site to be unoccupied in subsequent years, only to be re-occupied by the same or different spotted owls two, three or even more years later (Dugger *et al.* 2009). While temporarily unoccupied, these sites provide conservation value to the species by providing habitat that can be used by spotted owls on nearby sites while also providing viable locations on which future pairs or territorial singles can establish territories. Where unique circumstances or questions arise (*e.g.,* multiple activity centers, etc.), the Service is available to assist land managers with applying this recovery action.

As a general rule, forest management activities that are likely to diminish a home range's capability to support spotted owl occupancy, survival and reproduction in the long-term should be discouraged. However, we recognize that land managers have a variety of forest management obligations and that spotted owls may not be the sole driver in these decisions. Here, active forest management may be necessary to maintain or improve ecological conditions. We support projects whose intent is to provide long-term benefits to forest resiliency and restore natural forest dynamic process, when this management is implemented in a landscape context and with carefully applied prescriptions to promote long-term forest health. Examples of active management projects include forest stand restoration, fire risk reduction, treatment of insect infestations and disease and the restoration of high quality early seral habitat as described by Swanson *et al.* (2010). It is recognized that these projects may have both short and/or long-term effects to spotted owls and that treatments will be designed to minimize impacts as much as possible in keeping with project's intent.

Given natural events such as fire, wind storms, and insect damage, not all habitat-capable lands in a spotted owl home range are likely to contain spotted owl habitat at any one time. The amount and distribution of existing habitat within a home range may determine which management options will have greater or lesser impacts to the ability of spotted owls to occupy and reproduce in those areas. This, in turn, may affect the flexibility for land managers to implement traditional timber harvests while meeting the intent of this recovery action.

In the drier and southern portions of the range, managing for dense older forest mixed with some younger or more structurally diverse stands may also be appropriate (Franklin *et al.* 2000, Olson *et al.* 2004, but see Dugger *et al.* 2005). The Service recognizes there is tremendous variation across the species' range in such habitat conditions, and therefore, we expect to work closely with the BLM, FS and other land managers to define how to best meet the intent of this recommendation.

There is a wide breadth of spotted owl occupancy data throughout the species' range. Where spotted owl occupancy data are unavailable (*e.g*., unsurveyed habitat), land managers have a variety of tools to assist in determining where likely occupied habitat is and how to implement this recovery action, including assumption of occupancy (a common practice during section 7 consultation), surveys, spotted owl modeling results, forest stand data, etc.

Monitoring data, interagency teams, and adaptive management feedback will be useful tools in future revisions of this recovery action and its implementation, and may result in more refined approaches to implementation of this recovery action in the future. In cases where active management is conducted, assessing the effectiveness of treatments within spotted owl home ranges will provide land managers valuable feedback on how to design future projects and approaches within spotted owl home ranges. Land managers and researchers have numerous tools available to assess project efficacy, including spotted owl surveys, habitat mapping, prey analysis and modeling results. When opportunities arise, integration of monitoring in an adaptive management framework would be particularly valuable. The utility of each tool is largely dependent on the pre-project data available for comparison.

Research directly evaluating spotted owl responses to vegetation management including thinning, fuels reduction, and management intended to restore ecosystem functions is needed to address: (1) whether vegetation treatments result in development of desired habitat conditions; (2) whether treatments designed to create spotted owl habitat are used by spotted owls as NRF habitat conditions develop; (3) whether thinning operations designed to create future spotted owl habitat result in site abandonment during or after the operation and what types of vegetation management operations will allow spotted owls to persist on existing territories (minimize short-term negative effects); and (4) whether fuel reduction treatments can be done in a manner consistent with retaining occupied spotted owl sites and developing future spotted owl habitat on the landscape.

- ***Recovery Action 11: When vegetation management treatments are proposed to restore or enhance habitat for spotted owls (e.g., thinnings, restoration projects, prescribed fire, etc.), consider designing and conducting experiments to better understand how these different actions influence the development of spotted owl habitat, spotted owl prey abundance and distribution, and spotted owl demographic performance at local and regional scales.***

Additional research that identifies both short-term and long-term responses of prey populations (northern flying squirrels, woodrats, and other small mammals) to thinning treatments is also needed. Such forest management experiments should recognize the management activities known to negatively affect spotted owls discussed earlier and seek to expand our understanding of practices that will improve conditions for spotted owls and their prey.

We encourage collaborative efforts among State and Federal agencies, research scientists, and other interested parties where possible. In order to address the questions presented above, both intensive field research projects and larger, retrospective analyses that examine how different forest practices influence development of spotted owl habitat over time are needed.

Post-fire Logging

Decisions to harvest timber after wildfires often are based on financial considerations, human safety, a desire to modify the composition and resource production of forests, and a desire to "clean up the forest" (Foster and Orwig 2006, Noss and Lindenmayer 2006, Lindenmayer *et al.* 2008). Possible beneficial ecological effects of post-fire timber harvest include: decreased erosion due to placement of debris on the forest floor which intercepts surface water flow; decreased buildup of insect pests due to dead tree removal; decreased magnitude and extent of lethal soil temperatures around burning coarse woody debris; and, in stands where harvest-generated slash is treated, decreased fire risk due to removal of snags (McIver and Starr 2000, Lindenmayer *et al.* 2008, Monsanto and Agee 2008, Peterson *et al.* 2009). However, support is lacking for the contention that reduction of fuels from post-fire harvest reduces the intensity of subsequent fires (McIver and Starr 2000), and planting of trees after post-fire harvest can have the opposite effect. For example, forests in southwest Oregon that were logged and planted after a 1987 fire burned more severely in a 2002 fire than areas that were not logged or planted due, evidently, to high fuel conditions in conifer plantations (Thompson *et al.* 2007).

Detrimental ecological effects of post-fire timber harvest include: increased erosion and sedimentation, especially due to construction of new roads; damage to soils and nutrient-cycling processes due to compaction and displacement of soils; reduction in soil-nutrient levels; removal of snags and, in many cases, live trees (both of which are habitat for spotted owls and their prey); decreased regeneration of trees; shortening in duration of early-successional ecosystems; increased spread of weeds from vehicles; damage to recolonizing vegetation; reduction in hiding cover and downed woody material used by spotted owl prey; altered composition of plant species; increased short-term fire risk when harvest generated slash is not treated and medium-term fire risk due to creation of conifer plantations; reduction in shading; increase in soil and stream temperatures; and alterations of patterns of landscape heterogeneity (Perry *et al.* 1989, McIver and Starr 2000, Beschta *et al.* 2004, Karr *et al.* 2004, Donato *et al.* 2006, Lindenmayer and Noss 2006, Reeves *et al.* 2006, Russell *et al.* 2006, Thompson *et al.* 2007, Lindenmayer *et al.* 2008, Johnson and Franklin 2009, Peterson *et al.* 2009, Swanson *et al.* 2010). Soil damage and erosion are higher with traditional harvesting systems (*e.g.*, tractors) than they are with advanced systems (*e.g.*, helicopters) (Klock 1975, Peterson *et al.* 2009). After the 1988 Yellowstone fire, rates of soil loss were greatest where litter cover was minimal, percent silt content was high, and postfire logging had been conducted (Marston and Haire 1990 in McIver and Starr 2000). Moreover, post-fire timber harvest activities "undermine many of the ecosystem benefits of major disturbances" (Lindenmayer *et al.* 2004:1303) and frequently "ignore important ecological lessons, especially the role of disturbances in diversifying and rejuvenating landscapes" (DellaSala *et al.* 2006:51). To avoid crisis-mode decision-making and to minimize these detrimental effects, ecologically-informed policies based on pre-fire management direction should be developed before fires occur (Lindenmayer *et al.* 2008, Johnson and Franklin 2009).

Results from the three radio-telemetry studies of spotted owls in post-fire landscapes indicate that spotted owls use forest stands that have been burned, but generally do not use stands that have been burned and logged. For example, California spotted owls tracked 4 years post-fire in burned, unlogged stands: (1) had 30 percent of their nonbreeding-season roost locations within the fire's perimeter (Bond *et al.* 2010); (2) selected low-severity burned forests for roosting during the breeding season (Bond *et al.* 2009); and (3) selected low-, medium-, and high-severity burned forests for foraging within 1.5 km of the nest or roost site, with the strongest selection for high-severity burned forest (Bond *et al.* 2009). However, for spotted owls in stands that had been harvested post-fire: (1) infrequent foraging in stands burned with low-, medium-, and high-severity fires was restricted to areas with live trees such as those in riparian areas (Clark 2007), and (2) use shifted away from burned stands during 3 years post-fire (King *et al.* 1998). Comprehensive analyses quantifying how spatial configuration of forest type, burn intensity, and post-fire logging affects spotted owl demographic and occupancy rates will provide critical information for maintaining habitat during fuels-management activities.

Consistent with restoration goals, post-fire management in these areas should promote the development of habitat elements that support spotted owls and their prey, especially those which require the most time to develop or recover (*e.g.*, large trees, snags, downed wood). Such management should include retention of large trees and defective trees, rehabilitation of roads and firelines, and planting of native species (Beschta *et al.* 2004, Hutto 2006, Peterson *et al.* 2009). We anticipate many cases where the best approach to retain these features involves few or no management activities. Forests affected by medium- and low-severity fires are still often used by spotted owls and should be managed accordingly. Many researchers supported the need to maintain habitat for spotted owl prey. For example, Lemkuhl *et al.* (2006) confirmed the importance of maintaining snags, downed wood, canopy cover, and mistletoe to support populations of spotted owl prey species. Gomez *et al.* (2005) noted the importance of fungal sporocarps which were positively associated with large downed wood retained on site post-harvest. Carey *et al.* (1991) and Carey(1995) noted the importance of at least 10 to 15 percent cover of downed wood to benefit prey. The costs and benefits of post-fire harvest to the development of habitat for spotted owls and their prey should be evaluated by interagency teams (*e.g.*, Level 1 teams) during the consultation process.

- ***Recovery Action 12: In lands where management is focused on development of spotted owl habitat, post-fire silvicultural activities should concentrate on conserving and restoring habitat elements that take a long time to develop (e.g., large trees, medium and large snags, downed wood).*** Examples of areas where we believe this recovery action would greatly benefit future spotted owl habitat development include such fire-affected areas as the Biscuit fire, the Davis fire and the B&B complex.

Habitat Definitions

While some area-specific definitions of habitat have been developed in parts of the spotted owl's range, identification of existing spotted owl habitat and the management of lands to provide new habitat in the future would benefit greatly from a range-wide set of province-specific definitions of spotted owl habitat (*e.g.,* high-quality, nesting/roosting, foraging, dispersal). Variation in habitat structure and use across the spotted owl's range drives the need for province-specific definitions. The definitions should use forest composition and structure vernacular so that spotted owl habitat can be described in forest-management terms, and may also incorporate spatial and abiotic features that help determine where spotted owls use these types of stands. As part of our habitat modeling process (Appendix C), we solicited information from spotted owl experts on the regional biotic and abiotic factors that dictated where on the landscape spotted owls nested and roosted, and on regional definitions of spotted owl foraging habitat. These data will provide a good starting point for this effort.

- ***Recovery Action 13: Standardize province-specific habitat definitions across the range of the spotted owl using a collaborative process.***

Tribal Lands

The Service received comments from a number of American Indian Tribes on the draft Revised Recovery Plan indicating concerns that Tribal lands were not recognized separately from other non-federal lands. It was not the Service's intent to imply that Tribal lands are the same as other non-federal lands. The Revised Recovery Plan is not intended to affect the American Indian Tribal governments' rights to manage their lands. We understand Tribal lands are managed in accordance with Tribal goals and objectives, within the framework of applicable laws.

The Service recognizes the special government-to-government relationship between the Federal government of the United States and American Indian Tribal governments derived from the Constitution of the United States, treaties, Supreme Court doctrine, and Federal statutes. The Service acknowledges American Indian Tribal governments as sovereign nations with inherent powers of self-governance.

The Service also recognizes American Indian Tribes have long worked to conserve and monitor spotted owls on their lands. The efforts of many Tribes have contributed to spotted owl conservation and maintained the Tribal cultural values of the spotted owl and its habitat. Many Tribal lands have been managed with a holistic perspective, including reserves and modified silvicultural practices, and therefore can be islands of high quality habitat that support many species as well as healthy ecosystems. The Service is proud of our many positive government-to-government collaborations with American Indian Tribes and the benefits to fish and wildlife conservation.

The Service is committed to engaging in regular and meaningful consultation and collaboration with American Indian Tribal governments to determine what cooperative and voluntary measures Tribes may take to support spotted owl recovery actions and address other recovery needs and opportunities for spotted owls, recognizing the special status of Tribal lands. Consistent with existing laws and policies, and to honor this spirit of consultation and collaboration, the Service will give full consideration to tribal recovery plans, habitat and modeling data, and other conservation efforts.

All of the Service's actions, including our consultation and collaboration, will take place on a government-to-government basis and be consistent with applicable executive and secretarial orders, memoranda, and policies, including Executive Order 13175, "Consultation and Coordination with Indian Tribal Governments" (11/6/2000); Secretarial Order 3206, "American Indian Tribal Rights, Federal-Tribal Responsibilities, and the Endangered Species Act" (6/5/97); Presidential Memorandum (11/5/09); the U.S. Fish and Wildlife Service's Native American Policy (6/28/94), and the Endangered Species Act.

The Service may enter Memoranda of Understanding with Tribes for (a) mutually agreeable species conservation efforts, (b) utilizing Tribal habitat and modeling data regarding the presence of threatened, endangered, or candidate species on Tribal lands, and (c) processes to discuss and resolve matters regarding each government's spotted owl recovery efforts and obligations.

State and Private Lands

This Revised Recovery Plan acknowledges the role State and private lands can contribute toward recovering the spotted owl. The relative importance of this role to spotted owl recovery should be assessed. In 1994, in its biological opinion on the NWFP, the Service concluded that the NWFP met or exceeded the standards expected for the Federal contribution to recovery of the spotted owl. The Service also concluded in that opinion that overall recovery of the species would be further evaluated to determine recovery needs on non-federal lands. Since 1994, Federal lands have provided the majority of contribution to spotted owl recovery, and in many portions of the range it provides the sole contribution. However, there are portions of the range where habitat on Federal lands are lacking or of low quality or where there is little Federal ownership, and State and private lands may be able to improve recovery potential in key areas.

Given the continued decline of the species, the apparent increase in severity of the threat from barred owls, and information indicating a recent loss of genetic diversity for the species, we recommend conserving occupied sites and unoccupied, high-value spotted owl habitat on State and private lands wherever possible. This recommendation is primarily driven by the concern associated with displacement of spotted owls by barred owls, the need to retain good quality habitat to allow for displaced or recruited spotted owls to reoccupy such habitat, and the need to retain a spotted owl distribution across the range where Federal lands are lacking. Examples of these areas include portions of southwestern Washington, northwestern Oregon (potentially including parts of the Tillamook and Clatsop State Forests), and northeastern California.
Because spotted owls on established territories are likely to be more successful if they remain in those locations (Franklin *et al.* 2000), managing to retain spotted owls at existing sites should be the most effective approach to conserving spotted owls. Retention of long-term occupancy and reproduction at established spotted owl sites will require a coordinated and cooperative effort to craft management approaches tailored to regional, provincial or local conditions.

This Revised Recovery Plan acknowledges the important role State and private lands can play toward implementing a coordinated and cooperative effort to recover the spotted owl. The relative importance of this role to spotted owl recovery can be addressed in a variety of ways. Using the rangewide habitat modeling framework will help identify areas where State and private lands can make the best contribution to spotted owl recovery. The Service will continue to work with these landowners to use a variety of voluntary incentives and approaches that will help contribute to spotted owl recovery through protection and development of unoccupied, high-quality habitat.

During the past 20 years, the Service has worked cooperatively with non-federal landowners to minimize negative impacts to spotted owls and to encourage conservation of spotted owl habitat. The Service has worked with a number of different applicants to implement habitat conservation plans (HCPs) and safe harbor agreements (SHAs) that minimize and mitigate impacts or provide for a net conservation benefit. Lands covered under section 10 of the ESA provide for the conservation of key habitat areas and occupied sites.

Although HCPs are not required to advance the recovery of listed species, voluntary recovery actions included in an HCP can promote recovery. These plans generally are designed to provide: (1) high-quality habitat and retain spotted owl sites; or (2) foraging and dispersal opportunities to make important contributions to spotted owl recovery. SHAs must provide a net conservation benefit to the species, while allowing the landowner to return to baseline habitat conditions after a pre-defined period of time. The net conservation benefits are often direct contributions to recovery, even if of a limited temporal nature. We recommend these efforts be continued and expanded in certain portions of the range to retain and recruit spotted owl habitat on State and private lands in areas with a lack of proximal high-quality habitat on Federal lands and where future distribution of spotted owls would improve long-term recovery potential. These areas include, but are not limited to, southwest Washington, northwest Oregon and the north coast of California.

This Revised Recovery Plan also identifies several recovery actions meant to encourage State and private landowners to work voluntarily toward recovery through economic incentives. There are a number of established and emerging incentive-based options that currently exist for non-federal landowners, including conservation banking and carbon sequestration that could provide valuable spotted owl habitat maintenance or restoration. Spotted owls could receive either directed or indirect benefits from ecosystem services market incentives.

- ***Recovery Action 14: Encourage applicants to develop Habitat Conservation Plans and Safe Harbor Agreements that are consistent with the recovery objectives.***

Habitat conservation plans and safe harbor agreements are important tools that non-federal landowners can voluntarily use to assist in the recovery of the spotted owl. On July 27, 2010, the Service finalized a SHA for small woodlot owners in Oregon that will enroll up to 50,000 acres of non-federal lands within the State over a total of 50 years. The primary goal of this SHA is to increase the time between harvests (*i.e.*, defer harvest), and to lightly to moderately thin younger forest stands that are currently not habitat to increase tree diameter size and stand diversity (*e.g.*, species, canopy layers, presence of snags).

- ***Recovery Action 15: The Service will solicit individual recommendations from stakeholders to develop a comprehensive set of tools and business and economic incentives that facilitate creative opportunities for non-federal landowners to engage in management strategies consistent with the recovery objectives.***

Many non-federal landowners and land managers in the region have adjusted their management strategies to emphasize short harvest rotations (*e.g.*, 40 to 50 years) and the processing of comparatively small diameter trees. Incentives should be identified and developed as a means to reward landowners and land managers for implementing "ecological forestry" practices (Franklin *et al.* 2007) designed to recruit and retain higher-quality spotted owl habitat. Such incentives may include extending tax credits for recovery–related activities that are carried out under the Farm Bill to timber production, development of State or Federal subsidies for lands that meet carbon sequestration and habitat development goals, or conservation banks that facilitate mitigation for actions that impact the spotted owl. Many of the emerging ecosystem services incentives could allow landowners to receive financial compensation for providing co-benefits that include growing higher-quality spotted owl habitat. Implementation of the incentives program could be coupled with the SHA process to provide regulatory protection for landowners who create or enhance spotted owl habitat. Aspects of this recovery action may also be implemented more efficiently at the individual state levels as described under Listing Factor D.

- ***Recovery Action 16: Federal, State, and local managers should consider long-term maintenance of local forest management infrastructure as a priority in planning and land management decisions.***

This Revised Recovery Plan documents the need for active forest management and restoration in many parts of the spotted owl's range to meet long-term ecological goals, especially in dry forest areas, which will benefit spotted owl recovery. Meeting this need will require local capability to treat, remove, and process various types of forest biomass under a variety of logistical and economic conditions.

Timber-based economies and communities in the western United States have experienced significant changes during the last half-century. Some declines in workforce can be attributed to changes in environmental regulation at the Federal, State, and local levels during this time period. However, changing domestic and international markets, competition, industry automation, and depleted supply of older timber have all combined to create a sometimes volatile and unpredictable economic environment for local timber-based economies. Many of these economic changes were well underway prior to the listing of the spotted owl and have occurred outside of the spotted owl's range as well (Raettig and Christensen 1999, Conway and Wells 1994, Power 2006).

Several representatives from smaller timber companies and rural communities have stated that the ability to implement forest restoration projects in the future will suffer because of a continued decline in local workforce, expertise, equipment, and milling or processing capacity (Storm 2007, Mason and Lippke 2009, Carrier 2010). The Service recognizes this concern and recommends it be evaluated at the State and local scales.

Although it is beyond the scope of this Revised Plan to address these broader economic issues, it is in the general interest of long-term forest health -- and therefore spotted owl recovery -- to maintain a local ability to implement forest management and restoration projects on public lands. Therefore, it is appropriate for agency land managers to take into account this need when designing, prioritizing, and locating projects. Stewardship contracting by the BLM and the USFS may be applicable to this goal (Newberry 2011).

LISTING FACTOR B: OVERUTILIZATION FOR COMMERCIAL, SCIENTIFIC, OR EDUCATIONAL PURPOSES

There is no known threat to the spotted owl relative to this listing factor, so no recovery criteria or recovery actions are identified specific to this listing factor.

LISTING FACTOR C: DISEASE OR PREDATION

Although there is no known imminent threat to the spotted owl from disease or predation (so no recovery criteria are identified specific to this listing factor) it is important to continue to monitor for diseases and pathogens so that appropriate action can be taken if necessary.

Diseases

Sudden oak death

Sudden oak death is a potential threat to spotted owl habitat (Courtney *et al.* 2004). This disease is caused by a non-native, recently introduced, fungus-like pathogen, *Phytopthora ramorum*. This pathogen has killed hundreds of thousands of oak and tanoak trees along the California coast (from southern Humboldt County to Monterey County) and hundreds of tanoak trees on the southern Oregon coast (southwestern Curry County) (Goheen *et al.* 2006).

According to Goheen *et al.* (2006:1):

> "The pathogen has a wide host range including Douglas-fir, grand fir, coast redwood, and many other tree and shrub species common in Oregon and Washington forests. Tree mortality, branch and shoot dieback, and leaf spots result from infection depending on host species and location. *Phytopthora ramorum* spreads aerially by wind and wind-driven rain and

> moves within forest canopies and tree tops to stems and shrubs and from understory shrubs to overstory trees. The pathogen survives in infected plant material, litter, soil, and water. It is moved long distances in nursery stock.…State and Federal personnel regularly survey forests and nurseries in the Pacific Northwest to detect the disease."

Due to its potential impact on forest dynamics and alteration of key prey and spotted owl habitat components (*e.g.,* hardwood trees, canopy closure, and nest tree mortality), sudden oak death poses a potential threat to spotted owls, especially in the southern portion of the spotted owl's range (Courtney *et al.* 2004).

Avian disease

At this time, no avian diseases are significantly affecting spotted owls. It is unknown whether avian diseases such as West Nile virus (WNV), avian flu, or avian malaria (Ishak *et al.* 2008) will significantly affect spotted owls. Carrying out the following monitoring action would alert us if any disease becomes a threat.

- ***Recovery Action 17: Monitor for sudden oak death and avian diseases (e.g., WNV, avian flu, Plasmodium spp.) and address as necessary.***

Monitoring is necessary to assess the degree to which sudden oak death affects spotted owl habitat and whether any avian disease becomes a threat. If one or more pathogens or diseases pose a threat to spotted owls or their habitat, specific responses would need to be developed and implemented.

Predation

Known predators of spotted owls are limited to great horned owls (Forsman *et al.* 1984), and, possibly, barred owls (Leskiw and Gutiérrez 1998). Other suspected predators include northern goshawks, red-tailed hawks, and other raptors (Courtney *et al.* 2004). Occasional predation of spotted owls by these raptors is not considered to be a threat to spotted owl populations, so no criteria or actions are identified. Actions relative to the threat from barred owls are presented in Listing Factor E.

LISTING FACTOR D: INADEQUACY OF EXISTING REGULATORY MECHANISMS

One of the original reasons for listing the spotted owl was the inadequacy of the applicable regulatory mechanisms as they existed in 1990. Although there were regulatory mechanisms in place at the time, they offered variable levels of protection to spotted owls and, to a lesser extent, spotted owl habitat. Since 1994, the NWFP has been implemented on Federal lands throughout the range of the spotted owl. On Federal lands, the Service continues to support the implementation of the NWFP and its associated Standards and Guidelines, as well as the implementation of the recovery actions in this Revised Recovery Plan. This section focuses primarily on the State regulations that cover the approximately 21 million acres of private- and State-owned forest lands in Washington, Oregon and California (see Table III-1).

State and private lands are regulated under various State authorities, and timber harvest within each state is governed by rules that provide varying degrees of protection of spotted owls or their habitat. In Washington, logging practices on State, State trust, and private lands are regulated by the Washington State Department of Natural Resources. In Oregon, the State Forest Practices Act regulates State and private lands. In California, the Forest Practice Rules and timber harvest plan review process on State and private lands substitute for an Environmental Impact Review under the California Environmental Quality Act of 1970. The California Department of Forestry and Fire Protection (CAL FIRE) is responsible for review and approval of timber harvest plans. See below for a more comprehensive treatment of each state.

Since the listing of the spotted owl, there have been some regulatory changes that have reduced the rate of habitat decline on State and private lands. However, in light of the continued decline of the species, the apparent increase in severity of the threat from barred owls, and information indicating a recent loss of genetic diversity for the species, this Revised Recovery Plan identifies a more important recovery role for State and private lands. The Service recommends the States evaluate existing spotted owl conservation efforts and consider changes where appropriate to contribute to recovery goals; specific geographical areas of interest include northeastern California, northwestern Oregon and southwestern Washington. This evaluation should consider the feasibility of restoring and conserving spotted owl habitat on non-federal lands where they can contribute to spotted owl recovery. The Service is available to assist States in evaluating the importance of spotted owl conservation efforts on State and private lands.

In addition, the Service suggests the States evaluate existing regulations affecting spotted owls and make changes where necessary and appropriate to meet recovery goals. We acknowledge the potential economic impacts such changes might have in certain parts of the spotted owl range, and we make several recommendations below to address these concerns.

Washington. In 1996, the State Forest Practices Board (Board) adopted Forest Practices Rules (Washington Forest Practices Board 1996, Washington Administrative Code 222) that would contribute to protection of spotted owls on strategic areas of non-federal lands. Adoption of the Forest Practices Rules was based in part on recommendations from a Science Advisory Group that identified important non-federal lands and recommended roles for those lands in spotted owl conservation (Hanson *et al.* 1993, Buchanan *et al.* 1994). The 1996 rule package was developed by a stakeholder policy group and then reviewed, modified, and approved by the Board.

The Board is currently working to develop an updated, long-term strategy to protect the spotted owl and its habitat on private and state forest lands. In 2008, the Forest Practices Board convened a Northern Spotted Owl Policy Working Group (Working Group). The Working Group's consensus recommendations were presented to the Board in February 2010. The Board accepted the Working Group consensus recommendations and directed Washington State Department of Natural Resources to form a Northern Spotted Owl Implementation Team (Washington NSO Implementation Team).

One of the Working Group's recommendations resulted in a rule change that reduces the likelihood that potentially important habitat near a spotted owl site center is lost through timber harvest while the Board completes its long-term conservation strategy. This rule change adds an evaluation by a three-member Spotted Owl Conservation Advisory Group whenever a site center is subject to possible decertification (and therefore loss of regulatory protections provided by the Forest Practices Rules). The purpose of this evaluation is to determine whether habitat at the site center should be maintained, regardless of the site center's occupancy status, while the Board is completing its long-term strategy.

The Board also directed the Washington NSO Implementation Team to develop a work plan, including prioritization, and directed the team to coordinate with the Federal agencies with regard to the Barred Owl control experiments. The Board also directed the Washington NSO Implementation Team to formally convene a technical team to assess spatial and temporal allocation of conservation efforts on non-federal lands using best available science.

- ***Recovery Action 18: The Washington State Forest Practices Board (Board) should use the final recovery plan and the habitat modeling tool to inform the process currently underway to identify areas on non-federal lands in Washington that can make strategic contributions to spotted owl conservation over time. The Service encourages timely completion of the Board's efforts and will be available to assist as necessary.***

Oregon. The Oregon Forest Practices Act provides for protection of 70-acre core areas around recently surveyed sites occupied by an adult pair of spotted owls capable of breeding (as determined by protocol surveys), but it does not provide for protection of resident single sites, nor of spotted owl habitat beyond these areas (ODF 2006). The Forest Practices Act does not require spotted owl surveys to identify potential nesting-pair or resident-single sites. The interim protection goals for spotted owl nesting sites initially adopted under the Forest Practices Act at the time of listing have yet to be finalized. There is a process under the Forest Practices Act (*see* Oregon Administrative Rule 629-680) to update resource (*i.e.*, spotted owl) site protection measures. Every two years the Oregon Department of Forestry reports to the Board of Forestry regarding any recommended changes to the resource site protection rules and to identify any research needed to further evaluate the protection levels. This on-going review has not been used to finalize the spotted owl resource site protection rules or to monitor their impact on spotted owls.

- ***Recovery Action 19: The Service will request the cooperation of Oregon Department of Forestry in a scientific evaluation of: (1) the potential role of State and private lands in Oregon to contribute to spotted owl recovery; and (2) the effectiveness of current Oregon Forest Practices in conserving spotted owl habitat and meeting the recovery goals identified in this Revised Recovery Plan. Based on this scientific evaluation, the Service will work with the Oregon Department of Forestry and other individual stakeholders to provide specific recommendations for how best to address spotted owl conservation needs on Oregon's non-federal lands.***

Such an analysis is beyond the scope of this Revised Recovery Plan and should be initiated as a cooperative effort between the Service and Oregon Department of Forestry. Among the issues this evaluation should address are the adequacy of the 70-acre core approach for spotted owl pair nest sites in contributing to recovery needs, an assessment of long-term residency and productivity of spotted owls in these territories, the potential application of the habitat modeling tool (Appendix C) to identify areas of high current or potential recovery value, and the potential application of these results to future land management decisions (*e.g.*, critical habitat revisions, HCPs, etc.).

Similar to the Washington Forest Practices Board's Northern Spotted Owl Policy Working Group, this group should identify voluntary and regulatory incentives that may improve spotted owl conservation on State and private lands, as well as areas where economic and other goals may be achieved while also benefiting spotted owls. The state-led Washington group provides a strong model for critically examining the contribution of State forestry regulations to spotted owl recovery.

This Oregon effort should focus on the identification of opportunities to address spotted owl recovery needs on State and private lands and an assessment of the various economic and social trade-offs necessary to meet this goal. Some specific issues this Oregon group should address are:

- potential recommendations to revise Forest Practice regulations, if appropriate and necessary;
- identification of specific opportunities to apply complimentary management goals that meet multiple economic, social, and ecological objectives compatible with spotted owl recovery, such as carbon sequestration, fuels treatment, silviculture, water quality, and recreation;
- coordination between the Oregon Department of Forestry and the Service to receive routine summaries of forest operations; and
- identification of financial and non-regulatory incentives to non-federal land managers that may encourage implementation of recovery actions on these lands (see Recovery Action 15).

California. State Forest Practice Rules, which govern timber harvest on private lands, were amended in 1990 to require surveys for spotted owls in nesting, roosting and foraging habitat and to provide habitat protection measures around activity centers (CFPR 2011, 14 CCR§§ 919.9 (a)-(g)). Under the Forest Practice Rules, a timber harvest plan cannot be approved if it is likely to result in incidental take of federally-listed species, unless the take is authorized by a Federal HCP (CFPR 2011, 14 CCR§§ 898.2(d) and (f)). The California Department of Fish and Game (CDFG) initially reviewed all Timber Harvest Plans (THPs) to ensure that take of State- and federally-listed species was not likely to occur. The Service currently provides technical assistance to CAL FIRE in its THP review of federally-listed species.

- ***Recovery Action 20: The Service will request the cooperation of CAL FIRE and individual stakeholders in an evaluation of: (1) the potential recovery role of spotted owl sites and high-quality habitat on non-federal lands in California, and (2) evaluation and implementation of appropriate conservation tools (e.g., carbon sequestration, Habitat Conservation Plans, Safe Harbor Agreements) to assist with supporting spotted owl recovery actions outlined in this Recovery Plan.***

Working with the State and stakeholders in this manner would create an opportunity to identify more locally-specific information to assist with outlining the potential contribution of private lands to spotted owl recovery. This sort of collaboration would also be an appropriate mechanism to identify and create voluntary and regulatory incentives that may improve spotted owl conservation on non-federal lands that integrate with existing State regulatory and incentive programs.

- ***Recovery Action 21: The Service will provide technical assistance to the California Board of Forestry and Fire Protection and CAL FIRE to develop scientifically based and contemporary Forest Practice Rules to provide for the breeding, feeding and sheltering of spotted owls.***

Currently, the State of California considers it a crime to “take, possess, or destroy” birds of prey, including all owl species (California Fish and Game Code: CA FISH & G § 3500 – 3857). While some barred owl removal has occurred in California forest lands under special permits, this statute could hinder the ability to reduce the effects of barred owls on spotted owls in the southern portion of the range.

- ***Recovery Action 22: If barred owl removal is determined to be effective, work with the State of California to explore options for managing barred owls using lethal means.***

Table III-1. Summary of the forestry rules that provide spotted owl protections for California, Oregon and Washington

State	NSO Surveys Required	Habitat Requirements				Noise Disturbance Restrictions			NSO Forest Rules last updated	Exceptions
		Which spotted owl sites	Size-Location	Habitat	Duration	Zone size	Duration	Restricted Disturbance Includes		
California[1]	Yes	All	Within 0.7–1.3 miles of center	Within 500 ft. of nest timber operations limited during breeding season and must retain functional nesting habitat[2] 500-1000 ft. retain functional roosting habitat[2] 500 acres spotted owl habitat in 0.7 -mile radius 1336 acres spotted owl habitat in 1.3- mile radius	All year as long as determined by CAL FIRE to be a site	500 ft.	Breeding season[3]	All timber harvest operations except planting and surveying	2009 – allowed designation of independent biological consultants to fulfill evaluation role for likelihood of take	CFPRs allow for deviations with FWS review and other sec. 7 and 10
Oregon	No	All	Nest site[4] is within 500 ft. of timber operations	70-acre no cut Core around nest with the outer edge of the Core no less than 300 ft. distance from the nest	Life of circle	0.25 mile	Critical period[5]	Timber operations except log hauling, reforestation, road maintenance, research and monitoring, ground application of chemicals, aerial applications that do not require multiple passes, and burning	2006	
Washington	No	SOSEA	Within 0.7 miles of site center Within home range of 1.8-2.7 mile radius	retain all suitable habitat [6,7] retain 40% of suitable habitat [6,7]	Life of circle	0.25 mile	Nesting season[8]	Felling and bucking, yarding, slash disposal, prescribed burning, road construction, and other such activities (operation of heavy equipment and blasting)	1996	For landowners whose forest land ownership within the SOSEA is ≤500 acres and where the activity is
		Non-SOSEA	70 acres around known nest site	retain best 70 acres[7]	Nesting season[8] only					

										>0.7 mile of the NSO site center and sec. 7, 10 and some State planning regulations

1. California Forest Practice Rules (CFPRs) rely on the Service's Guidelines as presented here.
2. Nest-Roost habitat in California is generally defined as 60-90% canopy closure, multi-layered/species canopy with trees >30 inches diameter, trees with deformities, woody debris on ground and open space below canopy to allow spotted owls to fly.
3. Breeding season for Coastal California is defined as February 1-July 30, Interior as February 1-August 31.
4. Nest site requires a pair of spotted owls.
5. The critical period in Oregon is defined as March 30 to September 30.
6. Suitable habitat in Washington is defined as: forest stands which meet the description of old forest habitat, sub-mature habitat or young forest marginal habitat per Washington Forest Practices Regulations (Washington Forest Practices Board 1996).
7. These thresholds are used as guidance in SEPA review and do not necessarily preclude harvest.
8. Nesting season in Washington is defined as March 1 to August 31.

LISTING FACTOR E: OTHER NATURAL OR MANMADE FACTORS AFFECTING ITS CONTINUED EXISTENCE

Barred Owl

The three main threats to the spotted owl are competition from barred owls, past habitat loss, and current habitat loss. Barred owls reportedly have reduced spotted owl site occupancy, reproduction, and survival (see Appendix B). Limited experimental evidence, correlational studies, and copious anecdotal information all strongly suggest barred owls compete with spotted owls for nesting sites, roosting sites, and food, and possibly predate spotted owls. The threat posed by barred owls to spotted owl recovery is better understood now than when the spotted owl was listed. Because the abundance of barred owls continues to increase, the effectiveness in addressing this threat depends on action as soon as possible.

Because the abundance of barred owls continues to increase, the effectiveness in addressing this threat depends on action as soon as possible.

There are substantial information gaps regarding ecological interactions between spotted owls and barred owls, and how those interactions may be managed to meet the Recovery Criteria. Recovery actions should provide the information needed to identify effective management approaches and guide the implementation of appropriate management strategies. Many of the following actions should be done concurrently; Figure III-1 shows how these Actions may inform one another. The Service is the primary agent to oversee implementation of any strategy for the management of barred owls.

Coordination among all agencies and non-governmental organizations that can contribute to research on ecological interactions between spotted owls and barred owls is needed to prioritize research topics, maximize funding opportunities, minimize redundancies, increase efficiency, identify potential management strategies, and communicate with decision-makers. Included as Recovery Action 21 in the 2008 Recovery Plan, the Barred Owl Work Group was appointed as a Recovery Implementation Team to implement the 2008 Recovery Plan and has provided coordination on numerous analyses, topics and issues. Currently, representatives from 10 Federal, State and non-governmental agencies and organizations comprise the Work Group helping to implement its technical and scientific functions.

This Barred Owl Work Group is chaired by the Service and guided by its charter, along with the Northern Spotted Owl Implementation Team (NSOIT). The Barred Owl Work Group has guided, and will continue to guide, implementation of numerous recovery actions addressing the barred owl threat to spotted owls.

- ***Recovery Action 23: Analyze existing data sets from the demographic study areas relative to the effects of barred owls on spotted owl site occupancy, reproduction, and survival.***

Through implementation of this recovery action, many of the long-term demographic data sets have been studied, resulting in white papers and pending publications. Additional analysis of these data has provided a greater understanding of the effects of barred owls on spotted owl detection rates, survival, site occupancy and the role of habitat in site occupancy. The Barred Owl Work Group will continue to work with the Principal Investigators of the demographic studies to mine data as appropriate.

- ***Recovery Action 24: Establish protocols to detect barred owls and document barred owl site status and reproduction.***

Protocols to detect barred owls and document important population information, including pair status and reproduction, provide vital data needed to help manage barred owls to reduce their threat to spotted owls. A subgroup of the Barred Owl Work Group was formed in 2008 to develop a barred owl-specific survey protocol. The subgroup developed a draft protocol in 2009 with the purpose of providing a high likelihood of determining barred owl presence for research studies. During the 2009 field season, the draft protocol was tested in several areas with the objectives of determining barred owl detection rates and the survey effort needed to adequately detect barred owls. These data have been analyzed allowing the subgroup to refine the protocol based on the field tests.

- ***Recovery Action 25: Ensure that protocols adequately detect spotted owls in areas with barred owls.***

The presence of barred owls has been shown to decrease the detectability of spotted owls. Consequently, the Barred Owl Work Group enlisted scientific support and analysis from many individual spotted owl researchers from the Federal, State and private sectors across the range of the spotted owl. Additional analysis of data from demographic study areas focused on addressing the questions of: 1) what are the per visit detection rates of spotted owls with and without barred owls, and 2) what are the site occupancy rates of spotted owls at historical spotted owl sites? These efforts have led to several white papers and pending publications. A draft revised spotted owl survey protocol was released for use and comment during the 2010 field season along with direction on how to transition from the 1992 protocol. Field testing of, and commenting on, several provisions of the draft protocol will occur during the next several field seasons leading to finalization of a survey protocol.

- ***Recovery Action 26: Analyze resource partitioning of sympatric barred owls and spotted owls.***

Radio-telemetry studies of sympatric spotted and barred owls help to: determine how the two species use their habitat and resources, including prey, in various areas; identify characteristics of habitats used by spotted owls in areas with substantial barred owl populations; and determine how habitat use by barred owls and spotted owls changes as barred owl numbers increase.

In anticipation of the need for this information, several research projects were initiated in 2007 and led by USGS, PNW, OSU and private industry researchers. This research is focused on interspecific competition and niche partitioning by spotted owls and barred owls. Results from the research are either incorporated in Appendix B or soon will be released in peer-reviewed publications. This information will provide the opportunity for adaptive management of this Revised Recovery Plan when it becomes available.

- ***Recovery Action 27: Create and implement an outreach strategy to educate the public about the threat of barred owls to spotted owls.***

Outreach and education are important components in addressing the barred owl threat, and we continue to look for opportunities to provide this. For example, since completion of the 2008 Recovery Plan, a Barred Owl Stakeholder Group has been formed. The Barred Owl Stakeholder Group, comprised of nearly 40 private and public stakeholders with interest in spotted owl and barred owl issues, met twice in 2009 with members of the barred owl work group and a professional ethicist to discuss the ethical considerations associated with permitting the experimental removal of barred owls and provided their individual feedback on the issue. The results of these discussions are part of the pre-scoping process, and are being considered, along with the results of public scoping, in the development of the draft EIS for issuance of a permit for barred owl removal to ensure we are aware of all potential issues. We will be conducting extensive outreach as part of the NEPA process for issuance of the Migratory Bird Treaty Act permit for the experimental removal of barred owls.

It is crucial that the general public be kept informed concerning this difficult aspect of spotted owl recovery and the potential consequences of not addressing this threat. Public outreach could include production and distribution of brochures, kiosk displays, press releases, and public meetings relative to research and management options.

- ***Recovery Action 28: Expedite permitting of experimental removal of barred owls.***

The concern regarding the current and future negative effects of barred owls on the recovery of spotted owls is considerable, and immediate research is needed. State and Federal permitting of scientifically sound research on removal experiments will be necessary to answer the question of the impacts of barred owls on spotted owls.

- ***Recovery Action 29: Design and implement large-scale control experiments to assess the effects of barred owl removal on spotted owl site occupancy, reproduction, and survival.***

We believe removal of barred owls would provide benefits to spotted owls in the vicinity of the removal and may have larger population effects. Given the rapidity and severity of the increasing threat from barred owls, barred owl removal should be initiated as soon as possible in the form of well-designed removal experiments. These experiments will have the potential to substantially expand our knowledge of the ecological interactions between spotted owls and barred owls (Dugger *et al.* in press) and the effectiveness of barred owl removal in recovering spotted owls. Removal experiments should be conducted in various parts of the spotted owl's range, including a range of barred owl/spotted owl densities, to provide the most useful scientific information.

In the fall of 2009 the Service initiated an Environmental Impact Statement for a proposed experimental removal of barred owls to determine if the removal benefits spotted owls. Public scoping was completed in January 2010 and a draft Environmental Impact Statement is in process.

- ***Recovery Action 30: Manage to reduce the negative effects of barred owls on spotted owls so that Recovery Criterion 1 can be met.***

Implement the results of research to adaptively manage the effects of barred owls to meet Recovery Criterion 1. Management could include silvicultural treatments for stand structure and composition (*e.g.*, habitat management for spotted owl prey), local or large-scale control of barred owl populations, and/or other activities at present unforeseen but informed by research results.

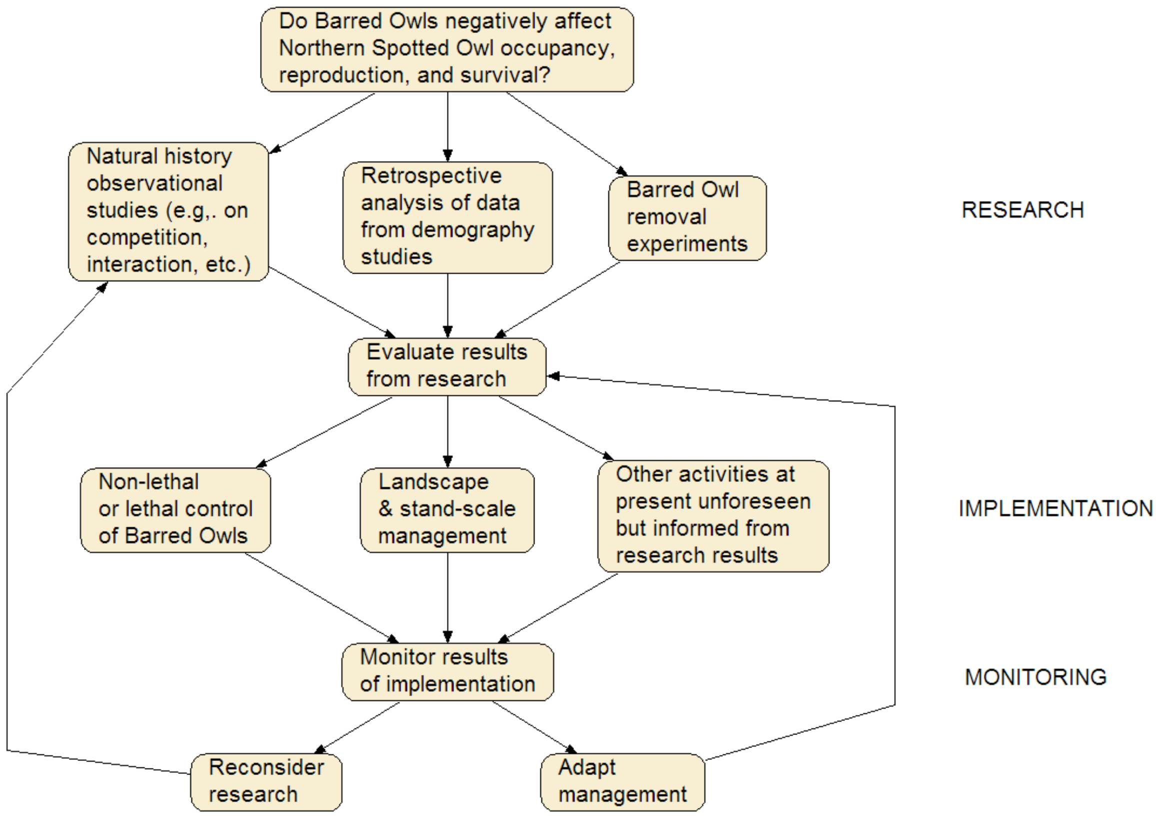

Figure III-1. Flowchart of barred owl Recovery Actions.

Conducting natural history studies (Figure III-1) is ongoing. Retrospective analysis of data from past and ongoing studies involves evaluating past data sets from demography study areas by adding barred owl covariates to test whether presence of barred owls affected detection rates, occupancy, reproduction, and survival of spotted owls (Dugger *et al.* 2009, Forsman *et al.* 2011, Dugger *et al.* in press). Many actions (*e.g.*, additional analysis of data, improving detection protocols for both species', outreach, identification of key spotted owl areas) have already begun. Preliminary findings from barred owl removal experiments could be realized in 1-3 years, whereas estimates of spotted owl vital rates may require more time. Evaluation of results from research is ongoing, and includes research already completed. Identification of management strategies should be based on research results, considerations for different geographic areas, costs, and changes in risk-levels to spotted owls over time. This may lead to the removal of barred owls through non-lethal or lethal methods. If research indicates local or large-scale maintenance removal of barred owl populations is needed, then public outreach, coordination among agencies, Migratory Bird Treaty Act permitting, and NEPA compliance would be required. Evaluation of results from research also may result in landscape and stand-scale management of spotted owl habitat and/or other activities unforeseen at present.

- ***Recovery Action 31: Develop mechanisms for landowners and land managers to support barred owl management using a collaborative process.***

Incentives, such as easily implemented safe harbor agreements or habitat conservation plans, can decrease a private landowner's concern regarding barred owl management that may result in an increase of spotted owls, as well as the associated issues that come with a listed species under the ESA.

- ***Recovery Action 32: Because spotted owl recovery requires well distributed, older and more structurally complex multi-layered conifer forests on Federal and non-federal lands across its range, land managers should work with the Service as described below to maintain and restore such habitat while allowing for other threats, such as fire and insects, to be addressed by restoration management actions. These high-quality spotted owl habitat stands are characterized as having large diameter trees, high amounts of canopy cover, and decadence components such as broken-topped live trees, mistletoe, cavities, large snags, and fallen trees.***

Maintaining or restoring forests with high-quality habitat will provide additional support for reducing key threats faced by spotted owls. Protecting these forests should provide spotted owls high-quality refugia habitat from the negative competitive interactions with barred owls that are likely occurring where the two species' home ranges overlap. Maintaining or restoring these forests should allow time to determine both the competitive effects of barred owls on spotted owls and the effectiveness of barred owl removal measures. Forest stands or patches meeting the described conditions are a subset of NRF habitat and actual stand conditions vary across the range. These stands or patches may be relatively small but important in a local area, may not be easily discernable using remote sensing techniques, and likely require project-level analysis and field verification to identify.

This recommendation can be justified at several scales and is supported by the best available research. At the scale of a spotted owl territory, Dugger *et al.* (in press) found an inverse relationship between the amount of old forest within the core area and spotted owl extinction rates from territories. At the population scale, Forsman *et al.* (2011) found a positive relationship between recruitment of spotted owls into the overall population and the percent cover of spotted owl NRF habitat within study areas. Both of these studies provide scientific support for the value to spotted owls of retaining structurally complex stands on the landscape.

Because the characteristics of the stands or patches targeted by this recovery action vary widely across the range of the species, the Service believes implementation and/or mapping of this recovery action is best left to interagency teams with localized expertise. To facilitate implementation of this recovery action on Federal lands, local, interagency Level 1 teams should continue to identify RA 32 stands or patches when necessary and evaluate the effects of proposed management activities in these areas on spotted owls, with assistance from management (Level 2) and Regional Technical Specialists, as needed. This approach will continue to ensure that interagency localized expertise will be utilized in identifying and managing Recovery Action 32 stands or patches and will be the result of interagency cooperation. Non-federal landowners are welcome to utilize the tools developed during the cooperative Federal process. The Service is available to assist non-federal landowners with the implementation of this recovery action.

On-the-ground application of this action has been, and continues to be, implemented on the west side of the Cascades on Federal lands as part of the level 1 team consultation process since shortly after the 2008 Recovery Plan was finalized. Our recent experience reinforces that the BLM and FS are aware of the conservation value of this recovery action and have been proactive and collaborative in the application of Recovery Action 32.

In dry forest areas, actively manage habitat to meet the overlapping goals of spotted owl recovery, restoration of dry forest structure, composition and process including fire, insects and disease. Managers should refer to earlier discussions in this Plan for specific recommendations about landscape scale, science based adaptive restoration treatments to meet Recovery Action 32 goals. Land managers that utilize and document the application of these recommendations in their project planning are consistent with the intent of Recovery Action 32. An existing example of a site-specific plan that could be emulated at the National Forest, BLM District, or project level in other dry forest areas is the Okanogan-Wenatchee National Forest Restoration Strategy (USDA 2010).

The Dry Cascades and the Klamath Province Work Groups will both assist the Service with implementation of this recovery plan by developing multiple province-specific management strategies. Given the dynamic disturbance regimes of these provinces, the strategies developed by these two work groups may address the goals of this recovery action differently than outlined above when finalized. If these strategies require amendments to this Revised Recovery Plan the Service will provide an additional opportunity for public comment.

This recovery action may be temporary in nature, until such time as the competitive pressures of the barred owl on the spotted owl can be reduced to an extent that retention of these stands or patches is not necessary for spotted owl recovery. The 5-year review process will help inform assessments of reduction of threats posed by barred owls. If the 5-year review finds this recommendation unnecessary we will amend this Revised Recovery Plan as needed.

Post-delisting Monitoring

Once the spotted owl is delisted the Service is required to continue to monitor its population for at least 5 years to ensure it does not require the protections of the ESA after those protections have been lifted. Currently, spotted owl populations are monitored through the demographic study areas described in Appendix A under **Population Trends and Distribution**.

Recovery Criterion 4 – Post-delisting Monitoring**:** To monitor the continued stability of the recovered spotted owl, a post-delisting monitoring plan has been developed and is ready for implementation with the States of Washington, Oregon, and California (ESA 4(g)(1)).

- ***Recovery Action 33: Develop a post-delisting monitoring plan ready for implementation with the States of Washington, Oregon, and California (ESA 4(g)(1)).*** Such a plan is necessary to meet the requirements of the ESA.

IV. IMPLEMENTATION SCHEDULE AND COST ESTIMATES

Recovery plans are intended to assist the Service and other stakeholders in planning and implementing actions to recover or protect threatened or endangered species. The following implementation schedule identifies priority number, duration, potential stakeholders, responsible agencies, and estimated costs for the recovery actions described in this Revised Recovery Plan. It is a guide for planning and meeting the objectives discussed in this Revised Recovery Plan.

Due to the uncertainties associated with the effects of barred owl interactions, results from ongoing and new research, and habitat changes that may occur as a result of climate change, the actions needed to stabilize and begin to recover the spotted owl may change over time. The Service and other implementers of this Revised Recovery Plan will have to employ an active adaptive management strategy to achieve results and focus on the most important actions for recovery. This Revised Recovery Plan will be amended as necessary.

The implementation schedule and cost estimate (Table IV-1) outlines recovery actions and their estimated costs for the first 5 years of this recovery program; total costs are estimated for the entire 30-year period. The costs are broad estimates and identify foreseeable expenditures that could be made to implement the specific recovery actions. Actual expenditures by identified agencies and other partners will be contingent upon appropriations and other budgetary constraints.

The actions identified in the implementation schedule are those that, in our opinion, should bring about the recovery of this species. However, these actions are subject to modification as dictated by new findings, changes in the species' status, and the completion of other recovery actions. The priority for each action is assigned as follows:

Priority 1: An action that must be taken to prevent extinction or prevent the species from declining irreversibly in the foreseeable future.

Priority 2: An action that must be taken to prevent a significant decline in the species' population/habitat quality or some other significant negative impact short of extinction.

Priority 3: All other actions deemed necessary to meet the recovery objectives.

The column "Action Duration" indicates whether the action is one of five types. (1) Discrete actions are shown by the number of years estimated to complete the action. (2) Continuous actions are to be implemented every year once begun. (3) Ongoing actions are currently being implemented and will continue until the action is no longer necessary. (4) Intermittent actions are to be implemented as needed. (5) "TBD" (to be determined) actions are those for which the duration was not possible to estimate.

While the ESA assigns a strong leadership role to the Service for the recovery of listed species, it also recognizes the importance of other Federal agencies, States, and other stakeholders in the recovery process. The "responsible parties" identified in the implementation schedule are those partners who can make significant contributions to specific recovery tasks and who may voluntarily participate in any aspect of recovery actions listed. In some cases, the most logical lead agency has been identified with an asterisk. The identification of agencies and other stakeholders in the implementation schedule does not constitute any additional legal responsibilities beyond existing authorities. However, parties willing to participate may benefit by being able to show in their own budgets that their funding request is for a recovery action identified in an approved recovery plan and is therefore considered a necessary action for the overall coordinated effort to recover the spotted owl. Also, section 7(a)(1) of the ESA directs all Federal agencies to use their authorities in furtherance of the purposes of the ESA by carrying out programs, such as these recovery actions, for the conservation of threatened and endangered species.

We listed the agencies and other parties that we believe are the primary stakeholders in the recovery process, and have the authority, expertise, responsibility, or expressed interest to implement a specific recovery action. However, the list of possible stakeholders is not limited to the parties below; other stakeholders are invited to participate.

There are four assumptions associated with these cost estimates:

1. Estimates include Federal government reimbursement of travel and per-diem costs of non-governmental employees to participate in recovery actions.
2. Responsible parties include both organizations that carry out the activity and organizations that fund the activity.
3. The cost of each Action is estimated independently, unless otherwise noted.
4. The opportunity cost of managing these lands for spotted owls instead of other uses is not included in this analysis.

For most of the actions identified in this Revised Recovery Plan, there is no way of deriving a precise cost estimate. A variety of assumptions were used to produce these estimates. For actions that called for meetings or formation of work groups, we assumed the cost of meetings based on the cost of a single Recovery Team meeting. For research and monitoring related actions, current similar research or monitoring projects were used as surrogates to estimate these costs. In some cases, researchers were asked to estimate the cost of a particular study or monitoring program. The cost estimates shown include certain actions that have no new costs (*e.g.*, certain agencies or organizations are already staffed and committed to participating in some of the actions identified).

Several actions call for habitat alteration to benefit the spotted owl. These comprise two categories: actions calling for modification of existing practices to benefit the spotted owl, and actions calling for specific types of management. For modifications of existing practices, the cost of adjusting the action during planning was estimated, rather than the actual entire cost of implementing the project since the "existing practices" cost would already be incurred by the land manager. For the actions that call for specific management, actual estimates for conducting a given type of management were used, but the cost attributable to spotted owl recovery was set at 10 percent of this total cost as an estimate of the added cost to the agencies of implementing such actions. To complete the estimates for some habitat-related actions, base numbers were obtained using the costs and accomplishments of the FS and BLM within the range of the spotted owl.

The costs are broad estimates and identify foreseeable expenditures that could be made to implement the specific recovery actions. Actual expenditures by identified agencies and other partners will be contingent upon appropriations and other budgetary constraints. There are no recovery actions for Listing Factor B.

In Table IV-1, "Land managers" means non-federal land managers, "Landowners" means non-federal landowners, and "States" means State governments of Washington, Oregon, and California. For some recovery actions the interagency Northern Spotted Owl Implementation Team is identified as a responsible party. In these cases it is likely the Northern Spotted Owl Implementation Team will coordinate within their agencies to complete these actions as opposed to the Northern Spotted Owl Implementation Team itself actually carrying out the activity.

Appendix A. Background

This section of the Revised Recovery Plan is designed to provide information necessary to understand the Revised Recovery Plan's strategy, goals, objectives, and criteria for the spotted owl. While it is not an exhaustive review, information on the spotted owl's status, basic ecology, demography, and past and current threats is included. Detailed accounts of the taxonomy, ecology, and reproductive characteristics of the spotted owl were presented in the 1987 and 1990 Status Reviews (USFWS 1987, 1990a), 1989 Status Review Supplement (USFWS 1989), Interagency Scientific Committee Report (Thomas *et al.* 1990), Forest Ecosystem Management Assessment Team (FEMAT) Report (USDA *et al.* 1993), final rule designating the spotted owl as a threatened species (USFWS 1990b), scientific evaluation of the status of the spotted owl (Courtney *et al.* 2004), and several key monographs (*e.g.*, Forsman *et al.* 2004, Anthony *et al.* 2006).

Species Description and Taxonomy

The spotted owl is a medium-sized owl and is the largest of the three subspecies of spotted owls (Gutiérrez *et al.* 1995). It is approximately 46 to 48 centimeters (18 inches to 19 inches) long and the sexes are dimorphic, with males averaging about 13 percent smaller than females. The mean mass of 971 males taken during 1,108 captures was 580.4 grams (1.28 pounds) (range = 430.0 to 690.0 grams) (0.95 pound to 1.52 pounds), and the mean mass of 874 females taken during 1,016 captures was 664.5 grams (1.46 pounds) (range = 490.0 to 885.0 grams) (1.1 pounds to 1.95 pounds) (P. Loschl and E. Forsman pers. comm. 2006). The spotted owl is dark brown with a barred tail and white spots on its head and breast, and it has dark brown eyes surrounded by prominent facial disks. Four age classes can be distinguished on the basis of plumage characteristics (Forsman 1981, Moen *et al.* 1991). The spotted owl superficially resembles the barred owl, a species with which it occasionally hybridizes (Kelly and Forsman 2004). Hybrids exhibit physical and vocal characteristics of both species (Hamer *et al.* 1994).

The northern spotted owl is one of three subspecies of spotted owls recognized by the American Ornithologists' Union. The taxonomic separation of these three subspecies is supported by genetic (Barrowclough and Gutiérrez 1990, Barrowclough *et al.* 1999, Haig *et al.* 2004), morphological (Gutiérrez *et al.* 1995), and biogeographic information (Barrowclough and Gutiérrez 1990). The distribution of the Mexican subspecies (*S. o. lucida*) is separate from those of the northern and California (*S. o. occidentalis*) subspecies (Gutiérrez *et al.* 1995). Recent studies analyzing mitochondrial DNA sequences (Haig *et al.* 2004, Chi *et al.* 2005, Barrowclough *et al.* 2005) and microsatellites (Henke *et al.* 2005) confirmed the validity of the current subspecies designations for northern and California spotted owls. The narrow hybrid zone between these two subspecies, which is located in the southern Cascades and northern Sierra Nevadas, appears to be stable (Barrowclough *et al.* 2005).

Population Trends and Distribution

There are no estimates of the size of the spotted owl population prior to settlement by Europeans. Spotted owls are believed to have inhabited most old-growth forests or stands throughout the Pacific Northwest, including northwestern California, prior to beginning of modern settlement in the mid-1800s (USFWS 1989).

The current range of the spotted owl extends from southwest British Columbia through the Cascade Mountains, coastal ranges, and intervening forested lands in Washington, Oregon, and California, as far south as Marin County (USFWS 1990b). The range of the spotted owl is partitioned into 12 physiographic provinces (Figure A-1) based on recognized landscape subdivisions exhibiting different physical and environmental features (Thomas *et al.* 1993). These provinces are distributed across the species' range as follows:

- Four provinces in Washington: Eastern Washington Cascades, Olympic Peninsula, Western Washington Cascades, Western Washington Lowlands
- Five provinces in Oregon: Oregon Coast Range, Willamette Valley, Western Oregon Cascades, Eastern Oregon Cascades, Oregon Klamath
- Three provinces in California: California Coast, California Klamath, California Cascades

The spotted owl has become rare in certain areas, such as British Columbia, southwestern Washington, and the northern coastal ranges of Oregon.

As of July 1, 1994, there were 5,431 known site-centers of spotted owl pairs or resident singles: 851 sites (16 percent) in Washington, 2,893 sites (53 percent) in Oregon, and 1,687 sites (31 percent) in California (USFWS 1995). By June 2004, the number of territorial spotted owl sites recognized by Washington Department of Fish and Wildlife was 1,070 (J. Buchanan pers. comm. 2010). The actual number of currently occupied spotted owl locations across the range is unknown because not all areas have been or can be surveyed on an annual basis (USFWS 1992a, Thomas *et al.* 1993). In addition, many historical sites are no longer occupied because spotted owls have been displaced by barred owls, timber harvest, or severe fires, and it is possible that some new sites have been established due to recruitment of new areas into NRF habitat since 1994. The totals in USFWS (1995) represent the cumulative number of locations recorded in the three States, not population estimates.

Many historical spotted owl sites are no longer occupied because spotted owls have been displaced by barred owls, timber harvest, or fires.

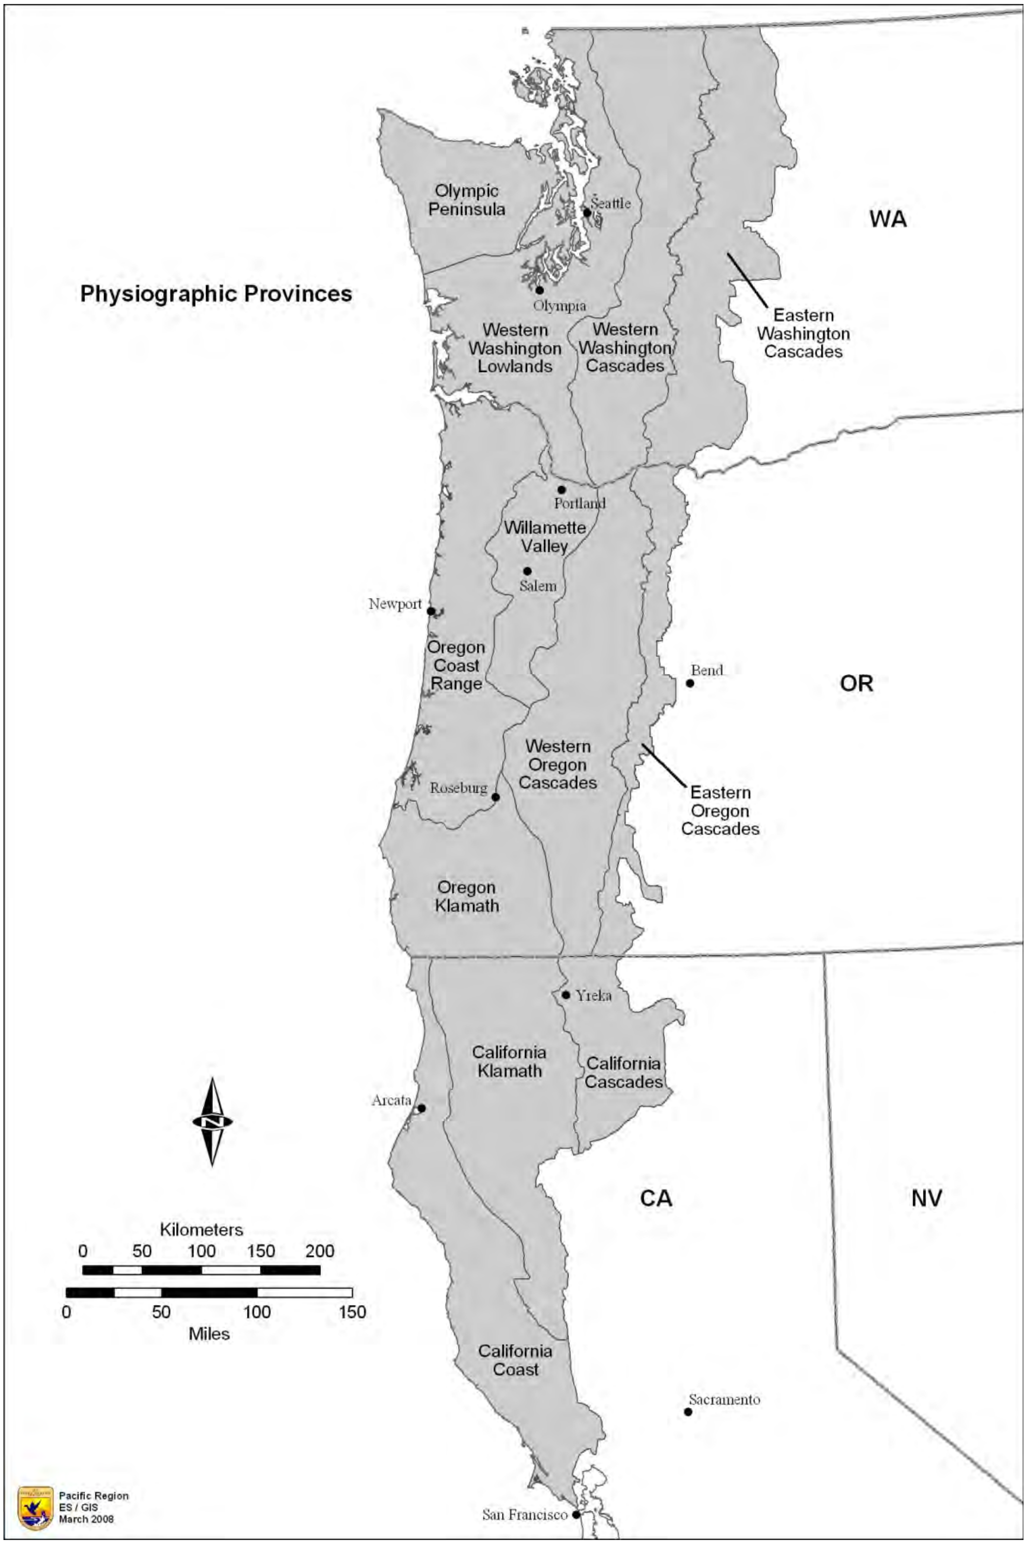

Figure A-1. Physiographic provinces within the range of the spotted owl in the United States.

Because the existing survey coverage and effort are insufficient to produce reliable range-wide estimates of population size, demographic data are used to evaluate trends in spotted owl populations. Analysis of demographic data can provide an estimate of the finite rate of population change (λ) (lambda), which provides information on the direction and magnitude of population change. A λ of 1.0 indicates a stationary population, meaning the population is neither increasing nor decreasing. A λ of less than 1.0 indicates a decreasing population, and a λ of greater than 1.0 indicates a growing population. Demographic data, derived from studies initiated as early as 1985, have been analyzed periodically (Anderson and Burnham 1992, Burnham *et al.* 1994, Forsman *et al.* 1996, Anthony *et al.* 2006, Forsman *et al.* 2011) to estimate trends in the populations of the spotted owl.

In January 2009, two meta-analyses modeled rates of population change for up to 24 years using the re-parameterized Jolly-Seber method (λ_{RJS}). One meta-analysis modeled the 11 long-term study areas (Table A-1), while the other modeled the eight study areas that are part of the effectiveness monitoring program of the NWFP (Forsman *et al.* 2011).

Point estimates of λ_{RJS} were all below 1.0 and ranged from 0.929 to 0.996 for the 11 long-term study areas. There was strong evidence that populations declined on 7 of the 11 areas (Forsman *et al.* 2011), these areas included Rainier, Olympic, Cle Elum, Coast Range, HJ Andrews, Northwest California and Green Diamond. On the other four areas (Tyee, Klamath, Southern Cascades, and Hoopa), populations were either stable, or the precision of the estimates was not sufficient to detect declines.

The weighted mean λ_{RJS} for all of the 11 study areas was 0.971 (standard error [SE] = 0.007, 95 percent confidence interval [CI] = 0.960 to 0.983), which indicated an average population decline of 2.9 percent per year from 1985 to 2006. This is a lower rate of decline than the 3.7 percent reported by Anthony *et al.* (2006), but the rates are not directly comparable because Anthony *et al.* (2006) examined a different series of years and because two of the study areas in their analysis were discontinued and not included in Forsman *et al.* (2011). Forsman *et al.* (2011) explains that the indication populations were declining was based on the fact that the 95 percent confidence intervals around the estimate of mean lambda did not overlap 1.0 (stable) or barely included 1.0. While estimates of mean λ_{RJS} are not directly comparable between Anthony *et al.* (2006) and Forsman *et al.* (2011), results from these studies indicate that rates of population decline for spotted owls have not moderated in recent years. In the most recent meta-analysis, Forsman *et al.* (2011) indicated that the number of populations that showed declines and the rates of decline on study areas in Washington and northern Oregon were noteworthy and should be cause for concern for the long-term sustainability of spotted owl populations throughout the range of the subspecies.

Demographic data suggest that populations over the 11 long-term demographic study areas decreased by about 2.9 percent from 1985 to 2006.

Table A-1. Spotted owl demographic parameters based on data from the spotted owl demographic study areas (adapted from Forsman *et al.* 2011).

Study Area	Fecundity	Apparent Survival[1]	λ_{RJS}	Population change[2]
Cle Elum	Declining	Declining	0.937	Declining
Rainier	Increasing	Declining	0.929	Declining
Olympic	Stable	Declining	0.957	Declining
Coast Ranges	Increasing	Declining since 1998	0.966	Declining
HJ Andrews	Increasing	Declining since 1997	0.977	Declining
Tyee	Stable	Declining since 2000	0.996	Stationary
Klamath	Declining	Stable	0.990	Stationary
Southern Cascades	Declining	Declining since 2000	0.982	Stationary
NW California	Declining	Declining	0.983	Declining
Hoopa	Stable	Declining since 2004	0.989	Stationary
Green Diamond	Declining	Declining	0.972	Declining

[1]Apparent survival calculations are based on model average.
[2]Population trends are based on estimates of realized population change.

The mean λ_{RJS} for the eight demographic monitoring areas (Cle Elum, Olympic, Coast Range, HJ Andrews, Tyee, Klamath, Southern Cascades, and Northwest California) that are part of the effectiveness monitoring program of the NWFP was 0.972 (SE = 0.006, 95 percent CI = 0.958 to 0.985), which indicated an estimated decline of 2.8 percent per year on Federal lands within the range of the spotted owl. The weighted mean estimate λ_{RJS} for the other three study areas (Rainier, Hoopa, and Green Diamond) was 0.969 (SE = 0.016, 95 percent CI = 0.938 to 1.000), yielding an estimated average decline of 3.1 percent per year. These data suggest that demographic rates for spotted owl populations on Federal lands were somewhat better than elsewhere; however, this comparison is confounded by the interspersion of non-federal land in study areas and the likelihood that spotted owls use habitat on multiple ownerships in some demography study areas.

The number of populations that declined and the rate at which they have declined are noteworthy, particularly the precipitous declines in the Olympic, Cle Elum, and Rainier study areas in Washington and the Coast Range study area in Oregon. Estimates of population declines in these areas ranged from 40 to 60 percent during the study period through 2006 (Forsman *et al.* 2011). Spotted owl populations on the HJ Andrews, Northwest California, and Green Diamond study areas declined by 20-30 percent whereas the Tyee, Klamath, Southern Cascades, and Hoopa study areas showed declines of 5 to 15 percent.

Decreases in adult apparent survival rates were an important factor contributing to decreasing population trends.

Decreases in adult apparent survival rates were an important factor contributing to decreasing population trends. Forsman *et al.* (2011) found apparent survival rates were declining on 10 of the study areas with the Klamath study area in Oregon being the exception. Estimated declines in adult survival were most precipitous in Washington where apparent survival rates were less than 80 percent in recent years, a rate that may not allow for sustainable populations (Forsman *et al.* 2011). In addition, declines in adult survival for study areas in Oregon have occurred predominately within the last five years and were not observed in the previous analysis by Anthony *et al.* 2006. Forsman *et al.* (2011) express concerns about the collective declines in adult survival across the subspecies range because spotted owl populations are most sensitive to changes in adult survival.

There are few spotted owls remaining in British Columbia. Chutter *et al.* (2004) suggested immediate action was required to improve the likelihood of recovering the spotted owl population in British Columbia. In 2007, the Spotted Owl Population Enhancement Team recommended to remove spotted owls from the wild in British Columbia. The primary recommendation consisted of two different options – 1) remove all spotted owls immediately and 2) remove most spotted owls in the first year and evaluate subsequently the need to remove additional spotted owls. The second option was selected for implementation (Fenger *et al.* 2007). Personnel in British Columbia captured and brought into captivity the remaining 16 known wild spotted owls. Prior to initiating the captive-breeding program, the population of spotted owls in Canada was declining by as much as 35 percent per year (Chutter *et al.* 2004). The amount of previous interaction between spotted owls in Canada and the United States is unknown (Chutter *et al.* 2004).

Life History and Ecology

Spotted owls are territorial and usually monogamous. Home-range sizes vary geographically, generally increasing from south to north (USFWS 1990b). Estimates of median size of their annual home range vary from 2,955 acres in the Oregon Cascades (Thomas *et al.* 1990) to 14,211 acres on the Olympic Peninsula (Forsman *et al.* 2001). Zabel *et al.* (1995) showed that spotted owl home ranges are larger where flying squirrels are the predominant prey and smaller where wood rats are the predominant prey. Home ranges of adjacent pairs overlap (Forsman *et al.* 1984, Solis and Gutiérrez 1990), suggesting that the defended area is smaller than the area used for foraging. The portion of the home range used during the breeding season is smaller than that used in the remainder of the year (Forsman *et al.* 1984, Sisco 1990).

The spotted owl is relatively long-lived, has a long reproductive life span, invests significantly in parental care, and exhibits high adult survivorship relative to other North American owls.

The spotted owl is relatively long-lived, has a long reproductive life span, invests significantly in parental care, and exhibits high adult survivorship relative to other North American owls (Forsman *et al.* 1984, Gutiérrez *et al.* 1995). Spotted owls are sexually mature at 1 year of age, but rarely breed until they are 2 to 5 years of age (Miller *et al.* 1985, Franklin 1992, Forsman *et al.* 2002). Breeding females lay one to four eggs per clutch, with the average clutch size being two eggs; however, most spotted owl pairs do not nest every year, nor are nesting pairs successful every year (Forsman *et al.* 1984, USFWS 1990b, Anthony *et al.* 2006). The small clutch size, temporal variability in nesting success, and delayed onset of breeding all contribute to the relatively low fecundity of this species (Gutiérrez 1996).

Courtship behavior usually begins in February or March, and females typically lay eggs in late March or April. The timing of nesting and fledging varies with latitude and elevation (Forsman *et al.* 1984). After they leave the nest in late May or June, juvenile spotted owls depend on their parents until they are able to fly and hunt on their own. Parental care continues after fledging into September (Forsman *et al.* 1984, USFWS 1990b). During the first few weeks after the young leave the nest, the adults often roost with them during the day. By late summer, the adults are rarely found roosting with their young and usually only visit the juveniles to feed them at night (Forsman *et al.* 1984).

Natal dispersal of spotted owls typically begins in September and October with a few individuals dispersing in November and December (Miller *et al.* 1997, Forsman *et al.* 2002). Natal dispersal occurs in stages. Juveniles will settle for up to seven months at temporary locations between larger movements (Miller *et al.* 1997, Forsman *et al.* 2002) and may do this multiple times before establishing a territory. The median natal dispersal distance from fledging

Dispersing juvenile spotted owls experience high mortality rates, exceeding 70 percent in some studies. Known or suspected causes of mortality during dispersal include starvation, predation, and accidents.

to "permanent" settlement is about 10 miles for males and 15.5 miles for females (Forsman *et al.* 2002).

During the transience (movement) phase, dispersers used mature and old-growth forest slightly more than its availability. Habitat supporting the transience phase of dispersal contains stands with adequate tree size and canopy closure to provide protection from avian predators and minimal foraging opportunities. This may include younger and less diverse forest stands than foraging habitat, such as even-aged, pole-sized stands, but such stands should contain some roosting structures and foraging habitat to allow for temporary resting and feeding during the movement phase. While the stand-level and landscape-level attributes of forests needed to facilitate successful dispersal have not been thoroughly evaluated (Buchanan 2004), an early attempt to describe dispersal conditions in the Interagency Scientific Committee (ISC) Report (Thomas *et al.* 1990) recommended managing the forested landscape such that 50 percent of each quarter-township has a mean diameter at breast height (dbh) of at least 11 inches and a canopy closure of at least 40 percent (the 50-11-40 rule). The minimum levels of this definition describe habitat supporting the transient phase of dispersal.

Spotted owl dispersal needs are better assessed at the landscape scale than at the stand- or habitat-patch scale (Thomas *et al.* 1990). Existing land allocations and congressional designations (*e.g.*, Wilderness Areas, Wild and Scenic Rivers, etc.) contribute significantly to spotted owl dispersal in some areas, but are not evenly distributed across the landscape. For example, many wilderness areas contain little spotted owl habitat due to elevation or topography. Spotted owls are able to move successfully through highly fragmented landscapes typical of the mountain ranges in western Washington and Oregon (Forsman *et al.* 2002). Still, barriers to spotted owl dispersal do exist and likely include large tracts of unforested lands, such as the Willamette, Rogue and Umpqua valleys and broad expanses of open water, such as Hood Canal and Puget Sound (Forsman *et al.* 2002). Spotted owls have dispersed from the Coastal Mountains to the Cascades Mountains in Oregon though broad forested regions between the Willamette, Umpqua, and Rogue Valleys of Oregon (Forsman *et al.* 2002, p. 22). These "corridors" primarily support relatively rapid movement through such areas, rather than colonization**.**

During the colonization phase, mature and old growth forest was used at nearly twice its availability (Miller *et al.* 1997). Closed pole-sapling-sawtimber habitat was used roughly in proportion to availability in both phases and may represent the minimum condition for movement. Open sapling and clearcuts were used less than expected based on availability during colonization (Miller *et al.* 1997). Habitat supporting the colonization phase of dispersal is generally equivalent to roosting and foraging habitat, although it may be in smaller amounts than needed to support nesting pairs.

Successful juvenile dispersal may depend on locating unoccupied NRF habitat in close proximity to other occupied sites (LaHaye *et al.* 2001). Spotted owls regularly disperse through highly fragmented forested landscapes that are typical of the mountain ranges in western Washington and Oregon (Forsman *et al.* 2002), and have dispersed from the Coastal Mountains to the Cascades Mountains in the broad forested regions between the Willamette, Umpqua, and Rogue Valleys of Oregon (Forsman *et al.* 2002). Corridors of forest through fragmented landscapes serve primarily to support relatively rapid movement through such areas, rather than colonization.

Dispersing juvenile spotted owls experience high mortality rates (more than 70 percent in some studies (Miller 1989, Franklin *et al.* 1999, USFWS 1990b) from starvation, predation, and accidents (Miller 1989, Forsman *et al.* 2002). Parasitic infection may contribute to these causes of mortality, but the relationship between parasite loads and survival is poorly understood (Gutiérrez 1989, Hoberg *et al.* 1989, Forsman *et al.* 2002). Juvenile dispersal is thus a highly vulnerable life stage for spotted owls, and enhancing the survivorship of juveniles during this period could play an important role in maintaining stable populations of spotted owls.

Analysis of the genetic structure of spotted owl populations suggests that gene flow may have been adequate between the Olympic Mountains and the Washington Cascades, and between the Olympic Mountains and the Oregon Coast Range (Haig *et al.* 2001). Although telemetry and genetic studies indicate that close inbreeding between siblings or parents and their offspring is rare (Haig *et al.* 2001, Forsman *et al.* 2002), inbreeding between more distant relatives is fairly common (E. Forsman pers. comm. 2006).

Spotted owls are mostly nocturnal, although they also forage opportunistically during the day (Forsman *et al.* 1984, Sovern *et al.* 1994). The composition of the spotted owl's diet varies geographically and by forest type. Generally, flying squirrels are the most prominent prey for spotted owls in Douglas-fir and western hemlock forests (Forsman *et al.* 1984) in Washington and Oregon, while dusky-footed wood rats are a major part of the diet in the Oregon Klamath, California Klamath, and California Coastal Provinces (Forsman *et al.* 1984, 2001, 2004, Ward *et al.* 1998, Hamer *et al.* 2001). Depending on location, other important prey include deer mice, tree voles, red-backed voles, gophers, snowshoe hare, bushy-tailed wood rats, birds, and insects, although these species comprise a small portion of the spotted owl diet (Forsman *et al.* 1984, 2004, Ward *et al.* 1998, Hamer *et al.* 2001).

Effects to spotted owls from barred owls are described above in Listing Factor E.

Habitat Characteristics

Forsman *et al.* (1984) reported that spotted owls have been observed in the following forest types: Douglas-fir, western hemlock, grand fir, white fir, ponderosa pine, Shasta red fir, mixed evergreen, mixed conifer hardwood (Klamath montane, Marin County), and redwood. In addition, spotted owls in Marin County, California use Bishop pine forests and mixed evergreen-deciduous hardwood forests. The upper elevation limit at which spotted owls occur corresponds to the transition to subalpine forest, which is characterized by relatively simple structure and severe winter weather (Forsman 1975, Forsman *et al.* 1984).

Spotted owls generally rely on older forested habitats (Carroll and Johnson 2008) because such forests contain the structures and characteristics required for nesting, roosting, and foraging. Features that support nesting and roosting typically include a moderate to high canopy closure (60 to 90 percent); a multi-layered, multi-species canopy with large overstory trees (with dbh of greater than 30 inches); a high incidence of large trees with various deformities (large cavities, broken tops, mistletoe infections, and other evidence of decadence); large snags; large accumulations of fallen trees and other woody debris on the ground; and sufficient open space below the canopy for spotted owls to fly (Thomas *et al.* 1990). Forested stands with high canopy closure also provide thermal cover (Weathers *et al.* 2001) and protection from predators.

Foraging habitat generally has attributes similar to those of nesting and roosting habitat, but such habitat may not always support successfully nesting pairs (USFWS 1992b). Dispersal habitat, at a minimum, consists of stands with adequate tree size and canopy closure to provide protection from avian predators and at least minimal foraging opportunities (USFWS 1992b). Forsman *et al.* (2002) found that spotted owls could disperse through highly fragmented forest landscapes, yet the stand-level and landscape-level attributes of forests needed to facilitate successful dispersal have not been thoroughly evaluated (Buchanan 2004). Therefore, a more complete description of dispersal habitat may be determined in the future. There is little evidence that small openings in forest habitat influence the dispersal of spotted owls, but large, non-forested valleys such as the Willamette Valley apparently are barriers to both natal and breeding dispersal (Forsman *et al.* 2002). The degree to which water bodies, such as the Columbia River and Puget Sound, function as barriers to dispersal is unclear, although radio telemetry data indicate that spotted owls move around large water bodies rather than cross them (Forsman *et al.* 2002).

Recent landscape-level analyses in portions of southwest Oregon and California Klamath Province suggest that a mosaic of late-successional habitat interspersed with other seral conditions may benefit spotted owls more than large, homogeneous expanses of older forests in areas where woodrats are a major component of spotted owl diets (Meyer *et al.* 1998, Franklin *et al.* 2000, Zabel *et al.* 2003). In Oregon Klamath and Western Oregon Cascade Provinces, Dugger *et al.* (2005) found that apparent survival and reproduction was positively associated with the proportion of older forest near the territory center (within 730 meters) (2,395 feet). Survival decreased dramatically when the amount of non-habitat (non-forest areas, sapling stands, etc.) exceeded approximately 50 percent of the home range (Dugger *et al.* 2005). The authors concluded there was no support for either a positive or negative direct effect of intermediate-aged forest—that is, all forest stages between sapling and mature,

One study indicated that while mid-seral and late-seral forests are important to spotted owls, a mixture of these forest types with younger forest and non-forest may be best for spotted owl survival and reproduction in certain parts of the range.

with total canopy cover greater than 40 percent—on either the survival or reproduction of spotted owls. It is unknown how these results were affected by the low habitat fitness potential in their study area, which Dugger *et al.* (2005) stated was generally much lower than those in Franklin *et al.* (2000) and Olson *et al.* (2004), and the low reproductive rate and survival in their study area, which they reported were generally lower than those studied by Anthony *et al.* (2006). Olson *et al.* (2004) found that reproductive rates fluctuated biennially and were positively related to the amount of edge between late-seral and mid-seral forests and other habitat classes in the central Oregon Coast Range. Olson *et al.* (2004) concluded that their results indicate that while mid-seral and late-seral forests are important to spotted owls, a mixture of these forest types with younger forest and non-forest may be best for spotted owl survival and reproduction in their study area.

While the effects of wildfire on spotted owls and their habitat vary, in the fire-adapted portions of the spotted owl's range, low- to moderate-severity fires may contribute to this mixture of habitats. Bond *et al.* (2002) examined the demography of the three spotted owl subspecies after wildfires, in which wildfire burned through spotted owl nest and roost sites in varying degrees of severity[1]. Post-fire demography parameters for the three subspecies were similar or better than long-term demographic parameters for each of the three subspecies in those same areas (Bond *et al.* 2002). In a preliminary study conducted by Anthony and Andrews (2004) in the Oregon Klamath Province, their sample of spotted owls appeared to be using a variety of habitats within the area of the Timbered Rock fire, including areas where burning had been moderate. In 1994, the Hatchery Complex fire burned 17,603 hectares in the Wenatchee National Forest in Washington's eastern Cascades, affecting six spotted owl activity centers (Gaines *et al.* 1997). Spotted owl habitat within a 2.9 km (1.8 mile) radius of the activity centers was reduced by 8 to 45 percent (mean = 31 percent) as a result of the direct effects of the fire and by 10 to 85 percent (mean = 55 percent) as a result of delayed mortality of fire-damaged trees and insects. Direct mortality of spotted owls was assumed to have occurred at one site, and spotted owls were present at two of the six sites 1 year after the fire, with reproduction occurring at only one. In 1994, two wildfires burned in the Yakama Indian Reservation in Washington's eastern Cascades, affecting the home ranges of two radio-tagged spotted owls (King *et al.* 1997). Although the amount of home ranges burned was not quantified, spotted owls were observed using areas that burned at low and medium intensities. No direct mortality of spotted owls was observed, even though thick smoke covered several spotted owl site-centers for a week. Spotted owls have been observed foraging in areas

[1] Fire severity is defined in several ways. See the individual studies cited for further information on the definitions of fire severity.

burned by fires of all severity categories (Clark 2007, Bond *et al.* 2009). While Clark (2007) found that spotted owls did not use large patches of high-severity burns, Bond *et al.* (2009) found spotted owls selecting burned areas, even high-severity burns, when they were within 1.5 km of a nest or roost site. Results of several of these studies are confounded because of post-fire salvaging that occurred (*e.g.*, King *et al.* 1997, Clark 2007). More research is needed to further understand the relationship between fire and spotted owl habitat use.

Spotted owls may be found in younger forest stands that have the structural characteristics of older forests or retained structural elements from the previous forest. In redwood forests and mixed conifer-hardwood forests along the coast of northwestern California, considerable numbers of spotted owls also occur in younger forest stands, particularly in areas where hardwoods provide a multi-layered structure at an early age (Thomas *et al.* 1990, Diller and Thome 1999). The results of numerous studies of spotted owl habitat relationships in the Redwood zone suggest stump-sprouting and rapid growth rates of redwoods, combined with high availability of large-bodied prey (woodrats) in patchy, intensively-managed forests, enables spotted owls to maintain high densities in a wide range of forest structural conditions.

In mixed conifer forests in the eastern Cascades in Washington, 27 percent of nest sites were in old-growth forests, 57 percent were in the understory reinitiation phase of stand development, and 17 percent were in the stem exclusion phase (Buchanan *et al.* 1995). In the western Cascades of Oregon, 50 percent of spotted owl nests were in late-seral/old-growth stands (greater than 80 years old), and none were found in stands of less than 40 years old (Irwin *et al.* 2000).

In the western Washington Cascades, spotted owls roosted in mature forests dominated by trees greater than 50 centimeters (19.7 inches) dbh with greater than 60 percent canopy closure more often than expected for roosting during the non-breeding season. Spotted owls also used young forest (trees of 20 to 50 centimeters (7.9 inches to 19.7 inches) dbh with greater than 60 percent canopy closure) less often than expected based on this habitat's availability (Herter *et al.* 2002). In the Coast Ranges, western Oregon Cascades and the Olympic Peninsula, radio-marked spotted owls selected for old-growth and mature forests for foraging and roosting and used young forests less than predicted based on availability (Forsman *et al.* 1984, Carey *et al.* 1990, 1992, Thomas *et al.* 1990). Glenn *et al.* (2004) studied spotted owls in young forests in western Oregon and found little preference among age classes of young forest.

Habitat use also is influenced by prey availability. Ward (1990) found that spotted owls foraged in areas with lower variance in prey densities (*i.e.*, where the occurrence of prey was more predictable) within older forests and near ecotones of old forest and brush seral stages. Zabel *et al.* (1995) showed that spotted owl home ranges are larger and smaller where flying squirrels and wood rats, respectively, are the predominant prey.

Critical Habitat

On January 15, 1992, the Service designated critical habitat for the spotted owl within 190 Critical Habitat Units encompassing nearly 6.9 million acres (2.2 million acres in Washington, 3.3 million acres in Oregon, and 1.4 million acres in California (USFWS 1992a). Primary constituent elements (the physical and biological features of critical habitat essential to a species' conservation) identified in the spotted owl critical habitat final rule include those features that support nesting, roosting, foraging, and dispersal (USFWS 1992b). In 2008 the Service completed a revision of spotted owl critical habitat, designating 5.3 million acres (1.8 million acres in Washington, 2.3 million acres in Oregon, and 1.2 million acres in California). The primary constituent elements included suitable forest types and the areas within these containing nesting, roosting, foraging, or dispersal habitat.

Revised spotted owl critical habitat was designated based on large blocks of habitat identified for spotted owl conservation in the 2008 Recovery Plan (MOCAs) on the west side of the range (USFWS 2008a). The Service designated the Federal lands within these MOCAs as critical habitat, excluding congressionally-reserved areas such as Wilderness Areas and National Parks. Because the 2008 Recovery Plan did not include mapped areas in the eastern Cascades of Oregon and Washington, focusing instead on a landscape approach, we relied on the information used to map the areas in these provinces for the 2007 draft Recovery Plan(USFWS 2007).

As part of this recovery plan, the Service has completed a habitat modeling effort which provides a more in-depth evaluation of various habitat features that affect spotted owl habitat use, when compared to the process used to develop the MOCAs. This information will be used to evaluate potential habitat conservation network scenarios. The Service will use this information and other results of the modeling as it evaluates revisions to spotted owl critical habitat.

Conservation Efforts

Federal Lands

Since it was signed on April 13, 1994, the NWFP has guided the management of Federal forest lands within the range of the spotted owl (USDA and USDI 1994a, b). The NWFP was designed to protect large blocks of late-successional forest and provide habitat for species that depend on those forests including the spotted owl, as well as to "produce a predictable and sustainable level of timber sales and non-timber resources that will not degrade or destroy the environment" (USDA and USDI 1994a). The NWFP includes land-use allocations that would provide for population clusters of spotted owls (*i.e.,* demographic support) and maintain connectivity between population clusters. Certain land-use allocations in the NWFP contribute to supporting population clusters: LSRs, Managed Late-Successional Areas, and Congressionally Reserved

Areas. Riparian Reserves, Adaptive Management Areas and Administratively Withdrawn Areas can provide both demographic support and connectivity/dispersal between the larger blocks, but are not necessarily designed for that purpose. Matrix areas were to support timber production while also retaining biological legacy components important to old-growth obligate species that would persist into future managed timber stands.

The NWFP was directly incorporated into 4 National Forest LRMPs and amended the LRMPs that guide the management of each of the 15 National Forests and six BLM Districts across the range of the spotted owl to adopt a series of reserves and management guidelines that were intended to protect spotted owls and their habitat. The LRMPs adopted a set of reserves and standards and guidelines described in the Record of Decision for the NWFP.

The NWFP with its rangewide network of LSRs was adapted from work completed by three previous studies (Thomas *et al.* 2006): the 1990 ISC Report (Thomas *et al.* 1990), the 1991 report for the Conservation of Late-successional Forests and Aquatic Ecosystems (Johnson *et al.* 1991), and the 1993 report of the Scientific Assessment Team (Thomas *et al.* 1993). In addition, the 1992 Draft Recovery Plan for the Northern Spotted Owl (USFWS 1992b) was based on the ISC report.

The FEMAT predicted, based on expert opinion, the spotted owl population would decline in non-reserve lands over time, while the population would stabilize and eventually increase within LSRs as habitat conditions improved over the next 50 to 100 years (USDA *et al.* 1993, USDA and USDI 1994a, b). Based on the results of the first decade of monitoring, Lint (2005) could not determine whether implementation of the NWFP would reverse the spotted owl's declining population trend because not enough time had passed to provide the necessary measure of certainty. However, the results from the first decade of monitoring do not provide any reason to depart from the objective of habitat maintenance and restoration as described in the NWFP and incorporated into LRMPs (Lint 2005, Noon and Blakesley 2006). Bigley and Franklin (2004) suggested that more fuels treatments are needed in east-side forests to preclude large-scale losses of habitat to stand-replacing wildfires. Other stressors that occur in NRF habitat, such as the range expansion of the barred owl (already in action) and infection with WNV (which may or may not occur) may complicate the conservation of the spotted owl. Recent reports about the status of the spotted owl offer few management recommendations to deal with these emerging threats.

Results from the first decade of monitoring do not provide any reason to depart from the objective of habitat maintenance and restoration as described in the Northwest Forest Plan.

Non-federal Lands

In the report from the ISC (Thomas *et al.* 1990), the draft Recovery Plan (USFWS 1992b), and the report from the FEMAT (USDA *et al.* 1993), it was noted that limited Federal ownership in some areas constrained the ability to form a network of old-forest reserves to meet the conservation needs of the spotted owl. In these areas in particular, non-federal lands would be important to the range-wide goal of achieving conservation and recovery of the spotted owl.

There are 17 current and ongoing conservation plans (CP) including HCPs and SHAs that have incidental take permits issued for spotted owls—eight in Washington, three in Oregon, and six in California. The CPs range in size from 76 acres to more than 1.8 million acres, although not all acres are included in the mitigation for spotted owls. In total, the CPs cover approximately 3 million acres (9.4 percent) of the 32 million acres of non-federal forest lands in the range of the spotted owl. The period of time that the HCPs will be in place ranges from 20 to 100 years. While each CP is unique, there are several general approaches to mitigation of incidental take:

- Reserves of various sizes, some associated with adjacent Federal reserves
- Forest management that maintains or develops nesting habitat
- Forest management that maintains or develops foraging habitat
- Forest management that maintains or develops dispersal habitat
- Deferral of harvest near specific sites

Washington. In Washington State, there are over 2.1 million acres of land in conservation plans (6 HCPs and 2 SHAs). Some of these CPs focus on providing nesting, roosting habitat throughout the area or in strategic locations; while others focus on providing connectivity through foraging habitat and/or dispersal habitat. Most of the Washington HCPs have foraging as a minimal target for habitat quality. In addition, there is a long-term habitat management agreement covering 13,000 acres in which authorization of take was provided through an incidental take statement (section 7) associated with a Federal land exchange.

Two Washington HCPs are based upon municipal watershed management and will provide older forest conditions over time. One HCP occurs within checkerboard ownership in the central Cascades and focuses on connectivity through a combination of nesting habitat in strategic locations as well as a distribution of nesting habitat and foraging habitat across the ownership and the planning area. Several HCPs, a Habitat Management Agreement (via section 7), and one safe harbor agreement focus on connectivity from a dispersal standpoint, including providing foraging habitat and landscape conditions conducive to spotted owl movement and potential residence. The largest HCP in Washington State (WDNR State lands) was designed by a scientific advisory team which analyzed the manner in which State lands could contribute to support the NWFP reserves. That HCP has a system of designated areas designed to provide demographic support in some areas, and foraging and dispersal in other areas.

Oregon. The three spotted owl-related HCPs currently in effect cover more than 300,000 acres of non-federal lands. These HCPs are intended to provide some nesting habitat and connectivity over the next few decades. On July 27, 2010, the Service completed a Programmatic Safe Harbor Agreement with the Oregon Department of Forestry that will enroll up to 50,000 acres of non-federal lands within the State over a total of 50 years. It is primarily intended to increase the time between harvests (defer harvest), and to lightly to moderately thin younger forest stands that are currently not habitat to increase tree diameter size and stand diversity (species, canopy layers, presence of snags).

California. Four HCPs and 2 SHAs authorizing take of spotted owls have been approved; these CPs cover more than 622,000 acres of non-federal lands. Implementation of these plans is intended to provide for spotted owl demography and connectivity support to NWFP lands.

Appendix B. Threats

Habitat Changes

Historical Levels of Spotted Owl Habitat and Rates of Loss

In 1990, the Service estimated spotted owl habitat had declined 60 to 88 percent since the early 1800s (USFWS 1990b). This loss, which was concentrated mostly at lower elevations and in the Coast Ranges, was attributed primarily to timber harvest and land-conversion activities, and to a lesser degree to natural perturbations (USFWS 1990a). Davis and Lint (2005) compared the current condition of forests throughout the range of the species to maps from the 1930s and 1940s and found that, in Oregon and Washington, fragmentation of forests had increased substantially; in some physiographic provinces, the increase was more than five-fold. However, fragmentation in California decreased, which the authors speculate may be due to fire suppression in fire-dependent provinces (Davis and Lint 2005).

Recent Rates of Loss of Spotted Owl Habitat as a Result of Timber Harvest

Until 1990, the annual rate of removal of spotted owl habitat on national forests as a result of logging was approximately 1 percent per year in California and 1.5 percent per year in Oregon and Washington. Anticipated future rates of habitat removal on BLM lands in Oregon at that time were projected to eliminate all NRF habitat on non-protected BLM lands (except the Medford District) within 26 years (USFWS 1990b).

Since 1990, there have been only a few efforts that have produced indices or more direct estimates of trends or change in the amount of NRF habitat for spotted owls. Cohen *et al.* (2002) reported landscape-level changes in forest cover across the Pacific Northwest using remote sensing technology. Their study indicated, "a steep decline in harvest rates between the late 1980s and the early 1990s on State and Federal and private industrial forest lands" (as described in Bigley and Franklin 2004:6-11).

Recent data has become available through the NWFP monitoring efforts (Davis and Dugger in press). This information tracked changes in spotted owl nesting and roosting habitat across all ownerships from timber harvest and natural disturbances (wildfire, insects, and disease); it did not track all foraging habitat. Based on vegetation data, they produced maps of forest stands that compared the stand's level of similarity to stand conditions known to be used for nesting and roosting by spotted owls. These stands were placed into one of four categories: highly suitable, suitable, marginal, and unsuitable. Highly suitable and suitable categories are likely nesting or roosting habitat, marginal stands may occasionally contain the habitat characteristics associated with nesting or roosting (see Davis and Dugger in press for more details). Data from California covered 14 years from 1994 to 2007, data from Oregon and Washington covered 10 years from 1996 to 2006 (Table B-1). Changes in habitat were evaluated comparing mapped differences in habitat condition between the initial and final vegetation maps. Habitat was considered "lost" if its condition moved from suitable or highly suitable to marginal or unsuitable.

Harvest rates for spotted owl nesting and roosting habitat on Federal lands were highest in the California Cascades (3.0 percent, 6,500 acres) and lowest in the Olympic Peninsula (0.06 percent, 500 acres). Overall, timber harvest on Federal lands removed 0.6 percent (53,800 acres) of nesting and roosting habitat during the reporting period.

Table B-1. Spotted owl habitat loss on Federal lands resulting from harvest and natural disturbances from 1994/96[1] to 2006-7[1] (acres) (adapted from Davis and Dugger in press).

[1] 1996 and 2006 for Oregon and Washington, 1994 and 2007 for California.
[2] Percent of 1994/96 habitat.
[3] Loss is the term used in Davis and Dugger (in press) to describe their data, which is summarized here.

Raphael (2006) estimated that approximately 7.5 million acres of spotted owl habitat existed on non-federal lands within California, Oregon, and Washington in 1994. Cohen *et al.* (2002) reported that, from the early 1970s through the mid-1990s, the harvest rates on private industrial lands were consistently about twice the average rate of harvest on public land. Bigley and Franklin (2004:6-11) noted that:

> "In the late 1980s and early 1990s the harvest rate was estimated at 2.4 percent per year for private industrial land. An increase in non-industrial private landowner's harvest rates started in the 1970s when the rate was 0.2 percent per year and continued to increase to the early 1990s when the rate was similar to that of the private industrial lands."

Recently, data on actual information on harvest of nesting and roosting habitat for non-federal lands became available through the NWFP monitoring program. On non-federal lands, 14.92 percent (625,600 acres) of the nesting and roosting habitat was harvested in the 10-14 years of the analysis. This compares to 0.6 percent (53,800 acres) on Federal lands in the same period.

Table B-2. Estimated amount of spotted owl nesting and roosting habitat1 at the start of the Northwest Forest Plan (baseline 1994/96[2]) and losses owing to harvest through 2006/7[2], by State and ownership (adapted from Davis and Dugger in press).

Land class	Baseline (1994/96[2])	Harvest	Total Percent loss[3]
Federal reserved			
Washington	2,274,200	7,900	0.3%
Oregon	2,699,600	6,100	0.2%
California	1,214,000	2,500	0.2%
Range-wide total	**6,187,800**	**16,500**	**0.3%**
Federal non-reserved			
Washington	470,200	4,800	1.0%
Oregon	1,561,400	23,800	1.5%
California	634,400	8,700	1.4%
Range-wide total	**2,666,000**	**37,300**	**1.4%**
Non-federal			
Washington	1,258,900	234,200	18.6%
Oregon	1,382,400	301,200	21.8%
California	1,556,700	90,200	5.8%
Range-wide total	**4,198,000**	**625,600**	14.9%
Range-wide total	**13,052,000**	**679,400**	**5.2%**

[3] Loss is the term used in Davis and Dugger (in press) to describe their data, which is summarized here.

Recent Rates of Loss of NRF Habitat as a Result of Natural Events

The effects of wildfire and other natural disturbances on spotted owls and their habitat vary by location, severity, and habitat function, though most of the data is related specifically to fire. Spotted owl use of post fire habitat varies, depending on fire severity and the function of the site for spotted owls (*i.e.*, nesting, roosting, or foraging). Few studies are available to clarify this relationship, and many of these are complicated by small sample sizes, post-fire logging, lack of long-term data, and inadequate pre-fire spotted owl data. Spotted owl reproduction and nesting have been observed in the short-term in some burned landscapes and even in core areas in which some portion was burned by high-severity fire. No nest trees were found in high-severity burns, though have been observed in moderate and low severity burned areas. Spotted owls have been observed roosting in forests experiencing the full range of fire severity, though most were associated with low or moderate severity burns. Spotted owls were observed to forage in burned areas within their home range in areas where dusky-footed woodrats are a primary food source, but there is no similar data in more northern conditions. Based on this information we conclude that, while spotted owls can make use of some post-fire landscapes, fire also reduces the function of some habitat and likely removes some from immediate usability, particularly in areas of high-severity fire.

Recent data from the NWFP Effectiveness Monitoring program provides an insight into the change in spotted owl nesting and roosting habitat from natural disturbances on Federal (Table B-1) and non-federal lands (Table B-3). Changes in habitat were evaluated comparing mapped differences in habitat condition over time. Habitat was considered “lost” if its condition moved from suitable or highly suitable to marginal or unsuitable. We use the term “loss” in this case because this is how the authors describe their data, though as described above, not all burned areas are necessarily lost as habitat. The level of losses varies widely by province, from extremely low (0.03percent of the nesting and roosting habitat) in the Olympic Peninsula Province to 9.5 percent in the Oregon Klamath Province. Wildfire caused most of the loss (236,700 acres) while insects and disease resulted in 8,100 acres of habitat. On non-federal lands, the level was very low, less than 1percent in each state (Table B-3).

Table B-3. Spotted owl nesting and roosting habitat loss from natural disturbances on non-federal lands from 1994/96[1] to 2006-7[1] (acres) (adapted from Davis and Dugger in press).

State	1994/96 habitat	Fire	Insects and disease	Total	Percent habitat loss[2]
Washington	1,258,900	2,400	6,000	8,400	0.7%
Oregon	1,382,400	5,100	2,700	7,800	0.6%
California	1,556,700	5,600	1,900	7,500	0.4%
Total	4,198,000	13,100	10,600	23,700	0.6%

[1] 1996 and 2006 for Oregon and Washington, 1994 and 2007 for California.

[2] Loss is the term used in Davis and Dugger (in press) to describe their data, which is summarized here.

Summary of Recent Rates of Loss of Spotted Owl Habitat as a Result of Timber Harvest and Natural Disturbances

Range-wide, 0.6 percent (53,800 acres) of the spotted owl nesting and roosting habitat on Federal lands were lost to timber harvest and 2.8 percent (244,800 acres) to natural disturbances, primarily wildfire, resulting in a total range-wide loss of 3.4 percent (298,600 acres). The greatest percentage of Federal land habitat loss was in Oregon, specifically in the Oregon Klamath Province (10.9 percent of the habitat) due primarily to wildfire. Two provinces, the Oregon and California Klamath accounted for 60 percent of the total habitat loss on Federal lands. In contrast, less than 1 percent of the nesting and roosting habitat in the Olympic Peninsula, Western Washington Cascades, and Oregon Coast Ranges were loss during the time period.

Habitat Recruitment

Several groups have attempted to estimate the rate or amount of spotted owl habitat recruitment. Most of these estimates were not specific to spotted owl habitat. In reality, projecting the transition of a forest's age and size classes to different levels of habitat function requires extensive field verification. The SEI report (SEI 2004:6-29) provided a clear caution relative to habitat development.

> "Habitat development certainly is not a mechanistic process and there is considerable variability with predictions of habitat development. The habitat complexity that most definitions project as suitable habitat develops

> over multiple decades and is not a threshold that is achieved with an average size class. Stand age or size does not account for the history, growing conditions, species composition, and other factors that determine the rate of habitat development. There is considerable uncertainty in the transition between mid-seral stage stands and suitable habitat. These uncertainties still exist with remote sensing information or inventory methods that are not specifically designed to sample the key components of suitable habitat."

In addition, determining when a forest progresses from non-habitat to habitat on an ecologically-short time frame (10-15 years) is fraught with assumptions and potential inaccuracy. Given the uncertainty about the rate of complex forest structure, it is likely that habitat development was overestimated, although the extent of overestimation cannot be determined (Bigley and Franklin 2004).

Given the degree of uncertainty, potential inaccuracy, and disagreements between results, we cannot at this time reach any conclusions on the issue of habitat recruitment. We will continue to follow this issue as new information becomes available.

Disease

WNV has killed millions of wild birds in North America since it arrived in 1999 (McLean *et al.* 2001, Caffrey 2003, Fitzgerald *et al.* 2003, Marra *et al.* 2004). Mosquitoes are the primary carriers of this virus that causes encephalitis in humans, horses, and birds. Although birds are the primary hosts of WNV, additional non-human hosts include horses and other ungulates, felines, canines, rodents, rabbits, bats, alligators, and frogs (Hubálek and Halouzka 1999, Gubler 2007). Mammalian prey may play a role in spreading WNV, if predators like spotted owls contract the disease by eating infected prey (Garmendia *et al.* 2000, Komar *et al.* 2001). One captive spotted owl in Ontario, Canada, is known to have contracted WNV and died (Gancz *et al.* 2004), but there are no documented cases of the virus in wild spotted owls.

Health officials expect that WNV eventually will spread throughout the range of the spotted owl (Blakesley *et al.* 2004), but it is unknown how the virus will ultimately affect spotted owl populations. Susceptibility to infection and the mortality rates of infected individuals vary among bird species (Blakesley *et al.* 2004), but most owls appear to be quite susceptible. For example, eastern screech-owls breeding in Ohio that were exposed to WNV experienced 100 percent mortality (T. Grubb pers. comm. in Blakesley *et al.* 2004). Barred owls, in contrast, showed lower susceptibility (B. Hunter pers. comm. in Blakesley *et al.* 2004). Wild birds may develop resistance to WNV through immune responses (Deubel *et al.* 2001).

Blakesley *et al.* (2004) offer competing scenarios for the likely outcome of spotted owl populations being infected by WNV. One scenario is that spotted owls can tolerate severe, short-term population reductions caused by the virus because spotted owl populations are widely distributed and number in the several thousands. An alternative scenario is that the virus will cause unsustainable mortality because of the frequency and/or magnitude of infection, thereby resulting in long-term population declines and extirpation from parts of the spotted owl's current range.

Ishak *et al.* (2008) document Plasmodium spp. in a spotted owl. They also found 10 spotted owls with multiple infections (Ishak *et al.* 2008). It is unclear, however, if this rate of infection is significant and if it might affect the recovery of the species.

Inadequacy of Regulatory Mechanisms

The original listing document (USFWS 1990b), Franklin and Courtney (2004), and the 5-year review (USFWS 2004b) noted some inadequacies in existing regulatory mechanisms. The 1990 listing rule concluded that current State regulations and policies did not provide adequate protection for spotted owls; less than 1 percent of the non-federal lands provided long-term protection for spotted owls (USFWS 1990b). The listing rule stated that the rate of harvest on Federal lands, the limited amount of permanently reserved habitat, and the management of spotted owls based on a network of individually protected sites did not provide adequate protection for the spotted owl. If continued, these management practices would result in an estimated 60 percent decline in the remaining spotted owl habitat, and the resulting amount of habitat might not be sufficient to ensure long-term viability of the spotted owl.

When it was adopted in 1994, the NWFP significantly altered management of Federal lands (USDA and USDI 1994a, b, Noon and Blakesley 2006, Thomas *et al.* 2006). The substantial increase in reserved areas and associated reduced harvest (ranging from approximately 1 percent per year to 0.24 percent per year) has substantially lowered the timber-harvest threat to spotted owls. However, the NWFP allows some loss of habitat and assumed some unspecified level of continued decline in spotted owls. Franklin and Courtney (2004) noted that many, but not all, of the scientific building blocks of the NWFP have been confirmed or validated in the decade since the plan was adopted. One major limitation appears to be the inability of the conservation network presented in the plan to deal with invasive species. However, this deficiency does not diminish the important contribution of the relevant LRMPs to spotted owl conservation (Franklin and Courtney 2004).

As the Federal agencies develop new LRMPs, they will consider the conservation needs of the spotted owl and the goals and objectives of this Revised Recovery Plan. If needed, actions to implement Federal land use plans will be accompanied with either plan or project level consultations to assure management actions align with recovery goals.

Barred Owls

Barred owls expanded their range from eastern to western North America during the past century. They were first documented in British Columbia in 1943 (Rand 1944, Munro and McTaggart-Cowan 1947), Washington in 1965 (Rogers 1966), Oregon in 1972 (E. Forsman in Livezey 2009a), California in 1976 (B. Marcot in Livezey 2009a). This range expansion may have been facilitated by increases in distribution of trees in the Great Plains due to exclusion of fires historically set by Native Americans, fire suppression, tree planting , extirpation of bison and beaver, and other factors (Dark *et al.* 1998, R. Gutiérrez in Levy 1999, 2004, Mazur and James 2000, USFWS 2003, Livezey 2009b). The range of the barred owl now completely overlaps that of its slightly smaller congener, the spotted owl (Gutiérrez *et al.* 1995).

Barred owls have been observed physically attacking spotted owls (pers. comms. in Pearson and Livezey 2003) and circumstantial evidence suggests that a barred owl killed a spotted owl (Leskiw and Gutiérrez 1998). Based on early studies conducted on the west slope of the Washington Cascades (Hamer 1988, Iverson 1993), barred owls were thought by some to be more closely associated with early successional forests than spotted owls are, though even then they were known to use old-growth. Recent studies in the Pacific Northwest (Herter and Hicks 2000, Pearson and Livezey 2003, Gremel 2005, Schmidt 2006, Hamer *et al.* 2007, Singleton *et al.* 2010) show that barred owls also use, and in some cases, appear to prefer old-growth forest and older forest. Diets of spotted and barred owls in the western Washington Cascades overlap by approximately 76 percent (Hamer *et al.* 2001). Barred owl diets are more diverse than those of spotted owls (Forsman *et al.* 2004) and include more species associated with riparian and other moist habitats, along with more terrestrial and diurnal species (Hamer *et al.* 2001). The more-diverse food habits of barred owls appears to be the reason that barred owls have much smaller home-ranges than spotted owls do (Hamer *et al.* 2007).

Barred owls reportedly have reduced probability of detection (response behavior), site occupancy, reproduction, and survival of spotted owls. The probability of detecting spotted owls during surveys in Washington, Oregon, and California was significantly reduced by the presence of barred owls (Olson *et al.* 2005, Crozier *et al.* 2006). In the eastern Cascades of Washington, probabilities of detecting any spotted owl or a pair of spotted owls were significantly lower when barred owls were detected during surveys than when no barred owls were detected (Kroll *et al.* 2010). In addition, studies in Oregon showed that detection of both species was negatively influenced by presence of the other (Bailey *et al.* 2009) and barred owls frequently were not detected during surveys for spotted owls (Bailey *et al.* 2009).

Forsman *et al.* (2011) and Anthony *et al.* (2006) have documented increasing barred owl numbers across Washington, Oregon, and California from 1990-2008. While barred owls have expanded into California more recently (Kelly *et al.* 2003), Forsman *et al.* (2011) provides strong evidence of increasing barred owl populations in this region. Occupancy of territories by spotted owls in study areas in Washington and Oregon was significantly lower after barred owls were detected within 0.5 miles of the territory center but was “only marginally lower” if barred owls were located more than 0.5 miles from the spotted owl territory center (Kelly *et al.* 2003:51). In the Gifford Pinchot National Forest, there were significantly more barred owl site-centers in unoccupied spotted owl circles than in occupied spotted owl circles with radii of 0.5 miles, 1 mile, and 1.8 miles centered on spotted owl sites (Pearson and Livezey 2003). In the eastern Washington Cascades, barred owls had a significant negative effect on site occupancy by any spotted owl (both single and pair spotted owl detections combined); however, barred owls did not have a negative effect on site occupancy by spotted owl pairs (Kroll *et al.* 2010). Spotted owl simple extinction probabilities (probability that a site center changed from occupied to unoccupied) were significantly higher in the eastern Washington Cascades when barred owls were detected in a site center during the year (Kroll *et al.* 2010). In Olympic National Park, spotted owl pair occupancy declined significantly at sites where barred owls had been detected, whereas pair occupancy remained stable at spotted owl sites without barred owls (Gremel 2005). Annual probability that a spotted owl territory would be occupied by a pair of spotted owls after barred owls were detected at the site declined by five percent in the HJ Andrews study area, 12 percent in the Coast Range study area, and 15 percent in the Tyee study area (Olson *et al.* 2005).

Barred owls evidently are appropriating spotted owl sites in flatter, lower-elevation forests in some areas (Pearson and Livezey 2003, Gremel 2005, Hamer *et al.* 2007). Apparently in response to barred owls, some marked spotted owl site centers have moved higher up slopes (Gremel 2005). According to one study, “the trade-off for living in high elevation forests could be reduced survival or fecundity in years with severe winters (Hamer *et al.* 2007:764).” It is unknown whether this slope/elevation tendency found in Washington is prevalent throughout the range of the spotted owl, how long spotted owls can persist where they are relegated to only steep, higher-elevation areas, and whether barred owls will continue to move upslope and eventually supplant the remaining spotted owls in these areas.

Reproduction of spotted owls in the Roseburg study area, Oregon, was negatively affected by the presence of barred owls (Olson *et al.* 2004). Apparent survival of spotted owls was negatively affected by barred owls in two (Olympic and Wenatchee) of 14 study areas throughout the range of the spotted owl (Anthony *et al.* 2006). The researchers attributed the equivocal results for most of their study areas to the coarse nature of their barred owl covariate. It is likely that this study underestimated the effects of barred owls on the reproduction of spotted owls because spotted owls often cannot be relocated after they are displaced by barred owls (E. Forsman pers. comm. 2006).

Only 47 spotted owl/barred owl hybrids were detected in an analysis of more than 9,000 banded spotted owls throughout their range (Kelly and Forsman 2004). Consequently, hybridization with the barred owl is considered to be “an interesting biological phenomenon that is probably inconsequential, compared with the real threat—direct competition between the two species for food and space" (Kelly and Forsman 2004:808).

Data indicating negative effects of barred owls on spotted owls are largely correlational and are almost exclusively gathered incidentally to data collected on spotted owls (Gutiérrez *et al.* 2004, Livezey and Fleming 2007). Competition theory predicts that barred owls will compete with spotted owls because they are similar in size and have overlapping diet and habitat requirements (Hamer *et al.* 2001, 2007, Gutiérrez *et al.* 2007). Limited experimental evidence (Crozier *et al.* 2006), preliminary response by spotted owls to a scientific collection of barred owls (L. Diller pers. comm. 2010), correlational studies (Kelly *et al.* 2003, Pearson and Livezey 2003, Gremel 2005, Olson *et al.* 2005, Hamer *et al.* 2007, Dugger *et al.* in press), and anecdotal information (Leskiw and Gutiérrez 1998, Gutiérrez *et al.* 2004) suggest that barred owls are negatively affecting spotted owls through exploitive and interference competition. The preponderance of evidence suggests barred owls are contributing to the population decline of spotted owls, especially in Washington, portions of Oregon, and the northern coast of California (Gutiérrez *et al.* 2004, Olson *et al.* 2005) which may explain the sharper decline in the spotted owl population trend in the northern portion of the spotted owl's range compared to those in the southern portion of the range.

Loss of Genetic Variation

One possible threat to spotted owls is a loss of genetic variation from population bottlenecks which could lead to increased inbreeding depression and decreased adaptive potential. Funk *et al.* (2010) found evidence of recent genetic bottlenecks in the spotted owl population, estimating these have occurred within the last few decades. They found the strongest evidence for recent bottlenecks in the Washington Cascades, which they correlate with data on significant population declines in the same area. However, they did not find strong evidence of bottlenecks in other areas that showed population declines. While they could not determine "whether inbreeding is contributing to vital rate reductions" (pg. 7), they do caution that "future efforts to conserve northern spotted owl populations will require greater consideration of genetic threats to persistence" (pg. 7).

SEI (2008) reviewed a presentation and two unpublished manuscripts, provided by Dr. Susan Haig, on the evidence for genetic bottlenecks in spotted owl populations. Using microsatellite markers and a computer program called "Bottleneck," Haig provided evidence of recent genetic bottlenecks at several spatial scales (individual "populations" [demographic study areas], regions, and subspecies). Haig explicitly stated she could not conclude these bottlenecks were the cause for, nor were they necessarily related to, the recently documented declines in spotted owl populations. However, she did present a "cross-walk" of her results with a table depicting the status of spotted owl populations from Anthony *et al.* (2006).

SEI (2008) concluded Haig's observed bottlenecks are likely the result of population declines and not the cause of it; they are signatures of something that occurred in the past. SEI (2008) advises the population dynamics of the spotted owl likely will be more important to its short-term survival than will be its genetic makeup, regardless of the evidence for bottlenecks having occurred in the past (Barrowclough and Coats 1985).

Appendix C. Development of a Modeling Framework to Support Recovery Implementation and Habitat Conservation Planning

Introduction by U.S. Fish and Wildlife Service

The Service believes a spatially explicit demographic model would greatly improve recovery planning and implementation for the spotted owl. Peer reviewers were critical of the 2008 Recovery Plan's habitat conservation network strategy and the general lack of updated habitat modeling capacity. The Service considered this criticism and concluded that a spatially explicit demographic model would greatly improve recovery implementation for the spotted owl, as well as other land use management decisions.

For this Revised Recovery Plan, the Service appointed a team of experts to develop and test a modeling framework that can be used in numerous spotted owl management decisions. This spatially-explicit approach is designed to allow for a more in-depth evaluation of various factors that affect spotted owl distribution and populations**.** This approach also allows for a unique opportunity to integrate new data sets, such as information from the NWFP 15-year Monitoring Report (Davis and Dugger in press) and the recent spotted owl population meta-analysis (Forsman *et al.* 2011).

The Service expects this modeling framework will be applied by Federal, State, and private scientists to make better informed decisions concerning what areas should be conserved or managed to achieve spotted owl recovery. Specifically, the modeling framework can be applied to various spotted owl management challenges, such as to:

1) Inform evaluations of meeting population goals and Recovery Criteria.
2) Develop reliable analysis and modeling tools to enable evaluation of the influence of habitat suitability and barred owls on spotted owl demographics.
3) Support future implementation and evaluation of the efficacy of spotted owl conservation measures described in various recovery actions.
4) Provide a framework for landscape-scale planning by both Federal and non-federal land managers that enables evaluation of potential demographic responses to various habitat conservation scenarios, including information that could be used in developing a proposed critical habitat rule.

These and other potential applications of the modeling framework described herein represent a significant advancement in spotted owl recovery planning. Although the completed model framework will be included in the Revised Recovery Plan, the Service hopes that future application of this modeling approach will lead to refinement and improvements, such as incorporation of population connectivity and source-sink dynamics, over time as experience and new scientific insights are realized.

To meet these objectives, the Service established the Spotted Owl Modeling Team (hereafter the "modeling team") to develop and apply modeling tools for the Service's use in designing and evaluating various conservation options for achieving spotted owl recovery. The modeling team was informally organized along lines of function and level of participation. Jeffrey Dunk (Humboldt State University), Brian Woodbridge (USFWS), Bruce Marcot (USFS, Pacific Northwest Research Station), Nathan Schumaker (USEPA), and Dave LaPlante (a contractor with Natural Resource Geospatial) composed the primary group which was responsible for conducting the data analyses and modeling. They were assisted by spotted owl researchers, agency staff and modeling specialists who individually provided data sets and advice on particular issues within their areas of expertise, and reviewed modeling processes and outputs. These experts were: Robert Anthony (Oregon State University), Katie Dugger (Oregon State University), Marty Raphael (USFS, Pacific Northwest Research Station), Jim Thrailkill (USFWS), Ray Davis (USFS, Northwest Forest Plan Monitoring Group), Eric Greenquist (BLM), and Brendan White (USFWS). Additionally, technical specialists—Craig Ducey (BLM), Karen West (USFWS) and Dan Hansen and M.J. Mazurek (contractors with Humboldt State University Foundation) conducted literature reviews and assisted with data collection and analyses.

To ensure that the modeling effort was based on the most current information, scientific knowledge and opinion, the modeling team also sought the assistance of numerous individual scientists and habitat managers from government, industry and a non-profit conservation organization (listed in acknowledgements) in development of habitat descriptions, modeling regions and many other aspects of spotted owl and forest ecology. To facilitate this effort, the Service held a series of meetings with spotted owl experts (habitat expert panels) to obtain additional information, data sets, and expertise regarding spotted owl habitats.

Representatives of the modeling team have prepared this Appendix to provide a thorough description of the modeling framework developed by the team, the results of model development and testing, and examples of how the modeling process can be used to evaluate habitat conservation scenarios and their relative contribution to recovery.

While this framework represents state-of-the-art science, it is not intended to represent absolute spotted owl population numbers or be a perfect reflection of reality. Instead, it provides a comparison of the relative spotted owl responses to a variety of potential conservation measures and habitat conservation networks. The implementation of spotted owl recovery actions should consider the results of the modeling framework as one of numerous sources of information to be incorporated into the decision-making process.

General Approach

The spotted owl modeling team (hereafter "modeling team" or "we") employed state-of–the-art modeling tools in a multi-step analysis similar to that proposed by Heinrichs *et al.* (2010) and Reed *et al.* (2006) for designing habitat conservation networks and evaluating their contributions to spotted owl recovery. In addition to this objective, the modeling tools in this framework, individually or in combination, are designed to enable evaluation of the efficacy of spotted owl conservation measures such as Recovery Action 10 and management of barred owls**.**

Our conservation planning framework integrates a spotted owl habitat model, a habitat conservation planning model, and a population simulation model. Collectively, these modeling tools allow comparison of estimated spotted owl population performance among alternative habitat conservation network scenarios under a variety of potential conditions. This will enable the Service and other interested managers to use relative population viability (timing and probability of population recovery) as a criterion for evaluating habitat conservation network scenarios and other conservation measures for the spotted owl.

The evaluation approach the modeling team developed consists of three main steps (Figure C1):

> **Step 1** – Create a map of spotted owl habitat suitability throughout the species' U.S. range, based on a statistical model of spotted owl habitat associations.
>
> **Step 2** – Develop a spotted owl conservation planning model, based on the habitat suitability model developed in Step 1, and use it to design an array of habitat conservation network scenarios.
>
> **Step 3** – Develop a spatially explicit spotted owl population model that reliably predicts relative responses of spotted owls to environmental conditions, and use it to test the effectiveness of habitat conservation network scenarios designed in step 2 in recovering the spotted owl. The simulations from this spotted owl population model are not meant to be estimates of what will occur in the future, but provide information on trends predicted to occur under differing habitat conservation scenarios.

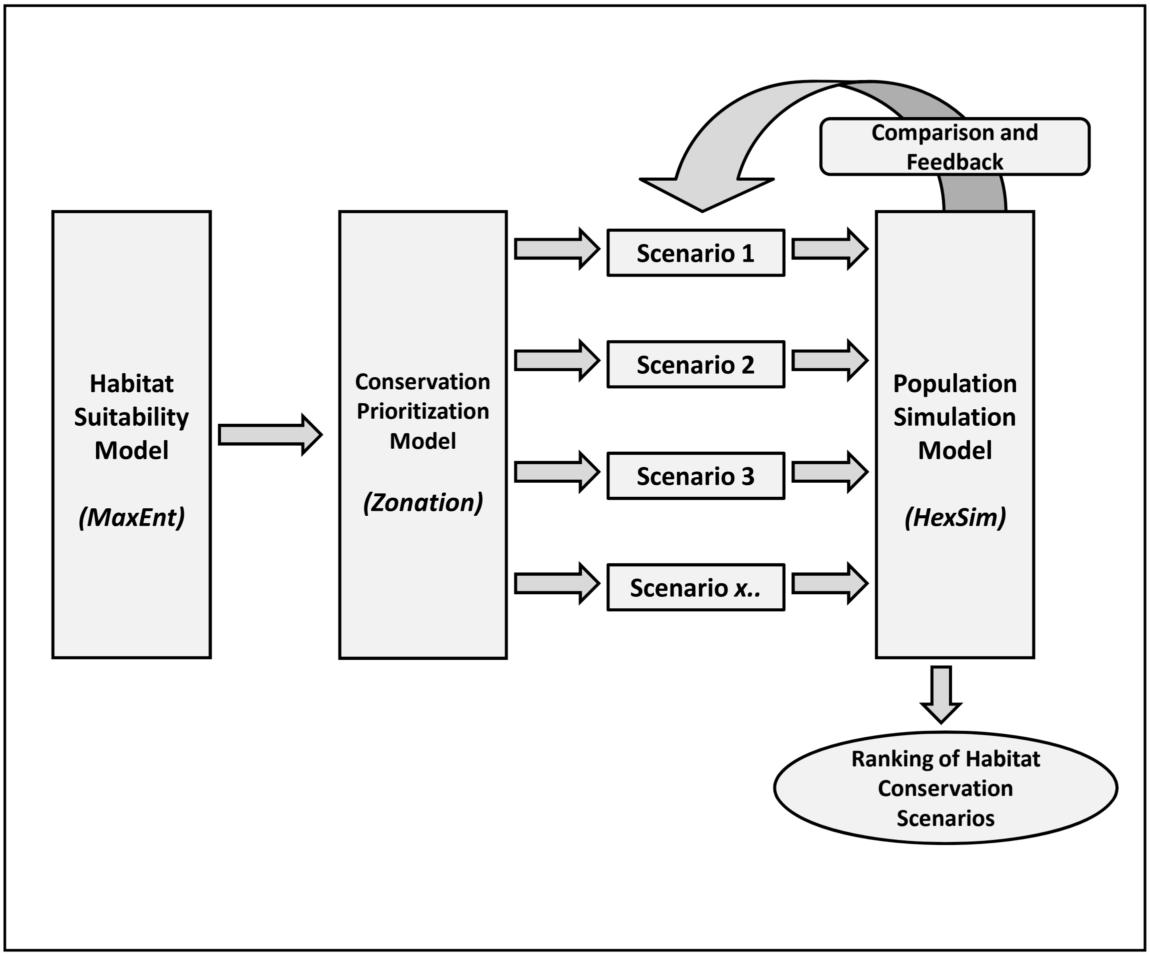
The Service or other practitioners can use the population simulation model developed in Step 3 to test the degree to which various recovery actions and habitat conservation network scenarios contribute to recovery of the spotted owl. For example, it can be used to evaluate relative population size and trend, as well as distribution and connectivity of modeled spotted owl populations through time.

Each of the steps noted above involved statistical and/or mathematical modeling and is not meant to be exact predictions of what currently exists or what will occur in the future, but represent our best estimates of current conditions and relationships. These models allow the use of powerful, up-to-date scientific tools in a repeatable and scientifically accepted manner to develop and evaluate habitat conservation networks and other conservation measures to recover the spotted owl. We view the benefit and utility of such models in the same way that Johnson (2001) articulated, "*A model has value if it provides better insight, predictions, or control than would be available without the model*." The modeling tools described herein meet this standard.

The overall framework and evaluations outlined in Figure C1 are somewhat similar to Raphael *et al.* (1998). Our modeling process differs fundamentally from the conservation planning approach used by the ISC (Thomas *et al*. 1990), 1992 Draft Recovery Plan (USFWS 1992b), FEMAT (1993), and the 2008 Recovery plan (USFWS 2008b), which were based on *a priori* rule sets derived from best expert judgment regarding the size of reserves or habitat conservation blocks, target number of spotted owl pairs per reserve or block, and targeted spacing between reserves or blocks. The new modeling framework we developed instead uses a series of spatially explicit modeling processes to develop habitat conservation networks (or "reserves") based on the distribution of habitat value. Issues of habitat connectivity and population isolation are identified within the population simulation model outputs.

The spotted owl modeling team has completed the development and evaluation of the overall modeling framework described in Steps 1 through 3 above. The *use* of the modeling framework, for example, to inform design and evaluation of various habitat conservation network scenarios (including potential effects of barred owl management), other conservation measures described in recovery actions, and evaluate potential effects of climate change will be completed as a part of recovery plan implementation or other analytical and regulatory processes.

Figure C-1. **Diagram of stepwise modeling process for developing and evaluating habitat conservation scenarios for the spotted owl.**



Modeling Process Step 1 – Create a spotted owl habitat suitability map covering the U.S. range of the subspecies based on a statistical model of spotted owl habitat associations.

Habitat modeling objective and overall approach:

A variety of methods are available for modeling species-habitat relationships (Morrison *et al*. 1992, Elith *et al.* 2006), with divergent assumptions and underlying statistical bases (Breiman 2001). The selection of a modeling tool is influenced foremost by the objectives of the modeling exercise, and by the characteristics of data available for modeling. The primary objective of our recovery plan modeling was to develop a map that reliably predicts relative habitat suitability for the spotted owl. Our primary goals were to develop predictive models that: 1) had good discriminatory ability, 2) were well calibrated, 3) were robust, and 4) had good generality. Our modeling was not an attempt to quantify or refine our understanding of the spotted owl's niche; but instead focused on predictions. Because we were primarily focused on obtaining reliable predictions, we were less concerned about covariates and their associated parameter estimates, or the relative importance of each habitat variable. This objective enabled us to consider newer algorithmic modeling approaches that emphasize prediction (Breiman 2001).

The nature of the spotted owl data available to us also influenced our choice of a modeling approach. We gathered several datasets which resulted in a large number of spotted owl locations, but only a relatively small subset of those data sets also had survey effort information (that could be used for occupancy modeling) and absence data (locations that were adequately sampled and where spotted owls were not detected). Because the majority of spotted owl data available was best characterized as 'presence-only' data, we elected not to employ occupancy modeling approaches.

Our objectives and the nature of the data available to us lead us to choose the species distribution model MaxEnt (Phillips *et al*. 2006, Phillips and Dudik 2008) to model spotted owl relative habitat suitability. MaxEnt is specifically designed for presence-only data. Moreover, MaxEnt has been thoroughly evaluated on a number of taxa, geographic regions, and sample sizes and has been found to perform extremely well (Elith *et al.* 2006, Wisz *et al*. 2008).

Distributional Models and the Spotted Owl:

Species distributional models are used to evaluate species-habitat relationships, evaluate an area's suitability for the species, and to predict a species' presence (Elith and Leathwick 2009). These models, also called environmental (or ecological) niche models, correlate environmental conditions with species distribution and thereby predict the relative suitability of habitat within some geographic area (Warren and Seifert 2011). When translated into maps depicting the spatial distribution of predicted habitat suitability, these models have great utility for evaluating conservation reserve design and function (Zabel *et al.* 2002, Zabel *et al*. 2003, Carroll and Johnson 2008, Carroll *et al.* 2010). Because the spotted owl is one of the most studied raptors in the world; we had available hundreds of peer-reviewed papers on various aspects of the species' ecology, including habitat use and selection (see reviews by Gutiérrez *et al.* 1995, Blakesley 2004). Only a few range-wide (in the U.S.) evaluations of habitat association (Carroll and Johnson 2008) or habitat distribution (Davis and Lint 2005, Davis and Dugger in press) have been conducted. While we capitalized on this large body of literature and other information to build models for conservation planning purposes, we were primarily interested in using such models to map relative habitat suitability rather than to provide new ecological understanding of spotted owl habitat associations.

Meetings with spotted owl habitat experts and review of literature and data sets:

Because the spotted owl is among the most-studied birds in the world, there is a wealth of information on its ecology and habitat associations. To ensure that the modeling effort was based on this scientific foundation, our first step was to conduct an extensive review of published and unpublished information on the species. Concurrent with this effort, team members travelled throughout the spotted owl's range and met with researchers and biologists with extensive experience studying spotted owls. Some of these meetings were one-on-one, and at other times we held meetings with several experts at one time to seek their individual advice. We have sometimes referred to these meetings as "expert panels." At these meetings, biologists were each asked to identify (1) the environmental factors to which spotted owls respond within particular physiographic provinces (*e.g.* Klamath Mountains of southern Oregon and northern California, Olympic Peninsula, Redwood Coast), and (2) regions believed to be distinct where spotted owls may be responding to conditions uniquely. In order to identify distinct modeling areas and definitions of spotted owl habitat (see below), we used both empirical findings (*i.e.*, published information) and the professional judgment of spotted owl experts.

Modeling regions - Partitioning the species' range:

Several authors have noted that spotted owls exhibit different habitat associations in different portions of their range, which is often attributed to regional differences in forest environments and factors such as important prey species (Carey *et al.* 1992, Franklin *et al.* 2000, Noon and Franklin 2002, Zabel *et al.* 2003), or presence of Douglas-fir dwarf mistletoe (expert panels). The distribution of these features is likely influenced by relatively large east-west and north-south gradients in ecological conditions (*e.g.*, temperature, precipitation, net primary productivity) and subsequent variation in forest environments. Hence, we developed and evaluated region-specific habitat suitability models under the assumption that spotted owls *within* a modeling region respond to habitat conditions more similarly than do spotted owls *between* modeling regions where conditions differ.

For monitoring, management and regulatory purposes, the spotted owl's range has historically been divided into 12 physiographic provinces (USDI 1992, Davis and Lint 2005) based largely on the regional distribution of major forest types and state boundaries. Based on differences and similarities in spotted owl habitat, we combined some provinces (California and Oregon Klamath provinces), retained others, and divided some provinces into smaller modeling regions (see Figure C2). We did not establish modeling regions or develop models for the Puget Lowlands, Southwestern Washington, and Willamette Valley, where spotted owls are almost completely absent and sample sizes were too small to support for model development. Instead, we projected the models developed for the closest adjacent area to those areas. This decision had the influence of allowing those regions to have at least some potential value to simulated spotted owls as opposed to assuming zero value.

The predictive ability and accuracy of habitat suitability models are influenced by the range of environmental conditions that are incorporated into the training data used in model development. Models developed from data sets encompassing broad environmental gradients tend to be overly general; conversely, models developed with data representing a small subset of conditions have limited applicability across the species' larger distribution. The practice of partitioning a species' range into "modeling regions" that encompass relatively dissimilar subsets of species-habitat relationships and developing models specific to each region was used to reduce this source of variability. The challenge is balancing the high degree of variability within large regions against the tendency to create many small modeling regions (with potentially small sample sizes) based on locally unique environmental conditions.

We queried experts to suggest potential modeling region boundaries, and they provided input on broad-scale patterns in climate, topography, forest communities, spotted owl habitat relationships, and prey-base that supported delineation of the draft spotted owl modeling regions (Figure C2). Franklin and Dyrness (1973), Kuchler (1977) and other published sources of information on the distribution of major ecological boundaries were also consulted. Using information provided through our discussions with the expert panels and existing ecological section and subsection boundaries (McNab and Avers 1994), we delineated 11 spotted owl modeling regions (Figure C2).

In general, the spotted owl modeling regions varied in terms of these ecological features:

1) Degree of similarity between structural characteristics of habitats used by spotted owls primarily for nesting/roosting and habitats used for foraging and other nocturnal activities. This similarity is largely influenced by habitat characteristics of the spotted owl's dominant prey (proportion of flying squirrels versus woodrats).

2) Latitudinal patterns of topography and climate. For example, in the WA Cascades, spotted owls are rarely found at elevations above 1,219-1,372 m, whereas in southern Oregon and the Klamath province spotted owls commonly reside up to 1,830 m.

3) Regional patterns of topography, climate, and forest communities.

4) Geographic distributions of habitat elements that influence the range of conditions occupied by spotted owls. For example, several panelists pointed out that the distribution of dwarf mistletoe influences the range of stand structural values associated with spotted owl use. Other examples include the geographic distribution of elements such as evergreen hardwoods, Oregon white oak woodlands, and ponderosa pine-dominated forests.

Modeling Region Descriptions:

North Coast Ranges and Olympic Peninsula (NCO): This region consists of the Oregon and Washington Coast Ranges Section M242A (McNab and Avers 1994). This region is characterized by high rainfall, cool to moderate temperatures, and generally low topography (448 to 750 m). High elevations and cold temperatures occur in the interior portions of the Olympic Peninsula, but spotted owls in this area are limited to the lower elevations (<900 m.). Forests in the NCO are dominated by western hemlock, Sitka spruce, Douglas-fir, and western red cedar. Hardwoods are limited in species diversity (consist mostly of bigleaf maple and red alder) and distribution within this region, and typically occur in riparian zones. Root pathogens like laminated root rot (*Phellinus weirii*) are important gap formers, and vine maple, among others, fills these gaps. Because Douglas-fir dwarf mistletoe is unusual in this region, spotted owl nesting habitat consists of stands providing very large trees with cavities or deformities. A few nests are associated with western hemlock dwarf mistletoe. Spotted owl diets are dominated by species associated with mature to late-successional forests (flying squirrels, red tree voles), resulting in similar definitions of habitats used for nesting/roosting and foraging by spotted owls. This region contains the Olympic Demographic Study Area (DSA).

Oregon Coast Ranges (OCR): This region consists of the southern 1/3 of the Oregon and Washington Coast Ranges Section M242A (McNab and Avers 1994). We split the section in the vicinity of Otter Rock, OR, based on gradients of increased temperature and decreased moisture that result in different patterns of vegetation to the south. Generally this region is characterized by high rainfall, cool to moderate temperatures, and generally low topography (300 to 750 m.). Forests in this region are dominated by western hemlock, Sitka spruce, and Douglas-fir; hardwoods are limited in species diversity (largely bigleaf maple and red alder) and distribution, and are typically limited to riparian zones. Douglas-fir and hardwood species associated with the California Floristic Province (tanoak, Pacific madrone, black oak, giant chinquapin) increase toward the southern end of the OCR. On the eastern side of the Coast Ranges crest, habitats tend to be drier and dominated by Douglas-fir. Root pathogens like laminated root rot (*P. weirii*) are important gap formers, and vine maple among others fills these gaps. Because Douglas-fir dwarf mistletoe is unusual in this region, spotted owl nesting habitat tends to be limited to stands providing very large trees with cavities or deformities. A few nests are associated with western hemlock dwarf mistletoe. Spotted owl diets are dominated by species associated with mature to late-successional forests (flying squirrels, red tree voles), resulting in similar definitions of habitats used for nesting/roosting and foraging by spotted owls. One significant difference between OCR and NCO is that woodrats comprise an increasing proportion of the diet in the southern portion of the modeling region. This region contains the Tyee and Oregon Coast Range DSAs.

Redwood Coast (RDC): This region consists of the Northern California Coast Ecological Section 263 (McNab and Avers 1994). This region is characterized by low-lying terrain (0 to 900 m.) with a maritime climate; generally mesic conditions and moderate temperatures. Climatic conditions are rarely limiting to spotted owls at all elevations. Forest communities are dominated by redwood, Douglas-fir-tanoak forest, coast liveoak, and tanoak series. The vast majority of the region is in private ownership, dominated by a few large industrial timberland holdings. The results of numerous studies of spotted owl habitat relationships suggest stump-sprouting and rapid growth rates of redwoods, combined with high availability of woodrats in patchy, intensively-managed forests, enables spotted owls to maintain high densities in a wide range of habitat conditions within the Redwood zone. This modeling region contains the Green Diamond and Marin DSAs.

Western Cascades North (WCN): This region generally coincides with the northern Western Cascades Section M242B (McNab and Avers 1994), combined with western portion of M242D (Northern Cascades Section), extending from the U.S. - Canadian border south to Snoqualmie Pass in central Washington. It is similar to the Northern Cascades Province of Franklin and Dyrness (1974). This region is characterized by high mountainous terrain with extensive areas of glaciers and snowfields at higher elevation. The marine climate brings high precipitation (both annual and summer) but is modified by high elevations and low temperatures over much of this modeling region. The resulting distribution of forest vegetation is dominated by subalpine species, mountain hemlock and silver fir; the western hemlock and Douglas-fir forests typically used by spotted owls are more limited to lower elevations and river valleys (spotted owls are rarely found at elevations greater than 1,280 m. in this region) grading into the mesic Puget lowland to the west. Root pathogens like laminated root rot (*P. weirii*) are important gap formers, and vine maple, among others, fills these gaps. Because Douglas-fir dwarf mistletoe occurs rarely in this region, spotted owl nests sites are limited to defects in large trees, and occasionally nests of other raptors. Diets of spotted owls in this northern region contain higher proportions of red-backed voles and deer mice than in the region to the south, where flying squirrels are dominant (expert panels). There are no Demographic Study Areas in this modeling region.

Western Cascades Central (WCC): This region consists of the midsection of the Western Cascades Section M242B (McNab and Avers 1994), extending from Snoqualmie Pass in central Washington south to the Columbia River. It is similar to the Southern Washington Cascades Province of Franklin and Dyrness (1974). We separated this region from the northern section based on differences is spotted owl habitat due to relatively milder temperatures, lower elevations, and greater proportion of western hemlock/Douglas-fir forest and occurrence of noble fir to the south of Snoqualmie Pass. Because Douglas-fir dwarf mistletoe occurs rarely in this region, spotted owl nest sites are largely limited to defects in large trees, and occasionally nests of other raptors. This region contains the Rainier DSA and small portions of the Wenatchee and Cle Elum DSAs.

Western Cascades South (WCS): This region consists of the southern portion of the Western Cascades Section M242B (McNab and Avers 1994) and extends from the Columbia River south to the North Umpqua River. We separated this region from the northern section due to its relatively milder temperatures, reduced summer precipitation due to the influence of the Willamette Valley to the west, lower elevations, and greater proportion of western hemlock/Douglas-fir forest. The southern portion of this region exhibits a gradient between Douglas-fir/western hemlock and increasing Klamath-like vegetation (mixed conifer/evergreen hardwoods) which continues across the Umpqua divide area. The southern boundary of this region is novel and reflects a transition to mixed conifer sensu Franklin and Dyrness (1974). The importance of Douglas-fir dwarf mistletoe increases to the south in this region, but most spotted owl nest sites in defective large trees, and occasionally nests of other raptors. The HJ Andrews DSA occurs within this modeling region.

Eastern Cascades North (ECN): This region consists of the eastern slopes of the Cascade range, extending from the Canadian border south to the Deschutes National Forest near Bend, OR. Terrain in portions of this region is glaciated and steeply dissected. This region is characterized by a continental climate (cold, snowy winters and dry summers) and a high-frequency/low-mixed severity fire regime. Increased precipitation from marine air passing east through Snoqualmie Pass and the Columbia River results in extensions of moist forest conditions into this region (Hessburg *et al.* 2000b). Forest composition, particularly the presence of grand fir and western larch, distinguishes this modeling region from the southern section of the eastern Cascades. While ponderosa pine forest dominates lower and middle elevations in both this and the southern section, the northern section supports grand fir and Douglas fir habitat at middle elevations. Dwarf mistletoe provides an important component of nesting habitat, enabling spotted owls to nest within stands of relatively younger, small trees. This modeling region contains the Wenatchee and Cle Elum DSAs.

Eastern Cascades South (ECS): This region incorporates the Southern Cascades Ecological Section M261D (McNab and Avers 1994) and the eastern slopes of the Cascades from the Crescent Ranger District of the Deschutes National Forest south to the Shasta area. Topography is gentler and less dissected than the glaciated northern section of the eastern Cascades. A large expanse of recent volcanic soils (pumice region: Franklin and Dyrness 1974), large areas of lodgepole pine, and increasing presence of red fir and white fir (and decreasing grand fir) along a south-trending gradient further supported separation of this region from the northern portion of the eastern Cascades. This region is characterized by a continental climate (cold, snowy winters and dry summers) and a high-frequency/low-mixed severity fire regime. Ponderosa pine is a dominant forest type at mid-to lower elevations, with a narrow band of Douglas-fir and white fir at middle elevations providing the majority of spotted owl habitat. Dwarf mistletoe provides an important component of nesting habitat, enabling spotted owls to nest within stands of relatively younger, smaller trees.

The Warm Springs DSA and eastern half of the South Cascades DSA occur in this modeling region.

Western Klamath Region (KLW): This region consists of the western portion of the Klamath Mountains Ecological Section M261A (McNab and Avers 1994). A long north-south trending system of mountains (particularly South Fork Mountain) creates a rainshadow effect that separates this region from more mesic conditions to the west. This region is characterized by very high climatic and vegetative diversity resulting from steep gradients of elevation, dissected topography, and the influence of marine air (relatively high potential precipitation). These conditions support a highly diverse mix of mesic forest communities such as Pacific Douglas-fir, Douglas-fir tanoak, and mixed evergreen forest interspersed with more xeric forest types. Overall, the distribution of tanoak is a dominant factor distinguishing the Western Klamath Region. Douglas-fir dwarf mistletoe is uncommon and seldom used for nesting platforms by spotted owls. The prey base of spotted owls within the Western Klamath is diverse, but dominated by woodrats and flying squirrels. This region contains the Willow Creek, Hoopa, and the western half of the Oregon Klamath DSAs.

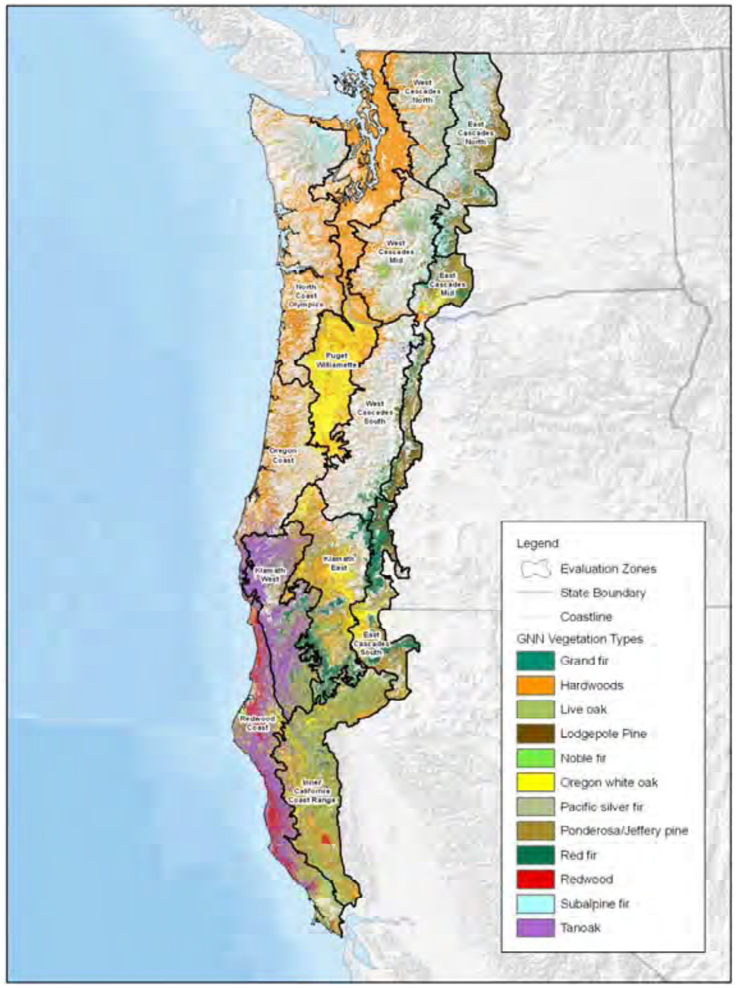
Eastern Klamath Region (KLE): This composite region consists of the eastern portion of the Klamath Mountains Ecological Section M261A (McNab and Avers 1994) and portions of the Southern Cascades Ecological Section M261D in Oregon. This region is characterized by a Mediterranean climate, greatly reduced influence of marine air, and steep, dissected terrain. Franklin and Dyrness (1974) differentiate the mixed conifer forest occurring on the "Cascade side of the Klamath from the more mesic mixed evergreen forests on the western portion (Siskiyou Mountains), and Kuchler (1977) separates out the eastern Klamath based on increased occurrence of ponderosa pine. The mixed conifer/evergreen hardwood forest types typical of the Klamath region extend into the southern Cascades in the vicinity of Roseburg and the North Umpqua River, where they grade into the western hemlock forest typical of the Cascades. High summer temperatures and a mosaic of open forest conditions and Oregon white oak woodlands act to influence spotted owl distribution in this region. Spotted owls occur at elevations up to 1,768 m. Dwarf mistletoe provides an important component of nesting habitat, enabling spotted owls to nest within stands of relatively younger, small trees. The western half of the South Cascades DSA and the eastern half of the Klamath DSA are located within this modeling region.

Northern California Interior Coast Ranges Region (ICC): This region consists of the Northern California Coast Ranges ecological Section M261B (McNab and Avers 1994), and differs markedly from the adjacent redwood coast region. Marine air moderates winter climate, but precipitation is limited by rainshadow effects from steep elevational gradients (100 to 2,400 m.) along a series of north-south trending mountain ridges. Due to the influence of the adjacent Central Valley, summer temperatures in the interior portions of this region are among the highest within the spotted owl's range. Forest communities tend to be relatively dry mixed conifer, blue and Oregon white oak, and the Douglas-fir-tanoak series. Spotted owl habitat within this region is poorly known; there are no DSAs and few studies have been conducted here. Spotted owl habitat data obtained during this project suggests that some spotted owls occupy steep canyons dominated by liveoak and Douglas-fir; the distribution of dense conifer habitats is limited to higher-elevations on the Mendocino National Forest.

Figure C-2. Modeling regions used in development of relative habitat suitability models for the spotted owl.

Modeling Regions

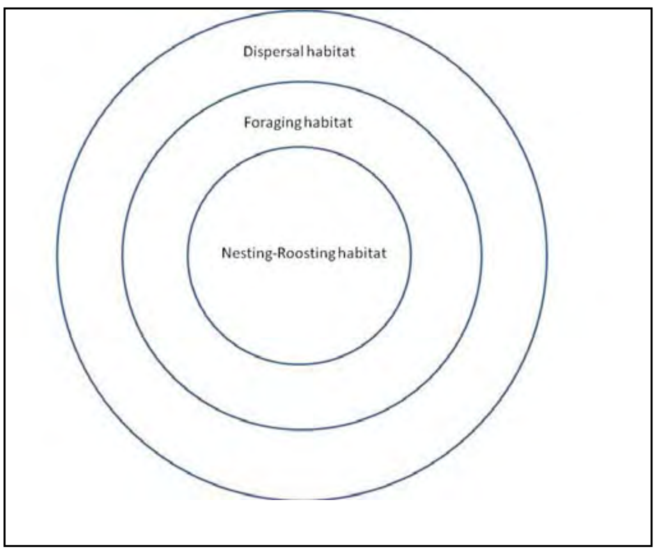
CODE	Description
NCO	North Coast and Olympic
OCR	Oregon Coast
RDC	Redwood Coast
WCN	Western Cascades - North
WCC	Western Cascades - Central
WCS	Western Cascades - South
ECN	Eastern Cascades - North
ECS	Eastern Cascades - South
KLW	Klamath-Siskiyou - West
KLE	Klamath-Siskiyou - East
ICC	Interior California Coast



Habitat Modeling Process

Because spotted owl habitat use is influenced by factors occurring at different spatial scales, we developed habitat suitability models in two stages. In the first stage we used information from our literature review and experts to develop a series of alternative models of forest conditions corresponding to nesting-roosting habitat and foraging habitat within each modeling region. We used statistical modeling to test the effectiveness of these models and identify the forest structural models that best predicted the relative likelihood of a spotted owl territory being present. Spotted owl habitat is often subdivided into distinct components including: nesting habitat, roosting habitat, foraging habitat, and dispersal habitat. Habitats used for nesting and roosting are very similar, and so we combined them into nesting-roosting. Such areas are used for nesting, roosting, foraging, and dispersal by spotted owls, and are usually forests with more late-seral forest characteristics than "foraging" or "dispersal" habitat. Foraging habitat is thought to be largely used for foraging and other nocturnal activities, but also for dispersal (USFWS 1992; see Figure C3). Dispersal habitat is thought to largely have value for dispersal, to lack nest/roost sites and to provide few foraging opportunities. These categories are not absolutes, but instead represent generalizations (*e.g.*, one should not infer that spotted owls never roost in "foraging" habitat). That said, it is important to understand that

Figure C-3. Venn diagram of relationships among spotted owl nesting-roosting, foraging, and dispersal habitats.



nesting-roosting habitat is generally considered to provide all or most habitat requirements, whereas foraging and dispersal habitats are considered to provide only a subset of the spotted owl's habitat requirements. For this effort, we attempted to accurately model the suitability of breeding habitat for spotted owls. Thus, we evaluated and modeled nesting-roosting and foraging habitat, but not dispersal habitat. While we recognized that dispersal plays an important role in population performance, we elected not to formally model dispersal habitat. This is because relatively little is known about habitat selection during dispersal and, more importantly, the likely influences of habitat conditions on dispersal success. The influence of habitat on dispersal and population performance is treated within the HexSim portion of the modeling framework (see Overview of HexSim Spotted Owl Scenario, page C-56).

Spatial scale for developing and evaluating models:

To determine the spatial scale at which to develop habitat models, the modeling team sought a uniform analysis area size that generally corresponded to large differences between use and availability. Spotted owls have been found to respond to habitats at a variety of spatial scales (Solis and Gutiérrez 1990, Meyer *et al.* 1998, Franklin *et al*. 2000, Swindle *et al.* 1999, Thome *et al*. 1999, Zabel *et al.* 2003). Spotted owls do not build their own nests, but primarily utilize broken-top snags, tree cavities, dwarf mistletoe witch's brooms, or nests made by other species (Gutiérrez *et al.* 1995). Spotted owl habitat selection in the immediate vicinity of the nest (tens of meters around the nest tree) has been found to be strongly non-random, and largely associated with late-seral forest characteristics (Solis and Gutiérrez 1990, Meyer *et al.* 1998, Swindle *et al.* 1999). Areas at this small spatial scale are necessary, but often not sufficient to be selected by spotted owls because areas at larger spatial scales around the nest-site must contain attributes that also contribute to their survival and reproductive success (*e.g.*, Franklin *et al*. 2000, Olson *et al.* 2004, Dugger *et al.* 2005).

Ripple *et al.* (1991), Carey *et al.* (1992), Hunter *et al.* (1995), Thome *et al.* (1999), Meyer *et al*. (1998), and Zabel *et al.* (2003) all evaluated spotted owl habitat selection at a variety of spatial scales beyond the nest site itself. Spatial scales evaluated in these studies were based on the distribution of radio telemetry locations, presumed territorial behavior (nearest-neighbor distances), or various 'nested rings'. All studies found differences between spotted owl-centered (nest or activity center) locations and random or unoccupied locations across the range of spatial scales examined. However, the largest differences were often found in areas approximately the size of what Bingham and Noon (1997) defined as "core areas" (areas of the home range that received disproportionately more use than would be expected). An area of 158 to 200-ha has been used to describe/define spotted owl 'territory core areas', in western Oregon and the Klamath region (Hunter *et al.* 1995, Meyer *et al.* 1998, Franklin *et al*. 2000, Zabel *et al*. 2003, Olson *et al.* 2004, and Dugger *et al.* 2005). In northwestern Oregon, Glenn *et al.* (2005) found mean cumulative core areas to be 94 ha (SE = 14.9; n = 24). For the northern portion of the range we found little information directly comparable to the abovementioned studies, but estimated home range and core areas sizes and nearest-neighbor distances are larger in the extreme northern portion of the spotted owl's range (Forsman *et al*. 2005, Hamer *et al.* 2007, Davis and Dugger in press). Based on this review, we felt a 200-ha analysis area represented an area that is disproportionately used (more than expected) surrounding nest sites. We deal explicitly with geographic variation in home range size in HexSim (see below).

Data Used for Model Development and Testing

Vegetation data – the GNN-LT Database:

To develop rangewide models of relative habitat suitability for spotted owls, we required maps of forest composition and structure of sufficient accuracy to allow discrimination of attributes used for nesting, roosting and foraging by spotted owls. Past efforts to model, map and quantify habitat selection by spotted owls at regional scales have often suffered from lack of important vegetation variables, inadequate spatial coverage, and/or coarse resolution of available vegetation databases (Davis and Lint 2005). However, recent development of vegetation mapping products for the NWFP's Effectiveness Monitoring program (Hemstrom *et al*. 1998, Lint *et al.* 1999) provided detailed maps of forest composition and structural attributes for all lands within the NWFP area (coextensive with the range of the spotted owl). These maps were developed using Gradient Nearest Neighbor (GNN) imputation (Ohmann and Gregory 2002) and LandTrendr algorithms (Kennedy *et al.* 2007, 2010) and were available for two "bookend" dates (1996 and 2006 in Oregon and Washington, 1994 and 2007 in California).

The GNN approach is a method for predictive vegetation mapping that uses direct gradient analysis and nearest-neighbor imputation to ascribe detailed attributes of vegetation to each pixel in a digital landscape map (Ohmann and Gregory 2002). Forest attributes from inventory plots (Forest Inventory and Analysis, Current Vegetation Surveys, etc.) are imputed to map pixels based on modeled relationships between plots and predictor variables from Landsat thematic mapper imagery, climatic variables, topographic variables, and soil parent materials. The assumption behind GNN methods is that two locations with similar combined spatial "signatures" should also have similar forest structure and composition. The GNN models were developed for habitat modeling regions used for the NWFP northern spotted owl effectiveness monitoring modeling (Davis and Dugger in press). For the NWFP Effectiveness Monitoring program, GNN maps were created for the two bookend time periods mentioned above to 'frame' their analysis period for habitat status and trends. This novel bookend mapping approach presents challenges associated with spectral differences due to different satellite image dates, which might produce false vegetation changes. To minimize the potential for this, the bookend models were based on Landsat imagery that was geometrically rectified and radiometrically normalized using the LandTrendr process (Kennedy *et al.* 2007, 2010).

The large list of forest species composition and structure variables provided by GNN vegetation maps constitute an improvement in vegetation data for modeling and evaluating spotted owl habitat. For our modeling, we selected from a set of 163 variables, including basal area and tree density by size class and species, canopy cover of conifers and/or hardwoods, stand height, age, mean diameter and quadratic mean diameter by dominance class, stand density index, and measures of snags and coarse woody debris. Additional variables pertaining to stand structural diversity and variability proved particularly useful for modeling spotted owl habitat.

The reliability or accuracy of vegetation databases poses a primary concern for wildlife habitat evaluation and modeling. The GNN maps come with a large suite of diagnostics detailing map quality and accuracy; these are contained in model region-specific accuracy assessment reports available at the LEMMA website (http://www.fsl.orst.edu/lemma/). For developing *a priori* models of spotted owl nesting/roosting habitat and foraging habitat, we generally selected GNN structural variables with plot correlation coefficients > 0.5 for an individual modeling region (42% were >0.7). On a few occasions when expert opinion or research results suggested a particular variable might be important, we used variables with plot correlations from 0.31 to 0.5 (Table C-1). For species composition variables, we attempted to use only variables with Kappas > 0.3. However, because we combined species variables into groups that expert opinion and research results suggested may represent influential community types, we occasionally accepted variables with Kappas > 0.2 and < 0.3 for individual variables within a group (Table C-2).

The GNN vegetation database was specifically developed for mid- to large-scale spatial analysis (Ohmann and Gregory 2002), suggesting that accuracies at the 30-m pixel scale may be less influential to results obtained at larger scales. Because we were interested in the utility of GNN at our analysis area (200 ha) spatial scale, we conducted less formal assessments where we compared the distribution of GNN variable values at a large sample of actual locations (known spotted owl nest sites and foraging sites) to published estimates of those variables at the same scale. In addition, we received comparisons of GNN maps to a number of local plot-based vegetation maps prepared by various field personnel. Based on these informal evaluations, we determined that GNN represents a dramatic improvement over past vegetation databases used for modeling and evaluating spotted owl habitat, and used the GNN-LandTrendr maps as the vegetation data for our habitat modeling.

Table C-1. Pearson correlation coefficients for GNN structural variables used in modeling relative habitat suitability models for spotted owls.

Spotted owl location data:

Spotted owl data used in model development consisted of site center locations documented within three years (plus or minus) of the date of the GNN vegetation data. Site centers are the location of spotted owl nests or daytime roosts containing paired spotted owls. Site center data for the habitat suitability modeling was made available through the cooperation of a variety of sources throughout the spotted owl's range. Data come from long-term demographic studies as well as locations from other research projects, public, private, and tribal sources.

Substantial effort was expended on verification of both the spatial accuracy and territory status of each site center in the data set. We specifically requested and received very high-quality data from spotted owl demography study areas (DSAs). For areas outside of DSAs, we obtained a large set of additional locations from NWFP Effectiveness Monitoring program (Davis and Dugger in press); the majority of these site centers had been evaluated for spatial accuracy. We also obtained and verified data sets from private timber companies, USFS Region 5 NRIS database and a number of research and monitoring projects across the species' range.

Because of the spatial extent of our analysis area (>23 million ha), we do not have the luxury of having equal survey effort throughout the region. Instead we have data from research studies, monitoring of demographic rates, management efforts, and other sources. While spotted owl demographic study areas have been intensively and extensively studied for long periods of time (see Anthony *et al.* 2006 and Forsman *et al.* 2011) and provide the highest- quality data sets, they comprise ~12% of the spotted owl's geographic range (based on our masked modeling regions). As importantly, for some modeling regions the proportion of total area and/or spotted owl locations within DSAs is very low. Given the DSAs represent nearly the only areas within the spotted owl's range that have consistently been surveyed over long periods of time and that they represent a smaller portion of the species' geographic range, the data from them (at the scale of a modeling region) is generally spatially aggregated. Spotted owl site location data from the DSAs represent a much smaller portion of the spotted owl's range than the full data set we used (Table C-3), and the larger data set represents more fully the spectrum or gradient of biotic and abiotic features that spotted owls select for nesting and roosting. For example, the total number of spotted owl site locations inside DSAs was 1,199, and when thinned by 3 km was 755. In contrast, the total number of site locations outside of DSAs was 2,591, and when thinned was 2,110. With our 200-ha analysis area, if we would have sampled from only the DSAs we would have sampled ~151,000 ha around thinned DSA sites versus the 573,000 ha sampled around all thinned sites.

Table C-3. Comparison of area and spotted owl location data within modeling regions and demographic study areas (DSAs).

Modeling Region	Acronym	Percentage of Region in DSA	Number of NSO Sites in DSA	Number of NSO Sites Outside DSA
ALL MODELING REGIONS	ALL	12.34%	1199	2591

Inner California Coast Ranges	ICC	0.75%	8	300
Redwood Coast	RDC	10.23%	121	603

Outside of DSAs, the quantity and density of site center data varies widely. While we have attempted to compile a large sample of site centers that is broadly representative of the entire distribution of spotted owls, the overall distribution of sample sites is somewhat clumped. Areas with few nest locations are a result of: 1) few surveys being conducted, 2) the absence of spotted owls, or 3) data being unavailable. We did not want the modeling results to be a function of the intensity of spotted owl sampling throughout the region, but to be as close of an approximation as possible of spotted owl-habitat relationships. Phillips *et al*. (2009) noted that spatially biased survey data present major challenges to distributional modeling by over-weighting areas where intensive sampling has occurred. Therefore, within each modeling region we "thinned" the spotted owl nest locations such that the minimum distance between nest locations would be 3.0 km (thinning with a 3 km distance resulted in removing ~25% of the locations available to us). Carroll *et al.* (2010) used a similar approach in their modeling of other species whereby clusters of records were identified and one record from the cluster was randomly selected from the set. Using a 3 km thinning distance retained 75% of the total data, and did not have a large effect on those modeling regions with small initial sample sizes (<100) of site center locations (Table C4).

Table C-4. Sample size of spotted owl site center locations (1993-1999) by modeling region and the impact of various thinning distances (minimum allowable distance between site centers) on sample size.

Due to the increased influence of the barred owl on spotted owls, we followed, in part, the modeling approach used by Davis and Dugger (in press) to reduce the influence of barred owls on apparent habitat associations of spotted owls. For our effort, we wanted our models to identify areas with more or less nesting suitability for spotted owls. Because barred owls have apparently displaced many spotted owls from previously-occupied nesting areas, sometimes into habitat types/conditions that spotted owls only rarely used prior to the barred owl's invasion (Gremel 2005, Gutiérrez *et al.* 2007), we did not want to evaluate their "displaced habitat use", but instead their use of habitat without the larger, current impact of barred owls. Although barred owls were known to be widely distributed in the northern portion of the spotted owl's range in 1996, Gremel (pers. comm. 2010) suggested barred owl densities were substantially lower in 1996 than in 2006. Pearson and Livezey (2003) reported that barred owls had increased by an average of 8.6% per year between 1982 and 2000 on parts of the Gifford Pinchot National Forest (GPNF), Washington. Subsequently, Livezey *et al.* (2007) reported that the 98 known barred owl sites on the GPNF in 2001 had increased to 143 sites in 2006. Thus, in an attempt to reduce the influence of barred owls on spotted owl habitat use, we developed and tested models using GNN vegetation data from 1996 (assumed to be the period with lower barred owl influence) along with spotted owl location information plus or minus three years from 1996. Those models were then projected to the most current (2006) GNN layer to predict contemporary relative habitat suitability (RHS). Each region's model was then tested by comparing with RHS values at independent sites from the 2006 spotted owl locations (only those that did not overlap with the 1996 locations).

Developing Habitat Definitions:

Nesting and roosting habitat

Prior to developing models, we attempted to synthesize both the literature and information from experts. From the literature, we emphasized studies evaluating habitat selection over those that described habitat features (associations) around spotted owl locations, but did not evaluate selection. This synthesis resulted in the development of a series of definitions of spotted owl nesting-roosting and foraging habitat. For example, several published studies concluded that nesting spotted owls strongly select for areas with canopy cover >70% and many large trees nearby and strongly select against areas with lower amounts of canopy cover and few or no large trees nearby. We therefore created definition “NR_1” (nesting-roosting definition number 1) based on canopy cover and density of large trees (*e.g.*, trees >75 cm dbh). Because experts and/or other published studies typically supported several (i) alternative NR definitions, we created roughly ten alternative NR habitat definitions (NR_2, NR_3, NR_i, etc.) per modeling region. We used an identical process to develop a series of foraging (F) habitat definitions for each modeling region (Tables C5 and C6 provide an example of this process). It is important to recognize that these habitat definitions are binary for each pixel; either the pixel contained each of the features in the definition (and was therefore considered habitat), or it did not (it was considered non-habitat).

Table C-5. Spotted owl nesting-roosting habitat variables for the northern Coast Ranges and Olympic Peninsula.

Habitat characteristics from expert panel, literature	GNN Variable expression
Canopy cover of conifers is ≥ than 80%	CANCOV_CON_GE_80
Mean stand diameter is ≥ than 50cm	MNDBHBA_CON_GE_50
Structure should include ≥ 70 medium trees/ha	TPH_GE_50_GE_70
Structure should include ≥ 20 larger trees/ha	TPH_GE_75_GE_20
Very large remnant trees are important (≥5/ha)	TPH_GE_100_GE_5
Canopy layering/diversity is important	DDI_GE_6 *

*DDI = Diameter Diversity Index (ranges from 1-10)

Table C-6. Sample definitions of spotted owl nesting-roosting habitat based on variables and values from Table 5.

	Candidate nesting/roosting habitat definitions
NR_1	CANCOV_CON_GE_80 + MNDBHBA_CON_GE_50 + DDI_GE6
NR_2	CANCOV_CON_GE_80 + MNDBHBA_CON_GE_50 + TPH_GE_75_GE_20 + TPH_GE_100_GE_5 + DDI_GE_6
NR_3	CANCOV_CON_GE_80 + TPH_GE_50_GE_70 + TPH_GE_75_GE_20 + TPH_GE_100_GE_5 + DDI_GE_6
NR_4	CANCOV_CON_GE_70 + MNDBHBA_CON_GE_50 + TPH_GE_75_GE_20 + DDI_GE_5

Foraging habitat

Foraging habitat definitions were informed by published and unpublished literature and input from experts. In this process, foraging habitat was, by definition, different than nesting-roosting habitat. This is not to suggest that spotted owls do not forage in nesting-roosting habitat, but for the sake of being explicit in this process, foraging habitat was distinct from nesting-roosting habitat. In general, foraging habitat definitions had lower thresholds of canopy cover, tree size, and canopy layering than nesting-roosting definitions (Tables C7 and C8 provide an example of this process).

Table C-7. Spotted owl foraging habitat variables for the northern Coast Ranges and Olympic Peninsula.

Habitat characteristics from expert panel, literature	**GNN Variable expression**
Canopy cover of conifers is ≥ than 70%	CANCOV_CON_GE_70
Mean stand diameter is ≥ than 40 cm	MNDBHBA_CON_GE_40
Structure should include ≥ 50 medium trees/ha	TPH_GE_50_GE_50
Structure should include ≥ 8 larger trees/ha	TPH_GE_75_GE_8
Canopy layering/diversity is important	DDI_GE_4 *

*DDI = Diameter Diversity Index (ranges from 1-10)

Table C-8. Sample definitions of spotted owl foraging habitat based on variables and values from Table C7.

	Candidate nesting/roosting habitat definitions
F_1	CANCOV_CON_GE_70 + MNDBHBA_CON_GE_40 + DDI_GE_4
F_2	CANCOV_CON_GE_70 + MNDBHBA_CON_GE_40 + TPH_GE_75_GE_8 + DDI_GE_6
F_3	CANCOV_CON_GE_70 + TPH_GE_50_GE_50 + TPH_GE_75_GE_8 + DDI_GE_4
F_4	CANCOV_CON_GE_60 + MNDBHBA_CON_GE_40 + TPH_GE_75_GE_8 + DDI_GE_4

Because attributes of habitat such as amount of edge and core area have been shown to influence both habitat selection and fitness (Franklin *et al.* 2000) of spotted owls, we also included NR "core" and "edge" metrics.

Abiotic variables

Because published literature and information from experts suggested that abiotic features might be important in determining spotted owl habitat use and selection, we evaluated a series of abiotic features known or suspected to influence spotted owl habitat selection and use (Table C9). Numerous studies have shown that local geographic features such as slope position, aspect, distance to water, and elevation have been found to influence spotted owl site selection (Stalberg *et al.* 2009, Clark 2007). Several authors (Blakesley *et al.* 1992, Hershey *et al.* 1998, LaHaye and Gutiérrez 1999) have noted the absence of spotted owls above particular elevational limits (whether this limit is due to forest structure, prey, competitors, parasites, diseases, and/or extremes of temperature or precipitation is not known). At broader scales, temporal variation in climate has been shown to be related to fitness (Franklin *et al.* 2000, Olson *et al.* 2004, Dugger *et al.* 2005, Glenn *et al.* 2010), suggesting that spatial variation in climate may also influence habitat suitability for spotted owls. Ganey *et al.* (1993) found that Mexican spotted owls (*S. o. lucida*) have a narrow thermal neutral zone and others (*e.g.*, Franklin *et al*. 2000) have assumed the northern spotted owl to be similar in this regard. Furthermore, the spotted owl's selection for areas with older-forest characteristics has been hypothesized to, in part, be related to its needing cooler areas in summer to avoid heat stress (Barrows and Barrows 1978). Temperature extremes (winter low and summer high) as well as potential breeding-season specific stressors (spring low temperature and high spring precipitation) are also considered potentially useful predictor variables for our purposes (Carroll 2010, Glenn *et al.* 2010). By including climate variables as candidate variables in our habitat suitability modeling, we evaluated whether climate effects on spotted owl fitness are translated into patterns of the species' distribution.

Developing models:

MaxEnt compares the characteristics (variables included in the models) of the training data sites to a random selection of ~10,000 random "background" (available) locations. We only used the linear, quadratic, and threshold features within MaxEnt (*i.e.,* hinge and product features were not used).

We used the following model-building and evaluation process within each modeling region

1) Each nesting-roosting habitat definition is a single-variable model. Thus, if we developed 10 nesting-roosting habitat definitions for a region, we compared 10 nesting-roosting habitat models for that region. We used MaxEnt to determine the best nesting-roosting habitat definition within each region (see model evaluation, below).
2) Within each modeling region that has foraging habitat definitions, we combined the best nesting-roosting habitat definition(s) with each foraging habitat definition to evaluate whether the addition of foraging habitat improved model performance. Models were considered to have been improved if the addition of foraging habitat increases the ranking of the model. If the addition of foraging habitat improved the model's performance, we used the nesting-roosting + foraging habitat model for step 3 (below). If not, we used the best nesting-roosting model(s) for step 3.
3) For abiotic variables, we developed univariate or multivariate models using the variables in Table C9. Carroll (2010) found that mean January precipitation, mean July precipitation, mean January temperature, and mean July temperature were the variables in the best, of 30, climate models he evaluated. He found the two precipitation metrics were the most influential of the four. Franklin *et al.* (2000) also found climate variables to influence spotted owl survival and reproduction. We included three climate models: 1) the four variables Carroll (2010) reported, 2) mean January precipitation and mean July precipitation, 3) mean January precipitation and mean January temperature. We "challenged" the best model(s) after step 2 by adding each abiotic model to it (*sensu* Dunk *et al.* 2004), in an attempt to improve its predictive ability. The abiotic models were not compared to each other, but were compared in order to see if their addition to the best biotic (nesting-roosting or nesting-roosting + foraging) model resulted in an improved model (see step 2). If the biotic plus abiotic model was an improvement over the biotic-only model, we used the combination model, otherwise we used the biotic-only model. The reason abiotic-only models were not evaluated is that it is illogical to suggest that spotted owls (a species that nests in trees) might only respond to abiotic factors when selecting nesting areas. In contrast, we could develop a logical biological argument that spotted owls might respond only to biotic features when selecting nesting areas. We could also develop logical biological arguments

articulating how a combination of biotic and abiotic factors might influence the selection of nesting areas.

Model-building hierarchy

The spatial distribution of spotted owl territories is influenced by a wide variety of environmental gradients operating at different spatial scales. At the smallest scale we evaluated, features such as the amount of nesting-roosting and/or foraging habitat within a core area, the amount of edge between spotted owl habitat and non-habitat, or amount of "core habitat" (*sensu* Franklin *et al*. 2000) have all be shown to influence spotted owl distribution, abundance, or fitness. Each of those variables, however, is a structural variable. That is, they are based on habitats comprised of various structural elements (*e.g*., large trees, high canopy cover). However important and influential these variables are to spotted owls, other variables such as plant species composition (broadly speaking), topographic position, climate, and/or elevation are also likely to influence their distribution, abundance, and perhaps fitness (Franklin *et al.* 2000, Olson *et al*. 2004, Dugger *et al.* 2005, Glenn 2009).

In part, the partitioning of the spotted owl's geographic range into 11 modeling regions should act to reduce the influence of broad patterns in plant species composition, climate and/or elevation on the species. Nonetheless, we were interested in evaluating whether habitat suitability is influenced by local variation in these non-structural variables.

Stand structure and the spatial arrangement of forest patches have been found to influence spotted owl fitness (Franklin *et al*. 2000, Olson *et al*. 2004, Dugger *et al*. 2005). Edge between nesting-roosting habitat and other habitat types is thought to afford foraging spotted owl opportunities when habitats, but which are rarely used, are juxtaposed closely with habitats spotted owls use. "Core" habitat includes those areas of spotted owl nesting habitat not subjected to edge-effects. Franklin *et al*. (2000) estimated core habitat by buffering all spotted owl habitat (largely mature forest areas) by 100 m and estimating the size of the habitat excluding the 100 m buffer.

Spotted owl experts noted that mid-scale or landscape level patterns such as tree species composition and topography may also influence the local distribution and density of spotted owls. For example, within many of the modeling regions, there exists variation in tree species composition, but forests with different species compositions may still have similar structural attributes (*e.g*., high canopy cover, multi-storied, large trees). Some forest types (regardless of their structural attributes) are rarely, if ever, used by spotted owls, so we attempted to account for this variation by evaluating models that include some compositional variables.

Many of our 11 modeling regions contain high-elevation areas above the elevational extremes normally used by spotted owls. In some higher elevation areas there exist structurally complex, multi-storied forests with large trees – areas with similar structural characteristics to those used by spotted owls.

However, spotted owls rarely if ever use such areas. Our intention was to attempt to account for this in our modeling.

We recognize the hierarchical nature of these environmental factors and their possible influence on spotted owl distribution. Our model building approach took this into consideration, by starting at the smallest scale and sequentially "challenging" models with variables from larger spatial scales. In order to focus on environmental features most directly linked to territory location, habitat selection, and individual fitness of spotted owls, we employed a bottom-up approach to building models (Table C9).

Table C-9. Categories of candidate variables, variable names, and order of the entry of variables into modeling process.

Category	Variable	Order
Best climate/elevation model	Mean July Precipitation	
	Mean July Temperature	
	Mean July Precipitation	
	Mean July Temperature	
	Mean Elevation	
Topographic position	Curvature	
	Insolation	
	Slope Position	
Compositional variables (percent of basal area)	Redwood	
	Oak Woodland	
	Pine-dominated	
	Northern Deciduous Hardwoods	
	Evergreen Hardwoods	
	Douglas-fir	
	Subalpine forest	
Habitat pattern	Core of NR habitat	
	Edge of NR habitat	
Habitat structure	Foraging Habitat Amount	
	Nesting/Roosting Habitat	

Goals of MaxEnt Modeling:

Our goals for the relative habitat suitability models were to find models that: 1) had good discriminatory ability, 2) were well calibrated, 3) were robust, and 4) had good generality. We sought models that were not over-fit, the consequences of which would be to have models that fit the developmental data very closely, but which would not have worked well on data that were not used in their development. That is we sought models with good generality (*i.e.*, models that worked well in the modeling regions in general, not simply at classifying the developmental/training data). MaxEnt attempts to balance model fit and complexity through the use of regularization (see Elith *et al.* 2011). Elith *et al.* (2011) noted that MaxEnt fits a penalized maximum likelihood model, closely related to other penalties for complexity such as Akaike's Information Criterion (AIC, Akaike 1974). In order to evaluate whether any model region's model was over-fit we conducted rigorous cross-validation on each model (see below), and, when available we evaluated how well models classified independent data (see below).

Model discrimination

Once the best model was found for each region, we conducted a cross-validation of each model to evaluate how robust the model was. Each of 10 times we removed a random subset of 25% of the spotted owl locations, developed the model with the remaining 75% and classified using the withheld 25%. The area under the receiver operating characteristic curve (AUC) was evaluated for both training and test data within each region. AUC is a measure of a model's discrimination ability; in our case discrimination between spotted owl-presence locations and available locations (not discrimination of presence versus absence locations). AUC values, theoretically, range between 0 and 1.0, with values less than 0.5 having worse discriminatory ability than expected by chance, values closer to 0.5 suggesting no to poor discriminatory ability, and values closer to 1.0 suggesting excellent discriminatory ability.

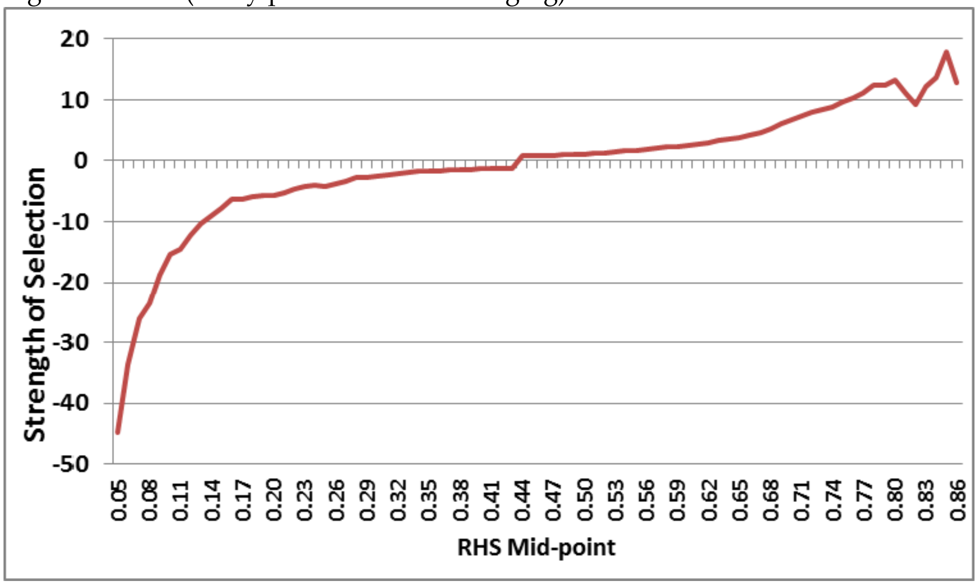
For these analyses, AUC values essentially describe the proportion of times one could expect a random selection of an actual spotted owl nest site location to have a larger relative habitat suitability value than a random selection from available locations. It is therefore a threshold-independent measure of model discriminatory ability. Because our evaluation represents use versus availability and not use versus non-use, AUC values have an upper limit somewhat less than 1.0 (because some of the available locations are actually used by spotted owls). Even for good (well-discriminating) models, AUC values should be lower in areas where the background areas contain larger amounts of suitable habitat. Two contrasting examples are provided to make this point: 1) a model estimating a riparian-dependent bird species' distribution in the Great Basin may have a very high AUC value because there is large contrast between riparian vegetation where the bird nests and the vast majority of background locations in sage-steppe, vs. 2) a model estimating the distribution of a generalist omnivore (like a black-bear) in a national forest may have a lower AUC because so much of the background habitat is suitable for the species. The point is that AUC is a measure of discrimination, but that a use-versus-availability model's ability to discriminate is a function of both the animal's habitat specificity and the abundance of the animal's habitat in the region of interest. To evaluate the degree to which AUC values from each modeling region's MaxEnt model were related to the abundance of suitable habitat we regressed AUC values against the proportion of each modeling region comprised of RHS values >30, >40, and >50 (the SOS values for all modeling regions showed selection for areas within this range – see Figure C-5 below). If the abundance of suitable habitat is high in areas with lower AUC values, and lower in areas with higher AUC values, the interpretation would be that the abundance of suitable habitat, not model discrimination ability, best explains this relationship.

In order to evaluate the degree to which AUC values were a function of the amount of suitable habitat in modeling regions, and thus help us interpret whether somewhat lower AUC values represented poor models versus a larger amount of suitable habitat in the modeling region, we evaluated the correlation between AUC values and the percentage of each modeling region with RHS scores above various thresholds corresponding to RHS values showing higher use than expected (see Model Calibration section below).

Model Calibration

To assess model calibration we evaluated the agreement between RHS and observed proportions of sites occupied. Phillips and Elith (2010) noted that model discrimination and model calibration are independent measures. Model calibration refers to the agreement between predicted probabilities of occurrence (habitat suitability for our study) and observed proportions of sites occupied (Pearce and Ferrier 2000, Phillips and Elith 2010). Phillips and Elith (2010) note that model discrimination and model calibration are independent measures. Hirzel *et al.* (2006) (whose work Phillips and Elith [2010] expand upon), developed "strength of selection" metrics for species distribution models using a moving-window approach. Strength of selection (SOS) evaluations allow for an understanding of the use that areas with various habitat suitability values receive (by nesting spotted owls in our case) relative to the abundance of such areas in the study area (see Figure C4 below). Essentially, a well-calibrated model will show the species to use higher suitability areas disproportionately more and lower suitability areas disproportionately less. The shape of the relationship provides insights into the degree to which the species avoids or is attracted to areas with particular habitat suitability values.

Figure C-4. This *example* of the strength of selection (SOS) evaluation shows a well-calibrated model. Areas with a mid-point RHS (*i.e.*, relative habitat suitability value) of 0.05 (the moving window size here was 0.1) were used ~45-times *less* than would be expected based on its extent in the study area. Similarly, areas with a mid-point RHS of 0.8 (window of 0.75-0.85) were used ~12-times *more* than expected based on its extent in the study area. This figure was developed from a model trained on >3,000 spotted owl night locations (many presumed to be foraging).



Habitat Modeling Results:

The following section provides summary descriptions of the final "best" models for each modeling region; including information on the relative contribution of each covariate to the model, model evaluation metrics, and the results of validation against independent data sets conducted to date. Because the primary objective of this habitat modeling step was to provide accurate prediction of relative habitat suitability and subsequent likelihood of spotted owl occupancy, we focus on presenting evaluation of model performance, rather than description of spotted owl habitat associations. Tables and table series C10 to C17 provide descriptions of the best nesting-roosting habitat model, foraging habitat model, and full model for each modeling region, as well as model evaluation metrics (AUC and Gain) and the relative contribution of each variable to the full model (a heuristic estimate provided in the standard output from MaxEnt). AUC values were highly correlated with the percentage of each modeling region comprised of RHS values >30, >40, and >50 (r^2 = 0.9685, 0.9649, 0.9574, respectively). Hence, variation in AUC values among modeling regions (which ranged from 0.76 – 0.93) has less to do with model discrimination ability (*i.e.*, the quality of the model) and more to do with the quantity of suitably habitat in each modeling region.

See Table C18 for codes and descriptions of variables used in the models.

Table C-18. Codes and descriptions of stand structural variables from GNN and compositional variables used in relative habitat suitability models.

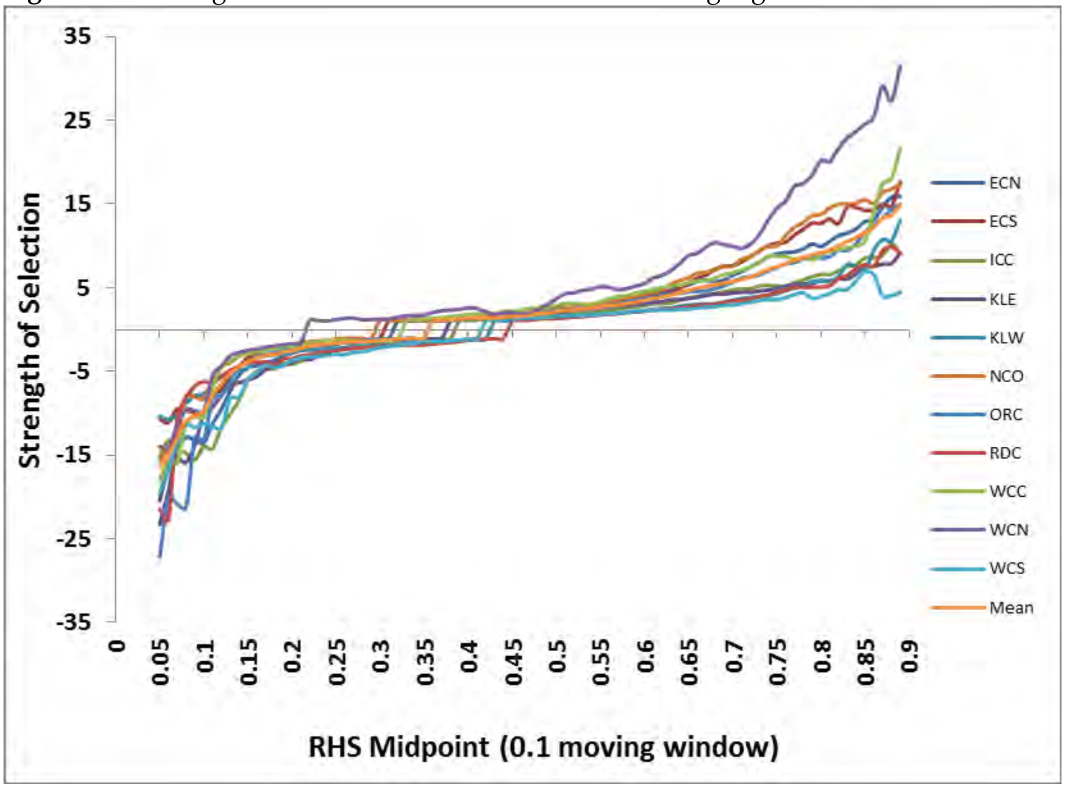
Variable	Definition
CANCOV	Canopy cover of all live trees
CANCOV_CON	Canopy cover of all conifers
DDI	Diameter diversity index (structural diversity within a stand, based on tree densities within different DBH classes)
SDDBH	Standard deviation of DBH of all live trees
MNDBHBA_CON	Basal area weighted mean diameter of all live conifers
TPH_GE_50	Live trees per hectare greater than or equal to 50 cm DBH
TPHC_GE_50	Conifers per hectare greater than or equal to 50 cm DBH
TPH_GE_75	Live trees per hectare greater than or equal to 75 cm DBH
TPHC_GE_75	Conifers per hectare greater than or equal to 75 cm DBH
TPHC_GE_100	Conifers per hectare greater than or equal to 100 cm DBH
QMDC_DOM	Quadratic mean diameter of all dominant and co-dominant conifers
BAA_GE_3	Basal area of all live trees greater than or equal to 2.5 cm DBH
BAA_3_25	Basal area of all live trees 2.5 to 25 cm DBH
BAA_GE_75	Basal area of all live trees greater than or equal to 75 cm DBH
BAC_GE_3	Basal area of conifers greater than or equal to 2.5 cm DBH
BAC_GE_50	Basal area of conifers greater than or equal to 50 cm DBH
BAH_PROP	Proportion of BAA_GE_3 that is hardwood
BAH_3_25	Basal area of all live hardwoods 2.5 to 25 cm DBH
Compositional Variables	
Evergreen Hardwoods	Basal area of tanoak, canyon, coast and interior live oaks, giant chinquapin, California bay and Pacific madrone
Subalpine	Basal area of silver fir, mountain hemlock, subalpine fir, red fir, Englemann spruce,
Pine	Basal area of ponderosa pine, Jeffrey pine, lodgepole pine, and Bishop pine
Northern Hardwoods	Basal area of red alder and bigleaf maple
Oak Woodland	Oregon white oak and blue oak

Results of Model Evaluation and Testing:

Strength of selection results

We plotted the observed use that areas with various RHS values receive (by nesting spotted owls in our case) relative to the abundance of such areas in each modeling region. Figure C5 shows the SOS curves for all 11 modeling regions. Although the degree of calibration varies among modeling regions, the RHS models are generally well-calibrated, with strong selection for areas of RHS > 0.6 to 0.7, and avoidance of RHS <0.15 to 0.25.

Figure C-5. Strength of Selection evaluation for all modeling regions.



Results of Model Cross-Validation

Overall, each modeling region's model proved to be fairly robust, and thus gave us confidence in the model's generality. When we evaluated the differences in the percentages of spotted owl sites classified among 10 equally-sized RHS bins between the full model (using all of the spotted owl locations – thinned by 3 km) and the cross-validated (CV) models (*i.e.*, the 25% of observations that were withheld from the developmental model, each of 10-times for each modeling region) there were generally very small differences (Table C19). The maximum percentage point difference (percentage of observations from the full model minus percentage of observations CV model) was 11.1 (see Table C19). The mean difference of the absolute values among modeling regions ranged from 1.6 (for the Klamath West) to 4.5 (for the West Cascades North). Absolute values were used for calculating means because without doing so, the positive and negative values within a modeling region will always have a mean of 0, and thus don't accurately represent overall differences between full and cross-validated models. There was an inverse (negative logarithmic) relationship between sample size of spotted owl sites and mean difference in absolute value ($r^2 = 0.537$, $P = 0.01$). Nonetheless, the magnitude of differences was generally quite low. For example, 39% of the differences were <2.0, 81% of the differences were <5.0, and only 7% of the differences were >7.0 (absolute value in each case). These findings suggest that none of the modeling region's full models were over-fit, and that all full models have good generality.

Table C-19. Results from cross-validation tests, showing absolute values of differences (% classified by full model - % classified in cross-validated model) among modeling regions.

Results of comparisons with independent data sets

To further evaluate the reliability of the models' predictions, we obtained independent (*i.e.* not used in model development) samples of spotted owl territory locations that represented the period 1993 to 1999 (Test96) and 2003 to 2009 (Test06) and compared their associated RHS values to corresponding values for spotted owl sites used in model development. All test sites were greater than 0.8 km from a training site. Because the RHS models were developed using spotted owl territories from the 1996 time period, comparison with Test96 most directly addresses model accuracy. Comparison with independent spotted owl locations from 2006, however, enabled us to evaluate accuracy of the models when projected to a new time period (model transferability), and to investigate systematic shifts in RHS at spotted owl sites. These shifts may occur, for example, in areas where densities of barred owls have increased during the 1996 to 2006 period, and are displacing spotted owls from favorable habitat. If this is the case (as has been hypothesized), we might expect to see reduced use of RHS area at 2006 spotted owl sites, relative to 1996 values (see Methods: Spotted owl location data).

We obtained adequate (N ≥ 100) test samples for 2006 in four modeling regions. As data for additional modeling regions and Test96 become available, further evaluation of model accuracy should be conducted. Table C20 shows the proportions of spotted owl sites in each of five RHS "bins" for the training data (Train), and Test06. Because they allow comparison of RHS values across a gradient of relative habitat suitability, these comparisons are more informative than binary "correct classification" analyses.

Table C-20. Comparison of percentage of 1996 training sites versus test samples of 2006 spotted owl locations in 5 categories of Relative Habitat Suitability.

Model evaluation summary:

All modeling regions' models were well calibrated and showed a quite similar pattern in terms of strength of selection (see Figure C5). Cross-validation results by modeling region showed that all models were relatively robust to the 25% iterative reduction in sample size (see Table C19). Lastly, comparison of model results with independent test data showed the models had good ability to predict spotted owl locations (Table C20), and performed well when projected to 2006 vegetation conditions. Overall, these evaluations suggest that our RHS models were robust and have good generality. Subsequently, we used the full dataset models.

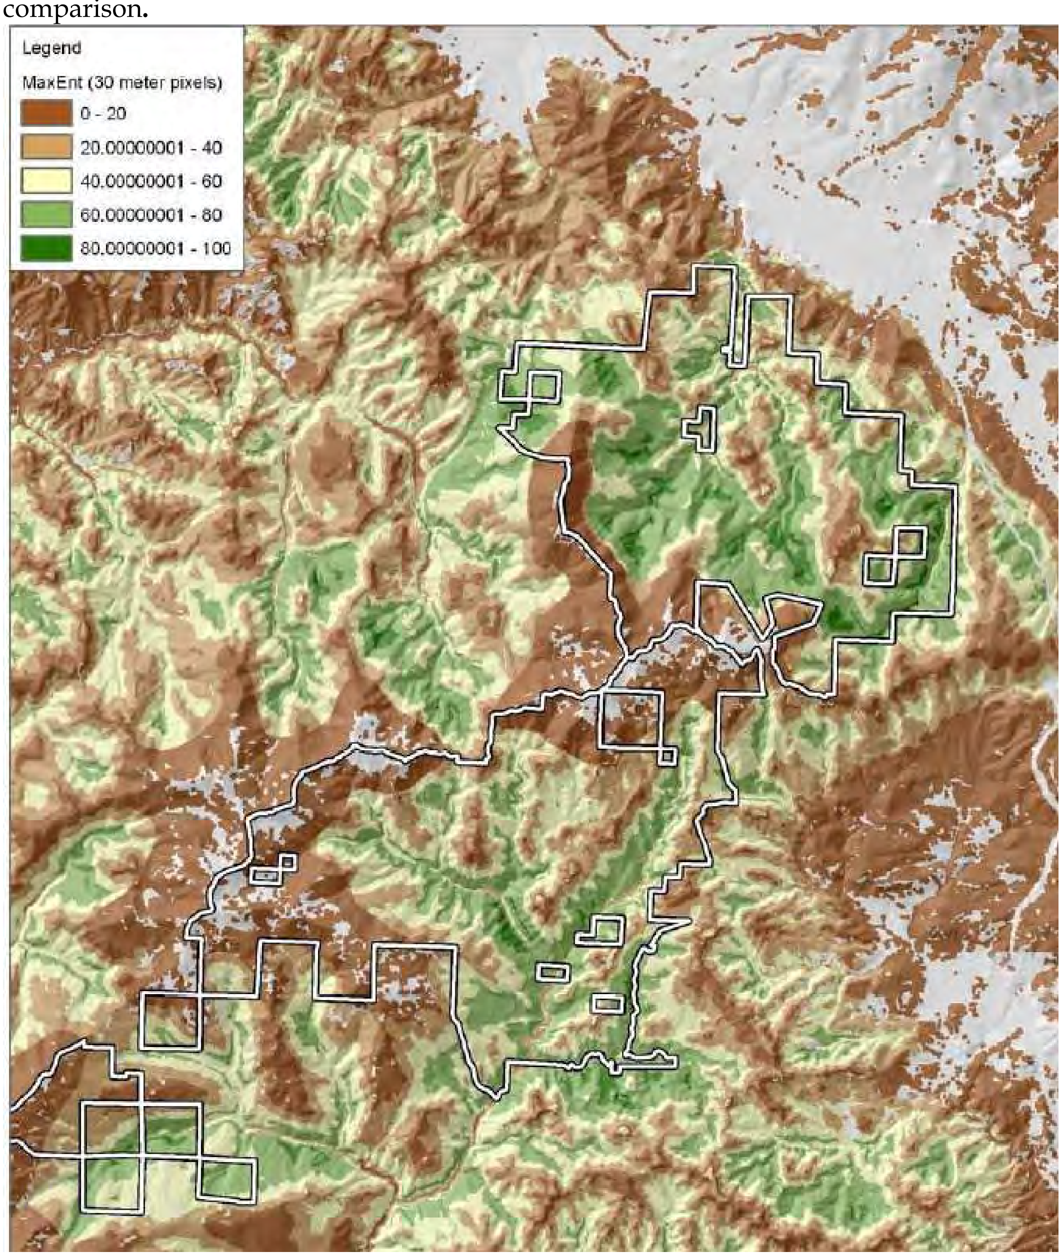
Interpretation of model output:

Elith *et al.* (2011) state that the MaxEnt logistic output is an attempt to estimate the probability that a species is present, given the environment (*i.e.*, the environmental conditions). For our purposes, we have taken a more conservative interpretation of the MaxEnt logistic output and interpret it to represent the relative habitat suitability (RHS) for nesting spotted owls within each modeling region. The map below (Figure C6) is the result of running each modeling region's best RHS model on each 30-m pixel within the region. That is, MaxEnt estimates a RHS value for each pixel based on the biotic and abiotic features within the 200-ha (~800 m radius) area around it (*i.e.*, based only on the variables in the best MaxEnt model for that modeling region). It is important to understand that a high RHS value is possible for a pixel that has little inherent value (*e.g.*, there are no trees in the 30x30 m focal pixel). It may, however, be that the surrounding 200-ha has many of the attributes associated with high RHS. Similarly, a focal pixel could have many of the positive characteristics that spotted owls generally select for, but it receives a low RHS value owing to the surrounding 200-ha having few or none of the attributes associated with high RHS values.

As noted above the RHS map is designed to facilitate and enable a wide variety of processes, discussions and analyses, including section 7 consultation, implementation and evaluation of the efficacy of spotted owl conservation measures such as Recovery Action 10 and management of barred owls. This model likely has utility for a wider variety of uses and processes than we currently envision, and it can be refined by future advances in the understanding of spotted owl habitat associations.

Maps depicting the RHS model outputs for the range of the spotted owl are available at:
http://www.fws.gov/oregonfwo/Species/Data/NorthernSpottedOwl/Recovery/Library/Default.aspx#Files
Once there, click on "maps" and "AppendixCMaps.pdf" The layers can be turned on and off using the "layers" button in the upper left-hand corner. The RHS values are the base layer on this map.

Figure C-6. Map depicting Relative Habitat Suitability from MaxEnt model. Higher suitability habitat conditions are indicated by darker green areas; brown colors denote lower suitability. Outline of the Mount Ashland Late-successional Reserve is shown for comparison**.**



Modeling Process Step 2 – Develop a spotted owl conservation planning model, based on the habitat suitability model developed in Step 1, and use it to design an array of habitat conservation network scenarios.

Because the RHS maps from Step 1 consisted of finely-distributed patterns of habitat suitability across the spotted owl's geographic range, we also wanted to provide a rigorous, repeatable method for aggregating habitat value into habitat conservation networks. We used the conservation planning model "Zonation" (Moilanen and Kujala 2008) to develop a spotted owl conservation planning model which can be used to design an array of habitat conservation network scenarios. To test this model we mapped a series of alternative spotted owl conservation network scenarios based on a series of rule-sets (*e.g.*, varying land ownership categories, the inclusion of existing reserves, identifying a specific amount of "habitat value" to include). The primary output of a Zonation analysis of the landscape is a "hierarchical ranking" of conservation priority of all cells or pixels in the landscape. Zonation allows analysts to incorporate species-specific factors such as dispersal capabilities and response to habitat fragmentation into the ranking of cells, and also allows the inclusion of factors such as land ownership and status into various evaluations. It is important to recognize that the maps produced by Zonation represent user-defined scenarios that were evaluated and compared in subsequent population modeling to test this modeling process; they do not represent decisions about the size or distribution of habitat conservation areas. While Zonation uses the term "reserve" to describe the conservation areas it identifies, this term does not dictate the types of management actions that could occur in those areas.

Zonation produces a hierarchical prioritization of the landscape based on the conservation value or "habitat value" of cells. A cell's habitat value is a function of its "base" value (*i.e.*, its RHS value) as well as the value of cells surrounding it. Thus, two cells of identical RHS may have different habitat value depending on how many other high, medium, and low value cells are nearby. The term habitat value therefore incorporates a larger spatial context than does RHS. Hierarchical, in this case, means that the most valuable five percent is also within the most valuable 10 percent; the top two percent is within the top five percent, and so on. Zonation uses minimization of marginal loss as the criterion to decide which cell is removed, and iteratively removes the least valuable cells from the landscape until no cells remain. The order of cell removal and its proportion of the total habitat value are recorded and can later be used to select any top fraction of cells or habitat value, the best 10 percent of cells or the top 10 percent of habitat value, for example, of the landscape.

To ensure that spotted owls and their habitat would be well-distributed throughout their range (one of the goals for recovery), Zonation analyses were conducted separately for each modeling region. This modeling region decision also had the impact of ensuring that conservation areas would be better distributed across the range of the species.

Zonation allows analysts to identify specific areas of the landscape that represent a particular percentage of the total estimated habitat value to the species. An important attribute of the Zonation algorithm is that it attempts to produce "efficient" solutions. That is, it prioritizes cells into units that maximize the habitat value per unit area within the solution (Figure C7). For example, in one Zonation scenario, 70% of the habitat value existed on ~40% of the landscape.

Figure C-7. *Hypothetical* relationship between total size of habitat conservation system (x-axis) and percentage of habitat value "captured" (y-axis). Theoretically, the only way to capture 100% of the habitat value is to have the entire area to be considered reserve (or all areas with value >0). For this example, the entire area is ~ 19 million ha. In this example, a reserve system that is ~4 million ha "captures" ~50% of the habitat value, one that is ~9 million ha captures ~75% of the habitat value, etc.

Because Zonation is spatially explicit, in a GIS environment the user can control several aspects of how the program evaluates the distribution of habitat value. This enables the program to emulate important aspects of the species' life history, landscape pattern of habitat, and desired attributes of a habitat conservation network.

Zonation's **Distribution Smoothing** function is a species-specific aggregation method that retains high-value areas (pixels) that are better-connected to others, resulting in a more compact solution. The user specifies the area or "smoothing kernel" within which Zonation averages or smooths habitat values, based on a two-dimensional habitat density calculation, in accordance with attributes of an organism's movement patterns or abilities, such as home range area. We compared kernel sizes corresponding to the core use area (800 m radius), median home range (2100 m), and median dispersal distance (27.7 km; Forsman *et al.* 2002). The main difference in the resulting solutions from these three different settings is that the results from the kernel estimated from dispersal distance or home range were less fine-grained than the results from the kernel value estimated from a core area. Given that we are estimating habitat conservation network scenarios at relatively large scales, the coarser-grained (home range-derived kernel values) maps provided more discrete areas as estimated networks, and thus we used the home range scale kernel size.

Zonation's **Cell Removal Method** function allows users to control the spatial pattern or "grain" of priority areas by specifying whether cell removal begins around the edges of the analysis area or at cells scattered across the analysis area. The idea behind the "Edge Removal" setting is that it is more likely to result in connectivity of higher-value areas within the more central areas of the landscape. However, because cell removal is limited to the perimeters of large landscapes, the Edge Removal option can result in large blocks containing extensive areas of unsuitable habitat such as interior valleys and high mountain peaks. The "Edge Removal with Add Edge Points" option allows the user to randomly distribute a specified number of edge points where cell removal occurs within large landscapes. This setting allows more flexibility than edge removal and provides a greater chance that interior areas of poor-suitability habitat will be removed from the solution, and results in more finely-grained pattern of priority areas. The "No Edge Removal" option does not predispose Zonation to start cell removal from any particular area or region, but removes the lowest value cells in the landscape first, then the next lowest, and so on. This results in very finely-grained prioritized areas (and very long computer run times). We conducted side-by-side comparisons and found that Add Edge Points and No Edge Removal end up with nearly identical solutions (~95% overlap in identifying the top 25% habitat value areas in the landscape). To develop a series of alternative habitat conservation networks, we selected Add Edge Points, distributing 2,000 edge points into each modeling region.

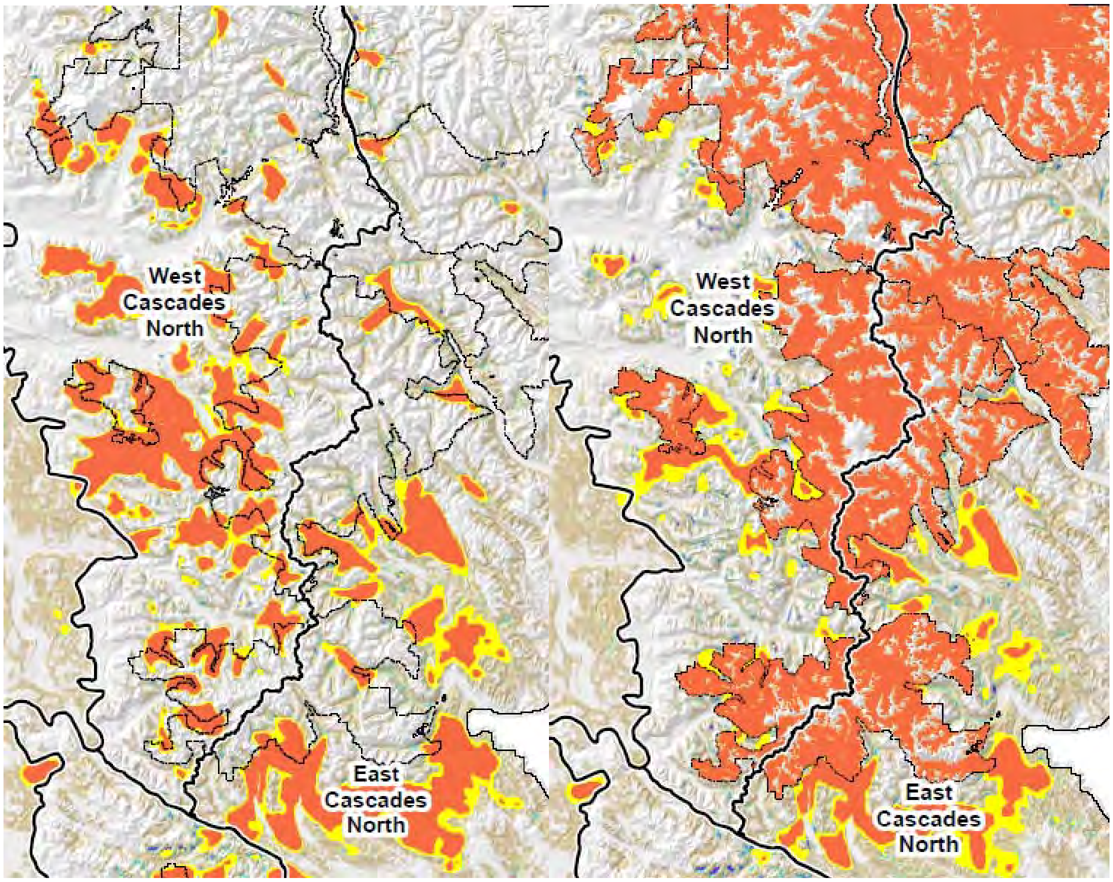
Exclusion Areas are areas that were excluded from the habitat suitability base maps prior to running Zonation. Examples are areas such as high elevation alpine areas as well as generally low elevation valley areas (*e.g.*, the Willamette Valley) that are considered incapable of supporting spotted owls. Including these areas in Zonation runs would give a false impression of habitat conservation block efficiency. That is, the algorithm would be able to remove large amounts of area (high elevation and valley areas) with no impact on the loss of spotted owl habitat value. Thus, we believed these areas should be masked out from the start. The GIS layer used to represent exclusion areas is the same one (mask) developed for the NWFP Monitoring Group (Davis and Dugger in press) and used in our MaxEnt modeling.

Selection of values for conservation value ranking: Zonation enables the user to specify the proportion of habitat value to display as maps of habitat conservation networks. Selection of the quantity of habitat value has a large influence on the size and distribution of habitat conservation networks. Because there is a near-infinite number of values that could be selected for evaluation, we compared results across a broad gradient of habitat values (20%, 30% 40%, 50%, 60%, 70%, and 80%), with the objective of identifying a smaller subset of reasonably diverse habitat conservation network scenarios for testing with the population model (see below). In addition, we compared habitat conservation networks from the above habitat values to the habitat values contained in existing networks such as spotted owl critical habitat (1992 and 2008) and the NWFP reserve network.

Precedence Masking allows the analyst to identify areas that must be or must not be included in the habitat conservation network. For example, existing protected areas such as Wilderness Areas and National Parks can be "forced" into the priority areas, regardless of their habitat value. Similarly, various land ownership categories can be "forced" out of priority areas. To accomplish this, the user identifies zones (land ownership, existing reserves, etc.) and ranks them by conservation priority (Zone 1, Zone 2, and so on) into a 'precedence mask'. In processing, Zonation removes the lowest value cells in Zone 1 first, , and continues by removing the next lowest value cell until all cells are removed in Zone 1 before moving on to Zone 2 and any potentially subsequent zones. Because the cells in Zone 2 are assigned a higher ranking, in terms of removal order, than those in Zone 1, they are disproportionately included in the solution. This process is repeated until all zones defined by the precedence mask have been fully evaluated. Zonation does not re-calculate or otherwise change the habitat value of a cell according to which zone it is in. Instead, identifying zones identifies discrete areas of the landscape that are to be given higher or lower priority of consideration for reasons other than the cells' habitat value.

The basis for precedence masking in Zonation is to allow factors such as land status to be incorporated into the landscape prioritization. For example, forcing existing National Parks and Wilderness Areas into habitat conservation networks would recognize that these areas exist as protected areas, and thus should be included in a habitat conservation networks regardless of their value to spotted owls. However, because we used Zonation to *help identify* areas estimated to provide the most conservation value for the spotted owl, we proceeded by first conducting an evaluation based purely on habitat value (unforced), and *then* evaluated how much overlap the resulting habitat conservation networks had with existing protected areas and other land designations or ownerships. Forcing existing reserves into priority areas will likely predispose Zonation to not find optimal solutions (*i.e.*, because some non-optimal areas are forced into the solution). For example, in areas such as the northern Cascades where high-value spotted owl habitat is relatively sparsely distributed, forcing Congressionally Reserved land allocations into priority areas resulted in an extremely inefficient network design (Figure C8).

Figure C-8. Comparison of Zonation 40% (orange) and 50% (yellow) solutions on all land ownerships (left) and with Congressional Reserves prioritized (right). Outlines of habitat conservation network solutions in the right frame correspond largely to National Park and National Forest boundaries.



After evaluating Zonation results employing a range of values for distributional smoothing, cell removal methods, ranking values, and land status and ownership prioritization, we selected habitat conservation network scenarios comprised of 30 percent, 50 percent, and 70 percent of habitat value as reference points. These scenarios sample along a gradient from somewhat smaller than the current habitat conservation network (NWFP) to a habitat conservation network approximately twice as large as the LSR network (Table C21). We recognize that the results of population modeling may indicate other Zonation scenarios that should or could be developed and tested (feedback loop in Figure C1). ***Also, it is important to recognize these scenarios are not recommendations for the specific size or location of habitat conservation blocks – they are only scenarios for the purpose of comparing to other scenarios to evaluate how they influence spotted owl population performance in the population simulation model.***

Settings and Values Used in Zonation

Distribution Smoothing: Home range area (2100 m radius)
Cell Removal Method: Add Edge points (2000 points/modeling region)
Exclusion Areas: Used NWFP non-capable habitat mask from NWFP Monitoring
Ranking Values: Used 30%, 50%, and 70% of habitat value
Precedence Masking: Land ownership scenarios evaluated include:

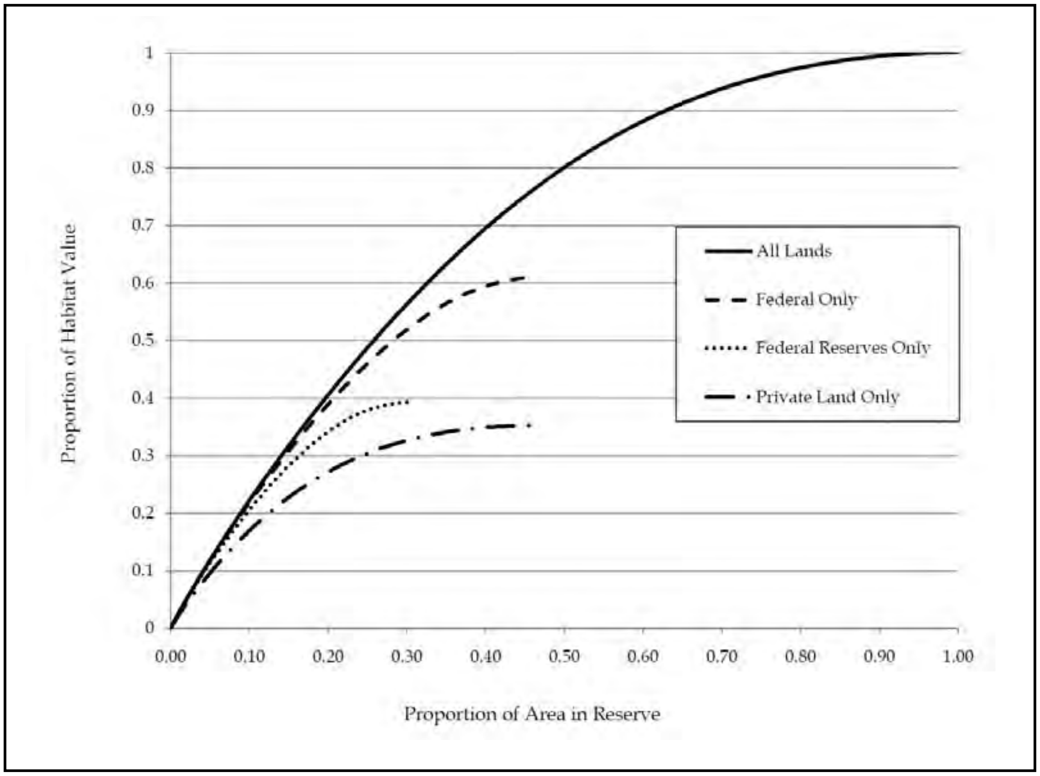
1) **No limit on inclusion** – No hierarchical masking - all land ownerships were allowed to be included and existing reserves were not forced into the priority areas. This scenario was chosen to represent the potential of the entire area to provide for spotted owls.

2) **Public lands only** – precedence masking was done such that non-public lands were removed first, and public lands were removed last. This had the effect of emphasizing reserves on public lands, but if the total amount of habitat value specified (*e.g.*, 50% or 70%) could not be acquired from cells in public lands, other lands could be included in the solution.

Maps depicting all of the initial Zonation scenarios are available at:
http://www.fws.gov/oregonfwo/Species/Data/NorthernSpottedOwl/Recovery/Library/Default.aspx#Files
Once there, click on "maps" and "AppendixCMaps.pdf" The layers can be turned on and off using the "layers" button in the upper left-hand corner.

Zonation outputs can be used to compare the contributions of different land classes (ownership, reserve status, etc.) based on the area and proportion of habitat value of each land class. Figure C9 depicts the relationship between area (proportion of the spotted owl's range) that could, hypothetically, be included in a habitat conservation network and the amount of spotted owl habitat value that various habitat conservation networks would contain among four categories: 1) all lands, which represents no limits on ownerships in the habitat conservation network; 2) Federal lands only, with no priority for currently existing reserves; 3) Federal reserves only, this scenario includes only NWFP reserves (Congressional Reserves and LSRs); and 4) private lands only; no reserves on Federal lands. These depictions are for demonstrative purposes only, not recommendations. They are essentially asking what would be the conservation value to spotted owls if habitat conservation areas were restricted to various land ownership categories. For example, private lands constitute about 45 percent of the spotted owl's range and provide roughly 35 percent of the rangewide habitat value (RHS), whereas the NWFP reserve network provides 40 percent of rangewide habitat value on 30 percent of the area (Figure C9).

Figure C-9. Relationship between proportion of various land ownerships/categories (no restriction, Federal lands only, Federal reserves only, or private lands only) included in a habitat conservation network and proportion of spotted owl habitat value included in the habitat conservation network.



While Zonation outputs do not evaluate or predict potential spotted owl population sizes associated with different habitat conservation network scenarios, they nonetheless permit comparison of the sizes of existing reserve or conservation networks to possible habitat conservation areas, and enable additional comparisons to be made in a GIS environment. For example, Table C21 shows a comparison of network size, percent of spotted owl training locations from the habitat modeling that falls within various habitat conservation network scenarios, and percent of the top two Zonation habitat value ranks among 10 habitat conservation network scenarios. Table C22 shows the relationship the proportion of RHS bins within each of 20 Zonation and 4 non-Zonation habitat conservation network scenarios. The results show the efficiency with which Zonation selects high RHS areas.

Table C-21. Comparison of area, percent of 1996 spotted owl sites used in model development, and percent of top 10% and 20% Zonation ranked habitat value for 10 spotted owl reserve scenarios.

Network scenario	Network scenario size (million hectares)	Percent of 1996 spotted owl sites	Percent of top 10% Zonation-ranked	Percent of top 25% Zonation-ranked
NWFP	6.63	46	56.7	55.2
MOCA	4.77	33	46.3	43.8
1992 Critical Habitat	5.75	44	57.3	55.4
2008 Critical Habitat	5.17	37	49.6	47.7

Modeling Process Step 3 - Develop a spatially explicit spotted owl population model that reliably predicts relative responses of spotted owls to environmental conditions, and use it to test the effectiveness of habitat conservation network scenarios designed in step 2 in recovering the spotted owl. The simulations from this spotted owl population model are not meant to be precise estimates of what will occur in the future, but provide information on comparative trends predicted to occur under differing habitat conservation scenarios.

To meet this objective, the modeling team elected to use a spatially explicit, individual-based modeling approach. While other approaches such as population level population viability analysis (PVA) and metapopulation models have been used for evaluating spotted owl populations, we required an approach that enabled comparison of a wide range of spatially explicit conditions such as variation in habitat conservation networks. Dunning *et al.* (1995) wrote the following regarding spatially explicit population models:

> *"Spatial models, structured and parameterized according to a species' life history, allow one to explore the efficiency of various reserve designs. The models can be*

> *used to estimate the potential effects on a species' persistence by systematically varying factors such as the percentage of the landscape that is suitable habitat, and the size, shape, and spacing of habitat patches. The addition of marginal (i.e., sink) habitat to a reserve can be assessed for negative effects on a managed population (Pulliam and Danielson 1991). These exercises can be done on artificial landscape maps to explore general reserve design principles (Lamberson et al. 1992, 1994) or on GIS-based maps that incorporate land-use and ownership constraints (Murphy and Noon 1992, Noon and McKelvey 1992)."*

Individual-based models (IBMs) allow for the representation of ecological systems in a manner consistent with the way ecologists view such systems as operating. That is, emergent properties such as population increases or declines are the result of a series of effects and interactions operating at the scale of individuals. Individuals select habitat based on what is available to them, disperse as a function of their individual circumstance (age), compete for resources, etc.

Grimm and Railsback (2005) noted that IBMs need to be simple enough to be practical, but have enough resolution to capture essential structures and processes. The spotted owl is perhaps the most studied raptor in the world, and thus there exists a tremendous quantity and quality of data (*e.g.*, vital rates are evaluated in a meta-analysis for several long-term demographic study areas every 5 years; *e.g.*, Anthony *et al.* 2006, Forsman *et al.* (2011)); habitat selection (see review by Blakesley 2004) has been thoroughly evaluated; large numbers of individuals have been followed during dispersal (Forsman *et al.* 2002); among many other aspects of the species' ecology. The spotted owl is therefore ideally suited for spatially explicit IBM. Bart (1995), however, noted that the question "Does the model improve our ability to make decisions?" needs to be explicitly considered. The modeling team believes that the spatially explicit IBM HexSim, which is parameterized largely with empirically-derived values from spotted owl studies, improves our ability to make land management decisions, and therefore we have decided to use this approach.

The HexSim Model:

HexSim (Schumaker 2011) was designed to simulate a population's response to changing on-the-ground conditions by considering how those conditions influence an organism's survival, reproduction, and ability to move around a landscape. The modeling team developed a HexSim spotted owl scenario based on the most up-to-date demographic data available on spotted owls (Forsman *et al.* 2011), published information on spotted owl dispersal, and home range size as well as on parameters for which less empirical information was available (see below). Initially, the HexSim spotted owl model allows users to evaluate the efficacy of existing conservation strategies, under currently-estimated barred owl impacts and with currently-estimated habitat conditions, to meet recovery goals. Subsequently, the model serves as a consistent framework into which variation in spatial data layers (*e.g.*, reserve or conservation block boundaries, different assumptions about habitat conditions (RHS) inside and outside of reserves or blocks, different assumptions about RHS change on public versus private lands, and different assumptions about the impact of barred owls among modeling regions) can be introduced. Comparison of estimates of simulated spotted owl population performance estimates across the range of scenarios incorporating variation in habitat conservation network sizes, habitat trends, and barred owl influence, can inform evaluations of habitat conservation networks and other conservation measures designed to lead to spotted owl recovery.

In very general terms, we tried to design the model to answer the following questions: (1) Given current circumstances (reserves, habitat, barred owls, spotted owl demographic rates, etc.), is recovery of the spotted owl likely in the foreseeable future?; (2) Given current estimates of habitat, barred owls, and spotted owl demographics, is recovery of the spotted owl likely in the foreseeable future under different habitat conservation network scenarios?; and (3) To what degree would management of habitat and barred owls contribute to or detract from reaching spotted owl recovery goals under a range of habitat conservation networks and management scenarios? Evaluation and ranking of the population simulation results from the model obtained across a range of habitat conditions, barred owl effects, and conservation network scenarios, and comparison with established recovery criteria, should provide important insight into these questions. **The HexSim model is available at: www.epa.gov/hexsim.**

HexSim Overview:

HexSim is a spatially explicit, individual-based computer model designed for simulating terrestrial wildlife population dynamics and interactions. HexSim is a generic life history simulator; it is not specifically a spotted owl model. HexSim was designed to quantify the cumulative impacts to wildlife populations of multiple interacting stressors.

HexSim simulations are built around a user-defined life cycle. This life cycle is the principal mechanism driving all other model processing and data needs. Users develop the life cycle when initially setting up a simulation. The life cycle consists of a sequence of life history events that are selected from a list. This event list includes survival, reproduction, movement, resource acquisition, species interactions, and many other actions. Users can impose yearly, seasonal, daily, or other time cycles on the simulated population. Each event can work with all, or just a segment of a population, and events can be linked to static or dynamic spatial data layers. Each life cycle event has its own data requirements. Simple scenarios may use few events with minimal parameterization and little spatial data. When more complexity is warranted, HexSim allows a great deal of data and behavior to be added to its simulations.

HexSim scenarios include descriptions of one or more populations, spatial data needs, life cycle definitions, event data, and basic simulation criteria such as the number of replicates and time steps. Each population is composed of individuals, and individuals have traits that can change probabilistically, or based on age, resource availability, disturbance, competition, etc. HexSim also includes optional genetics and heritable traits (though these were not used for the spotted owl model). The use of traits allows members of the simulated population to have unique properties that change in time and space. Traits also allow populations to be segregated into classes, such as males and females, fitness categories, disease categories, etc. Combinations of trait values can be used to stratify events such as survival, reproduction, movement, etc.

Traits are a fundamental part of HexSim scenarios. Traits can be used to control most life cycle events because events can be stratified by trait combinations. For example, a movement event might be set up to operate only on a fledgling stage class. Or a survival event might assign mortalities based on the values of a trait that reflects resource acquisition. In addition, one trait's values can also be influenced by multiple other traits, which makes it possible to set up stressor interactions and complex feedback loops. Traits can also be used to capture interactions such as parasitism, competition, mutualism, breeding, etc.

Overview of the Spotted Owl Scenario

Because females are the most influential sex in terms of population dynamics, the HexSim spotted owl scenario is a females-only model. The life cycle is simple except that the acquisition of resources by individual spotted owls is spatially stratified, and thus somewhat complex. The scenario depends on two static spatial data layers; one representing the distribution and relative suitability of habitat, and an "exclusion layer" to prevent spotted owls from moving out into the Pacific Ocean, or into areas outside of their geographic range .

An additional layer comprised of the boundaries of both the modeling regions and demographic study areas (DSAs were used to generate HexSim reports (*i.e.*, we extracted information about spotted owls in DSAs as well as within modeling regions and for all modeling regions overall), had no effect on the simulated population. All spatial data layers are converted to grids consisting of 86.6- ha hexagons. To the extent possible, simulation parameter values were estimated based on published empirical data.

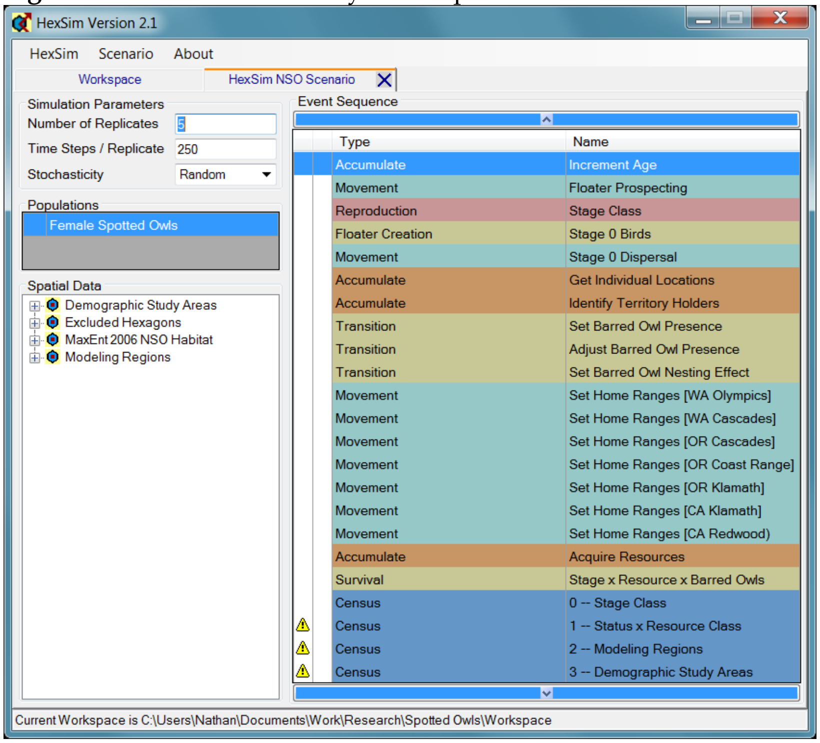
The HexSim simulations began with 10,000 spotted owls being virtually introduced into the study landscape. The initial population's ages were randomly distributed, and they were placed preferentially into areas of high RHS. Once initialization was complete, individual spotted owls were subjected to the event cycle shown in Figure C11. The year begins with each individual becoming a year older. Next, floaters (spotted owls without a territory) prospect for a territory. This is followed by reproduction and fledgling dispersal. Dispersing fledglings do not prospect for a territory.

We assumed that the RHS map developed in MaxEnt was a proxy for the amount of resources available to spotted owls within each hexagon. Because nesting spotted owls showed relatively strong selection for some RHS categories and against others (see Figure C5), we reasoned that this selection was based on a combination of factors (including, but not limited to, those we included as covariates in our models) that influence spotted owl natural selection. That is, spotted owls select some areas and avoid other areas in order to maximize their survival and reproductive success. Spatially-explicit data on competitors, prey, predators and other factors influencing spotted owls were unavailable, and thus we were unable to incorporate more direct measures of resource quantity and quality.

In the HexSim Spotted Owl Scenario, a primary influence of RHS on simulated spotted owl populations occurs in territory acquisition (occupancy). To the extent that some areas aren't selected by spotted owls (or disproportionately selected against), habitat suitability acts to limit survival and reproduction (*i.e.*, spotted owls don't survive or reproduce in areas that they don't occupy). Subsequent to territory establishment, resource acquisition (RHS values) determines the resource class a spotted owl is placed in, which influences survival rates. Reproduction was not influenced by resource acquisition, and thus was not influenced by habitat quality. Individual studies (*e.g.*, Franklin *et al*. 2000) and meta-analyses have reported influences of habitat on survival and in some cases fecundity (see Forsman *et al*. 2011).

We recognized the importance of dispersal and habitats used by dispersing spotted owls in developing habitat conservation planning models. However, relatively little is known about the characteristics of areas used by dispersing spotted owls. In the spotted owl modeling effort, the modeling team therefore elected not to define or attempt to model dispersal habitat, but instead to rely on reasonable assumptions about the influence of relative habitat suitability (for nesting) on successful dispersal. Success (survival) of spotted owls dispersing through variable landscapes may be influenced by factors similar to those affecting territorial spotted owls (*e.g.* availability of prey, cover from predation, thermal stress) albeit at a different scale. Because the RHS values generated by MaxEnt retain the full gradient of habitat suitability (*i.e.* not 'thresholded' or categorized), it is reasonable to assume that relative habitat suitability is correlated with relative success of dispersal occurring in those areas (pixels). In HexSim, dispersing spotted owls are allowed to disperse through the full range of RHS values, with some degree of repulsion to the lowest RHS values.

Figure C-11. HexSim event cycle for spotted owls.



After floater spotted owls finish prospecting for territories, the modeling region they are in is recorded. Then the determination of whether each territorial spotted owl is in the presence of a barred owl is made probabilistically, with the probability of being in the presence of a barred owl dependent on the modeling region (Table C25). The region-specific probabilities for spotted owl exposure to barred owls were based on the proportion of spotted owl territories where barred owls were detected each year on the 11 DSAs (see Appendix B; Forsman *et al*. 2011). This decision is only made once per "bird-territory" (*i.e.*, once the decision is made for an individual spotted owl at a territory, the barred owl presence/absence is fixed for that territory until another spotted owl takes over the territory). All non-territorial spotted owls are placed in an 'undetermined status' category until they obtain a territory. A newly territorial spotted owl that has this undetermined status is assigned a "barred owl present" or "barred owl absent" status, based on the barred owl encounter probability for that modeling region.

Next, spotted owls that have the "barred owl present" status are placed in either a "*nesting normal*" or "*nesting halted*" class. At present, every spotted owl is placed into the *nesting normal* class. If spotted owls were assigned to the *nesting halted* class, they would not reproduce. Unlike the barred owl presence/absence trait described above, the *nesting normal* vs. *nesting halted* decision could be revisited every year, for every territorial spotted owl. Spotted owl floaters do not reproduce, so although they are always assigned to the *nesting normal* category, this has no impact on the simulation results. We mention these features (even when they aren't used) that were built into the HexSim Spotted Owl Scenario model to show how the model can adapt to and incorporate new information when it becomes available.

In the HexSim simulation, barred owls affect spotted owls through survival only. However, the simulation has been developed to facilitate a barred owl impact on spotted owl reproduction. This feature has not yet been used. It would also be possible to have barred owls impact habitat selection by spotted owls, or site fidelity. Neither of these processes has been implemented. Reproductive rates were obtained from Table 3 of Forsman *et al*. (2011). Those estimates were for time periods as long as 1985 to 2008 and as short as 1992 to 2008. It is generally agreed that barred owl populations have increased in most areas of the spotted owl's range over that time. Thus, to the degree that barred owls have an influence on fecundity, that influence is incorporated into these estimates.

Spotted owl reproduction is stratified by both stage class and nesting status (see above). Spotted owls that are in the *nesting halted* class have 100% probability of producing a clutch of size 0. Otherwise, the reproductive rates vary by stage class.

Spotted owl survival is stratified by barred owl presence, stage class, and resource class. Spotted owls in the barred owl present class have lower survival rates. Those in the barred owl absent, or undetermined classes, have higher survival rates.

At present, barred owls are not explicitly simulated, but are instead captured probabilistically. Accounting for barred owl impacts on spotted owl habitat selection or site fidelity would require that barred owls be actually located on the simulated landscape, and possibly even fully simulated within HexSim. The modeling team felt that sufficient data did not exist range-wide to permit either option to be incorporated into the current simulations. When such data become available, they can be integrated into the framework we have developed.

Next, each spotted owl establishes a home range. The simulated spotted owls have small defended territories, but large overlapping home ranges. Home range size varies with modeling region. The spotted owls extract resources from their home ranges, and thus they experience competition for resources from conspecifics. Finally, resource acquisition and survival are simulated. Survival varies based on stage class, resource acquisition class, and exposure to barred owls.

Home range sizes were set to the mean of the available regional-specific estimates (see summary in Schilling 2009). Spotted owl survival rates were based on study area-specific estimates from Forsman *et al*. (2011), with adjustment for the impact of barred owls across all study areas as calculated from the survival meta-analysis model containing an additive barred owl effect, also from Forsman *et al.* (2011).

The Population Parameters

Three distinct component groups were involved in the specification of the HexSim spotted owl population. These involved a set of basic properties, the definition of several different population traits, and finally the establishment of rules for the spotted owl's use of space and resource needs. The basic properties were used to establish an initial population size of 10,000 spotted owls, and to define an exclusion layer. Individuals were initially placed into the best hexagons in the simulation landscape, but only one spotted owl was allowed per hexagon.

Seven traits were created as part of the spotted owl population definition. These traits track stage class, location (modeling region and possibly DSA), resource class, territory status (territorial vs. floater), exposure to barred owls, and barred owl impacts on spotted owl nesting. Table C23 shows each possible trait value.

The simulated spotted owls produced each year begin life at age zero, and stage class zero. Each year they transition into the next stage class. At age 3 they reach stage class three, which is the terminal stage class. The spotted owls always belong to one of three resource classes, depending on the amount of resources they are able to acquire from their home range. Resources are a function of the mean RHS of hexagons, derived from the MaxEnt models (see above). Spotted owls that acquire 2/3 or more of their resource target are placed in the high resource class. Those that attain less than 1/3 of their resource target are placed into the low resource class. All other spotted owls are placed into the medium resource class. Resource targets vary by modeling region, and are described below.

The territory status trait is used to record whether individual spotted owls own a territory, or are floaters. The barred owl presence trait categorizes individual spotted owls as being exposed, or unexposed, to a barred owl. This decision is made once for each territorial spotted owl. The barred owl nesting effect trait is used to assign a probability that exposure to a barred owl will cause a spotted owl to avoid nesting. This evaluation is repeated every year for every spotted owl.

Table C-23. Spotted owl scenario traits and value categories.

The modeling region and demographic study area traits are used to track individual spotted owl locations. The 11 modeling regions are space-filling and non-overlapping. Each individual spotted owl occupies one modeling region at any one time. If a spotted owl territory spanned multiple modeling regions, it was assigned to the region in which the majority of its territory hexagons fell. The demographic study areas (DSAs) take up just a fraction of the landscape. So at any moment most spotted owls will not be in a DSA. Resource targets (explained below) and home range size vary by modeling region.

The population parameters also control individual's use of space. The simulated spotted owls had territory sizes of no more than three 86.6-hectare hexagons. This territory size represents a reasonable approximation of a spotted owl core area (see discussion of spatial scale above). Hexagons had to have at least a score of 35 (out of 90 possible) to be usable in forming a territory. We decided on a minimum score of 35 after evaluating the scores of hexagons overlaid on 3,790 spotted owl nest sites. We evaluated the score for the focal hexagon (the one in which the nest resided), the second, and third closest hexagons, as well as the mean scores of the first, second, and third hexagons. More than 75% of the nest sites were in hexagons with scores >35. Similarly, 73% of the spotted owl sites had a mean score >35 for the focal, second, and third closest hexagons. Although other scores might be reasonable, we reasoned that increasing the score would unreasonably inhibit settlement on suitable areas, whereas decreasing the score would result in unrealistic densities in areas with relatively low RHS. Territory size had little significance for the simulated population dynamics, as the spotted owls derive resources from their home ranges. The territories served as a core area around which home ranges could be constructed. Territories, in the HexSim simulations, were exclusively used areas, whereas the remainder of the home range area could overlap with that of neighboring spotted owls.

Each simulated spotted owl has a resource target, which controlled how much resource it must have access to in order to be placed into the highest resource class. The resource targets vary by modeling region. Spotted owls that acquire 2/3 or more of their resource target are placed into the high resource acquisition class. Those that attain less than 1/3 of their resource acquisition target are placed into the low resource acquisition class. All other spotted owls end up in the medium resource acquisition class. The resource targets are listed in Table C24.

Table C-24. Estimated resource targets based on RHS values at 3,790 spotted owl locations.

Modeling Region	Home Range Size ha (# hexagons)	Resource Target
North Coast Olympics	11,052 (128)	1250
East Cascades North	7,258 (84)	1000
West Cascades North	7,258 (84)	1250
West Cascades Central	7,258 (84)	1250
Oregon Coast	4,123 (48)	375
West Cascades South	3,949 (46)	375
Inner CA Coast Range	3,165 (37)	375

Klamath East	3,033 (35)	375
Klamath West	3,033 (35)	375
Redwood Coast	1,173 (14)	250

The Event Sequence

There are 23 events in the HexSim spotted owl scenario. Not all of these events modify the population, and some have similar or related functions. These events are described in turn below. Each event is listed by type (*e.g.,* movement) and specific name (in square brackets).

Accumulate [Increment Age]

This event makes each individual one year older. As a result, stage 0 individuals will move into stage 1, stage 1 individuals will move into stage 2, and stage 2 individuals will move into stage 3.

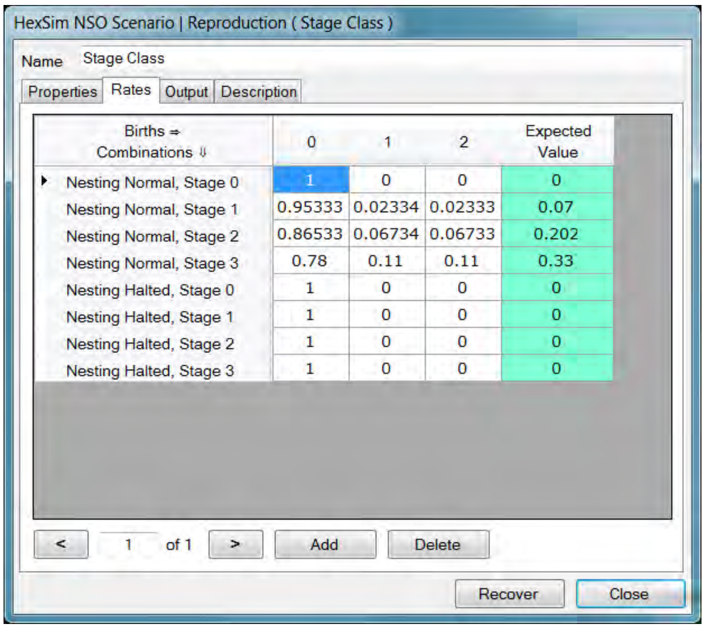
Movement [Floater Prospecting]

HexSim's movement event controls dispersal and prospecting behavior. But any one event may do either or both. This event only performs prospecting, but it does so for all spotted owls that are floaters (*i.e.,* those who do not own a territory). Individual floaters are allowed to search an area of up to 500 86.6 - hectare hexagons in search of a vacant area from which a territory could be constructed. The search strategy is imperfectly informed by resource availability. That is, spotted owls tended to construct home ranges from high RHS hexagons, but they did not select the best sites with certainty.

Reproduction [Stage Class]

HexSim's reproduction module is parameterized by assigning probabilities to each possible clutch size. Reproduction is also stratified by traits. In this case, the maximum clutch size was set to 2, and reproduction rates were varied by stage class, and based on the Barred Owl Nesting Effect trait values. The reproductive rates used in the event are shown in Figure C12. The unperturbed (by barred owls) reproductive rates were obtained from Table 3 of Forsman *et al.* (2011).

Figure C-12. Estimated spotted owl reproductive rates by stage class.



Births ⇒ Combinations ⇓	0	1	2	Expected Value
Nesting Normal, Stage 0	1	0	0	0
Nesting Normal, Stage 1	0.95333	0.02334	0.02333	0.07
Nesting Normal, Stage 2	0.86533	0.06734	0.06733	0.202
Nesting Normal, Stage 3	0.78	0.11	0.11	0.33
Nesting Halted, Stage 0	1	0	0	0
Nesting Halted, Stage 1	1	0	0	0
Nesting Halted, Stage 2	1	0	0	0
Nesting Halted, Stage 3	1	0	0	0

The column headings in Figure C12 correspond to clutch sizes. The rows contain all of the permutations of the two trait values. The right-most column shows the expected values, which, in a females-only model, equal fecundities. Individuals whose nesting has been halted by a barred owl are assigned a 100% probability of having a clutch size of zero. The same is true for stage class 0 individuals. Otherwise, the probabilities of having clutches of size 1 and 2 were set as equal as possible, to whatever value was necessary to produce the fecundity values reported in Forsman *et al.* (2011). Finally, the probability of having a clutch of size zero was set so that each row summed to exactly 1.0.

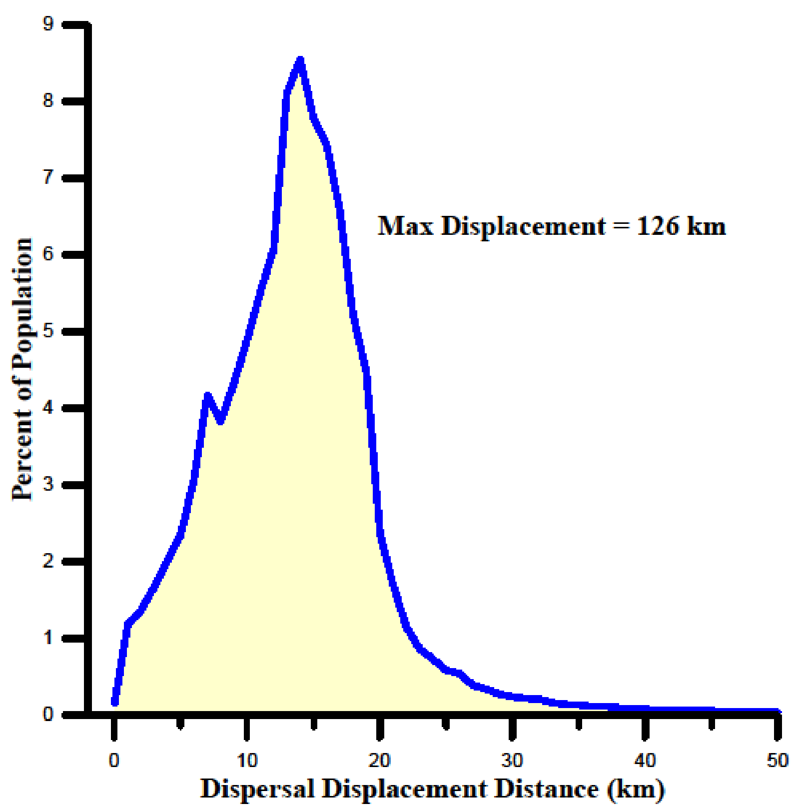
Floater Creation [Stage 0 Birds]

In HexSim, recruits become a co-owner of their mother's territory. They will disperse from their natal territory when forced to by a floater creation event at the end of Year 1. This floater creation event removes all stage 0 birds from their natal groups. These animals disperse in the next event.

Movement [Stage 0 Dispersal]

HexSim's movement event controls dispersal and prospecting behavior. Any one movement event may do either or both. This event strictly performs dispersal for stage class 0 spotted owls. The dispersing birds move with moderate auto-correlation until they encounter enough resource that a territory may be constructed (see above). Territory construction does not actually take place at this time. The dispersers are limited to moving 250 km total distance. The birds have a slight repulsion to lower RHS areas of the landscape, but are not prevented from moving into zero-valued hexagons. Figure C13 shows an example of the distribution of simulated dispersal displacement distances produced by this movement event. These data were gathered from five replicate simulations, for years 100-250. The total number of dispersal events in this period was approximately 852,000. The shape of this frequency distribution will change if either the rules for stopping (3 territory-quality hexagons encountered in succession) or the degree of autocorrelation (50%) are modified.

Figure C-13. Distribution of 852,000 simulated Year 1 dispersal distances.



Accumulate [Get Individual Locations]

This event records which modeling region each spotted owl is in. If an individual falls within a demographic study area then this event will captures that information, as well.

Accumulate [Identify Territory Holders]

This event updates a trait that segregates into two classes: floaters and territory-holders.

Transition [Set Barred Owl Presence]

This transition event assigns values to the Barred Owl Presence trait. Each modeling region was assigned a separate barred owl encounter probability, based on field data illustrating the proportion of spotted owl territories on DSAs where a barred owl was documented each year (Appendix B; Forsman *et al.* 2011). Using these probabilities, this event places each territorial spotted owl into one of two classes. The classes indicate whether the spotted owl is exposed to a barred owl or not. Once this determination is made for a specific spotted owl, it is not changed until that spotted owl dies or otherwise leaves the territory. The probabilities that were used are shown in Table C25.

Table C-25. Barred owl encounter probabilities estimated from Forsman *et al.* (2011).

Region	Encounter Probability
North Coast Olympics	0.505
East Cascades North	0.296
West Cascades North	0.320
West Cascades Central	0.320
Oregon Coast	0.710
West Cascades South	0.364
Inner CA Coast Range	0.213
East Cascades South	0.180
Klamath East	0.245
Klamath West	0.315
Redwood Coast	0.205

Transition [Adjust Barred Owl Presence]

This transition event simply removes the barred owl presence designation from floater spotted owls. This way, if a spotted owl was to give up its territory and leave, it would not retain its barred owl presence / absence designation. In the present scenario territorial spotted owls have perfect site fidelity, so this event has no impact.

Transition [Set Barred Owl Nesting Effect]

This transition event uses the barred owl presence trait to set the value of a barred owl nesting effect trait. This allows spotted owls that are exposed to a barred owl to be placed into a non-nesting category with some probability. As this probability increases from zero, barred owls have an increasingly strong influence over spotted owl nesting rates, and hence reproductive output. In these simulations, the barred owl effect on spotted owl nesting was set to zero.

Movement [Set Home Ranges]

Eight different movement events are used to set home range sizes differently based on modeling region. These movement events only establish home ranges for territorial spotted owls. The home range sizes used are listed in Table C26. Spotted owls acquire resources from their home ranges, and the home ranges for different birds may overlap; territories however, cannot overlap. This results in competition among spotted owls for resources. Spotted owl home ranges were always contiguous, but their shapes were not constrained. The home range sizes used were developed from the published results of many field studies, and were compiled by the modeling team.

Table C-26. Spotted owl home range sizes used in population modeling.

Region	Home Range Size (in hexagons)
North Coast Olympics	128
East Cascades North	84
West Cascades North	84
West Cascades Central	84
Oregon Coast	48
West Cascades South	46
Inner CA Coast Range	37
East Cascades South	35
Klamath East	35
Klamath West	35
Redwood Coast	14

Accumulate [Acquire Resources]

This "accumulate event" assigns individual spotted owls to a resource class, based on how much resource they acquire from their home ranges. Habitat suitability and quantity, plus competition with conspecifics will dictate what resource class individual spotted owls end up in.

Survival [Stage x Resource x Barred Owls]

The survival event is stratified by stage class, resource class, and exposure to barred owls (which is binary). The survival rates that were used are shown in Table C27. The derivation of these values is discussed in a separate section below.

Census [x 4]

Four census events are used to track the number of spotted owls by stage class, resource class, modeling region, and demographic study area.

Table C-27. Estimated survival rates of spotted owl based on stage class, resource class, and barred owl effect.

Without Barred Owls			With Barred Owls		
Stage Class	**Resource Class**	**Survival Rate**	**Stage Class**	**Resource Class**	**Survival Rate**
Stage 0	Low	0.366	Stage 0	Low	0.28
	Medium	0.499		Medium	0.413
	High	0.632		High	0.546
Stage 1	Low	0.544	Stage 1	Low	0.458
	Medium	0.718		Medium	0.632
	High	0.795		High	0.709
Stage 2	Low	0.676	Stage 2	Low	0.590
	Medium	0.811		Medium	0.725
	High	0.866		High	0.780
Stage 3	Low	0.819	Stage 3	Low	0.733
	Medium	0.849		Medium	0.763
	High	0.865		High	0.779

Spatial Data

The Baseline HexSim spotted owl scenario uses four different map files. All four maps are static (they do not change with time), and each is made up from 538,395 hexagons arranged in 1430 rows and 377 columns. Individual hexagons are 1000 meters in diameter, and 86.6 hectares in area. The spatial data were developed by sampling raster imagery, using a tool that is built into the HexSim model. The sampling process involves intersecting a grid of hexagonal cells with a raster image, and then computing a per-hexagon mean from a series of weights assigned to the land cover classes present in the raster data.

The habitat map (*MaxEnt 2006 NSO Habitat)* depicts spotted owl RHS values developed using MaxEnt in Step 1 (see above). In HexSim, each pixel was assigned a weight equal to its RHS score. Pixel scores ranged between zero and 97. Thus when the HexSim RHS map was constructed from this raster file, the largest possible hexagon score was 97.00; this upper limit was never realized because each hexagon's value represented an average of the pixels underneath it. The hexagons in the HexSim RHS map vary between 0.00 and 90.37. Hexagon scores were assumed to be proxies for the value of resources available to NSOs within the hexagon.

The habitat map (*MaxEnt 2006 NSO Habitat)* captures spotted owl resource quality, and was derived from RHS values developed using MaxEnt in Step 1 (see above). In HexSim, each land cover class was assigned a weight equal to its category ID. The category IDs ranged between zero and 97. Thus when the HexSim resource quality map was constructed from this raster file, the best possible hexagon score was 97.00; this upper limit was never realized because each hexagon's value represented an average of the pixels underneath it. The hexagons in the HexSim resource quality map vary between 0.00 and 90.37.

A map delineating the study area (*Excluded Hexagons)* was binary, with ones being assigned to each hexagon within the range of the spotted owl, and zeros elsewhere. Simulated spotted owls were not allowed to move into hexagons that were zero-valued in this map. This map included boundaries to the study area, such as the Pacific Ocean and other areas outside of spotted owl's range, or outside our area of inquiry (*e.g.*, the spotted owl's range in British Columbia).

The final two maps depict the locations of the modeling regions and DSAs. The map called *Modeling Regions* breaks the range of the spotted owl up into 11 different regions. This map was used to identify which region individual spotted owls occupied, because each modeling region had different resource requirements and home range sizes. Similarly, a map called D*emographic Study Areas* indicates the locations of 14 different DSAs.

Survival Rates

The survival event is stratified by stage class, resource class, and exposure to barred owls. To begin with, 9 survival rates (estimated apparent survival) were derived from Table 12 in Forsman *et al.* (2011). Because true adult survival is unknown we made the assumption that apparent adult survival is equal to, or a reliable surrogate for, true adult survival. These rates corresponded to the three oldest stage classes x 3 resource classes. Forsman *et al.* (2011) provided stage class-specific survival estimates for each of 11 DSAs. For each study area and stage class, mean apparent survival values for males and females were provided. We computed the mean of each pair and identified the smallest and largest of these mean values. For any given stage class, the smallest mean value was assigned to individuals in the low resource class. Likewise, the largest stage-specific mean value was assigned to individuals in the high resource class. The stage-specific survival rates for individuals in the medium resource class were set equal to the mean taken over all of the survival estimates present in Table 12 of Forsman *et. al* (2011) for that stage class. Through this process survival rates were obtained for stage 1-3 spotted owls in all three resource classes.

Stage class 0 survival estimates were taken from Franklin *et al.* (1999: 27-28). This is the final report titled "Range-wide status and trends in northern spotted owl populations" that was written after a major workshop held in Corvallis, Oregon, in 1999 to estimate demographic rates of the subspecies. The estimates of juvenile survival rates for three study areas from banding studies were adjusted to compensate for emigration rates, based on radio telemetry studies conducted by Eric Forsman (unpublished data). Mean, minimum and maximum juvenile survival rates were taken from this reference and used in the model. The mean value for Stage class zero was set to the midpoint between the minimum and maximum value.

Finally, survival rates were varied based on the presence or absence of barred owls, and the magnitude of their effect was based on the best meta-analysis model for survival with an additive barred owl covariate across all DSAs from Forsman *et al.* (2011). These values were stratified by both stage class and resource class.

Evaluation of Model Calibration

The HexSim model simulated a females-only population of spotted owls throughout their range. The principal metric used to evaluate the model was the simulated population size. The numbers of female spotted owls were tracked range-wide, per modeling region, and also per DSA. The model's performance was assessed by comparing all three measures of simulated population size to field data. We compared simulation year 50 HexSim estimates to field data for 8 DSAs. For this comparison, we used the HexSim simulations during which barred owl impacts were inserted during year (or time-step) 40. After barred owl impacts were incorporated at time-step 40, they remained constant for the remaining 210 time-steps. For these simulations we did not attempt to back-cast barred owl "invasion" dynamics. Our "scenario", therefore, predisposed barred owl impacts to occur all at once, not incremented. We determined by inspection that simulation year 50 most closely represented the present day.

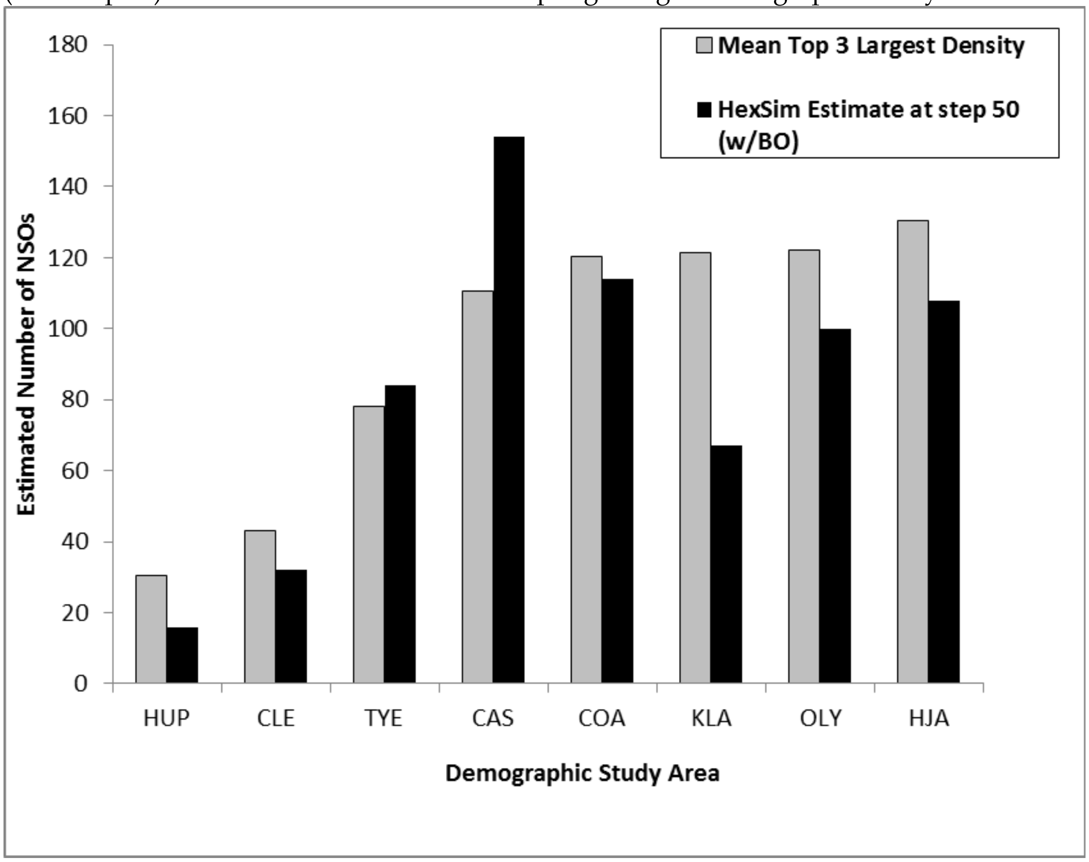
HexSim simulations are stochastic, and to quantify population size, the mean was taken from 5 replicate simulations. Each simulation was 250 time-steps (years) in duration. This does not suggest that spotted owl population sizes were forecasted 250 years into the future. Doing so would at minimum require performing the simulations with a series of maps illustrating habitat changes through time. In contrast, these initial simulations were performed with static data from year 0 to year 40, then (if changes were introduced) changes in barred owl or RHS were introduced and remained static until year 250. The length of the simulations (250 years) simply allowed a steady-state population size and trend to be estimated.

Most, but not all DSAs had data that could be used to approximate density of female spotted owls. Additionally, not all DSAs functioned as "density study areas", and they did not always sample spotted owls identically, nor present data consistently (among DSAs at least). Nonetheless, most DSA annual reports contained tables of historic data which revealed trends. For calibration purposes data from the following DSAs were used: Cle-Elum, Olympic, Oregon Coast, HJ Andrews, Tyee, Klamath, Cascades, and Hoopa. Several calibration iterations were performed by varying resource requirements one modeling region at a time.

Discrepancies in the fit between simulated and observed population size were addressed by varying the resource targets (described above). The resource targets were specified on a modeling-region basis, and they indicated how much resource an individual spotted owl living in a specific region would attempt to acquire. The resource targets were a proxy for resource availability, which varied from region to region and was not fully captured in the RHS maps. As the resource targets increased, individual spotted owl's needs for resources increased. An inability to acquire sufficient resources could cause spotted owls to drop into the lower resource acquisition classes, which would then lower their survival rates.

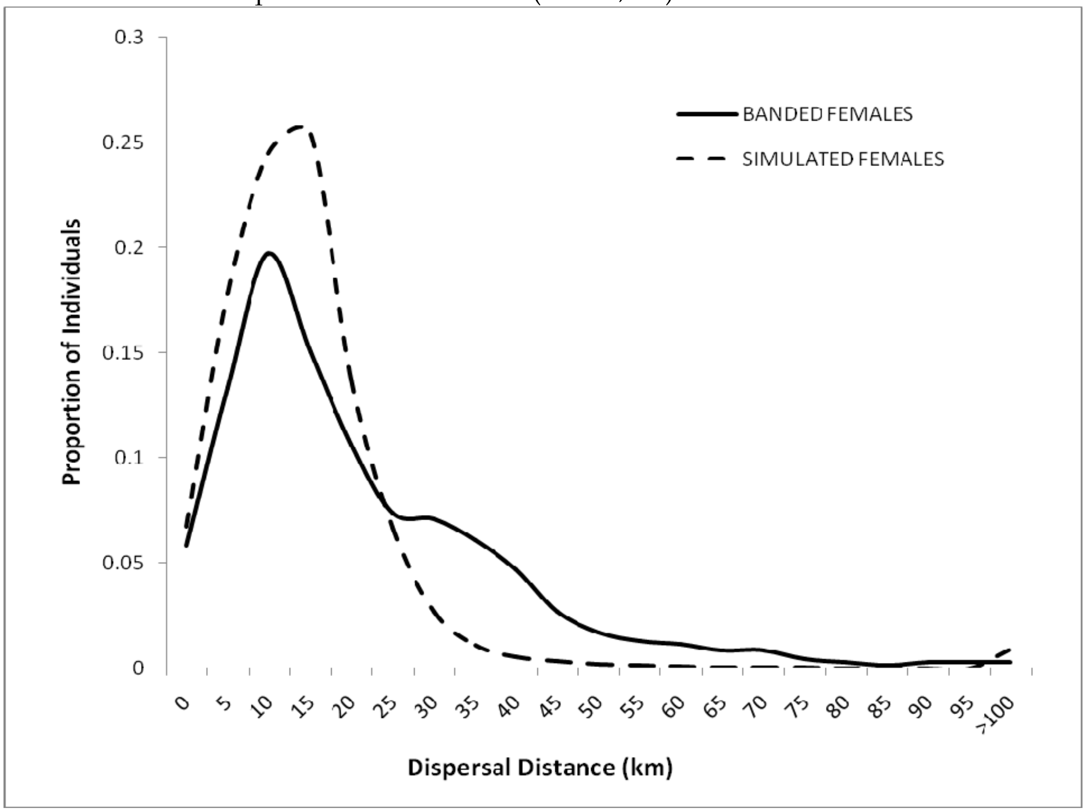
The Baseline HexSim simulations, in which barred owl impacts were introduced at time-step 40, then held static, produced an estimated total female spotted owl population size within the eight DSAs of 675. From field sampling, the total estimated female spotted owls in those DSAs based on the largest number recorded between 1996 and 2006 was 778. The average of the three highest density years from the annual reports (using only data from 1996-2006) for total estimated spotted owl females was 756. The mean of the highest three years (1996-2006) was selected instead of the highest single year in order to reduce the chance that a single year was uncharacteristic of the DSA (Figure C14). Differences in number of female spotted owls on the eight DSAs between those estimated from field sampling and those estimated from our HexSim runs ranged from 5% to 47%, with a mean absolute percentage difference of 26%. Subsequent changes to HexSim did not eliminate these differences.

Figure C-14. Model calibration: Comparison of simulated spotted owl population size (time step 50) to estimates based on field sampling in eight Demographic Study Areas.



Dispersal is a critical process through which landscape structure impacts spotted owl population size and meta-population structure, and is a primary concern in habitat conservation network design (Murphy and Noon 1992). Of particular importance is natal dispersal; the movements of juvenile spotted owls between their natal site and the site where they eventually establish breeding territories. We evaluated the performance of HexSim relative to natal dispersal by comparing graphs of simulated versus observed natal dispersal displacement distances (Figure C15). HexSim generates reports of annual dispersal events by non-territorial (juvenile and floater) spotted owls. The dispersal behavior of the simulated spotted owls was affected principally by landscape structure, the dispersal stopping criteria, and the amount of autocorrelation (both discussed above). Observed natal dispersal distances were estimated from movements of banded spotted owls (Forsman *et al.* 2002).

Figure C-15. Model calibration: Comparison of natal dispersal distances of banded female spotted owls (N= 328) from Forsman *et al.* (2002) to simulated natal dispersal distances for female spotted owls in HexSim (N=850,000).



Because our HexSim spotted owl scenario consists solely of females, we limited the comparison to banded female spotted owls. The distributions of natal dispersal distances for 328 banded female spotted owls were generally similar to 850,000 natal dispersal events recorded during a 250 time-step (years) HexSim simulation. The majority of both observed and simulated dispersal distances were between one and 25 km, however, about 10 % fewer simulated dispersal distances were greater than 10 km and 20% fewer were greater than 25 km.

Uncertainties and Limitations

An important goal of the spatial population modeling effort is to provide a tool to evaluate and compare the suitability of suites of habitat conservation network scenarios. Each scenario represents a unique ensemble of conditions that could affect future spotted owl population size and trends. The overall amounts of spotted owl habitat, the arrangement of habitat conservation networks, and barred owl influences will vary from scenario to scenario.

Several conclusions about each scenario could be drawn from the HexSim spotted owl simulations. Very specific results, such as estimates of absolute population size, will be the most sensitive to parameter uncertainties. Less specific conclusions, such as the relative differences between scenarios, will be increasingly robust. The HexSim simulations provide, at a minimum, a repeatable methodology for qualitatively ranking the efficacy of the habitat conservation scenarios. This analysis might also extend further, to include a quantification of individual reserve or block carrying capacities, and attendant probabilities of extinction. The conclusions that are drawn from a simulation model must balance concern over uncertainties with the desire to preserve a threatened species.

The HexSim spotted owl simulation model resulted from an attempt to construct the simplest model that could do a credible job of ranking habitat conservation network scenarios. HexSim makes adding realism relatively simple. But more life history detail does not automatically translate into more accurate forecasts. Realism comes at a cost since complex models have larger numbers of parameters, and thus greater data requirements.

There are many details that could be added to the existing HexSim simulation model. Examples include environmental stochasticity, the explicit modeling of spotted owl males (including mate-finding and pairing) and barred owl populations, genetics, disturbance regimes such as fire, etc. Some of these "enhancements" might provide more accurate forecasts of future spotted owl population sizes and probabilities of extinction, and decisions whether to incorporate some of them can be made in the future by model users depending on their specific needs. These enhancements, however, are not necessary in order to reliably rank habitat conservation network scenarios based on their likelihood of facilitating recovery of the spotted owl.

The modeling team considered several enhancements that could be added to the current HexSim spotted owl model. Some enhancements that might be made to the HexSim model are listed below.

Environmental Stochasticity

Incorporation of environmental stochasticity into HexSim scenarios will be necessary when estimates of population size or extinction probability need to be made. However, the addition of environmental stochasticity is unlikely to change the order in which habitat conservation network scenarios rank (*i.e.*, from least to most likely to recover the spotted owl). Developing a modeling process to determine the rank-ordering of scenarios was the modeling team's primary goal, and environmental stochasticity was left out of these simulations in order to limit the computational burden associated with that analysis. Environmental stochasticity should be added to the HexSim model before it is used to estimate population sizes or extinction rates. At that time, the more variable model could be used to test a subset of the rank-ordering results obtained without environmental stochasticity. Recent research into the effects of variability in climate on spotted owl demographic rates (Glenn *et al.* 2010) suggested adding realistic variation in annual temperature and precipitation would provide an important element of environmental stochasticity into HexSim simulations.

Effect of relative habitat suitability on reproductive rates

The HexSim spotted owl model links habitat to survival rates through resource acquisition. Individual spotted owls acquire resources from their simulated home ranges, and home ranges with higher RHS values provide greater resources. But home ranges overlap, and competition between spotted owls will lower resource availability. Resource acquisition, because it links landscape structure and intra-specific competition, is a more realistic driver of survival rates than habitat would be on its own. Resource acquisition could easily influence reproduction in exactly the same way that it influences survival. Unfortunately, the most recent meta-analysis (Forsman *et al.* 2011) was inconclusive regarding the role that habitat played in determining reproductive rates. For this reason, the modeling team elected to not vary spotted owl reproductive rates as a function of resource acquisition.

Effect of barred owls on reproductive rates

The HexSim spotted owl model includes the machinery necessary for barred owl influences to include a lowering of spotted owl reproductive rates. This is done by setting a probability that a spotted owl in the presence of a barred owl will nest. Each year, every affected territorial spotted owl will make an independent nesting decision, based on this probability. However, in the current model, the probability that a spotted owl in the presence of a barred owl will forgo nesting entirely is set to zero.

Modeling team members determined that range-wide empirical estimates were not sufficient to assign region-by-region probabilities for barred owl impacts on spotted owl reproduction. Such impacts could come in several forms. For example, the presence of a barred owl could cause a spotted owl to abandon its territory, to keep the territory but forgo nesting (or calling for a mate), or a barred owl could lower effective spotted owl reproductive rates by interfering with nest-tending or preying on spotted owl offspring.

In order to simulate territory abandonment, it would be necessary to explicitly model barred owl locations across the landscape. But sufficient data on barred owl locations and habitat associations were not available range-wide to permit doing more than setting region-by-region probabilities of barred owl occurrence. Simulating barred owl predation on spotted owl offspring runs the risk of double-counting this impact, since barred owl presence does lower survival rates in the HexSim spotted owl model. As described above, the model is able to simulate a lowering of spotted owl nesting rates (when in the presence of a barred owl). But sufficient data was not available range-wide to do more than speculate on the associated parameter values.

Interaction between habitat and barred owl effect

By incorporating the barred owl into the spotted owl scenario as a dynamic spatially explicit stressor, the influence of habitat on barred owl presence and barred owls effects to spotted owl occupancy (extinction rates), recruitment and survival could be more realistically simulated. While there is new information suggesting that habitat and barred owl effects may interact, the data necessary to develop reliable models of barred owl habitat suitability (and subsequently, distribution) are not available. For this reason, the modeling team elected not to attempt this. Moreover, outcomes of modeling region-specific simulations suggest that the current barred owl parameterization is realistic; low to intermediate barred owl encounter probabilities act to depress spotted owl populations but do not result in extinction.

Sensitivity analyses

When the HexSim spotted owl model is used to make estimates of population size, or probabilities of extinction, it will be necessary to also conduct a sensitivity analysis. The modeling team has conducted some work on a traditional sensitivity analysis. Whereas a traditional sensitivity analysis is focused on making small changes to individual parameter values, it would be instructive to complement this work with an assessment of the consequences of varying elements of the model structure itself. Examples of model design elements that might be varied include the lack of direct effects of resource acquisition on reproductive rates, the number of resource acquisition levels being simulated, and some of the behavioral features associated with dispersal and prospecting.

The most important parameters in any model of the spotted owl are going to be the survival and reproductive rates. The rates used in the HexSim survival and reproduction events have been derived from the most recent compendium of spotted owl field data (Forsman *et al.* 2011). Still, some uncertainty is introduced when these survival data are used to assign rates to spotted owls in three different resource acquisition classes, as that process involves extrapolation. We therefore elected not to use a larger number of resource acquisition classes. Likewise, the impact of barred owls on spotted owl reproduction is not perfectly understood, and certainly varies from region to region (as we represent in the HexSim scenarios).

One element of realism that the modeling team deemed necessary for this analysis was ensuring that the simulated spotted owls' home ranges and resource requirements varied by modeling region. The variation in home range size is supported by much published information (see review in Schilling 2009). The variation in resource requirements was used to account for regional differences in resource availability that were not captured in the MaxEnt resource map. In areas where the resource availability was known to be lower, spotted owls were assigned a higher resource requirement. The resource requirements were used as a fitting parameter that made it possible to adjust regional population sizes independently.

The HexSim spotted owl model described here is simple, but not overly so. It is likely the most realistic spatially-explicit individual-based spotted owl simulation that has been developed to-date. Its design and complexity mirror what is being asked of it. Additional complexity may be added at a future time as needed to meet the goals that accompany other planning exercises.

Testing Modeling Process Applications – Using the HexSim Spotted Owl Scenario model to compare the demographic effectiveness of various habitat conservation network scenarios and other recovery strategies:

For the Revised Recovery Plan, the modeling team's objective was to develop and test a modeling framework (Steps 1-3) that would support a wide variety of recovery actions, including evaluation of habitat conservation network scenarios. To facilitate the implementation of recovery actions contained in the Revised Recovery Plan, the modeling team established a process for developing scenarios and conducted preliminary population simulations to compare a sample of habitat conservation network scenarios in order to test the modeling framework's reliability. The results from these preliminary comparisons were necessary in order to obtain feedback on the overall framework and provided the basis for revisions to the HexSim model. This objective was completed as part of the recovery planning process. The following evaluation consists of the actual comparison of simulated spotted owl population responses among many alternative scenarios representing various recovery strategies and habitat conservation networks.

Development of Scenarios for Evaluation and Comparison in HexSim

An important use of the modeling framework is to simulate spotted owl population performance relative to three primary sources of variation: size (area) and distribution of habitat conservation networks; trends in habitat conditions inside and outside of the habitat conservation networks; and trends in the influence of barred owls. Considering the many possible variations in network designs, land ownership limitations, future habitat trends, and barred owl effects that could be evaluated, it is clear the number of scenarios needed to evaluate all of the possibilities could increase rapidly and become unfeasible. Instead, the modeling team developed an iterative process for evaluation of scenarios; establishing broad sideboards in earlier comparisons, then testing the models' sensitivity to habitat conditions and barred owl effects. The HexSim spotted owl model can also be used to evaluate the response of spotted owl populations to future climate scenarios.

To test the modeling framework's ability to evaluate the influence of habitat conservation network size (area) and spatial distribution on spotted owl population performance, we analyzed a subset of 10 habitat conservation network scenarios from Step 2 representing a wide range of sizes (proportions of "habitat value"), as well as existing habitat conservation networks (Table C28).

Table C-28. Initial set of habitat conservation networks evaluated in population modeling Rounds 1-3.

Network **scenario**	**Code**
Northwest Forest Plan Reserve Network	**NWFP**
Managed Owl Conservation Areas	**MOCA**
1992 Critical Habitat	**1992CH**
2008 Critical Habitat	**2008CH**
30% Zonation (All Lands Available)	**Z30all**
50% Zonation (All Lands Available)	**Z50all**
70% Zonation (All Lands Available)	**Z70all**
30% Zonation (Public Lands Only)	**Z30pub**
50% Zonation (Public Lands Only)	**Z50pub**
70% Zonation (Public Lands Only)	**Z70pub**

Maps depicting each of the network scenarios listed above are available at: http://www.fws.gov/oregonfwo/Species/Data/NorthernSpottedOwl/Recovery/Library/Default.aspx#Files
Once there, click on "maps" and "AppendixCMaps.pdf" The layers can be turned on and off using the "layers" button in the upper left-hand corner.

The habitat conservation networks listed in Table C28 form the basis for a series of comparisons in the population modeling environment (called Rounds) wherein different environmental conditions such as barred owl effects and habitat conditions are manipulated both spatially and temporally (scenarios). Each habitat conservation network that is subjected to different conditions is termed a habitat conservation network scenario. Rounds simply articulate the specific modifications that are made. The following paragraphs provide descriptions of the scenarios developed by the modeling team, and the results of HexSim runs for the scenarios in Rounds 1-3.

Interpreting HexSim results:

Each HexSim simulation run provides estimates of population size at any chosen time period as well as population trend over any range of time steps. Estimates are reported at both range-wide and regional scales. It is important to recognize that the results are intended to allow comparison of *relative population performance* among alternative habitat conservation network scenarios, not predictions of actual population size or trend in the future.

When a HexSim simulation starts, the number of individuals, age class distribution, spatial arrangement of territories, and other population attributes will have values that reflect the model's initial conditions. It takes many years for these artifacts to subside, and thus for the population's stable-state dynamics to become evident. Simulations were started with 10,000 female spotted owls, thus this initial period of transitory dynamics involved a period of rapid (apparent) population decline for the first 25 or 30 time-steps; typically subsiding by approximately time step 50. It is important not to confuse this decline with an observed or predicted loss in spotted owl numbers that has resulted from changing environmental conditions. We could have chosen to begin simulations with many fewer spotted owls than are known to currently exist in the landscape (say 250), and waited many time-steps for them to increase and reach some sort of equilibrium with their simulated landscape. That would have resulted in a rapid (apparent) population *increase*, but again would simply be the transitory dynamics involved with the starting population conditions. The point is that the first 25-30 time steps are not meant to be interpreted, but can be thought of as a "burn-in" period for the simulation whereby the simulated spotted owls equilibrate with the simulated environment.

Round 1: Baseline (2006) conditions

This was the simple "Baseline" scenario that was used to evaluate parameterization of the HexSim spotted owl scenario. This scenario assumes no change in habitat through time (2006 RHS map); therefore the 10 habitat conservation networks listed above are not compared (because nothing different happens inside and outside of habitat blocks in this scenario). Also, barred owl effects remain constant over time (either at zero or constant at their currently-estimated impacts, beginning at time step 40).

Figures C16 through C18 highlight differences in the relative influence of barred owls among modeling regions. Rangewide, barred owls act to depress spotted owl populations to roughly 50 percent of potential population size without barred owls (Figure C16). However, spotted owl populations in modeling regions with high barred owl encounter rates such as the Oregon Coast Ranges (P_{BO} = 0.710; figure C17) decline rapidly in comparison to modeling regions with low to intermediate barred owl encounter rates such as the Western Klamath (P_{BO} = 0.315; figure C18).

Figure C-16. Results of HexSim Round 1 model runs with five replicates each for "Without STVA" (barred owl) impacts and "With STVA" impacts for the spotted owl's entire geographic range in the U.S. The apparent within-year variation that appears in the figure is a function of an "even-odd" year effect on reproduction that was included in this version of the HexSim model.

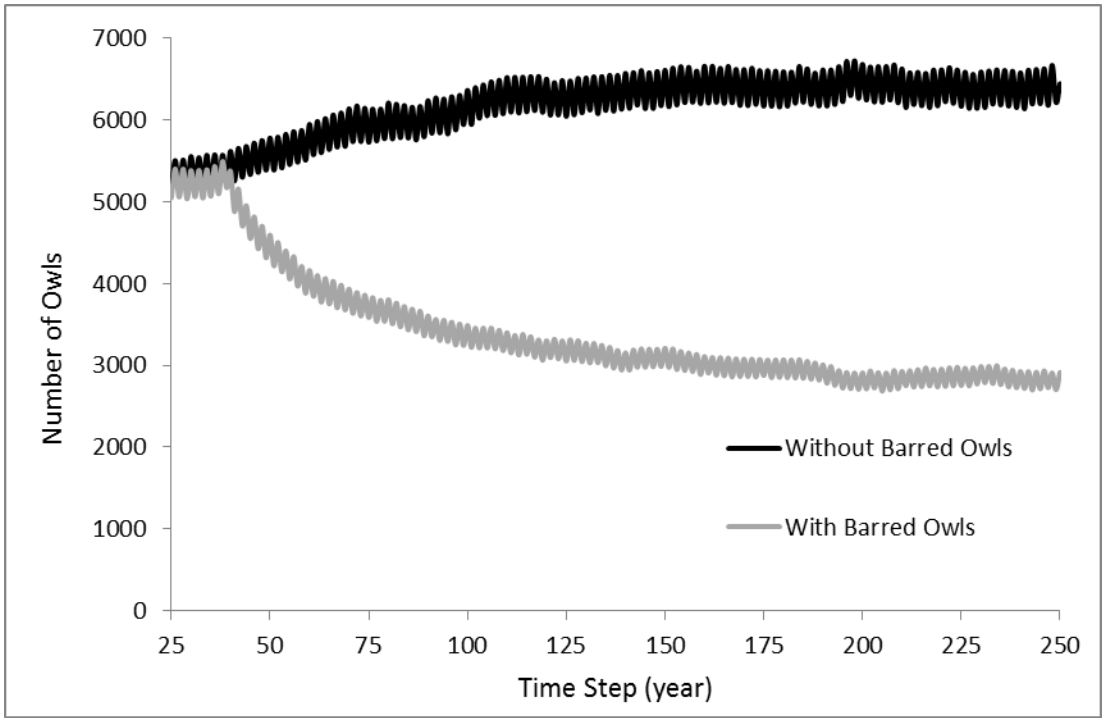


Figure C-17. Simulated Round 1 spotted owl population sizes in the Oregon Coast Ranges modeling region showing 1) current barred owl influence and 2) barred owl influence removed.

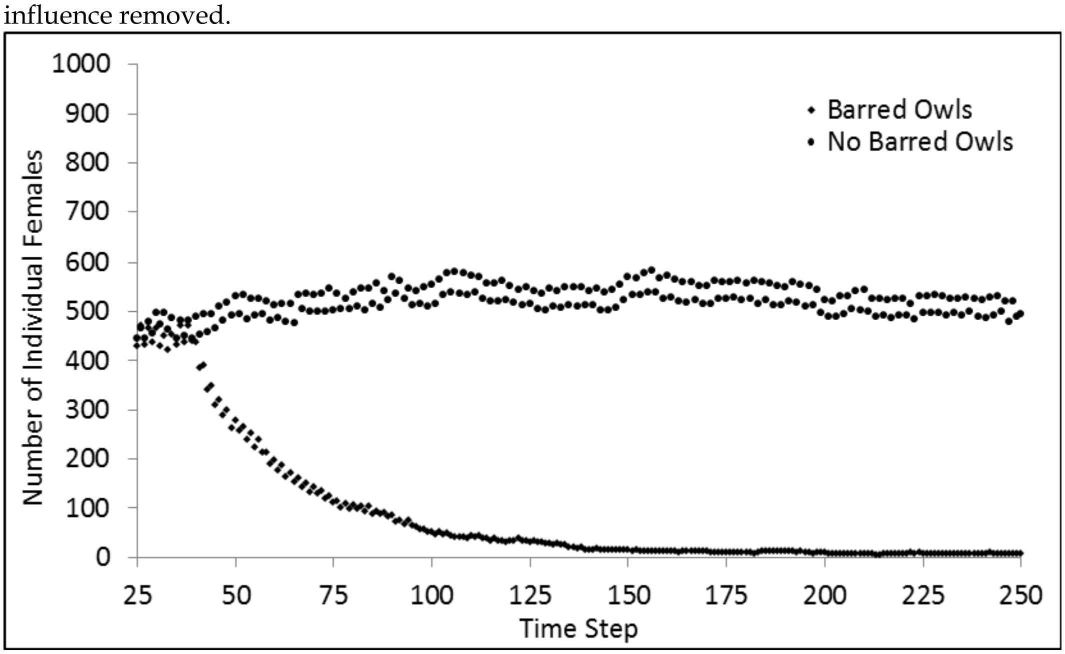

Figure C-18. Simulated Round 1 spotted owl population sizes in the Western Klamath modeling region showing 1) current barred owl influence, and 2) barred owl influence removed.

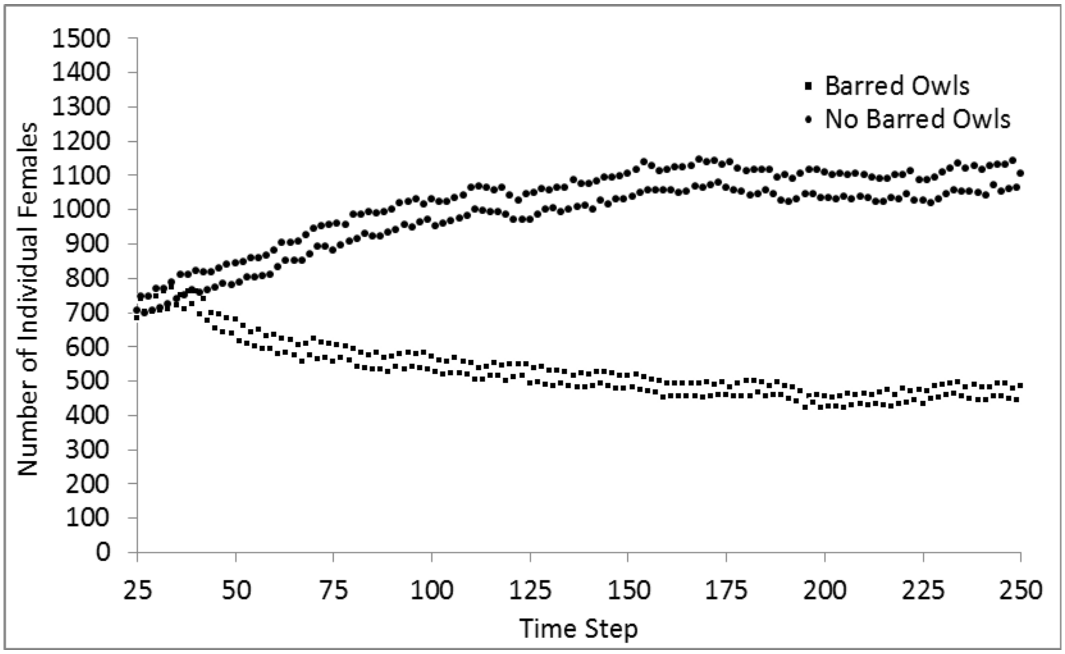

Round 2: Simulating a high degree of reliance on habitat conservation networks

Because the primary objective in this evaluation is to compare estimated spotted owl population performance across a range of habitat conservation network, the goal of Round 2 was to "isolate" the habitat conservation networks by devaluing non-network habitat suitability and holding habitat in networks at its 2006 estimated level throughout the simulation. In this scenario, we reduced relative habitat suitability (RHS) *outside* of habitat conservation networks to 34 (RHS=0.34); *just below* that needed for territory establishment; RHS within networks remained unchanged. The influence of barred owls was held to the currently-estimated encounter rates calculated from Forsman *et al.* (2011); the barred owl influence was slotted in at year 40. We repeated Round 2 with *No barred owl effect*, to evaluate the relative contribution of habitat and barred owl effects on simulated spotted owl population performance. The results of the Round 2 simulations allow for an evaluation of the relative influence of habitat conservation network size and distribution (relying primarily on public versus both public and private lands) and barred owls on spotted owl population performance – when the habitat conservation network provides nearly all nesting and roosting habitat.

Round 3: Simulating RA10 - retention of high-value habitat outside of habitat blocks

The goal of Round 3 was to evaluate the relative contribution of habitat conditions ***outside*** of habitat conservation networks to spotted owl populations; Scenarios R3S1 through R3S10 are intended to emulate the management approach of maintaining occupied spotted owl territories outside of network areas . RHS within habitat conservation networks was held constant, and areas of high RHS (>50) *outside* of networks (on public lands) were retained through time. Areas of RHS between 35 and 49 (outside of networks) were decremented to RHS 34. Scenarios R3S11 through R3S20 were similar but apply to *all* non-network lands (public and private). We repeated Round 3 with *No barred owl effect*, to evaluate the relative contribution of habitat and barred owl effects on simulated spotted owl population performance.

Figures C19 and C20 provide examples of different metrics that can be used to compare estimated spotted owl population outcomes among habitat conservation network scenarios, in this case Rounds 2 and 3 described above. Initial results using a wide range of population metrics can provide insights for meeting the recovery criteria established in the Revised Recovery Plan. Comparison of these estimates of spotted owl population performance across the range of scenarios can inform evaluation of habitat conservation networks designed to lead to spotted owl recovery.

Figure C19 provides results for the entire range of the spotted owl, but as described in Round 1 and evidenced in Figure C20, it is important to recognize that population outcomes may differ markedly among modeling regions.

Figure C-19. Comparison of percent population change (rangewide) between year 25 and year 250 under the scenarios in Rounds 2 and 3, with and without barred owl influence. MOCAs and critical habitat were not compared for Round 3.

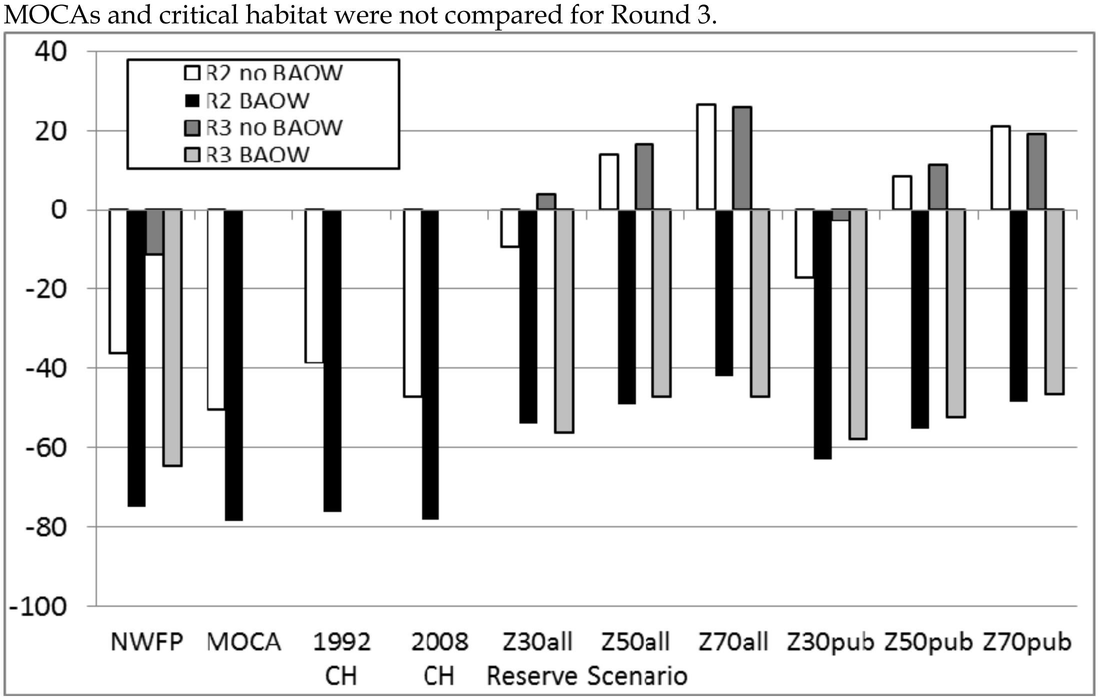

Figure C-20. Percentage of modeling regions whose simulated populations declined by more than 75% between years 25 and 250 (indication of extinction risk) under the scenarios in Rounds 2 and 3, with and without barred owl influence.

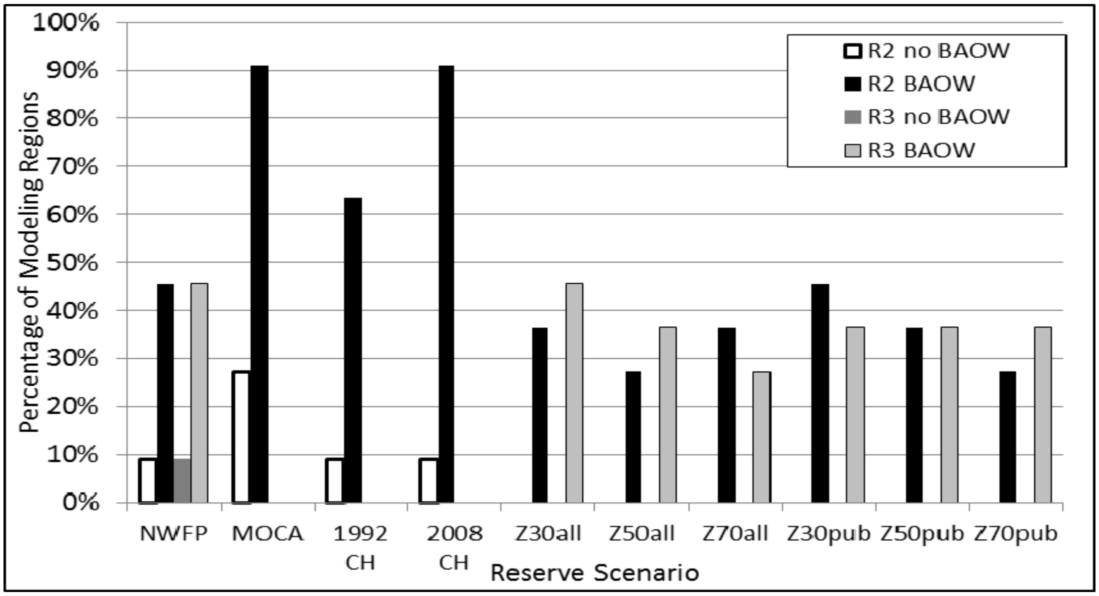

The interaction of network size with other conservation measures is highlighted in Figures C19 and C20. In Round 3 (simulated RA10 - retention of likely occupied, high-value habitat with RHS>50 in non-network areas), the amount of habitat "retained" is inversely proportional to the size of area within habitat conservation networks Subsequently, RA 10's benefit to simulated spotted owl populations is relatively less for larger habitat conservation network scenarios such as Z50 and Z70.

Conclusions:

The analysis presented in this appendix is intended to demonstrate how the three-part modeling framework can be used to evaluate spotted owl population response to a variety of environmental conditions such as habitat variation and barred owls. Although this initial analysis is intended to evaluate the modeling framework, it provides insight into factors influencing spotted owl populations and conservation planning for recovery of the spotted owl.

HexSim population simulations can be completed for the entire range of the spotted owl as well as for subsets of the species' range, such as individual modeling regions or DSAs. This capability enables evaluation of varying environmental conditions and subsequent population effects occurring in different parts of the species' range. For example, the relative effect of barred owls on spotted owl survival and subsequent population size varies among modeling regions, in accordance with different barred owl encounter rates (Table C29). Comparison of the relative differences between simulated spotted owl populations without barred owls and those resulting from different barred owl encounter rates among modeling regions (Figures C17 and C18) suggests there may be barred owl population levels (encounter rates) below which spotted owl populations remain stable (albeit at lower population sizes). Further evaluation of these relationships may inform planning of barred owl management scenarios.

Table C-29. Barred owl encounter probabilities estimated from Forsman *et al.* (2011).

Region	Encounter Probability
North Coast Olympics	0.505
East Cascades North	0.296
West Cascades North	0.320
West Cascades Central	0.320
Oregon Coast	0.710
West Cascades South	0.364
Inner CA Coast Range	0.213
East Cascades South	0.180
Klamath East	0.245
Klamath West	0.315
Redwood Coast	0.205

As shown in Figure C1, the modeling framework contains feedback loops that facilitate an iterative process, with each iteration informed by the results of previous scenarios and simulated population outcomes. This process enables an adaptive approach to developing and testing conservation measures. As new information from monitoring or other research becomes available, its influence on spotted owl conservation can be incorporated into subsequent evaluations in a consistent manner.

In sum, our goal was to develop a modeling framework that can be applied by interested parties to make better informed decisions concerning spotted owl management and recovery. The analyses described in this appendix represent a small subset of possible scenarios and are presented to test the framework and to give potential users of this approach some preliminary exposure to the models' potential utility. Future conservation planning for spotted owls will require development and evaluation of additional scenarios that are relevant to the management questions of particular interest to various stakeholders. These future planning efforts will likely address temporal factors such as changing barred owl populations, climate change, and future habitat change. They might also apply to private land managers who are evaluating different options within a Habitat Conservation Planning scenario, or Federal land managers who are considering recommendations for amending long-term forest management plans. Whatever the use to which this framework is applied, our goal was to provide managers with tools that will ultimately result in better informed decisions for spotted owl conservation.

Appendix F. Scientific Names for Common Names Used in the Text

Following is a list of scientific names for common names of plants and animals used in the text.

Trees

White fir	*Abies concolor*
Grand fir	*Abies grandis*
Shasta red fir	*Abies magnifica shastensis*
Western larch	*Larix occidentalis*
Tanoak	*Lithocarpus densiflorus*
Pinyon pine	*Pinus edulis*
Ponderosa pine	*Pinus ponderosa*
Sugar pine	*Pinus lambertiana*
Bishop pine	*Pinus muricata*
Lodgepole pine	*Pinus contorta*
Douglas-fir	*Pseudotsuga menziesii*
Coast redwood	*Sequoia sempervirens*
Western redcedar	*Thuja plicata*
Western hemlock	*Tsuga heterophylla*
Mountain hemlock	*Tsuga mertensiana*

Mammals

Tree voles	*Arborimus longicaudus, A. pomo*
Red-backed voles	*Clethrionomys* spp.
Northern flying squirrel	*Glaucomys sabrinus*
Snowshoe hare	*Lepus americanus*
Dusky-footed wood rat	*Neotoma fuscipes*
Bushy-tailed wood rat	*Neotoma cinerea*
Gophers	*Thomomys* spp.

Birds

Northern goshawk	*Accipiter gentilis*
Red-tailed hawk	*Buteo jamaicensis*
Great horned owl	*Bubo virginianus*
Eastern screech-owl	*Otus asio*
Northern spotted owl	*Strix occidentalis caurina*
California spotted owl	*Strix occidentalis occidentalis*
Mexican spotted owl	*Strix occidentalis lucida*
Barred owl	*Strix varia*

Other species

Bark beetle	*Dendroctonus* spp.
Mountain pine beetle	*Dendroctonus ponderosae*

Spruce beetle	*Dendroctonus rufipennis*
Western spruce budworm	*Choristoneura occidentalis*
West Nile virus	*Flavivirus*
Avian influenza	*Orthomyxoviridae*
Swiss needle cast	*Phaeocryptopus gaeumannii*
Sudden oak death	*Phytopthora ramorum*
Avian malaria	*Plasmodium* spp.
Truffles	*Tuber* spp.

Appendix G. Glossary of Terms

Many of these terms have a long history and various meanings in regard to spotted owl biology and management. This glossary defines the context in which they are used in this document.

Activity Center: Spotted owls have been characterized as central-place foragers, where individuals forage over a wide area and subsequently return to a nest or roost location that is often centrally-located within the home range (Rosenberg and McKelvey 1999). Activity centers are location or point within the core use area that represent this central location. Nest sites are typically used to identify activity centers, or in cases where nests have not been identified, breeding season roost sites or areas of concentrated nighttime detections may be used to identify activity centers.

Adaptive Management: Adaptive management is a systematic approach for improving resource management by learning from the results of explicit management policies and practices and applying that learning to future management decisions.

Conserve: To preserve to use, or manage wisely.

Core Use Area: An area of concentrated use within a home range that receives disproportionally high use (Bingham and Noon 1993), and commonly includes nest sites, roost sites, and foraging areas close to the activity center. Core use areas vary geographically, and in relation to habitat conditions. This is a biological definition of core use area and is not the same as a 70-acre core as defined by the Oregon Forest Practices Act nor is it equivalent to the 100-acre LSRs referred to as northern spotted owl cores on Federal lands.

Dispersal Habitat: Juvenile spotted owls often must disperse through a range of forest types prior to finding NRF habitat on which to establish a territory. These forest types include nesting, roosting, and foraging habitat in addition to forest that meets the definition of dispersal habitat. The Interagency Scientific Committee (ISC) defined dispersal habitat as forest stands with average tree diameters ≥11 inches and conifer overstory trees with closed canopies (>40 percent canopy closure in moist forests and >30 in dry forests) and with open space beneath the canopy to allow spotted owls to fly can provide the minimum conditions needed for successful dispersal (Thomas *et al.* 1990:310). We acknowledge that this definition primarily applies to moist forests in Oregon and Washington and may not capture the full range of dispersal habitat conditions in Northern California or drier forests across the range of the spotted owl.

Early-seral Forest: Stage of forest development that includes seedling, sapling, and pole-sized trees.

Foraging Habitat: Foraging habitat is defined as lands that provide foraging opportunities for spotted owls, but without the structure to support nesting and roosting (USFWS 1992b). Spotted owls often forage in forest conditions that meet the definition of nesting/roosting habitat, but also use a broader range of forest types for foraging. This definition identifies habitat that functions as foraging habitat, but does not meet requirements for nesting or roosting.

Habitat-capable Area: Forests below the elevation limits of occupancy by territorial spotted owls that are capable of growing and sustaining structural (Davis and Lint 2005) and ecological conditions of spotted owl habitat.

High-Quality Habitat: Older, multi-layered structurally complex forests that are characterized as having large diameter trees, high amounts of canopy cover, and decadence components such as broken-topped live trees, mistletoe, cavities, large snags, and fallen trees. This is a subset of spotted owl habitat and specific characteristics may vary due to climatic gradients and abiotic factors across the range.

High-Value Habitat: Habitat that is important for maintaining spotted owls on landscapes. Includes areas meeting definition of high-quality habitat, but also areas with current and historic use by spotted owls that may not meet the definition of high-quality habitat.

Historical Site: Sites that contained spotted owls in the past. These may be currently unoccupied or sites where spotted owls were detected in the past, but not surveyed more recently.

Home Range: The area in which a spotted owl conducts its activities during a defined period of time (USFWS 1992b) that provides important habitat elements for nesting, roosting, and foraging. Home range sizes vary generally increase from south to north and vary in relation to habitat conditions and prey availability and composition.

Known Spotted Owl Site: An occupied spotted owl site or a spotted owl site where spotted owls were documented to be present in the past.

Late-seral Forest: Stage in forest development that includes mature and old-growth forest (USDA *et al.* 1993). The appearance and structure of these forests will vary across the range of the spotted owl, particularly in the dry forest provinces.

Long-term: For the purposes of planning and managing the spotted owl and its forest habitat, a time frame estimated to be greater than 30 years at a minimum and usually referring to time periods ranging from 50 years to several centuries. Use of this term can be context dependent and relative, for example, when referring to gradual demographic changes in a spotted owl population or the development of late-successional habitat conditions.

Manage: To make and act upon decisions about which actions to take, if any, regarding a particular issue, area of land, etc. This may include a decision to take no action.

Mature Forest: Forests where the annual net rate of growth has peaked. Stand age, diameter of dominant trees, and stand structure at maturity vary by forest types and local site conditions. Mature stands generally contain trees with a smaller average diameter, less age-class variation and less structural complexity than old growth stands of the same forest type (USDA *et al.* 1993). The appearance and structure of these forests will vary across the range of the spotted owl, particularly in the dry forest provinces. Mature stages of some forests provide NRF habitat for spotted owls. However, mature forests are not always spotted owl habitat, and spotted owl habitat is not always mature forest.

Mid-seral Forest: Intermediate stages of tree growth between early-seral and late-seral. The appearance and structure of these forests will vary across the range of the spotted owl, particularly in the dry forest provinces.

Nesting and Roosting Habitat: Habitat that provides nesting and roosting opportunities for spotted owls. Important stand elements may include high canopy closure, a multi-layered, multi-species canopy with larger overstory trees and a presence of broken-topped trees or other nesting platforms (*e.g.,* mistletoe clumps (USFWS 1992b). The appearance and structure of these forests will vary across the range of the spotted owl, particularly in the dry forest provinces.

Occupied Site: Any location where territorial spotted owls are known to be present.

Old-growth Forest: Old-growth forests are forests that have accumulated specific characteristics related to tree size, canopy structure, snags and woody debris and plant associations. Ecological characteristics of old-growth forests emerge through the processes of succession. Certain features - presence of large, old trees, multilayered canopies, forest gaps, snags, woody debris, and a particular set of species that occur primarily in old-growth forests - do not appear simultaneously, nor at a fixed time in stand development. Old-growth forests support assemblages of plants and animals, environmental conditions, and ecological processes that are not found in younger forests (younger than 150-250 years) or in small patches of large, old trees. Specific attributes of old-growth forests develop through forest succession until the collective properties of an older forest are evident.

Protect: Guard or shield from loss.

Provincial: This is a qualifying term used with home range and core use area to reflect the fact that both vary in size according to latitude, amount of available habitat, prey availability, and forest structure and composition. Typically, home range and core use area sizes increase from south to north, and decrease as amount of high-quality habitat available to spotted owls increases.

Restoration: The recovery of vegetative structure, species composition, and self-regulating ecological processes at multiple spatial and temporal scales with the intent to provide for long-term ecological sustainability and ecological integrity.

Resilience: Resilience refers to the capacity of an ecosystem to not only accommodate gradual changes but to return toward a prior condition after disturbances including fire, extreme weather events, and climate change.

Retain: To keep.

Short-term: For the purposes of planning and managing the spotted owl and its forest habitat, a time frame estimated to be less than a few decades and usually between one to ten years. Use of this term can be context dependent and relative, for example, when referring to immediate changes in a forest stand due to a wildfire or vegetation treatment, or the behavioral response of individual spotted owls to habitat alteration or the removal of barred owls from a spotted owl territory.

Snag: Any standing dead or partially dead tree. A hard snag is composed primarily of sound (merchantable) wood while a soft snag is composed of wood in advanced stages of decay and deterioration, and is not generally merchantable.

Spotted Owl Site: Any location where territorial spotted owls are known to be present, were historically present, or may be present in unsurveyed habitat. Spotted owl sites can be identified through surveys where spotted owls were detected (USFWS 2010). In cases where survey data are unavailable, spotted owl sites can be identified by 1) conducting surveys, or 2) using a modeling approach that uses habitat and landscape characteristics to identify areas with a high probability of being occupied by spotted owls.

Uncharacteristic Wildfire – Fires that threaten the loss of key ecological attributes and functions, due primarily to the diminishment of natural landscape resilience mechanisms.

Unoccupied Site: Site where spotted owls were detected in the past, but more recent surveys have not detected owls. Surveys are required to establish unoccupied status, and criteria for determining unoccupied status are presented in the 2010 (2011) Northern Spotted Owl Survey Protocol (USFWS 2011).

Viable Population - a self-sustaining population with a high probability of survival despite the foreseeable effects of demographic, environmental and genetic stochasticity and of natural catastrophes.

Appendix H. Contributors To The 2008 Recovery Plan

A Recovery Plan for the Northern Spotted Owl (2008 Recovery Plan) was prepared with the assistance of a Recovery Team representing Federal agencies, State governments, and other affected and interested parties, as well as the assistance of a contractor (Sustainable Ecosystems Institute or SEI) and published May 14, 2008. The Recovery Team members served as independent advisors to the Service for the development of the 2007 Draft Recovery Plan. The 2008 Recovery Plan did not necessarily represent the view or official position of any individual or organization—other than that of the Service—involved in its development. Additional valuable support was provided by three work groups of Federal and State agency scientists and academic researchers.

The Service gratefully acknowledges the effort and commitment of the many individuals involved in the conservation and recovery of the northern spotted owl who participated in the preparation of the 2008 Recovery Plan. Without their individual expertise and support, this Revised Recovery Plan would not have been possible as it is the culmination of many years of labor.

The Service began preparing a recovery plan for the spotted owl in April 2006. To advise the Service, a Recovery Team was initially appointed which was supported by an Interagency Support Team (IST) and led by a Recovery Plan Project Manager. During the development of the 2007 Draft Recovery Plan, the Recovery Team convened several panels of experts to advise them and provide information on scientific and land management issues (noted as Scientist and Implementer Panelists below). The Service is indebted to all of the individuals for the guidance provided during the preparation of the 2007 Draft Plan. Their names, affiliations, and roles are listed below.

Recovery Team Members for 2007 Draft Recovery Plan

Tim Cullinan, National Audubon Society, Washington State Office
Dominick DellaSala, National Center for Conservation Science and Policy
Lowell Diller, Green Diamond Resource Company
Scott Gremel, National Park Service
Mike Haske, Bureau of Land Management
Cal Joyner, U.S. Forest Service
John Mankowski, Washington Office of the Governor/Lenny Young, Washington Department of Natural Resources
Ed Murphy, Sierra Pacific Industries
Jim Paul, Oregon Department of Forestry (April 2006 to November 2006)/ Mike Cafferata, Oregon Department of Forestry (November 2006 to November 2007)
John Siperek, California Department of Fish and Game
David Wooten, Bureau of Indian Affairs
David Wesley, Fish and Wildlife Service, Team Leader

Alternate Recovery Team Members for 2007 Draft Recovery Plan

Sarah Madsen, U.S. Forest Service
Rosemary Mannix, Oregon Department of Forestry

Scientist Panelists for 2007 Draft Recovery Plan

Robert Anthony, U.S. Geological Survey
Bill Baker, University of Wyoming
Joe Buchanan, Washington Department of Fish and Wildlife
Louisa Evers, Bureau of Land Management/U.S. Forest Service
Alan Franklin, U.S.D.A. Animal and Plant Health Inspection Service
Eric Forsman, Pacific Northwest Research Station
Rocky Gutiérrez, University of Minnesota
Tom Hamer, Hamer Environmental
Richy Harrod, U.S. Forest Service
Dale Herter, Raedeke Associates
Larry Irwin, National Council for Air and Stream Improvement
Bill Laudenslayer, U.S. Forest Service
John Lehmkuhl, Pacific Northwest Research Station
Trent McDonald, Western Ecosystems Technology
Ron Neilson, US Forest Service
Robert Pearson, Private Consultant
John Pierce, Washington Department of Fish and Wildlife
Marty Raphael, U.S. Forest Service
Peter Singleton, Pacific Northwest Research Station
Carl Skinner, U.S. Forest Service
Jim Thrailkill, U.S. Fish and Wildlife Service
Brian Woodbridge, U.S. Fish and Wildlife Service

Implementer Panelists for 2007 Draft Recovery Plan

Klaus Barber, U.S. Forest Service
Richard Bigley, Washington Department of Natural Resources
William Gaines, U.S. Forest Service
Eric Greenquist, U.S. Bureau of Land Management
Jim Harper, U.S. Bureau of Land Management
Scott Horton, Washington Department of Natural Resources
Margaret Kain, U.S. Forest Service
Patricia Krueger, U.S. Forest Service
Trent McDonald, Western Ecosystems Technology (WEST)
Steve Mealey, U.S. Forest Service, retired; Private Consultant
Tony Melchiors, Weyerhaeuser Company
Mark Nuetzmann, Yakama Nation
Ken Risenhoover, Port Blakely Tree Farms
Duane Shintaku, California Department of Forestry and Fire Protection

Peer Reviewers of the Background Section for 2007 Draft Recovery Plan

Robert Anthony, U.S. Geological Survey
Eric Forsman, Pacific Northwest Research Station

Alan Franklin, U.S.D.A. Animal and Plant Health Inspection Service
Larry Irwin, National Council for Air and Stream Improvement

Interagency Support Team Leader and Recovery Plan Project Manager for 2007 Draft Plan and 2008 Final Plan

Paul Phifer, U.S. Fish and Wildlife Service

Interagency Support Team Members for 2007 Draft Plan and 2008 Recovery Plan

Kath Collier, Bureau of Land Management
Joe Lint, Bureau of Land Management
Kent Livezey, U.S. Fish and Wildlife Service
Elaine Rybak, U.S. Forest Service
Brendan White, U.S. Fish and Wildlife Service

Additional Participants in the Interagency Support Team for 2007 Draft Plan and 2008 Recovery Plan

Bruce Marcot, Pacific Northwest Research Station
Steve Morey, U.S. Fish and Wildlife Service
Kristi Young, U.S. Fish and Wildlife Service
Rich Young, U.S. Fish and Wildlife Service
Michele Zwartjes, U.S. Fish and Wildlife Service

Contributors for 2007 Draft Plan and 2008 Recovery Plan

Scott Center, U.S. Fish and Wildlife Service
Ray Davis, U.S. Forest Service
Karl Halupka, U.S. Fish and Wildlife Service
Jim Hines, U.S. Geological Survey
Matt How, U.S. Fish and Wildlife Service
Jim Nichols, U.S. Geological Survey

The 2007 Draft Recovery Plan generated more than 75,800 public comments. To evaluate scientific and management issues highlighted during the comment period, the Service contracted with an independent consultant (SEI) to provide assistance. In addition, the Service appointed three scientific work groups to evaluate comments and provide guidance on the best science concerning the three major areas of concern raised during the comment period: spotted owl habitat, fire, and barred owls. Based on this input, and comments from the public, the Service finalized the 2008 Recovery Plan. We thank all of these individuals; they are listed below.

Contractor (Sustainable Ecosystems Institute) for 2008 Final Plan

Steven Courtney
Kate Engel
Katie Fehring
Lisa Sztukowski

Panel Members for Contractor for 2008 Final Plan

Andrew Bohonak, San Diego State University
Andy Carey, Pacific Northwest Research Station (retired)
Martin Cody, University of California, Los Angeles
Keith Crandall, Bringham Young University
Jerry Franklin, University of Washington
Mark Fuller, U.S. Geological Survey
Rocky Gutiérrez, University of Minnesota
Miles Hemstrom, Pacific Northwest Research Station
Paul Hessburg, Pacific Northwest Research Station
John Lehmkuhl, Pacific Northwest Research Station
Jim Nichols, Patuxent Wildlife Research Center
Ken Pollock, North Carolina State University
Scott Stephens, University of California, Berkeley
Robert Zink, University of Minnesota

Subject: Biological and Conference Opinions for the Issuance of a Section 10(a)(1)(B) Incidental Take Permit to the Fruit Growers Supply Company for its Multi-Species Habitat Conservation Plan (FWS Reference: 81333-2011-F-0018)

This document constitutes the U.S. Fish and Wildlife Service's (Service) biological and conference opinions (BO) regarding the proposed issuance of an incidental take permit (ITP) to Fruit Growers Supply Company (FGS) for the implementation of its Habitat Conservation Plan (HCP) on 152,178 acres of commercial timberland in Siskiyou County, California, and its effects on the federally threatened northern spotted owl (*Strix occidentalis caurina*) and federal candidate West Coast Distinct Population Segment (DPS) of fisher (*Martes pennanti*), hereafter "fisher." Issuance of an incidental take permit is pursuant to section 10(a)(1)(B) and section 7(a)(2) of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq*.; ESA).

Fruit Growers Supply Company is requesting 50-year coverage of incidental take for the northern spotted owl that may arise from timber management operations on its ownership. The proposed FGS HCP will not involve activities that would adversely affect the primary constituent elements of critical habitat for the northern spotted owl because the activities would not take place within critical habitat or directly or indirectly affect the primary constituent elements. This BO will address affects to northern spotted owls occupying critical habitat resulting from activities conducted by FGS on its own lands. Fruit Growers Supply Company did not request coverage for the fisher; however, since this species is a federal candidate and it is the Service's policy to treat candidate species as if they were proposed species, the Service conducted a conference opinion pursuant to section 7(a)(4) of the ESA.

Although take of plant species is not prohibited under the ESA, and therefore cannot be authorized under an ITP, the endangered Yreka phlox (*Phlox hirsuta*) would also be included on the permit in recognition of the conservation benefits provided to the species under the FGS HCP. The Service finds that the proposed action is not likely to adversely affect Yreka phlox because although suitable habitat for this species exists on FGS's ownership, currently there are no known populations on their property. Additionally, Yreka phlox will benefit from the conservation measures described in section 5.3.2 of the HCP, which include survey and monitoring efforts on FGS property, and equipment exclusion zones to avoid direct adverse impacts to the plants. Therefore, Yreka phlox will not be addressed further in this BO.

Fruit Growers Supply Company is also requesting an ITP from the National Marine Fisheries Service (NMFS) for take authorization of one federally listed species, the Southern Oregon/Northern California Coast coho salmon (*Oncorhynchus kisutch*) Evolutionarily Significant Unit (ESU), and two non-listed species, the Klamath Mountains Province steelhead (*Oncorhynchus mykiss*) ESU and the Upper Klamath and Trinity Rivers Chinook salmon (*Oncorhynchus tshawytscha*) ESU should they become listed within the term of the ITP. Assurances provided under the "No Surprises" rule at 50 C.F.R. 17.3, 17.22(b)(5) and 17.32(b)(5) would extend to all Covered Species. The HCP is a requirement of FGS's application to the Service and NMFS for ITPs pursuant to the Federal ESA, as amended.

These Opinions are based primarily on information provided in the Environmental Impact Statement (EIS; USDI FWS and USDC NMFS 2009), and Implementing Agreement (IA) and HCP (FGS 2009), which are incorporated by reference, and the sources cited herein. A complete administrative record of this consultation is on file at the Service's Yreka Fish and Wildlife Office.

Consultation History

In late 2007, the Red Bluff Fish and Wildlife Office (RBFWO) was asked to conduct Intra-Service consultation with the Yreka Fish and Wildlife Office (YFWO) on the FGS HCP in regards to the northern spotted owl once that document and supporting documents (e.g., EIS, IA) were prepared. In February 2008, draft documents were sent to the RBFWO for initial review. On March 11, 2008, Keith Paul of the RBFWO attended a public scoping meeting on the FGS HCP and EIS in Yreka, CA. Over the next year and a half, draft chapters of the HCP, EIS, and IA were sent to the RBFWO for review and comment. Minor comments were made on the draft documents and sent to YFWO and FGS for inclusion into the final draft. A Notice of Availability (NOA) of the HCP and Draft EIS was published in the Federal Register on November 13, 2009. On December 2, 2009, Keith attended a second public meeting in Yreka, CA shortly after the release of the NOA to allow the public to comment on the proposed HCP and Draft EIS. On May 5, 2011, due to staffing changes at the RBFWO, the BO was sent to YFWO for finalization. The conference opinion for fisher was developed by YFWO and incorporated into the BO.

BIOLOGICAL OPINION

1. DESCRIPTION OF THE PROPOSED ACTION

1.1 Introduction

The Service proposes to issue a 50-year ITP under the authority of section 10(a)(1)(B) of the ESA to FGS to cover the incidental take of the northern spotted owl that may result through implementation of the FGS HCP. Although take of plant species is not prohibited under the ESA and therefore cannot be authorized under an ITP, the Yreka phlox would also be a Covered Species in recognition of the conservation benefits provided to the species under the FGS HCP. Separately, FGS is also requesting an ITP from NMFS for coverage of three evolutionarily significant units of anadromous salmonids.

Fruit Growers Supply Company has been managing a portion of its ownership, the Hilt/Siskiyou forest, since the early 1900s. The Hilt/Siskiyou forest lies within the geographic range of the northern spotted owl. The Service regards the harvest of suitable habitat in areas occupied by northern spotted owls as having the potential for take in violation of the ESA. California Board of Forestry (CBF) regulations restrict timber harvest operations in suitable habitat within occupied owl territories in order to prevent the take of northern spotted owls. Surveys[1] of FGS lands and adjoining Federal and private lands have shown that many northern spotted owl activity centers[2] are located on or have a home range[3] that extends onto the FGS ownership.

---

[1] The California Department of Fish and Game (CDFG) Northern Spotted Owl Database contains the most comprehensive compilation of northern spotted owl detections in California, including results of protocol-level surveys of FGS lands and adjacent private and public lands. The database contains records beginning in 1987. For the HCP, owl records are used through 2007.

[2] For the purposes of the HCP, "activity center" is defined as the area of concentrated activity of either a pair of owls or a territorial single (USDI FWS 1992b).

[3] "Home range" is defined as the area to which an animal usually confines its daily activities. The home range of

Consequently, FGS's forest management activities in much of the Hilt/Siskiyou forest are restricted by CBF regulations. FGS indicates that the restrictions, in conjunction with the large number of owl territories that are located on or overlap FGS lands, have substantially reduced FGS's management and operational flexibility since the owl was listed in 1990 and resulted in FGS operating more intensively in other portions of its ownership in order to generate the timber volume necessary to remain economically viable.

Since November 2003, the Service has provided technical assistance to FGS in the development of an HCP covering company lands. In requesting the Service's approval of the HCP, FGS seeks to gain the management and operational flexibility necessary to administer its forest resources in a manner that will ensure the long-term sustainable production of timber (see section 2.1.4.5).

1.2 HCP Area Definitions

The HCP covers FGS's Hilt/Siskiyou ownership located in Siskiyou County, northern California. The ownership consists of three management units defined by FGS: Klamath River, Scott Valley and Grass Lake, covering 65,340, 39,153, and 47,685 acres, respectively, for a total of 152,178 acres. FGS's Klamath River and Scott Valley management units are located west of Interstate 5, adjacent to and intermixed with Klamath National Forest (KNF) lands. FGS's Grass Lake management unit (also adjacent to the KNF) lies east of Interstate 5 and predominantly north of State Highway 97.

It is recognized that FGS may buy, sell, or exchange timberlands in the general area covered by the HCP during the 50-year term of the ITP. To reflect this aspect of FGS's business practices, the HCP is designed to allow some flexibility in the application of the HCP and ITP since the ownership may adjust over time. The HCP and this BO use a number of defined terms to describe the area in which FGS's activities will be covered under the HCP, the area in which impacts of FGS's activities are analyzed, and the extent to which adjustments may occur to the area in which the HCP will be implemented. Those terms and their definitions are set forth as follows:

- "Plan Area" means all privately owned commercial timberlands that, over the term of the HCP, are either included within the Initial Plan Area (defined below) or are eligible for coverage by the HCP as provided in the IA (see "Adjustment Area" below). This represents the entire acreage analyzed in the HCP and the EIS prepared pursuant to the National Environmental Policy Act (NEPA) to support the HCP's provisions, allowing for additions and deletions of lands from the Plan Area over the term of the HCP and ITP. Lands within the Adjustment Area may be added to the HCP over the term of the ITP without amendment, given the proper analysis and approval by the Service and NMFS, and subject to the limitation that no more than 15,218 acres (an area equal to 10 percent of the Initial Plan Area) can be added over the term of the Permit.

- "Initial Plan Area" means FGS's land ownership as of the effective date of the ITP (152,178 acres in three management units as described above).

---

northern spotted owls in the California Klamath and Cascades provinces is considered to be approximately 3,400 acres, the equivalent of a circle with a 1.3 mile radius (the provincial radius) (USDI FWS 1992b).

- “Adjustment Area” means commercial timberlands that were not within the Initial Plan Area, but are eligible for addition to the Plan Area through acquisition, subject to the terms and conditions imposed by the IA.

- “Action Area” is defined as all areas to be affected directly or indirectly by the Federal action and not merely the immediate areas involved in the action (50 CFR 402.02). Action Area in regards to northern spotted owl means all acreage within a 1.3-mile radius around the FGS ownership. This 1.3-mile radius around the FGS ownership has been termed Action Area for the purposes of characterizing environmental baseline conditions and describing the direct and indirect effects of the Covered Activities on the northern spotted owl. The 1.3-mile distance criterion is based on the average home range size of the northern spotted owl within the California Klamath and California Cascades Provinces. The Action Area for fishers consists of FGS ownership with a surrounding 1.6-mile buffer that was based on the radius of an estimated circular home range (i.e., 7.7 $mile^2$) for female fishers in the Klamath Province (see Appendix E of the FGS HCP). The Action Area includes the portion of the fisher population that could be directly or indirectly affected by the HCP.

1.3 Plan Area Adjustments over Time

During the term of the HCP and ITP, FGS may elect to add commercial timberlands to the Plan Area within any of the identified drainages by submitting to the Service and NMFS a description of the lands within the Adjustment Area that it intends to add, along with a summary of relevant biological and physical characteristics in the area proposed for addition. Lands within the “Initial Plan Area” are similar in characteristics and conservation value to lands in adjacent areas that could be brought into the Plan Area via land purchase. Fruit Growers Supply Company estimates that there are approximately 338,900 acres of other privately held commercial timberlands in the drainages that could be added to the Plan Area if acquired by FGS in the future. However, expansion of the Plan Area under this process is limited to10 percent of the Initial Plan Area (15,218 acres). Addition of lands to the Plan Area (i.e., to be covered by the HCP) in excess of the 10 percent limit or outside of the identified Adjustment Area would require an amendment to the HCP and ITP.

Further, through a notification to the Service and NMFS, and subject to their review, lands covered by the HCP and ITP may be disposed of without limitation provided that the lands remain subject to the terms and conditions of the IA and HCP. The extent to which lands may be disposed of without adhering to the terms and conditions of the IA is limited to 10 percent of the Initial Plan Area (15,218 acres), and the remaining Plan Area must provide benefits and effectiveness equal to those intended in the HCP and ITP.

1.4 Plan Implementation

The primary administrator for implementation of this HCP is FGS. FGS will be responsible for the conduct of all conservation, mitigation, monitoring, and reporting activities specified in the

HCP; however, some of the activities may be delegated to and carried out by contractors, partners, or volunteers.

Although significant technical expertise and local knowledge of Covered Species and their habitats are held by the agency staff that advised FGS personnel and consultants that prepared this plan, FGS may seek to consult with outside scientists and other technical experts who can provide technical advice on implementation of the conservation and monitoring programs. In developing the conservation program for northern spotted owls, FGS, in consultation with the Service, consulted with noted authorities on northern spotted owl biology and behavior. These experts provided input on the analysis of impacts to northern spotted owls and development of an evaluation matrix used to establish the relative conservation value of northern spotted owl activity centers (see section 3.2.4). In the event of changed or unforeseen circumstances (described below) that substantially alter habitat for northern spotted owls in the Conservation Support Areas (CSAs) established on the FGS ownership, outside experts may be consulted to provide input on actions needed to ensure that FGS is meeting its mitigation obligations for take of northern spotted owl. However, the Service is responsible for monitoring and enforcing the terms of the HCP and ITP.

1.4.1 Covered Activities

This section describes FGS' activities that are covered under the HCP and associated ITP, which include forest practices and related land management activities on FGS's Hilt/Siskiyou forest (the Plan Area), and those activities necessary to carry out all mitigation and conservation measures identified in the HCP and/or the ITP. Timber management is the primary activity in the Plan Area, occurring on 152,178 acres. Covered Activities include activities associated with timber harvest, road construction and maintenance, silviculture, stand regeneration, harvest of minor forest products, and fire prevention. Collectively, these are referred to as Covered Activities. In addition to the ESA and California Endangered Species Act (CESA), the Covered Activities occurring on FGS's ownership are subject to numerous other State and Federal environmental and public safety laws. All Covered Activities will be implemented in accordance with the HCP and ITP, the California Forest Practice Rules (CFPRs), and other applicable Federal and State regulations.

1.4.1.1 Timber Harvest

Timber harvest includes activities necessary to the logging and transport of timber products [primarily ponderosa pine (*Pinus ponderosa*), sugar pine (*Pinus lambertiana*), Douglas-fir (*Pseudotsuga menziessii*), and white fir (*Abies concolor*)]: felling and bucking of timber, yarding timber, salvage and transport of timber products.

Felling and Bucking of Timber

The cutting of trees (felling) is the first step in any timber harvest operation, and bucking is cutting the felled tree in predetermined log lengths. Felling and bucking are generally done with chain saws by crews working in pairs. On gentle terrain, mechanical felling machines (feller-bunchers) can be used to fell the trees and place them in a pile for moving to the log landing.

Ground-based Yarding

Ground-based yarding usually involves the use of tracked or rubber-tired tractors (skidders) to move logs to the landing. The skidders are usually equipped with mechanical grapple attachments or wind lines to grasp the logs, and they follow constructed "skid trails" on all but the mildest terrain. Skidding is generally done in a downhill direction, and occasionally is used for uphill yarding where it is limited to short distances. If logs will be moved only a short distance, a shovel or a hydraulic boom log loader may be used. A shovel is a tracked excavator that has been fitted with a grapple for grasping logs. The shovel may move a short distance off the truck road to pick up felled logs and pass them back to the truck road using the boom structure. Construction of skid trails is not necessary when using the boom loader. Ground-based yarding is typically conducted on slopes less than 55 percent.

Cable Yarding

Cable yarding generally involves the use of steel cables to skid logs to a truck road or log landing using a yarder that is set up on the truck road or landing. A yarder has a vertical tower that is held in place by a number of guylines. The skidding cables, which are operated using powered drums, are used to haul or skid the logs to the landing. The tower is used to elevate and lift the cables, hence providing lift to logs as they are yarded to the landing. High-lead systems are designed to lift only the lead end of logs so that the logs do not dig into the soil surface as they are yarded. This system is typically used for short yarding distances. Skyline systems involve the use of a skyline cable that runs from the top of the tower to an anchor located at some elevated point beyond the harvest area. Logs are attached to a carriage that rides on the skyline cable, providing increased lift to suspend logs above the ground surface. Logs are generally yarded uphill with cable systems, but occasionally these systems are used for downhill yarding. Cable yarding is typically conducted on slopes greater than 55 percent.

Aerial Yarding

Aerial yarding by helicopter is used where roads cannot be constructed to provide access to a harvest unit for conventional (ground-based or cable) yarding systems. Aerial logging suspends logs from long cables and transports them to the landing with virtually no ground disturbance. In general, it is not necessary for the helicopter to land in the loading area. However, a separate service landing is needed that provides a clean, rocked, debris- and dust-free area to protect the helicopter's engine(s) from damage. This yarding technique is usually reserved for steep (greater than 65 percent) and/or unstable terrain, although lack of a road right-of-way may trigger its use.

Loading and Landing Operations

After logs are yarded to a landing or roadside, there may be additional saw work to remove limbs, buck long pieces into shorter segments, or to remove broken sections. These operations are conducted either with hand labor (chain saws) or a mechanical delimber. Logs are then loaded onto log trucks using a shovel or front-end loader (a wheeled bucket loader equipped with log forks instead of a bucket). Some log trucks have their own loading system (self-loaders).

Salvage of Timber Products

Dead, dying, and downed trees are periodically salvaged. Salvage is primarily related to road maintenance, fire damage, insect damage, or storm damage. Generally the economics and logistics involved in the potential harvest determine the feasibility of salvage operations. Salvage operations are feasible when damaged or weakened trees occur adjacent to ongoing logging operations, or are in heavy enough concentrations over a large enough area to justify sending in a salvage logger. It is typically not feasible to harvest individual occurrences of one or two trees, or trees that have been dead for more than 2 years. Salvage operations typically occur in isolated locations throughout the Plan Area, and consist of harvesting dead and dying conifers as individuals or in small groups.

Transport of Timber Products

Timber products are most commonly transported along roads via truck and trailer. Maintenance activities on these haul roads are described below.

1.4.1.2 Road Construction and Maintenance

Activities for maintenance, improvement, construction, and closure of roads and landings include the following:

- Construction of new roads in connection with timber management, including clearing vegetation from road rights-of-way, removing trees, grubbing (removing stumps and surface organics), grading, and compaction

- Extraction of rock, sand, and gravel from small borrow pits for use in road construction and maintenance

- Drainage facility repair and/or upgrade, and erosion control

- Construction of stream crossing (bridges, culverts, fords, and a variety of temporary crossings)

- Maintenance or reconstruction of surfaced roads, seasonal roads, culverts, bridges, fords, cuts, and fillslopes

- Closure of roads, temporarily (abandoned) or permanently (decommissioned)

- Dust abatement activities, such as treating road surfaces with materials commonly used for dust abatement, including but not limited to lignin, calcium chloride, magnesium chloride, and water

- Construction and maintenance of water holes used for water drafting (a short-duration, small-pump operation that withdraws water from streams or impoundments to fill conventional tank trucks or trailers)

- Water drafting for dust abatement, road construction, and routine maintenance

1.4.1.3 Silviculture

Silviculture is the culture and management of forest trees. FGS's silvicultural practices are designed to maintain and enhance the productivity of its timberlands by promoting prompt regeneration of harvested areas and rapid forest growth. Silvicultural treatments vary by stand age, stand condition, site class, and species composition. Not all treatments are applied to every site.

FGS forest inventory serves as the foundation for long-term planning by identifying stands of generally homogeneous site, stocking, and silvicultural potential. Forest conditions are currently estimated at the landscape level by a Maximum Sustainable Production (MSP) analysis (a sustained yield planning framework is required under the CFPRs [14 CCR 933.11a]). For planning purposes, stands of similar condition are combined and a range of feasible silviculture is modeled for each of these units with yields reported at the mid-point of each decade. Once a given silviculture treatment is applied, it limits the range of future opportunities for a given stand. The current MSP analysis is intentionally non-spatial so that silviculture can be developed at the landscape level and applied at the stand level on the basis of need. Each stand is part of a modeling unit in which a range of silvicultural practices are designated by acres by decade. The forester applies silviculture within these limits and within other spatial constraints, such as for areas protected for other resources.

Forest Management Regimes

The general categories of silviculture include even-aged regeneration, even-aged thinning, and uneven-aged treatments. Even-aged regeneration occurs on a 50- to 80-year rotation and produces stands that will remain in young seral stages for 20 to 50 years depending on site potential and stocking retained. These units are generally small, from 10 to 30 acres, and scattered on the landscape. In most cases, even-aged regeneration targets marginally stocked and/or deteriorating stands to improve their long-term productivity. Harvest methods include seed tree, shelterwood, and clearcutting methods. Regeneration occurs artificially through planting nursery-grown seedlings, or naturally by seed trees retained within harvest units. Seed trees are retained to propagate certain species or characteristics (for example, rust resistance). Even-aged thinning units are intermediate treatments of mid-seral even-aged stands designed to accelerate growth of trees. Uneven-aged harvests are generally designed to maintain a distribution of tree sizes at a stocking level that maximizes board foot growth at the stand level. Site potential determines the desired stocking level. Uneven-aged silviculture is used to harvest trees individually or in small groups with the goal of developing or maintaining a variety of age classes within a stand. Typically, sites are restocked through natural regeneration and, where necessary, supplemented by planting seedlings obtained from a nursery.

Silvicultural Methods

The types of silvicultural methods commonly employed by FGS throughout its ownership and its application in the development of the MSP analysis are consistent with the methods defined and regulated in the CFPRs.

Clearcutting

The clearcutting regeneration method involves the removal of a stand in one harvest. Under the CFPR's, regeneration after harvesting shall be obtained by direct seeding, planting, sprouting, or natural seed fall[4]. When practical, clearcuts shall be irregularly shaped and variable in size to mimic natural patterns and features found in landscapes. Even-aged regeneration harvests have been allocated to portions of most merchantable-sized timber types on the Hilt/Siskiyou Forest. Actual clearcut unit locations are determined during Timber Harvest Plan (THP) layout by the area foresters.

Commercial Thin

Commercial thinning is the removal of trees in a young-growth stand to maintain or increase the average diameter of the remaining trees, promote timber growth, and/or improve forest health. Commercial thinning is used as a tool to extend the "life" of some stands before using a regeneration harvest to better balance age class distributions across the forest. Commercial thinning is used to improve stand health and growth in relatively healthy, well-stocked stands of trees large enough to be harvested for lumber [> 10 inches diameter at breast height (dbh)] that exceed target stocking requirements.

Biomass Thin

This intermediate treatment is used to thin younger, overstocked, submerchantable-sized stands to improve stand health and growth. It is predominantly used in young ponderosa pine stands and in mixed conifer stands with a heavy pine component. Although some saw logs are harvested, the main product is hog fuel (an unprocessed mix of barks and wood fiber) or paper chips from trees ranging from 4 to 10 inches dbh. Biomass thinning has been periodically used in the Grass Lake management unit to improve stand condition. It is also a valuable tool to reduce wildfire potential.

Seedtree/Shelterwood Removal (Even-aged)

This silvicultural method is used where a two-tiered structure of healthy, well-stocked understory with a scattered overstory exists. Future harvests will be even-aged (one or two commercial thins followed by regeneration harvests). The benefits of using this method are improved stand health, increased growth of trees in the understory, and promoting a more regular structure. This silvicultural method is widely used in all of the management units on FGS ownership.

---

[4] Age and acreage limitations for clearcuts are regulated by the California Forest Practice Rules (14 CCR 913.1)

Selection/Group Selection (Uneven-aged)

This silvicultural method is used in heavily stocked, relatively healthy stands that have an uneven-aged structure. Merchantable trees are harvested from all size classes present. The intent is to maintain an uneven-aged structure, maintain stand health, and generate a harvest return. Harvest entries occur every 10 to 20 years. Selection harvest has also been applied to other stands throughout FGS ownership on the Hilt/Siskiyou forest, including those in watercourse protection zones and on potentially unstable slopes, including inner gorges and shallow, unstable soils.

Alternative Prescriptions

A number of alternative prescriptions are commonly used by FGS in its silvicultural management. All alternative prescriptions are analyzed and approved during the THP review process. In most cases where alternative prescriptions are employed, past management and timber harvest have created an irregular condition in stand structure and/or stocking. Standard silvicultural prescriptions as specified in the rules are difficult to apply in these irregular stands. FGS's management scheme is to maintain stand health and generate a periodic and economical harvest in these stands through the use of alternative prescriptions over the first 1 to 4 years, gradually building up inventory to a point when standard silvicultural prescriptions can be applied. These alternative prescriptions include, but are not limited to:

- Seedtree/shelterwood removal (uneven-aged)
- Modified selection
- Combination shelterwood removal/biomass thin
- Modified commercial thin
- Combination shelterwood removal/commercial thin

1.4.1.4 Stand Regeneration and Improvement

Timber stand regeneration and improvement includes activities necessary to establish, grow, and achieve the desired species composition, spacing, and rate of growth of forest stands on the ownership:

- Site preparation, prescribed burning, and slash treatment
- Tree planting
- Vegetation management
- Silvicultural thinning (includes biomass, pre-commercial, and commercial thinning)

Silvicultural thinning is described previously under silvicultural methods.

Site Preparation, Prescribed Burning, and Slash Treatment

Site preparation activities for even-aged regeneration involve the removal of logging residue and/or unwanted shrub and tree species. This is typically accomplished by using tractors to pile logging residue for burning, broadcast burning, or, less commonly, by mechanical methods. By removing fuels, this treatment has the additional benefit of reducing the potential for wildfire to ignite or spread. As needed, fuel breaks may be constructed to protect resources. The need and location of fuel breaks is determined by the area forester [in consultation with California Department of Forestry and Fire Protection (CAL FIRE) as needed]. Occasionally, site preparation also requires soil scarification for planting. This treatment applies only to regeneration harvest units where it may be necessary to ensure successful regeneration.

Tree Planting

Artificial regeneration is commonly used to ensure that sites are adequately stocked as per the stocking requirements specified in the CFPRs. The usual practice is to plant seedlings in those areas that have been either clearcut or burned by wildfire. Seedlings are grown at commercial nurseries from seed collected within the appropriate seed zones typically by FGS on its property, and/or purchased for the environmental conditions of each site where they will be planted.

Vegetation Management

Occasionally, sites may require one or more vegetation management treatments to reduce the impacts of unwanted competing vegetation on the growth of seedlings. Such treatments commonly involve the mechanical removal of competing brush species using tractors or hand crews. Brush is typically piled and burned, or may be chipped. FGS is not seeking coverage for herbicide use under the ITP.

1.4.1.5 Minor Forest Products

Minor forest products are occasionally harvested from the Plan Area and transported over private and public roads. These products include, but are not limited to, Christmas trees and bows, mistletoe, firewood, fence posts, poles, yew bark, stumps, root wads, and mushrooms. These are all very minor components of this forest and are regulated by contract. The management of Christmas trees includes pruning and growth control in scattered locations throughout the Plan Area. The harvest of Christmas trees is small enough to be considered a minor forest product.

1.4.1.6 Fire Prevention and Suppression

Wildfire prevention involves vegetation management and the construction of fuel breaks strategically located throughout the Plan Area. These activities are designed and implemented by the area forester on a local basis, and are therefore generally very limited in scale. The prescription typically includes thinning for shaded fuel breaks along property lines or between watersheds where FGS deems it beneficial. Wildfire suppression is typically under the authority of local, State, or Federal agencies. In cases of escaped prescribed burns where local, State, or Federal agencies are not involved, or for initial responses until responsible agencies have arrived, FGS employs emergency fire suppression activities, such as construction of fuel breaks by hand or bulldozer, lighting backfires, applying aerial fire suppressants, falling trees or snags, and water drafting for fire suppression.

1.4.1.7 Other Activities

In addition to FGS's forest management activities, this HCP and associated ITP will cover certain other activities undertaken by FGS and third parties pursuant to FGS obligations (for example, easements) or authorization (leases and licenses) in the future. Generally, such activities include those consistent with the zoning of FGS's lands as Timber Production Zone (TPZ). Under California's Timberland Productivity Act (CTPA), a TPZ is for growing and harvesting of timber and other designated "compatible uses." Examples of compatible uses are watershed management; fish and wildlife habitat improvement; and use of roads, landings, and log decks. Grazing is considered a compatible use, but will not be a Covered Activity under this HCP.

With regard to road use, the HCP and ITP will cover general road use, construction, and maintenance activities carried out on road segments owned by and under control of FGS. Construction and maintenance activities pursuant to cooperative road use and maintenance agreements between FGS and the United States Forest Service (USFS) would not be covered under this HCP. The USFS is developing a road use and maintenance plan through consultation with NMFS to cover roads on lands in the KNF. Rock quarrying activities would be covered under this HCP. FGS quarries rock from a number of locations on its ownership for the purpose of obtaining material for road surfacing. FGS has four primary rock quarries on the ownership that are each less than 2 acres in size. These quarries are used solely by FGS to provide rock products used on its ownership and in road construction and maintenance activities on roads governed by cooperative agreements with the USFS. Typically up to five or more local rock sources, commonly referred to as "borrow pits," are developed as needed for road upgrades associated with THPs. Each local rock source is rarely larger than 0.5 acre in size and is most often located in the upper portion of watersheds.

1.4.2 Conservation Measures

1.4.2.1 Overview of the Terrestrial Species Conservation Program

Biological Goals

The overall biological goal for northern spotted owl is to contribute to the sustainable maintenance of the local and regional populations of owls through both species and habitat objectives.

Northern Spotted Owl Biological Objectives

As described below, five specific objectives were developed to meet the biological goal for the northern spotted owl.

Objective 1: Demographic Support. Consistent with Service expectations for private lands as stated in the Revised Recovery Plan for the Northern Spotted Owl (USDI FWS 2011b), a biological objective of the HCP is to contribute to northern spotted owl conservation and recovery by providing demographic support to owl populations on nearby federal lands. This objective to support the federal conservation strategy will be accomplished through conservation of suitable habitat within 1.3-miles of selected high conservation value activity centers located near FGS's ownership, thus providing compensatory mitigation for incidental take of owls associated with other low conservation value activity centers that may occur over the term of the HCP.

Conservation Support Areas (CSAs) will be established on FGS's ownership within the 0.5-mile radius core around high conservation value activity centers, coinciding with the area of highest likelihood of owl use. Selected nesting/roosting and foraging habitat in these areas will be maintained, and strategic locations with the potential to grow into suitable habitat will be managed to promote use by northern spotted owls in the future. FGS will provide reasonable extensions of the CSAs into the 1.3-mile-radius home range around selected activity centers to maintain connectivity with nesting/roosting habitat, and to provide foraging opportunities for owls. Extensions into the 1.3-mile radius home range will be focused primarily along riparian zones, which generally provide greater prey abundance and diversity due to increased understory vegetation and moisture.

Objective 2: Riparian Management. The biological objective of the HCP for riparian management is to provide foraging and dispersal opportunities for the northern spotted owl across the landscape by establishing Watershed and Lake Protection Zones (WLPZs) that promote growth in stands toward a more mature state with a high level of overstory canopy coverage and legacy structures, such as old large trees, snags, and downed wood.

Objective 3: Dispersal Habitat. The biological objective of the HCP for dispersal habitat is to contribute to a general trend of increased quality and quantity of northern spotted owl dispersal habitat across the ownership over the term of the ITP.

Objective 4: Incidental Take Minimization. The biological objective of the HCP for take minimization is to avoid direct take of northern spotted owls resulting from authorized timber harvesting operations. This objective will be accomplished through a combination of: (1) seasonal timing restrictions; (2) pre-harvest surveys; and (3) on-site monitoring by a qualified biologist.

Objective 5: Threat Management. The biological objective of the HCP is to manage, to the maximum extent practicable, known threats to the northern spotted owl. Significant threats to the northern spotted owl within the Plan Area include the barred owl and catastrophic wildfire. This objective will be accomplished through actions that: (1) control barred owls through management actions within the Plan Area; and (2) reduce the potential for catastrophic wildfire on the FGS ownership that could diminish the quality and amount of owl nesting/roosting, foraging, and dispersal habitat both on and off the FGS ownership.

1.4.2.2 Terrestrial Species Conservation Program

Based on the stated biological goals and objectives, FGS developed a comprehensive conservation program with a number of specific conservation measures to provide protection for the northern spotted owl. Collectively these measures are termed the "Terrestrial Species Conservation Program," and they reflect the binding, enforceable commitments FGS will make to satisfy the requirements of section 10(a) of the ESA. The Terrestrial Species Conservation Program is incorporated by reference in the section of the IA that describes all FGS's conservation planning commitments that must be made and carried out to qualify for and comply with the ITP that FGS is seeking.

The following subsections describe the specific measures associated with each of the biological objectives for northern spotted owls.

Objective 1: Demographic Support

The following measures are associated with the demographic support objective:

- FGS will establish 24 CSAs on its ownership to provide demographic support to northern spotted owls associated with strategic activity centers located within 1.3 miles of the FGS ownership (Action Area), and whose home ranges overlap with Critical Habitat Units (CHUs).

- FGS will promote and maintain the following general conditions and habitat features on its ownership within the CSAs:

  - A multi-layered mature forest to provide a more stable and moderate microclimate

  - Areas composed of tree species associated with use by northern spotted owls (i.e., Douglas-fir with mistletoe infections to provide nesting platforms, hardwoods to provide food and shelter for prey)

  - Variable and increasing average tree diameter

  - A large tree component (trees greater than 26 inches dbh)

  - Variable tree densities

- FGS will ensure that specific habitat standards for both nesting/roosting and foraging habitat are met within the entire CSA (which includes lands owned by others) before harvest can occur on its ownership in a CSA (see below).

- Harvest on the FGS ownership within CSAs will be restricted, and any harvest on the FGS ownership within the CSAs will require evaluation for compliance with the HCP provisions, and written approval by the Service.

- FGS will prioritize conservation efforts on lower elevation, northern-facing slopes near the northern spotted owl nest sites. FGS will prioritize management of owl habitat on its ownership within the lower third of mesic slopes near riparian zones, including designated WLPZs.

- Existing large hardwoods on the FGS ownership within CSAs will be retained to provide nesting structures for owls and food for prey species.

- Large down woody material on the FGS ownership within CSAs will be retained to provide nesting and foraging habitat for northern spotted owl prey species.

- Existing snags on the FGS ownership within CSAs will be retained. Snags that are judged to be a safety hazard may be felled and left onsite.

Conditions for allowable harvest within the 500-acre core area: If there are more than 250 acres of nesting/roosting habitat and more than 150 acres of foraging habitat within the overall 500-acre core area (regardless of ownership) of mitigation sites, then harvest can occur on lands owned by FGS in the core area. Any harvest allowed must maintain more than 250 acres of nesting/roosting habitat and more than 150 acres of foraging habitat within the core area post-harvest. All existing substrate for northern spotted owl nest structures (tree deformities, mistletoe brooms, tree cavities) will be maintained within the 500-acre core area where it does not create a hazard for public safety.

Nesting/roosting habitat is defined as having the following attributes:

- ≥150 ft^2/acre of basal area
- ≥ 60 percent canopy closure
- ≥ 15 inches average quadratic mean diameter (qmd)
- ≥ 8 trees/acre (or ≥ 30 ft^2/acre basal area) of large conifers ≥ 26 inches dbh
- Multi-layered canopy, nesting substrates, snags, down woody material, decadent trees

Of the 250 acres of nesting/roosting habitat in the core area of the CSA (regardless of ownership), at least 100 acres must be high quality habitat with greater than or equal to 210 ft^2/acre of basal area, and at least 100 acres must be of at least moderate quality with 180 to 210 ft^2/acre of basal area for harvest to occur on lands owned by FGS in the CSA.

Foraging habitat is defined as having the following attributes:

- 80 to 180 ft^2/acre of basal area
- ≥ 40 percent canopy closure
- ≥ 13 inches average qmd
- ≥ 5 trees/acre (≥ 20 ft^2/acre basal area) of large conifers ≥ 26 inches dbh

Of the 150 acres of foraging habitat, at least 60 acres must be high-quality foraging habitat with 150 to 180 ft^2/acre of basal area and greater than or equal to 60 percent canopy closure. At least 40 acres can be of moderate-quality, with 120 to 150 ft^2/acre of basal area and greater than or equal to 40 percent canopy closure.

As part of the CSA selection process, specific areas on the FGS ownership with the potential to develop into suitable owl habitat over the term of the ITP were identified to support mitigation sites that currently contain less than 250 acres of nesting/roosting habitat and/or less than 150 acres of foraging habitat within the overall 500-acre core area. See Appendix D in the HCP for detailed maps. Harvest in these areas will be restricted until the habitat thresholds are exceeded. High priority for conservation was given to areas at low elevations, and on north-facing slopes near riparian zones that are relatively contiguous with the activity center.

These harvest restrictions, which are based on habitat targets for the mitigation sites as a whole (regardless of ownership), were established to promote a high probability of occupancy by northern spotted owl nesting pairs at known activity centers with high conservation value to the federal conservation strategy outlined in the Revised Recovery Plan for the Northern Spotted Owl (USDI FWS 2011b). The habitat targets guide management and stand development on FGS land within the core area. Harvest will be restricted on the entire FGS ownership within the CSAs because any harvest conducted by FGS within the CSAs will require evaluation and written approval by the Service. Overall, 78 percent of the total FGS ownership in the core areas of the mitigation sites will be managed to provide suitable owl habitat in support of the federal conservation strategy. The remaining portion of the FGS ownership in the core areas of the mitigation sites was either identified as non-habitat, could not be reasonably expected to provide habitat over the term of the ITP, or was of low priority given the amount and quality of habitat elsewhere in the core area. FGS's habitat commitments associated with the core area and home range of each mitigation site are summarized in Table 1.

Table 1. FGS Habitat Commitments in CSAs Supporting Mitigation Sites (acres).

Activity Center ID	Habitat Type	Suitable Northern Spotted Owl Habitat within the 502-Acre Core Area (0.5-mile radius around activity center)	Suitable Northern Spotted Owl Habitat within the 2,894-Acre Outer Ring Home Range (0.5 to 1.3-mile radius around activity center)	Suitable Northern Spotted Owl Habitat within the 3,396-Acre Home Range (1.3-mile radius around activity center)

	Nesting/Roosting	0	1	1

* The acreage listed in this table represents the amount of habitat that will be maintained on FGS property only. The remainder of the 500-acre core and 3,396-acre home range include FGS lands that were not designated for conservation in the CSAs (e.g., non-habitat, suitable habitat not prioritized for conservation), are located on lands that are owned by others (private, Federal and State) and may include overlap with adjacent CSAs.

While silvicultural practices will be tailored to individual activity centers, FGS will manage its lands within the CSAs to develop and maintain northern spotted owl habitat as described above to promote heterogeneous habitat conditions within the 500-acre core area around an activity center (i.e., promote variable basal areas and canopy closures). The habitat commitments in Table 1 will be incorporated into FGS's management of its land within the 500-acre core area in CSAs around the strategic activity centers. As stands develop over the term of the ITPs, the actual areas of suitable habitat may shift spatially due to natural events or silvicultural activities. If an area identified for conservation as foraging habitat grows into nesting/roosting habitat, then FGS can harvest this or other nesting/roosting habitat in the CSA down to the high quality foraging habitat standards, provided that their commitments for nesting/roosting and foraging habitat are met and at least 250 acres of nesting/roosting habitat and 150 acres of foraging habitat is maintained within the overall 500-acre core area, regardless of ownership.

Upon evaluation and written concurrence by the Service, exceptions may be made on a case-by-case basis for mitigation sites that lack the acreage or site potential to meet this requirement. Timber harvest on the FGS ownership in a CSA would not be allowed if such harvest would result in FGS being unable to meet its habitat commitment (Table 1) post-harvest. Any harvest conducted by FGS within the CSAs will require evaluation and written approval by the Service for compliance with the HCP provisions.

Conditions for Allowable Harvest within the Home Range: If there are more than 600 acres of nesting/roosting habitat (as defined above for the core area) and more than 1,050 acres of foraging habitat (with at least 730 acres of high- and moderate-quality foraging habitat, as defined above for the core area) within the 3,396-acre home range, then harvest can occur outside of these habitat retention areas. By definition, the home range includes the 500-acre core area around the activity center, and the acreage identified above for the core area must be maintained. Any harvest allowed must maintain more than 600 acres of nesting/roosting habitat and more than 1,050 of foraging habitat, including at least 730 acres of high and moderate quality foraging habitat, within the home range post-harvest. As part of the CSA selection process, specific areas on FGS's ownership with the potential to develop into suitable owl habitat over the term of the permits were identified to support mitigation sites that currently contain less than 600 acres of nesting/roosting habitat and/or less than 1,050 acres of foraging habitat within the entire 3,396-acre home range. Maps with these specified areas can be seen in Appendix D of the HCP. Harvest in these areas will be restricted until the habitat thresholds are exceeded. High priority for conservation was given to areas that provide connectivity with nesting/roosting habitat in the 500-acre core area and with other owl activity centers, and with a high likelihood of use by northern spotted owls (lower third of mesic slopes near riparian zones, including designated WLPZs) to provide additional foraging opportunities for owls.

These harvest restrictions are based on habitat targets, for the mitigation sites as a whole (regardless of ownership), established to promote a high probability of occupancy by northern spotted owl nesting pairs at known activity centers with high conservation value to the Federal conservation strategy. The habitat targets guide management and stand development on FGS land within the home range and any harvest conducted by FGS within the CSAs will require evaluation and written approval by the Service. Overall, 41 percent of the total FGS ownership in the home ranges of the mitigation sites will be managed to provide suitable owl habitat in support of the Federal conservation strategy. The remaining portion of the FGS ownership in the home ranges of the mitigation sites was either identified as non-habitat, could not be reasonably expected to provide habitat over the term of the Permit, or was of low priority given the amount and quality of habitat elsewhere in the home range. FGS's habitat commitments associated with the home range of each mitigation site are summarized in Table 1.

While silvicultural practices will be tailored to individual activity centers, the habitat commitments in Table 1 will be incorporated into the management of CSAs within the 1.3-mile radius home range around each mitigation site. The amount and location of nesting/roosting and foraging habitat will change through time as stands age and grow. If an area in the CSA identified for conservation as foraging habitat grows into nesting/roosting habitat, then FGS can harvest this or other nesting/roosting habitat in the CSA down to the high quality foraging habitat standards, provided that their commitments for nesting/roosting and foraging habitat in the home range are met and at least 600 acres of nesting/roosting habitat and 1,050 acres of foraging habitat is maintained within the entire 3,396-acre home range area, regardless of ownership.

Upon evaluation and written concurrence by the Service, exceptions may be made on a case-by-case basis for mitigation sites that lack the acreage or site potential to meet this requirement. Timber harvest on the FGS ownership in a CSA would not be allowed if such harvest would result in FGS being unable to meet its habitat commitment (see Table 1) post-harvest. Any harvest conducted by FGS within the CSAs will require evaluation and written approval by the Service for compliance with the HCP provisions.

Objective 2: Riparian Management Objective

The following measure is associated with the riparian management objective:

- FGS will establish WLPZs or Equipment Exclusion Zones (EEZs) along all stream classes, and implement the management prescriptions described in the Aquatic Species Conservation Program over the term of the Permit. The WLPZs will provide foraging habitat and dispersal corridors for the northern spotted owl. No additional riparian management measures are included in the Terrestrial Species Conservation Strategy.

Objective 3: Dispersal Habitat Objective

The following measure is associated with the dispersal habitat objective:

- Consistent with the Service's expectations for conservation efforts on private lands, as stated in the "Revised Recovery Plan for the Northern Spotted Owl (*Strix occidentalis caurina*)" (USDI FWS 2011b), FGS will promote forest management practices that develop and maintain dispersal habitat across its ownership to provide connectivity between the CSAs and nearby Federal lands.

Dispersal habitat is essential to the dispersal of juvenile, non-territorial, or displaced northern spotted owls (USFWS 2008a). Dispersal habitat can occur in intervening areas between larger blocks of nesting, roosting, and foraging habitat or within blocks of nesting, roosting, and foraging habitat. Dispersal habitat is essential to maintaining stable populations by filling territorial vacancies when resident northern spotted owls die or leave their territories, and to providing adequate gene flow across the range of the species. Dispersal habitat is composed of two types of habitat; habitat that supports the transience phase of dispersal and habitat that supports the colonization phase of dispersal (USFWS 2008b). Habitat supporting the transience phase of dispersal contains stands with adequate tree size and canopy closure to provide protection from avian predators and minimal foraging opportunities. This may include younger and less diverse forest stands than foraging habitat, such as even-aged, pole-sized stands, but such stands should contain some roosting structures and foraging habitat to allow for temporary resting and feeding during the movement phase. Habitat supporting the colonization phase of dispersal is generally equivalent to roosting and foraging habitat, although it may be in smaller amounts than that needed to support nesting pairs. One or both of these habitat components are essential the dispersal of northern spotted owls.

Objective 4: Take Minimization Objective

The following measures are associated with the take minimization objective:

- FGS will not conduct timber operations or create a noise disturbance in conducting Covered Activities within 0.25 mile of active northern spotted owl nest sites during the breeding season beginning February 1 and ending August 31. "Active northern spotted owl nest site" is defined as the nest tree of a pair of nesting northern spotted owls. Road use and maintenance within 0.25 mile of an active northern spotted owl nest site may occur during the breeding season, but will require evaluation by the Service. Other timber operations and other Covered Activities on FGS land within 0.25 mile of an active northern spotted owl nest site may commence without restriction after August 31 for activity centers authorized for take.

- To help ensure protection of active northern spotted owl nest sites on FGS lands and on adjacent land within 0.25-mile of a FGS THP boundary or Covered Activities during the active breeding season, FGS will conduct protocol surveys each year of operation at known activity centers and within unsurveyed suitable habitat to determine site occupancy and reproduction status. Survey results will be reviewed and approved by the Service prior to operations to ensure compliance with the current Service approved protocol.

- To help assure that all active northern spotted owl nest sites on FGS lands and on adjacent lands within 0.25-mile of a THP boundary established by FGS are identified, FGS will use the most recent information on northern spotted owl locations from DFG, the Service, and private timber companies with adjacent land, during the preparation of each THP. FGS will also provide training on northern spotted owl identification and signs of northern spotted owl presence for field personnel that will be conducting THP preparation and timber operations to increase the probability that previously unknown owl sites within or adjacent to THPs are identified. All new northern spotted owl activity centers located through surveys or incidentally will become "known" activity centers, and will be subject to the survey and avoidance provisions above. If there is no response from an historic activity center during three consecutive years of protocol-level northern spotted owl surveys, the Service will evaluate that activity center to determine its occupancy status. Recent analysis conducted on northern spotted owl site occupancy indicates that three years of surveys are not sufficient to conclude that a site will not become occupied (Dugger et al. 2009), thus other factors should be evaluated when making these determinations. Determinations regarding the likelihood of occupancy and the potential for re-occupancy of activity centers must consider the history and quality of northern spotted owl surveys, in combination with current habitat conditions and history of management activities. The Service is expected to provide additional guidance to address these situations later in 2011.

Objective 5: Threat Management Objective

The following measures are associated with the threat management objective and apply to CSAs established on the FGS ownership:

- FGS will implement the following barred owl control measures:

  - FGS will conduct barred owl monitoring using current Service-approved survey protocols every 4 years within the CSAs as long as deemed necessary by the Service. Barred owl monitoring will be conducted in coordination with protocol-level northern spotted owl surveys as described in the monitoring section of the HCP. Within the 4-year interval, FGS will conduct a barred owl survey for two consecutive years to determine if barred owls are present. Survey results will be compiled and a status report provided to the Service every 4 years.

  - If a barred owl is detected in the Plan Area, FGS will locate and monitor the barred owl and notify the Service within 10 days of detection.

  - As part of the ITP issuance, FGS will apply for a Federal Depredation Permit for barred owls as needed. FGS will help to facilitate (e.g., through providing access to and across its ownership) implementation of barred owl control measures deemed appropriate by the Service.

- Consistent with its fuels management guidelines for the Plan Area, FGS will implement the following stocking control and fuel maintenance measures within the CSAs:

  - Plantation and naturally regenerated stands will be maintained at or below stocking levels considered “normal” as defined in standard yield tables where feasible.

  - Fine fuels (slash, brush, and trees less than 3 inches in diameter) will not be permitted to accumulate to levels greater than 10 tons/acre. Thinning of suitable habitat in CSAs would require pre-approval by the Service.

- FGS will implement the following measures to prevent and/or control the spread of forest disease and insect outbreaks in the CSAs:

- Salvage of trees that are weakened or killed by disease or insects, or that are damaged by wildfire or climatic events. Except where human safety is a factor, or in instances where snags have the potential to promote wildfires, salvage is not allowed in WLPZs or in designated suitable habitat within the CSAs. Salvage operations in CSAs would require pre-approval by the Service.

1.4.3 Monitoring

1.4.3.1 Compliance Monitoring for the Northern Spotted Owl

Compliance monitoring for the northern spotted owl consists of documenting compliance with the measures set forth in the Terrestrial Species Habitat Conservation Strategy. Compliance monitoring for measures associated with each biological objective are described below.

Compliance Monitoring Associated with Objective 1 – Demographic Support.

Compensatory mitigation for incidental take of owls over the term of the ITP will be provided through establishment of CSAs on FGS's ownership to provide demographic support to activity centers with high conservation priority. FGS may harvest in CSAs only if general habitat conditions within the home range and core area of the activity center(s) set forth in section 5.3.1.1 of the HCP are met, and specific habitat targets within the CSA (see Table 1) will be maintained post-harvest. Harvest within a CSA will require written approval from the Service. Compliance monitoring for this objective consists of: 1) documenting that FGS has not conducted harvest activities within the CSAs unless the required general habitat conditions are met; and 2) if FGS conducts timber operations in the CSAs, verifying that the specific habitat targets are met following these activities.

To verify that no timber operations have occurred in CSAs without prior approval from Service, FGS will provide the Service with a list of the locations of active THPs on an annual basis (see "Reporting" section below).

If FGS proposes to conduct timber operations in a CSA, prior to conducting these activities, FGS will provide map(s) of the CSA showing suitable northern spotted owl habitat in the home range and core areas of the supported activity center to the Service. As part of the THP process, FGS will inventory areas proposed for harvest to verify that the specific targets for northern spotted owl habitat within the CSA pre-harvest can be met following harvest. FGS will provide the Service with a copy of the proposed THP encompassing the CSA, and obtain written approval for harvest in the CSA. Following completion of timber operations in a CSA, FGS will inventory harvested stands to document post-harvest stand conditions and submit a post-harvest report to the Service. The post-harvest report will quantify the amount of nesting, roosting, and foraging habitat in the harvested area, and characterize stand conditions in sufficient detail to verify compliance with the minimum habitat requirements for the CSA. FGS will submit the post-harvest report to Service within 6 months of completing timber operations.

Monitoring Type:	Compliance monitoring.
Sites:	CSAs with proposed timber operations.
Objective:	Demonstrate compliance with habitat commitments for the CSA within the core and home range of the activity center.
Methods:	Forest stand inventories documenting stand basal area, canopy cover, QMD, and number of large trees to identify suitable habitat for northern spotted owls.
Reporting:	Within 6 months following completion of timber operations in a CSA.

Compliance Monitoring Associated with Objective 2 – Riparian Management.

The Aquatic Species Habitat Conservation Strategy provides for protection of riparian zones through establishment of WLPZs with restrictions on harvest and other activities within the WLPZ. No additional riparian management measures for northern spotted owls are included in the Terrestrial Species Habitat Conservation Strategy. Compliance with the WLPZ measures will be documented through reporting and post-harvest WLPZ inspections as described in section 7.2.1 of the HCP.

Compliance Monitoring Associated with Objective 3 – Dispersal Habitat.

Dispersal habitat is composed of two types of habitat; habitat that supports the transience phase of dispersal and habitat that supports the colonization phase of dispersal (USFWS 2008b). Habitat supporting the transience phase of dispersal contains stands with adequate tree size and canopy closure to provide protection from avian predators and minimal foraging opportunities. This may include younger and less diverse forest stands than foraging habitat, such as even-aged, pole-sized stands, but such stands should contain some roosting structures and foraging habitat to allow for temporary resting and feeding during the movement phase. Habitat supporting the colonization phase of dispersal is generally equivalent to roosting and foraging habitat, although it may be in smaller amounts than that needed to support nesting pairs. One or both of these habitat components are essential the dispersal of northern spotted owls. Because FGS will maintain a forested landscape on its ownership, it is anticipated that the biological objective for dispersal habitat will be met. No compliance monitoring or additional reporting is required to document compliance with this measure. However, at 10-year intervals throughout the term of the ITP, FGS will provide a summary of acres in each California Wildlife Habitat Relationships (CWHR) diameter and canopy cover class in the Plan Area as part of the annual report for that year.

Compliance Monitoring Associated with Objective 4 – Incidental Take Avoidance and Minimization.

Incidental take avoidance and minimization will be accomplished through a combination of pre-harvest surveys and seasonal timing restrictions. In addition, FGS will provide formal training on owl identification and signs of northern spotted owl presence to field personnel that will be conducting THP preparation and timber operations. As described in section 5.3.1.4 of the HCP, FGS will conduct protocol surveys each year of operation at known activity centers if necessary to determine site occupancy and reproductive status and survey suitable habitat within 0.25-mile of Covered Activities planned for operations during the active breeding season. Survey plans and results must be reviewed and approved by the Service prior to operations to ensure compliance with the most current Service approved protocol. Compliance monitoring for this objective consists of documenting that pre-harvest surveys have been conducted, seasonal restrictions have been implemented as necessary, and personnel have been trained.

To demonstrate compliance with the incidental take avoidance and minimization measures, FGS will submit an annual report to the Service. The report will include the locations, dates, and results of the surveys conducted in association with THPs. Upon request, FGS will provide copies of the THPs in which take avoidance and minimization measures were implemented. FGS will document which employees have undergone northern spotted owl training and, upon request, provide the materials used in training employees to the Service.

Compliance Monitoring Associated with Objective 5 – Threat Management.

Threat management focuses on the CSAs and includes surveys for barred owl, measures for wildfire prevention in CSAs, and measures to control disease and insect outbreaks in CSAs. To demonstrate compliance with the barred owl control measures, FGS will submit an annual report to the Service of the results of any barred owl surveys conducted. The report will include the protocol followed, locations, dates, and results of the surveys. As described in section 5.3.1.5 of the HCP, FGS will monitor any barred owl detections in a CSA and notify the Service within 10 days of detection. FGS will work closely with the Service to implement barred owl control measures deemed appropriate by the Service at the time of detection. The annual report will also describe any control measures for barred owls that are implemented and the results of the control actions.

FGS may conduct fuel management or salvage in CSAs only if general habitat conditions within the home range and core area of the supported activity center(s) set forth in section 5.3.1.1 of the HCP are met and specific habitat commitments within the CSA (see Table 1) will be maintained post-harvest. Fuels management and salvage in CSAs will require prior written approval by the Service. If FGS proposes to conduct fuel management or salvage in a CSA, prior to conducting these activities, FGS will provide the Service with a copy of the proposed fuels management or salvage plan for the CSA and provide the agency an opportunity for pre-activity review of the proposed management activity. Following completion of management or salvage operations in a CSA, FGS will inventory harvested stands to document post-harvest stand conditions and submit the results of the post-harvest inventory to the Service. The post-harvest inventory will quantify the amount of nesting, roosting, and foraging habitat in the harvested area and characterize stand conditions in sufficient detail to verify compliance with the minimum habitat requirements for the CSA. FGS will submit the results of the post-harvest inventory to the Service as part of the annual report prepared for the year in which the inventory is completed.

1.4.3.2 Effectiveness Monitoring for the Northern Spotted Owl

Monitoring the effectiveness of the northern spotted owl conservation measures is necessary to evaluate whether the biological goals and objectives established in the HCP for the species are being met, and whether the effects of HCP implementation on northern spotted owls and their habitats are exceeding the levels anticipated by the Service in their BO.

FGS's effectiveness monitoring program for northern spotted owls focuses on monitoring habitat conditions and northern spotted owl occupancy of the CSAs.

Effectiveness Monitoring of Northern Spotted Owl Habitat in CSAs.

Under the HCP, timber harvest will be restricted in CSAs unless general habitat conditions within the home range and core areas of the supported activity center(s) are present and specific habitat targets within the CSA will be maintained post-harvest. Thus, the amount and quality of northern spotted owl habitat in the CSAs is expected to be maintained or to increase over the term of the ITP. To assess the effectiveness of the HCP in maintaining or improving habitat in the CSAs, habitat conditions for northern spotted owls within the core and home range of each activity center supported by a CSA on the FGS ownership will be monitored and compared to the habitat standards described in section 5.3.1.1 of the HCP.

Monitoring Type:	Effectiveness monitoring.
Sites:	All CSAs established on the FGS ownership.
Sampling Frequency:	Stand inventories within all CSAs will be completed within 2 years of issuance of the ITP and repeated every 10 years during the permit period.
Objectives:	Demonstrate that FGS's management activities in CSAs promote development of stand conditions that provide suitable owl habitat within the CSAs over the term of the ITP.
Methods:	Stand level inventories of areas in the CSAs identified as suitable northern spotted owl habitat or potential northern spotted owl habitat (see FGS HCP Appendix D – Maps of CSA habitat areas).
Reporting:	Baseline report following initial inventory of CSAs and periodic reports following repeat inventories at 10-year intervals.

***Monitoring for Northern Spotted Owl Use in CSAs*.**

The biological goal of establishing the CSAs and specifying habitat requirements within the CSAs is to enhance the likelihood that activity centers supported by CSAs will remain or become occupied by northern spotted owls, and thereby provide demographic support to the Federal conservation strategy. Occupancy of an area by northern spotted owls is influenced by many factors, of which habitat condition is only one. Also, home ranges for owls supported by CSAs encompass land managed by many different entities (e.g., USFS, other private timber companies) in addition to FGS. As a result of these circumstances, habitat conditions on FGS lands is only one factor affecting the presence or absence of northern spotted owls in these activity centers, and the absence of owls in an activity center cannot be used as a definitive measure of the HCP's effectiveness. Nonetheless, it is desirable to monitor occupancy of the activity centers supported by CSAs on the FGS ownership as one component for assessing the effectiveness of the HCP.

Fruit Growers Supply Company will conduct protocol surveys to detect the presence of northern spotted owls in activity centers supported by CSAs. Survey results will be reviewed and approved by the Service to ensure compliance with the "Protocol for surveying proposed management activities that may impact northern spotted owls" (USDI FWS, 2011a), or current northern spotted owl survey protocols approved by the Service. Fruit Growers Supply Company will conduct protocol surveys during two consecutive years, unless a northern spotted owl or owl pair is detected during the first year. If a northern spotted owl or owl pair is detected during the first year of surveys, and resident status is determined, this will indicate occupancy of the activity center, and no follow-up survey is required the second year. The surveys will be repeated at 4-year intervals for the duration of the permit to document and identify trends in occupancy and reproductive status of activity centers supported by CSAs on the FGS ownership. If there are no detections for two consecutive years at more than 40 percent of the CSAs (nine CSAs) within a 4-year period, then FGS will notify the Service and California Department of Fish and Game (CDFG), and enter into a discussion about why the sites are unoccupied and whether any alternative actions within the HCP commitments could promote occupancy. Alternatives such as delayed harvest in nearby activity centers where take is authorized, or establishment of an alternative CSA with similar conservation value could be proposed. If an alternative CSA is identified and approved through written concurrence by the Service, then FGS may conduct timber harvest operations within the unoccupied CSA without further restriction, other than as specified in other sections of this HCP (i.e., the CSA will no longer be considered a conservation or mitigation area).

Monitoring Type:	Effectiveness monitoring.
Sites:	All CSAs established on the FGS ownership.
Sampling Frequency:	Protocol surveys during breeding period for two consecutive years at 4-year intervals.

Objectives:	Determine northern spotted owl occupancy and reproductive status at activity centers supported by CSAs on the FGS ownership.
Methods:	Protocol surveys during the breeding period for northern spotted owl.
Reporting:	Annual reporting of results of any surveys conducted in the preceding year.

Monitoring for Barred Owls in CSAs.

The objective of threat management measures for barred owls is to prevent barred owls from displacing northern spotted owls and becoming established. Detections of barred owls could reflect a range expansion and increased risk of barred owls becoming established. Under the HCP, FGS will survey activity centers supported by the CSAs for barred owls. If barred owls are detected, FGS will work closely with the Service to implement appropriate barred owl control measures as necessary. Following implementation of any control measures, another individual could quickly move into the area. To monitor the effectiveness of the control strategy and minimize the potential for additional barred owls to become established following control actions FGS will, upon request by the Service, conduct annual surveys for barred owls within 1 mile of the detection site. Annual surveys will continue until no barred owls are detected for 3 consecutive years, or until the Service no longer requests additional surveys, after which the survey frequency will revert to the standard protocol of 2 consecutive years every 4 years.

Monitoring Type:	Effectiveness monitoring.
Sites:	Activity centers supported by CSAs on the FGS ownership in which barred owls have been detected and control measures have been implemented.
Sampling Frequency:	Annual protocol surveys during breeding period until no detections for 3 consecutive years or the Service determines that surveys are no longer necessary.
Objectives:	(1) Determine occurrence of barred owls in CSAs.
	(2) Demonstrate effectiveness of any barred owl control actions.
Methods:	Service-approved protocol surveys for barred owls.
Reporting:	Annual reporting of results of any surveys conducted in the preceding year.

1.4.3.3 Northern Spotted Owl Monitoring Adaptability

The monitoring outlined in the previous sections uses monitoring protocols that represent current, peer-reviewed, and accepted methods at the time of HCP development. It is possible that other monitoring methods may be developed during the term of the HCP, which would provide for better or more cost-effective assessment of compliance with and effectiveness of the conservation measures. FGS and the Service may mutually agree to modify the monitoring protocols listed in this HCP to better monitor the effectiveness of the conservation measures and ensure compliance with the terms of the conservation program at any time.

1.4.4 Reporting Requirements

FGS will regularly submit reports to the Service and CDFG to document its compliance with the terms of the HCP and report the results of effectiveness monitoring. FGS reporting obligations can be separated into three categories:

1. Annual reports
2. Periodic analyses
3. Event-driven analyses

1.4.4.1 Annual Reports

FGS will submit an annual report to the Service and CDFG on HCP activities occurring in the preceding year. At a minimum, the annual report will include:

- Any incidental take of northern spotted owls;
- List of the active THPs and their locations, and identification of THPs in which take minimization and avoidance measures for northern spotted owls were implemented;
- The amount of suitable habitat within the core area and home range of each activity center on the ‘take’ list that has been harvested or otherwise converted to nonhabitat;
- Dates, locations, and results of northern spotted owl surveys conducted in association with THPs;
- Dates, locations, and results of northern spotted owl surveys in CSAs in that year and preceding years; and
- Dates, locations, and results of barred owl surveys in that year and preceding years.

FGS will submit each year’s annual report by March 31 of the following year.

1.4.4.2 Periodic Analysis

FGS will periodically analyze northern spotted owl habitat in the CSAs. As part of the effectiveness monitoring program, FGS will conduct a baseline stand inventory of its lands within CSAs within 2 years of permit issuance and every 10 years thereafter. The inventory results will include:

- Maps of locations of stands that were inventoried;
- For each CSA, the amount and location of suitable northern spotted owl habitat in accordance with the definitions used in this HCP; and
- Estimates of snag, downed woody debris, and hardwood densities.

Results of the inventories and analysis of habitat for northern spotted owl will be included in the annual report for the year in which the inventories are completed.

1.4.4.3 Event-driven Analysis

During the term of the ITP, FGS will not conduct timber operations on its lands in CSAs unless specific habitat requirements are exceeded. If FGS proposes to conduct timber operations in a CSA, including wildfire management and salvage operations, FGS will inventory areas proposed for harvest to document pre-harvest stand conditions (including amount of hardwoods, downed woody debris, and snags) during THP preparation and obtain Service approval prior to operations in the CSA. Following completion of timber operations in a CSA, FGS will analyze habitat conditions for northern spotted owl in CSAs where timber operations have occurred. The post-harvest analysis will include:

- The amount and location of nesting, roosting and foraging habitat within the CSA prior to timber operations;
- The amount and location of nesting, roosting and foraging habitat within the CSA following timber operations;
- Results of stand level inventories of harvested stands in CSAs before and after timber operations; and
- Densities of snags, downed woody debris, and hardwoods in harvested CSAs before and after timber operations.

Results of the post-harvest analyses will be included in the annual report for the year in which the analyses are completed.

1.4.5 Changed and Unforeseen Circumstances

Section 10 regulations (as codified in [50 CFR, Sections 17.22(b)(2) and 17.32(b)(2)]) require that an HCP specify the procedures to be used for dealing with changed and unforeseen circumstances that may arise during the implementation of the HCP. In addition, the No Surprises Rule ([63 Federal Register 8859, February 23, 1998 as codified in 50 CFR 17.22 (b)(5), 17.32 (b)(5), and 222.307(g)]) describes the obligations of the permittee and the Services. The purpose of the No Surprises Rule is to provide assurance to the non-Federal landowners participating in habitat conservation planning under the ESA that no additional land restrictions or financial compensation will be required for species adequately covered by a properly implemented HCP, in light of unforeseen circumstances, without the consent of the permittee.

1.4.5.1 Changed Circumstances

Changed circumstances are defined in 50 CFR 17.3 and 222.102 as changes in circumstances affecting a species or geographic area covered by an HCP that can reasonably be anticipated by plan developers and the Service, and for which contingency plans can be prepared (e.g., the new listing of species, a fire, or other natural catastrophic event in areas prone to such event). If additional conservation and mitigation measures are deemed necessary to respond to changed circumstances, and these additional measures were already provided for in the plan's operating conservation program (e.g., the conservation management activities or mitigation measures expressly agreed to in the HCP or IA), then the permittee will implement those measures as specified in the plan. However, if such measures were not provided for in the plan's operating conservation program, the Service will not require these additional measures without the consent of the permittee, provided that the HCP is being "properly implemented" (properly implemented means the commitments and the provisions of the HCP and the IA have been or are being fully implemented). At no time does the ITP authorize Covered Activities to put a species in jeopardy.

For the purposes of this HCP, changed circumstances are those changes affecting a species or geographic area covered by the HCP that can reasonably be anticipated and planned for by FGS and the Service at the time of the HCP's preparation. In discussions with the Service, NMFS, and CDFG, FGS identified several reasonably foreseeable circumstances under which changes could occur during the term of the ITP that could result in a substantial and adverse change in the status of a species covered by the HCP. Foreseeable conditions that could result in "changed circumstances" as defined in applicable Federal regulations and policies that may affect terrestrial covered species are identified below.

- Global climate change, resulting in increased fire risk, flooding, drought, incidence of pests or pathogens, increase in the number or density of invasive species, or restriction in the range of Covered Species at a regional or local scale. These issues are individually addressed in the sections below as they would pertain to changed circumstances in the Plan Area.

- Listing of species that are currently unlisted but occur within the HCP Plan Area.

- A change in the listing status (including de-listing) of a Covered Species through a formal status review by the Service and NMFS.

- Designation or revision of critical habitat for covered species or species listed after the start of the term of the ITP that may be affected by a Covered Activity.

- Stand replacing fire that (alone or in combination with other events such as blow-down) downgrades suitable habitat within the core area or home range of an activity center supported by a CSA on the FGS ownership to non-habitat, such that the CSA no longer provides demographic support to the Federal conservation strategy or meets the biological objectives of the HCP.

- Blow-down that (alone or in combination with other events such as fire) downgrades suitable habitat within the core area or home range of an activity center supported by a CSA on the FGS ownership to non-habitat, such that the CSA no longer provides demographic support to the Federal conservation strategy or meets the biological objectives of the HCP.

- Stand modification (e.g., changes in average diameter or canopy coverage) due to pests or pathogens, or their control, that (alone or in combination with other events such as fire and blow-down) downgrades suitable habitat within the core area or home range of an activity center supported by a CSA on the FGS ownership to non-habitat, such that the CSA no longer provides demographic support to the Federal conservation strategy or meets the biological objectives of the HCP.

- Introduction or invasion by exotic plant or animal species (e.g., barred owl) that affect Covered Species or their habitat.

The potential for each of these circumstances is reasonably foreseeable. As described in this subsection, FGS also has considered the potential for earthquakes to have effects that could constitute "changed circumstances." FGS's strategy for addressing each of these changed circumstances is described in the following. If changed circumstances occur, FGS will implement the supplemental prescriptions set forth in the HCP and summarized below.

Global Climate Change

According to the Service (USDI FWS 2008a), the potential effects of increasing atmospheric concentrations of carbon dioxide and other "greenhouse gases," and the observed increase in the average temperature of the Earth's atmosphere and oceans, have been the subject of considerable technical analysis and political debate. There is growing consensus that climate change is occurring and additional change is predicted. Global climate change has the potential to influence fire risk and the incidence of exotic species, flooding, drought, and disease at a regional and local scale. The impacts of these proximal events (e.g., fire, flood) due to global climate change are addressed in the following subsections as they would pertain to changed circumstances in the Plan Area.

There is considerable uncertainty associated with projecting future climate change. This is partly due to uncertainties about future emissions of greenhouse gases and to differences among climate models and simulations (Stainforth et al. 2005, Duffy et al. 2006). There are no known climate change simulations for the Klamath-Siskiyou region, but the results of numerous climate change simulations for California and the Pacific Northwest have been published. Together, these simulations describe a range of plausible outcomes from increased emissions of greenhouse gases.

The projected effects of climate change on local and regional temperatures, precipitation, vegetation, and fire are described below. Much of the following discussion was taken from the 12-Month Finding on a Petition to List the Siskiyou Mountains Salamander (*Plethodon stormi*) and Scott Bar Salamander (*Plethodon asupak*) as Threatened or Endangered (73 FR 4380; January 24, 2008). The 12-month finding on this petition is particularly relevant to the FGS HCP because the range of both of these species overlaps the Plan Area; thus, the analysis represents the best available information on the effects of global climate change in the Plan Area.

All of the studies that were reviewed predicted continued increases in average surface temperatures in California and the Pacific Northwest in response to increased emissions of greenhouse gases (Leung and Ghan 1999, Snyder et al. 2002, Electric Power Research Institute [EPRI] 2003, Hayhoe et al. 2004, Cayan et al. 2006, Duffy et al. 2006, Maurer 2007, Salathé et al. submitted). The magnitude of projected increases in annual average temperature varied widely among studies, depending on the models and emissions scenarios used, from 3 to 10.4°F, by the year 2100 (EPRI 2003, Hayhoe et al. 2004, Cayan et al. 2006, Maurer 2007). Simulations consistently project more pronounced temperature increases in California during the summer months than during other times of the year, 3.9 to 14.9 °F by 2100 (Hayhoe et al. 2004, Cayan et al. 2006, Maurer 2007). Some simulations projected more rapid temperature increases at higher elevations than at lower ones (Leung and Ghan 1999, Salathé et al. submitted). Most researchers attributed this difference to a snow albedo feedback effect; this occurs when increased surface temperatures cause earlier and faster snow melt, which, in turn, allows more absorption of heat by the ground and further increases in surface temperatures.

Reviews of a large number and variety of climate change simulations found that projected changes to precipitation in California were highly variable but clustered around no change or a slight increase in annual precipitation (Cayan et al. 2006, Maurer 2007). Warming temperatures are consistently projected to increase the proportion of precipitation that falls as rain rather than as snow in California and the Pacific Northwest (Leung and Ghan 1999, Snyder et al. 2002, Hayhoe et al. 2004, Cayan et al. 2006, Maurer 2007). Earlier and more rapid snowmelt and decreases in the proportion of precipitation that falls as snow are expected to cause declines in spring snowpacks (Hayhoe et al. 2004, Cayan et al. 2006, Maurer 2007). Declines in spring snowpacks have already occurred in some areas and are correlated with global warming trends (Mote 2003). However, despite regional warming over the past half century, the glaciers of Mount Shasta have continued to expand following a contraction during a prolonged drought in the early twentieth century (Howat et al. 2007). Some areas will experience increased cloud cover as surface temperatures continue to increase (Croke et al. 1999).

Vegetation modeling by Lenihan et al. (2003a, 2003b) projected that increased emissions of greenhouse gases will cause large-scale replacement of evergreen conifer forest (e.g., Douglas fir-white fir) with mixed evergreen forest (e.g., Douglas-fir-tanoak) in the Klamath- Siskiyou region. This redistribution of vegetation types is predicted to occur under conditions created by two contrasting climate change models (Lenihan et al. 2003a).

Loarie et al. (2008) projected that up to 66 percent of California's endemic flora would experience >80 percent reductions in range size as a result of anticipated climate changes. While this is a worst-case scenario based on high levels of CO_2 emissions in the future, a global climate model with high sensitivity to atmospheric greenhouse gas levels, and no dispersal component, the models ignore several factors that would exacerbate the projected impacts of climate change, including specialization to restricted soil types and the spread of invasive species. Because Yreka phlox is restricted to ultramafic soil types and has limited dispersal capabilities, global climate change could result in a reduction in the range of this species. However, it is difficult to speculate as to the extent of range reduction that could occur within the Plan Area and the complete loss of local populations is not anticipated. The conservation strategy for Yreka phlox addresses this potential for a range reduction by allowing seeds to be collected on FGS lands for long-term storage and development of techniques to reestablish populations, consistent with the Federal recovery strategy.

Despite variability in climate change simulations, consistent projections for warmer summers, reduced spring snowpacks, and earlier and more rapid snowmelt suggest that forests in California and the Pacific Northwest will experience longer fire seasons and more frequent, extensive, and severe fires in the future (Flannigan et al. 2000, Lenihan et al. 2003a, Whitlock et al. 2003, McKenzie et al. 2004). Whether or not these fire predictions will occur is unknown due to inconsistent predictions for precipitation, including increased cloud cover and rainfall. However, the planned response to changed circumstances related to wildfire is described below in the Fire and Wind section.

Listing of Species that are Currently Unlisted

The preamble to the No Surprises rule states that the listing of a species as endangered or threatened could constitute a changed circumstance.

If a species that is not a Covered Species under the HCP ("Non-Covered Species") is listed the Federal ESA subsequent to the effective date of the ITP, and the Non-Covered Species is affected by the Covered Activities, such listing will constitute a changed circumstance. If a Non-Covered Species that may be affected by a Covered Activity is listed under the Federal ESA during the term of the ITP, the Section 10 Permits will be reevaluated by the Service. The HCP Covered Activities may be modified, as necessary, to ensure that the activities covered under the HCP are not likely to jeopardize or result in the take of Non-Covered Species. FGS shall implement the modifications to the HCP Covered Activities determined by the Service in consultation with FGS to avoid the likelihood of jeopardy to or take of the Non-Covered Species. FGS shall continue to implement such modifications until such time as they apply for and the Service approves an Amendment of the Section 10 Permit, in accordance with applicable statutory and regulatory requirements, to cover the Non-Covered Species or until the Service notifies FGS in writing that the modifications to the HCP Covered Activities are no longer required to avoid the likelihood of jeopardy of Non-Covered Species.

Change in the Listing Status of Covered Species

It is conceivable that the listing status of a Covered Species could be changed (i.e., from Threatened to Endangered) through a formal status review during the term of the ITP. Because conservation measures for these species are included in this HCP and these species are "Covered" by the ITP being issued, a change in the listing status of these species would not be considered a changed circumstance and will not have the effect of causing additional land, mitigation, restrictions, or compensation to be required of FGS if this HCP is being implemented in compliance with the take authorization conditions for that species. Notwithstanding the above, the ITP may be suspended or revoked if continuation of the ITP would result in jeopardy.

If the listing status of a Covered Species is downgraded (i.e., from Endangered to Threatened) or the species is de-listed during the term of the ITP through a formal status review, then the HCP may be modified, as appropriate, to reduce or eliminate required measures for that species, if the Service concludes that such measures did not contribute, in whole or in part, to the decision to de-list the species and that modification of such measures is not likely to lead to or contribute to re-listing of the species. FGS will continue to implement the HCP in accordance with all applicable provisions until such time the company applies for and the Service approves an Amendment of the ITP.

Designation or Revision of Critical Habitat for Covered or Non-Covered Species

Critical habitat has been designated for some of the federally listed species covered by this HCP. If in the future, critical habitat that is currently designated for a Covered Species is revised, or critical habitat is newly designated for a Covered Species, and such designated or revised critical habitat may be affected by one or more Covered Activities, or if critical habitat is designated or revised for a Non-covered species and such designated or revised critical habitat may be affected by one or more Covered Activities, such revision or designation of critical habitat would constitute a changed circumstance, and the Section 10 permit will be reevaluated by the affected Service in consultation with FGS. If the affected Service concludes that one or more Covered Activities would adversely modify designated or revised critical habitat, the Covered Activity(ies) shall be modified to the extent necessary to avoid adverse modification. The affected Service shall work with FGS and with the other Service to limit any modifications to the Covered Activities to those that necessary to avoid adverse modification of critical habitat and are the least disruptive to FGS's on-going timber operations. FGS shall either implement the modifications to the Covered Activities identified by affected Service until the affected Service notifies FGS in writing that the modifications to the Covered Activities are no longer required to avoid adverse modification of critical habitat, or FGS may relinquish the Permits in accordance with applicable Service regulations. Notwithstanding the above, the ITPs may be suspended or revoked if continuation of the Permits would result in adverse modification of any newly designated or revised critical habitat.

Fire and Wind

Fire frequency, intensity, and size within the Plan Area have changed since the fire-suppression era (1950 to present) (Fry and Stephens, 2006). Prior to the fire-suppression era, fires occurred frequently; and in most of the vegetation assemblages covering large portions of the Klamath Mountains, they were of generally low to moderate and mixed severity (Skinner et al., 2006). Fires occurring in the fire-suppression era are less frequent and have greater intensity, resulting in a more homogeneous effect on the habitat by damaging and removing all vegetation (Fry and Stephens, 2006). These are often considered "stand-replacing" fires. Stand-replacing fires can cause immediate long-term changes that affect watershed processes, terrestrial and aquatic species and their habitats, and timber. Fire suppression is not a covered activity. The strategy for responding to and suppressing forest fires is generally established by CAL FIRE and USFS. FGS has little ability to influence such strategy.

A blow-down event in a CSA that downgrades suitable habitat for northern spotted owls to non-habitat could have adverse effects on this species, although, in some cases, trees blown down by wind can benefit northern spotted owls by providing habitat for their prey base.

Alteration of forest stands in the CSAs due to fire and wind (alone or in combination with other factors such as pest damage), can adversely affect habitat quantity and quality for northern spotted owls, reducing the effectiveness of the CSAs in meeting the biological objectives of the HCP. Because fire and wind have similar effects (i.e., tree removal and subsequent alteration of terrestrial habitats), they are considered as a group in terms of defining what may constitute a changed circumstance.

For northern spotted owls, it is important that enough suitable habitat is maintained within the CSAs to provide demographic support to the Federal conservation strategy and meet the objectives of the HCP. For this reason, the conditions for allowable harvest in a CSA (see section 5.3.1.1 of the HCP) are used to identify when the CSA may no longer provide demographic support of the Federal conservation strategy and could constitute a changed circumstance.

Changed Circumstances with Respect to Protection of the Northern Spotted Owl

The terrestrial species conservation program for northern spotted owl (see section 5.3.1.1 of the HCP) includes specific conditions under which harvest activities can be conducted in CSAs. The harvest restrictions are based on habitat targets for the CSA as a whole (regardless of ownership, established to promote a high probability of occupancy by northern spotted owl nesting pairs at these known activity centers with high conservation value to the Federal conservation strategy. If a stand replacing fire or damage due to wind results in a downgrade of suitable habitat within the core area or home range of an activity center supported by a CSA on the FGS ownership to non-habitat, such that the conditions for allowable harvest in the CSA (see section 5.3.1.1 of the HCP) can no longer be met over the term of the ITP, this will indicate that the CSA may no longer meet the objectives of the HCP and may constitute a changed circumstance. In the event that fire or wind affects a CSA by alteration of suitable northern spotted owl habitat, FGS will provide the Service with information regarding the habitat alteration due to fire or wind within

30 days of detection. FGS, in consultation with the Service, will determine if a changed circumstance has occurred, based on the quantity and quality of habitat for northern spotted owls that remains in the CSA or could develop over the term of the ITP. Based on the fire history database maintained by the USFS, it is reasonably foreseeable that up to four CSAs could be adversely affected by stand replacing fires during the term of the ITP, potentially resulting in a changed circumstance. The frequency of adverse effects due to wind cannot be estimated, but is anticipated to be less than the incidence of stand-replacing fires. If a changed circumstance affecting a CSA due to fire or wind occurs, FGS will apply the following supplemental prescriptions within affected CSAs.

1. Trees damaged or killed outright by fire or wind, including those in WLPZs or Stream Management Zones (SMZs), will be considered by FGS for salvage.

2. Salvage of trees downed or dead by fire or wind within CSAs must comply with State law, other terms of this HCP (i.e., on unstable areas), and be approved by the Service prior to removal.

3. Reforestation of any CSA affected by the fire or wind will be implemented as soon as reasonably possible. Equipment Exclusion Zones will be avoided during any reforestation activities associated with fire or wind.

4. FGS will enter into discussions with the Service regarding alternatives that would maintain the approximate conservation value provided by the affected CSA(s) under the original conservation strategy. Alternatives could include, but are not limited to, delayed harvest around nearby activity centers where take is authorized, or establishment of an alternative CSA with similar conservation value. If an alternative CSA is identified and approved through written concurrence by the Service, then FGS may conduct timber harvest operations within the fire or wind damaged CSA without further restriction, other than as specified in other sections of the HCP (i.e., the CSA will no longer be considered a conservation or mitigation area).

Pest or Pathogen Infestation

Insects and diseases can usually be kept under control through careful forest management and proper treatments. Natural control of insects can take place through climatic conditions, parasites, or predators via biological control. Defoliators, borers, bark beetles, and various terminal and root feeders, along with sucking insects, are common types of insects in California forests. However, large outbreaks of insects or pathogens are uncommon in the Plan Area.

Introduced pathogens can also lead to the decline of native tree species. One example is Sudden Oak Death (SOD) caused by *Phytophthora ramorum*. In 14 coastal California counties and Curry County, Oregon, *P. ramorum* has caused outbreaks of SOD, killing more than 1 million native oak and tanoak trees (California Oak Mortality Task Force [COMTF], 2008). Under a worst case circumstance, as infected trees die, the niche they occupied becomes colonized by other forest tree species. Because there are no known incidences of SOD within the Plan Area, and the Plan Area is in an area considered to have a very low risk of establishment and spread of

SOD (COMTF, 2008), the disease is not expected to have a measurable adverse effect on the Covered Species or on the functional attributes of the HCP.

Site quality and nutrient availability play a key role in forest health and vigor and susceptibility to insect or pathogen damage. Since much of the Plan Area is of moderate site quality, infestations are less likely to occur within the healthy forests that occupy these sites. Criteria for changed circumstances apply only to pest and pathogen damage that occurs in CSAs established around northern spotted owl activity centers.

The conservation measures identified in section 5.3.1.1 of the HCP provide protection against most pest or pathogen invasions by promoting forest health. However, prolonged drought as a result of global climate change could alter the resistance of native forests to various pests or pathogens. If stand modification due to pests or pathogens, or their control, (alone or in combination with other factors such as fire and wind) downgrades suitable habitat within the core area or home range of an activity center supported by a CSA on the FGS ownership to non-habitat, such that the conditions for allowable harvest in the CSA can no longer be met over the term of the ITP, this will indicate that the CSA may no longer meet the objectives of the HCP and may constitute a changed circumstance. FGS will provide the Service with information regarding the damage within 30 days of detection and, in consultation with the Service, will determine if a changed circumstance has occurred, based on the quantity and quality of habitat for northern spotted owls that remains in the CSA or could develop over the term of the ITP. If a changed circumstance affecting a CSA due to pests or pathogens occurs, FGS will apply the following supplemental prescriptions within affected CSAs.

1. Trees damaged or killed outright by pests or pathogens in a CSA, including those in WLPZs and SMZs, will be considered by FGS for salvage.

2. Salvage of trees damaged or killed by pests or pathogens within CSAs must comply with State law and be approved by the Service prior to removal.

3. Reforestation of any CSA affected by pests or pathogens, or their control, will be implemented as soon as reasonably possible. Equipment Exclusion Zones will be avoided during any reforestation activities associated with pests or pathogens.

4. FGS will enter into discussions with the Service regarding alternatives that would maintain the approximate conservation value provided by the affected CSA(s) under the original conservation strategy. Alternatives could include, but are not limited to, delayed harvest around nearby activity centers where take is authorized, or establishment of an alternative CSA with similar conservation value. If an alternative CSA is identified and approved through written concurrence by the Service, then FGS may conduct timber harvest operations within the pest or pathogen damaged CSA without further restriction, other than as specified in other sections of the HCP (i.e., the CSA will no longer be considered a conservation or mitigation area).

Invasive Species

The Service anticipates that barred owls will colonize suitable habitat within the Plan Area within the term of the ITP. Because barred owls select habitat similar to that occupied by northern spotted owls, it is likely that newly established barred owl territories will overlap and may displace northern spotted owls within some of the known activity centers. The function of CSAs in providing conservation support to high value activity centers will be compromised in direct proportion to the number of barred owls that colonize the CSAs. Displacement of northern spotted owls from a CSA is considered a changed circumstance and may require implementation of barred owl control measures. This low threshold for triggering barred owl management is necessary because offspring produced at established barred owl territories, regardless of location within CSAs or not, will increase the threat to northern spotted owl territories supported by CSAs.

To maintain the functionality of the Terrestrial Species Conservation Program, FGS will monitor the CSAs and other activity centers on its ownership for barred owl presence. If barred owls are detected in any CSA or activity center on the FGS ownership, FGS will notify the Service within 10 days of detection. FGS will enter into discussions with the Service regarding alternative management actions for barred owls. Such actions could include, but are not limited to, control of barred owls through removal and study of barred owl/northern spotted owl interactions. As part of the ITP issuance, FGS will apply for a Federal Depredation Permit for barred owls as needed. FGS will help to facilitate (e.g., through providing access to and across its ownership) implementation of barred owl control measures deemed appropriate by the Service at the time of detection.

Earthquakes

The Plan Area is located in an area that is not known for earthquakes. Earthquakes are quite uncommon and are generally of a relatively insignificant magnitude, typically 2 to 3 on the Richter scale. Occasionally, greater magnitude events occur, but they are impossible to predict. In the forest environment, earthquakes of magnitude 6 or less on the Richter scale produce little, if any, visible change, and apparently have little impact on wildlife or fishery habitat.

While it may be speculated that localized landslides or other earth movements resulted from these earthquakes, there are no data to document that this occurred within the Plan Area.

An earthquake of such magnitude (greater than magnitude 6 on the Richter scale) that may substantially alter habitat status or require additional conservation or mitigation measures in excess of those already included in the Plan is not reasonably foreseeable during the life of the Plan, and would be considered an “unforeseen circumstance.”

1.4.5.2 Unforeseen Circumstances

Unforeseen circumstances are changes in circumstances affecting a species or geographic area covered by the HCP that could not reasonably have been anticipated by FGS and the Service at the time the HCP was developed and negotiated, and that result in a substantial and adverse change in the status of a Covered Species (50 CFR 17.3 and 222.102). The Service bears the burden of demonstrating that unforeseen circumstances exist, using the best scientific and commercial data available. All changes not described above as "changed circumstances" that would result in a substantial and adverse change in the status of a Covered Species are considered unforeseen circumstances.

In case of an unforeseen event, FGS will immediately notify the Service. In determining whether such an event constitutes an unforeseen circumstance, the Service shall consider, but not be limited to, the following factors: size of the current range of the affected species; percentage of range adversely affected by the HCP; percentage of range conserved by the HCP; ecological significance of that portion of the range affected by the HCP; level of knowledge about the affected species and the degree of specificity of the species' conservation program under the HCP; and whether failure to adopt additional conservation measures would appreciably reduce the likelihood of survival and recovery of the affected species in the wild.

If the Service determines that additional conservation and mitigation measures are necessary to respond to the unforeseen circumstances, and the HCP is being properly implemented, the additional measures required will be, to the maximum extent practicable, as close as possible to the terms of the original HCP, and must be limited to modifications within any conserved habitat area or to adjustments within lands or waters that already are set-aside in the HCP's operating conservation program. Additional conservation and mitigation measures shall not involve the commitment of additional land or financial compensation, or restrictions on the use of land or other natural resources otherwise available for development or use under the original terms of the HCP without the consent of the permit holder.

1.4.6 Funding

FGS has been a business entity since 1907 and has an established track record as a forest products company. In general, FGS will finance the HCP with revenues from its ongoing timber harvest operations. Accordingly, as harvesting is planned and carried out, it will provide the funds needed to carry out the HCP's measures to mitigate the impacts of take.

As described throughout the HCP, and as warranted in the IA, FGS has committed to expend the necessary funds to fulfill its obligations under the plan. After the issuance of the ITP by the Service, FGS will post a security deposit as an additional form of assurance that adequate funding will be provided for the HCP.

Further, by January 1st of each calendar year during the term of the ITP, and following the adoption of FGS company budget by its Board of Directors (which normally occurs by the end of November of the prior year), FGS will provide the Service with a Yearly Expenditure Report (YER). The YER will, when appropriate, identify the HCP tasks undertaken the prior year, and the funds expended to implement those tasks. The YER will also identify: (1) HCP tasks FGS intends to implement in the upcoming calendar year (e.g., monitoring, surveying), (2) out-of-pocket expenditures related to those tasks (e.g., hiring of outside specialists), (3) funds budgeted for those purposes, and (4) whether the budgeted funds are THP-related or not. FGS must provide this information to the Service for their review and concurrence before any activity authorized by the HCP may commence.

1.4.7 Modifications and Amendments

There are two types of changes that may be made to the HCP and/or the HCP Permits and/or its associated documents:

- Minor Modifications
- Amendments

Minor Modifications and Amendments shall be processed in accordance with the provisions of the IA and all applicable legal requirements, including but not limited to the ESA, NEPA, and any applicable Federal regulations.

1.4.7.1 Minor Modifications

Minor Modifications to the HCP are changes provided for under the operating conservation program. Minor Modifications do not (1) modify the scope or nature of activities or actions covered by the Section 10(a)(1)(B) permit; (2) result in operations under the HCP that are significantly different from those contemplated or analyzed in connection with the Plan as approved; (3) result in adverse impacts on the environment that are new or significantly different from those analyzed in connection with the Plan as approved; or (4) result in additional take not analyzed in connection with the HCP as approved. As noted above, Minor Modifications shall be processed in accordance with the provisions of the IA and all applicable legal requirements, including but not limited to the ESA, NEPA, and any applicable Federal regulations.

Minor Modifications to the HCP may include, but are not limited to, the following:

1. Correcting any maps or exhibits in mapping or boundary lines.

2. Modifying existing or establishing new avoidance or minimization measures that incorporate new nomenclature or technology. Any new or modified measures will not be substantially different in nature from existing measures and will achieve equivalent or greater protection for Covered Species.

3. Making minor changes to monitoring or reporting protocols.

4. Revising mitigation area enhancement and management techniques.

5. Making minor modifications to the HCP that are consistent with the biological goals and objectives of the HCP, and that the Service has analyzed and agreed to.

It is anticipated that FGS may, over the term of the ITP, sell or acquire additional timberlands in drainages where they currently have ownership. Sales and acquisitions of lands to be covered by the HCP shall be subject to the provisions of the IA and all applicable legal requirements, including but not limited to the ESA, NEPA, and any applicable Federal regulations.

1.4.7.2 Amendments to the HCP

Amendments to the HCP include, but are not limited to changes that affect the scope of the HCP and conservation strategy, increase the amount of take, add new species, or change significantly the boundaries of the HCP. Amendments to the HCP require an amendment to the Section 10(a)(1)(B) permits and to the Service decision documents, including NEPA documents, biological opinions, and findings and recommendations documents. Amendments will also require additional public review and comment. As noted above, Amendments shall be processed in accordance with the provisions of the IA and all applicable legal requirements, including but not limited to the ESA, NEPA, and any applicable Federal regulations.

The following describes several types of changes that would require an Amendment to the HCP.

1. The listing under the ESA of a new species within the Plan Area that is not an HCP Covered Species but may be affected by HCP Covered Activities, and for which the permittee seeks coverage under the HCP and Section 10(a)(1)(B) permit.

2. Significant changes to the HCP including, but not limited to the following:

    a. Changes to the method for calculating compensation for incidental take, which would increase the levels of incidental take permitted for the HCP.

    b. A material change in the level of funding except as otherwise provided for in the HCP to account for all adjustments for inflation and changed circumstances.

3. Changes to the Covered Activities that were not addressed in the HCP as originally adopted, and which otherwise do not meet the provisions for Minor Modifications above.

4. Extending the term of the ITP past the 50-year term.

5. Changes in the Plan Area through acquisition of properties that exceed the limit of 10 percent of the Initial Plan Area (15,218 acres).

6. Changes in the Plan Area through the sale of properties that provide suitable habitat for any of the Covered Species or mitigation for impacts to these species on the remaining ownership and the new owner(s) do not wish to assume the obligations of the ITP through the process identified below in section 1.4.7.6.

1.4.7.3 Amendments to the Section 10(a)(1)(B) Permits

Amendments to the HCP will require an amendment to the Section 10(a)(1)(B) permit. Amendments to the Section 10(a)(1)(B) permit shall be processed in accordance with the provisions of the IA and all applicable legal requirements, including but not limited to the ESA, NEPA, and any applicable Federal regulations.

1.4.7.4 Permit Transfer

All or a portion of the ITP may be transferred to a third party in accordance with the current statutory and regulatory requirements governing such transfers. Currently, regulations governing ITP transfers are codified at 50 C.F.R. 13.25(b). If the sale or transfer of a single or multiple parcels over the term of the ITP cumulatively involves more than 10 percent of the Initial Plan Area (15,218 acres) and the new owner(s) do not wish to accept transfer of the ITP, then FGS must apply for an Amendment to the HCP and ITP (see section 1.4.7.2). For the "No Surprises" assurances for Yreka phlox to be extended to the new owner(s), the new owner(s) must continue to implement the conservation measures specified in the HCP.

If the sale or transfer involves land committed as mitigation under the HCP (i.e., CSAs) and the new owner(s) do not wish to transfer the ITP, then FGS must provide mitigation on the remainder of its ownership that is equivalent in value to the mitigation areas being sold or transferred. In consultation with the Service, FGS will select and maintain CSAs around activity centers that provide an equivalent level of mitigation based on total conservation value. FGS will adhere to the Plan measures (meeting the biological goals and objectives) on the remaining Plan Area for the original term of the ITP (50 years from issuance).

If the sale or transfer involves land where incidental take of owls is authorized under the HCP (i.e., 'take' sites) and the new owner(s) do not wish to transfer the ITP, then FGS must provide mitigation for the take of owls at the 3:1 mitigation ratio provided for in the Terrestrial Species Conservation Strategy. In consultation with the Service, FGS will select and maintain CSAs around activity centers on the remaining ownership that meet the 3:1 mitigation ratio based on total conservation value. FGS's mitigation commitment does not relieve the new owner's obligation under the Federal ESA.

FGS, however, will not be required to establish additional CSAs for mitigation on its ownership if the new owner(s) apply for and receive authorization for transfer of the ITP or if the land sold or transferred is mitigation for the take sites (i.e., at a 3:1 ratio based on conservation value). FGS will adhere to the Plan measures (meeting the biological goals and objectives) on the remaining Plan Area for the original term of the ITP (50 years from issuance).

1.4.7.5 Early Termination

In the event of early termination of the HCP and ITP, FGS will carry out all outstanding mitigation obligations as follows:

- FGS will mitigate any incidental take that has occurred as a result of habitat modification by maintaining one or more CSAs that provide an overall conservation value equal to at least three (3) times the conservation value of the activity centers where take has occurred for the original term of the ITP.

Under the HCP, incidental take through habitat modification is authorized at 43 known activity centers that provide 18 percent of the total conservation value of known activity centers in the Action Area. The impacts of this taking are mitigated by the development, protection, and enhancement of suitable northern spotted owl habitat on the FGS ownership within 24 CSAs that provide 55 percent of the total conservation value of known activity centers in the Action Area (a 3:1 ratio). This same mitigation ratio (3:1) will be used in the event of early termination to identify the appropriate level of mitigation for incidental take that has occurred prior to termination of the HCP and ITP.

The level of incidental take that has occurred prior to termination of the HCP will be based on the amount (acreage) and location of suitable northern spotted owl habitat within the core and home range of known activity centers within the Action Area that are rendered unsuitable. In the event of early termination of the HCP and ITP, FGS will field verify the extent of habitat conversion for activity centers where incidental take is authorized to determine, in consultation with the Service, the level of take that has occurred prior to termination of the HCP and ITP. The sum of the conservation value of those activity centers where incidental take due to habitat modification has occurred is the level of impact that must be mitigated at a 3:1 ratio. In consultation with the Service, FGS will select an adequate number of CSAs from those established in the Plan to meet the 3:1 mitigation ratio based on total conservation value. FGS will adhere to the Plan measures (harvest restrictions and habitat commitments) (see Table 1) in the selected CSAs for the original term of the ITP (50 years from issuance).

2.0 STATUS OF THE SPECIES

2.1 Northern Spotted Owl

2.1.1 Legal Status

The northern spotted owl was listed as threatened on June 26, 1990 due to widespread loss and adverse modification of suitable habitat across the owl’s entire range and the inadequacy of existing regulatory mechanisms to conserve the owl (USDI FWS 1990a). The U.S. Fish and Wildlife Service recovery priority number for the northern spotted owl is 6C, on a scale of 1C (highest) to 18 (lowest) (USDI FWS 1983a, 1983b, 2004a). This number reflects a high degree of threat, a low potential for recovery, and the owl’s taxonomic status as a subspecies. The “C” reflects conflict with development, construction, or other economic activity. The northern spotted owl was originally listed with a recovery priority number of 3C, but that number was changed to 6C in 2004 during the 5-year review of the species (USDI FWS 2004a).

2.1.2 Life History

2.1.2.1 Taxonomy

The northern spotted owl is one of three subspecies of spotted owls currently recognized by the American Ornithologists’ Union. The taxonomic separation of these three subspecies is supported by genetic (Barrowclough and Gutiérrez 1990, Barrowclough et al. 1999, Haig et al. 2004), morphological (Gutiérrez et al. 1995), and biogeographic information (Barrowclough and

Gutiérrez 1990). The distribution of the Mexican subspecies (*S. o. lucida*) is separate from those of the northern and California (*S. o. occidentalis*) subspecies (Gutiérrez et al. 1995). Recent studies analyzing mitochondrial DNA sequences (Haig et al. 2004, Chi et al. 2004, Barrowclough et al. 2005) and microsatellites (Henke et al., unpubl. data) confirmed the validity of the current subspecies designations for northern and California spotted owls. The narrow hybrid zone between these two subspecies, which is located in the southern Cascades and northern Sierra Nevadas, appears to be stable (Barrowclough et al. 2005).

2.1.2.2 Physical Description

The northern spotted owl is a medium-sized owl and is the largest of the three subspecies of spotted owls (Gutiérrez et al. 1995). It is approximately 18 inches to 19 inches long and the sexes are dimorphic, with males averaging about 13 percent smaller than females. The mean mass of 971 males taken during 1,108 captures was 1.28 pounds (out of a range of 0.95 pound to 1.52 pounds), and the mean mass of 874 females taken during 1,016 captures was 1.46 pounds (out of a range of 1.1 pounds to 1.95 pounds) (P. Loschl and E. Forsman, pers. comm. cited in USDI FWS 2008a). The northern spotted owl is dark brown with a barred tail and white spots on its head and breast, and it has dark brown eyes surrounded by prominent facial disks. Four age classes can be distinguished on the basis of plumage characteristics (Forsman 1981, Moen et al. 1991). The northern spotted owl superficially resembles the barred owl, a species with which it occasionally hybridizes (Kelly and Forsman 2004). Hybrids exhibit physical and vocal characteristics of both species (Hamer et al. 1994).

2.1.2.3 Current and Historical Range

The current range of the northern spotted owl extends from southwest British Columbia through the Cascade Mountains, coastal ranges, and intervening forested lands in Washington, Oregon, and California, as far south as Marin County (USDI FWS 1990a). The range of the northern spotted owl contacts the range of the range of the California spotted owl in northern California near the southern end of the Cascade Range (Thomas et al. 1990, USDI FWS 1992b, Barrowclough et al. 1999, Haig et al. 2001). The range of the northern spotted owl is partitioned into 12 physiographic provinces (see Figure 1) based on recognized landscape subdivisions exhibiting different physical and environmental features (Thomas et al. 1993). These provinces are distributed across the species' range as follows:

- Four provinces in Washington: Eastern Washington Cascades, Olympic Peninsula, Western Washington Cascades, Western Washington Lowlands

- Five provinces in Oregon: Oregon Coast Range, Willamette Valley, Western Oregon Cascades, Eastern Oregon Cascades, Oregon Klamath

- Three provinces in California: California Coast, California Klamath, California Cascades

The northern spotted owl is extirpated or uncommon in certain areas such as southwestern Washington and British Columbia. Timber harvest activities have eliminated, reduced or fragmented northern spotted owl habitat sufficiently to decrease overall population densities across its range, particularly within the coastal provinces where habitat reduction has been concentrated (Thomas and Raphael 1993).

2.1.2.4 Behavior

Locomotion

Northern spotted owls spend virtually their entire lives beneath the forest canopy (Courtney et al. 2004). It is adapted to maneuverability beneath the forest canopy rather than strong, sustained flight, and mostly makes numerous short flights during the day (Gutiérrez et al. 1995). Foraging is accomplished by moving from perch to perch through the forest, perching and waiting for prey activity and then pouncing on prey once it is located by sight or sound (Forsman 1976, 1980; Forsman et al. 1984; Gutiérrez et al. 1995).

Roosting and Thermoregulation

Northern spotted owls seek sheltered roosts to avoid inclement weather, summer heat, and predation (Forsman 1976, 1980; Barrows and Barrows 1978; Barrows 1981; Forsman et al. 1984; Ting 1998). During warm weather, northern spotted owls seek roosts in shady recesses of understory trees and occasionally will even roost on the ground (Barrows and Barrows 1978; Barrows 1981; Forsman et al. 1984; Gutiérrez et al. 1995). In winter, they roost relatively high near the bole of canopy trees with overhanging branches to shelter themselves from precipitation, or when sunny, will seek roosts with sun exposure (Sisco 1984). Both adults and juveniles have been observed drinking water, primarily during the summer, and is thought to be associated with thermoregulation (Gutiérrez et al. 1995).

Daily Activity Pattern

Northern spotted owls are primarily noctural (Forsman et al. 1984). They forage between dawn and dusk and sleep during the day with peak activity occurring during the two hours after sunset and the two hours prior to sunrise (Forsman et al. 1984, Gutiérrez et al. 1995, Delaney et al. 1999). They will sometimes take advantage of vulnerable prey near their roosts during the day (Laymon 1991, Sovern et al. 1994).

Agonistic Behavior and Territoriality

Northern spotted owls are territorial. They become alert when roosting whenever large birds fly over the canopy or when potential predators enter their nesting or roosting stands (Forsman 1976, Gutiérrez et al. 1995). They will actively defend their nests and young from predators (Forsman 1976, Gutiérrez et al. 1995). Northern spotted owls will regularly confront other northern spotted owls with aggressive vocal displays (Forsman 1976, 1980, Forsman et al. 1984, Gutiérrez et al. 1995, Franklin et al. 1996). Territorial defense is primarily effected by hooting, barking and whistle type calls. However, home ranges of adjacent pairs overlap (Forsman et al. 1984, Solis and Gutiérrez 1990) suggesting that the area defended is smaller than the area used for foraging. It appears that they learn to recognize their neighbor's voices and respond to them much less vigorously (Fitton 1991, Waldo 2002). Some northern spotted owls are not territorial but either remain as residents within the territory of a pair or move among territories (Gutiérrez 1996). These birds are referred to as “floaters.” Floaters have special significance in northern spotted owl populations because they may buffer the territorial population from decline (Franklin 1992). Little is known about floaters other than that they exist and typically do not respond to calls as vigorously as territorial birds (Gutiérrez 1996).

Pair Behavior

Northern spotted owls are monogamous and usually form long-term pair bonds. “Divorces” occur but are relatively uncommon. There are no known examples of polygyny in this owl, although associations of three or more birds have been reported (Gutiérrez et al. 1995).

2.1.2.5 Habitat Relationships

Home Range

Home-range sizes vary geographically, generally increasing from south to north, which is likely a response to differences in habitat quality (USDI FWS 1990a). Estimates of median size of their annual home range (the area traversed by an individual or pair during their normal activities (Thomas and Raphael 1993) vary by province and range from 2,955 acres in the Oregon Cascades (Thomas et al. 1990) to 14,211 acres on the Olympic Peninsula (USDI FWS 1994a). Zabel et al. (1995) showed that these provincial home ranges are larger where flying squirrels (*Glaucomys sabrinus*) are the predominant prey and smaller where wood rats (*Neotoma* spp.) are the predominant prey. Home ranges of adjacent pairs overlap (Forsman et al. 1984, Solis and Gutiérrez 1990), suggesting that the defended area is smaller than the area used for foraging. Within the home range there is a smaller area of concentrated use during the breeding season (~20% of the home range), often referred to as the core area (Bingham and Noon 1997). Northern spotted owl core areas vary in size geographically and provide habitat elements that are important for the reproductive efficacy of the territory, such as the nest tree, roost sites and foraging areas (Bingham and Noon 1997). Northern spotted owls use smaller home ranges during the breeding season and often dramatically increase their home range size during fall and winter (Forsman et al. 1984, Sisco 1990).

Although differences exist in natural stand characteristics that influence home range size, habitat loss and forest fragmentation effectively reduce habitat quality in the home range. A reduction in the amount of suitable habitat reduces northern spotted owl abundance and nesting success (Bart and Forsman 1992, Bart 1995).

Habitat Use and Selection

Forest types that support the northern spotted owl across its geographic range include Douglas-fir, western hemlock (*Tsuga heterophylla*), grand fir (*Abies grandis*), white fir, Pacific silver fir (*Abies amabilis*), Shasta red fir (*Abies magnifica shastensis*), Sitka spruce (*Picea sitchensis*), mixed evergreen, mixed conifer hardwood (Klamath montane), redwood (*Sequoia sempervirens*) in coastal California and southwestern Oregon, and the moist end of the ponderosa pine coniferous forests zones at elevations up to approximately 3,000 feet near the northern edge of the range and up to approximately 6,000 feet at the southern edge (Forsman et al. 1984, Franklin and Dyrness 1988, Thomas et al. 1990, Davis and Lint 2005). The upper elevation limit at which northern spotted owls occur corresponds to the transition to subalpine forest, which is characterized by relatively simple structure and severe winter weather (Forsman 1976, Forsman et al. 1984).

Northern spotted owls generally rely on older forested habitats because such forests contain the structures and characteristics required for nesting, roosting, and foraging. Features that support nesting and roosting typically include a moderate to high canopy closure (60 to 90 percent); a multi-layered, multi-species canopy with large overstory trees (generally greater than 30 inches dbh); a high incidence of large trees with various deformities (large cavities, broken tops, mistletoe infections, and other platforms); large snags; large accumulations of fallen trees and other woody debris on the ground; and sufficient open space below the canopy for northern spotted owls to fly (Thomas et al. 1990). Nesting and roosting northern spotted owls consistently occupy stands with a high degree of canopy closure that may provide thermoregulatory benefits (Weathers et al. 2001), and protection from predators and adverse weather conditions. Patches of nesting habitat, in combination with roosting habitat, must be sufficiently large and contiguous to maintain northern spotted owl core areas and home ranges, and must be proximate to foraging habitat.

Northern spotted owls nest almost exclusively in trees. Like roosts, nest sites are found in forests having complex structure dominated by large diameter trees (Forsman et al. 1984, Hershey et al. 1998). Even in forests that have been previously logged, northern spotted owls select forests having a structure (i.e., larger trees, greater canopy closure) different than forests generally available to them (Folliard 1993, Buchanan et al. 1995, Hershey et al. 1998). Nesting habitat can also function as roosting, foraging, and dispersal habitat.

Roosting habitat differs from nesting habitat in that it need not contain those specific structural features used for nesting, such as cavities, broken tops, and mistletoe platforms. Roost sites selected by northern spotted owls have more complex vegetation structure than forests generally available to them (Barrows and Barrows 1978, Forsman et al. 1984, Solis and Gutiérrez 1990). These habitats are usually multi-layered forests having high canopy closure and large diameter trees in the overstory. Roosting habitat will also function as foraging and dispersal habitat, but not as nesting habitat due to lack of nesting structures.

Foraging habitat for northern spotted owls provides a food supply for survival and reproduction. Foraging habitat is the most variable of all habitats used by territorial northern spotted owls (USDI FWS 1992b). Descriptions of foraging habitat have ranged from complex structure (Solis and Gutiérrez 1990) to forests with lower canopy closure and smaller trees than forests containing nests or roosts (Gutiérrez 1996). Foraging activity is positively associated with tree height diversity (North et al. 1999), canopy closure (Irwin et al. 2000, Courtney et al. 2004), snag volume, density of snags greater than 20 in dbh (North et al. 1999, Irwin et al. 2000, Courtney et al. 2004), density of trees greater than or equal to 31 in dbh (North et al. 1999), volume of woody debris (Irwin et al. 2000), and young forests with some structural characteristics of old forests (Carey et al.1992, Irwin et al. 2000). Northern spotted owls select old forests for foraging in greater proportion than their availability at the landscape scale (Carey et al. 1992, Carey and

Peeler 1995, Forsman et al. 2004), but will forage in younger stands with high prey densities and access to prey (Carey et al. 1992, Rosenberg and Anthony 1992, Thome et al. 1999). Foraging habitat contains some roosting habitat attributes but can consist of more open and fragmented forests or, especially in the southern portion of the range, some younger stands may have high prey abundance and structural attributes similar to those of older forests (e.g., moderate tree density, subcanopy perches at multiple levels, multi-layered vegetation, residual older trees). Foraging habitat can also function as dispersal habitat.

Dispersal habitat is essential to maintaining stable populations by filling territorial vacancies when resident northern spotted owls die or leave their territories, and for providing adequate gene flow across the range of the species. Dispersal habitat includes forest types that support either the transience phase of dispersal or the colonization phase of dispersal. Habitat supporting the transience phase of dispersal consists, at a minimum, of stands with adequate tree size and canopy closure to provide protection from avian predators and at least minimal foraging opportunities. Dispersal habitat may include younger and less diverse forest stands than foraging habitat, such as even-aged, pole-sized stands, but such stands should contain some roosting structures and foraging habitat to allow for temporary resting and feeding for dispersing juveniles (USDI FWS 1992a). Habitat supporting the colonization phase of dispersal is generally equivalent to roosting and foraging habitat, although it may be in smaller amounts than that needed to support nesting pairs. Forsman et al. (2002) found that northern spotted owls could disperse through highly fragmented forest landscapes. However, the stand-level and landscape-level attributes of forests needed to facilitate successful dispersal have not been thoroughly evaluated (Buchanan 2004).

Northern spotted owls may be found in younger forest stands that have the structural characteristics of older forests or retained structural elements from the previous forest. In redwood forests and mixed conifer-hardwood forests along the coast of northwestern California, considerable numbers of northern spotted owls also occur in younger forest stands, particularly in areas where hardwoods provide a multi-layered structure at an early age (Thomas et al. 1990; Diller and Thome 1999). In mixed conifer forests in the eastern Cascades in Washington, 27 percent of nest sites were in old-growth forests, 57 percent were in the understory reinitiation phase of stand development, and 17 percent were in the stem exclusion phase (Buchanan et al. 1995). In the western Cascades of Oregon, 50 percent of northern spotted owl nests were in late-seral/old-growth stands (greater than 80 years old), and none were found in stands less than 40 years old (Irwin et al. 2000).

In the Western Washington Cascades, northern spotted owls roosted in mature forests dominated by trees greater than 19.7 inches dbh with greater than 60 percent canopy closure more often than expected during the non-breeding season. Northern spotted owls also used young forest (trees of 7.9 inches to 19.7 inches dbh with greater than 60 percent canopy closure) less often than expected based on the availability of this habitat (Herter et al. 2002).

In the Coast Ranges, Western Oregon Cascades and the Olympic Peninsula, radio-marked northern spotted owls selected old-growth and mature forests for foraging and roosting and used young forests less than predicted based on availability (Forsman et al. 1984, Carey et al. 1990, Forsman et al. 2005). Glenn et al. (2002) studied northern spotted owls in young forests in western Oregon and found little preference among age classes of young forest.

Habitat use is influenced by prey availability. Ward (1990) found that northern spotted owls foraged in areas with lower variance in prey densities (that is, where the occurrence of prey was more predictable) within older forests and near ecotones of old forest and brush seral stages. Zabel et al. (1995) showed that northern spotted owl home ranges are larger where flying squirrels are the predominant prey and smaller where wood rats are the predominant prey.

Recent landscape-level analyses in portions of the Oregon Coast and California Klamath provinces suggest that a mosaic of late-successional habitat interspersed with other seral conditions may benefit northern spotted owls more than large, homogeneous expanses of older forests (Meyer et al. 1998, Franklin et al. 2000, Zabel et al. 2003). In the Oregon Klamath and Western Oregon Cascade provinces, Dugger et al. (2005) found that apparent survival and reproduction was positively associated with the proportion of older forest near the territory center (within 2,395 feet). Survival decreased dramatically when the amount of non-habitat (e.g., non-forest areas, sapling stands) exceeded approximately 50 percent of the home range (Dugger et al. 2005). The authors concluded that they found no support for either a positive or negative direct effect of intermediate-aged forest (i.e., forest stages between sapling and mature, with total canopy cover greater than 40 percent) on either the survival or reproduction of northern spotted owls. It is unknown how these results were affected by the low habitat fitness potential in their study area, which Dugger et al. (2005) stated was generally much lower than those in Franklin et al. (2000) and Olson et al. (2004), and the low reproductive rate and survival in their study area, which they reported were generally lower than those studied by Anthony et al. (2006). Olson et al. (2004) found that reproductive rates fluctuated biennially and were positively related to the amount of edge between late-seral and mid-seral forests and other habitat classes in the central Oregon Coast Range. Olson et al. (2004) concluded that their results indicate that while mid-seral and late-seral forests are important to northern spotted owls, a mixture of these forest types with younger forest and non-forest may be best for northern spotted owl survival and reproduction in their study area.

2.1.2.6 Reproductive Biology

The northern spotted owl is relatively long-lived, has a long reproductive life span, invests significantly in parental care, and exhibits high adult survivorship relative to other North American owls (Forsman et al. 1984, Gutiérrez et al. 1995). Northern spotted owls are sexually mature at 1 year of age, but rarely breed until they are 2 to 5 years of age (Miller et al. 1985, Franklin 1992, Forsman et al. 2002). Breeding females lay one to four eggs per clutch, with the average clutch size being two eggs; however, most northern spotted owl pairs do not nest every year, nor are nesting pairs successful every year (Forsman et al. 1984, USDI FWS 1990b, Anthony et al. 2006), and renesting after a failed nesting attempt is rare (Gutiérrez 1996). The small clutch size, temporal variability in nesting success, and delayed onset of breeding all contribute to the relatively low fecundity of this species (Gutiérrez 1996).

Courtship behavior usually begins in February or March, and females typically lay eggs in late March or April. The timing of nesting and fledging varies with latitude and elevation (Forsman et al. 1984). After they leave the nest in late May or June, juvenile northern spotted owls depend on their parents until they are able to fly and hunt on their own. Parental care continues after fledging into September (Forsman et al. 1984, USDI FWS 1990a). During the first few weeks after the young leave the nest, the adults often roost with them during the day. By late summer, the adults are rarely found roosting with their young and usually only visit the juveniles to feed them at night (Forsman et al. 1984). Telemetry and genetic studies indicate that close inbreeding between siblings or parents and their offspring is rare (Haig et al. 2001, Forsman et al. 2002). Hybridization of northern spotted owls with California spotted owls and barred owls has been confirmed through genetic research (Hamer et al. 1994, Gutiérrez et al. 1995, Dark et al. 1998, Kelly 2001, Funk et al. 2008).

2.1.2.7 Dispersal Biology

Natal dispersal of northern spotted owls typically occurs in September and October with a few individuals dispersing in November and December (Miller et al. 1997, Forsman et al. 2002). Natal dispersal occurs in stages, with juveniles settling in temporary home ranges between bouts of dispersal (Miller et al. 1997, Forsman et al. 2002). The median natal dispersal distance is about 10 miles for males and 15.5 miles for females (Forsman et al. 2002). Dispersing juvenile northern spotted owls experience high mortality rates, exceeding 70 percent in some studies (Miller 1989, USDI FWS 1990a). Known or suspected causes of mortality during dispersal include starvation, predation, and accidents (Miller 1989, USDI FWS 1990a, Forsman et al. 2002). Parasitic infection may contribute to these causes of mortality, but the relationship between parasite loads and survival is poorly understood (Hoberg et al. 1989, Gutiérrez 1989, Forsman et al. 2002). Successful dispersal of juvenile northern spotted owls may depend on their ability to locate unoccupied suitable habitat in close proximity to other occupied sites (LaHaye et al. 2001).

There is little evidence that small openings in forest habitat influence the dispersal of northern spotted owls, but large, non-forested valleys such as the Willamette Valley apparently are barriers to both natal and breeding dispersal (Forsman et al. 2002). The degree to which water bodies, such as the Columbia River and Puget Sound, function as barriers to dispersal is unclear, although radio telemetry data indicate that northern spotted owls move around large water bodies rather than cross them (Forsman et al. 2002). Analysis of the genetic structure of northern spotted owl populations suggests that gene flow may have been adequate between the Olympic Mountains and the Washington Cascades, and between the Olympic Mountains and the Oregon Coast Range (Haig et al. 2001).

Breeding dispersal occurs among a small proportion of adult northern spotted owls; these movements were more frequent among females and unmated individuals (Forsman et al. 2002). Breeding dispersal distances were shorter than natal dispersal distances and also are apparently random in direction (Forsman et al. 2002). In California spotted owls, a similar subspecies, the probability for dispersal was higher in younger owls, single owls, paired owls that lost mates, owls at low quality sites, and owls that failed to reproduce in the preceeding year (Blakesley et al. 2006). Both males and females dispersed at near equal proportions and distances (Blakesley et al. 2006). Dispersal resulted in improved territory quality in 72 percent of cases (Blakesley et al. 2006).

2.1.2.8 Food Habits

Northern spotted owls are mostly nocturnal, although they also forage opportunistically during the day (Forsman et al. 1984, Sovern et al. 1994). The composition of the northern spotted owl's diet varies geographically and by forest type. Generally, flying squirrels are the most prominent prey for northern spotted owls in Douglas-fir and western hemlock forests (Forsman et al. 1984) in Washington and Oregon, while dusky-footed wood rats (*Neotoma fuscipes*) are a major part of the diet in the Oregon Klamath, California Klamath, and California Coastal provinces (Forsman et al. 1984, 2001, 2004, Ward et al. 1998, Hamer et al. 2001). Depending on location, other important prey include deer mice (*Peromyscus maniculatus*), tree voles (*Arborimus longicaudus, A. pomo*), red-backed voles (*Clethrionomys* gapperi), gophers (*Thomomys* spp.), snowshoe hare (*Lepus americanus*), bushy-tailed wood rats (*Neotoma cinerea*), birds, and insects, although these species comprise a small portion of the northern spotted owl diet (Forsman et al. 1984, 2004, Ward et al. 1998, Hamer et al. 2001).

Other prey species such as the red tree vole (*Arborimus longicaudus)*, red-backed voles, mice, rabbits and hares, birds, and insects may be seasonally or locally important (reviewed by Courtney et al. 2004). For example, Rosenberg et al. (2003) showed a strong correlation between annual reproductive success of northern spotted owls (number of young per territory) and abundance of deer mice ($r^2 = 0.68$), despite the fact they only made up 1.6±0.5 percent of the biomass consumed. However, it is unclear if the causative factor behind this correlation was prey abundance or a synergistic response to weather (Rosenberg et al. 2003). Ward (1990) also noted that mice were more abundant in areas selected for foraging by owls. Nonetheless, northern spotted owls deliver larger prey to the nest and eat smaller food items to reduce foraging energy costs; therefore, the importance of smaller prey items, like *Peromyscus*, in the northern spotted owl diet should not be underestimated (Forsman et al. 1984, 2001, 2004).

2.1.2.9 Population Dynamics

The northern spotted owl is relatively long-lived, has a long reproductive life span, invests significantly in parental care, and exhibits high adult survivorship relative to other North American owls (Forsman et al. 1984, Gutiérrez et al. 1995). The northern spotted owl's long reproductive life span allows for some eventual recruitment of offspring, even if recruitment does not occur each year (Franklin et al. 2000).

Annual variation in population parameters for northern spotted owls has been linked to environmental influences at various life history stages (Franklin et al. 2000). In coniferous forests, mean fledgling production of the California spotted owl, a closely related subspecies, was higher when minimum spring temperatures were higher (North et al. 2000), a relationship that may be a function of increased prey availability. Across their range, northern spotted owls have previously shown an unexplained pattern of alternating years of high and low reproduction, with highest reproduction occurring during even-numbered years (e.g., Franklin et al. 1999). Annual variation in breeding may be related to weather (i.e., temperature and precipitation; Wagner et al. 1996 and Zabel et al. 1996 *In*: Forsman et al. 1996) and fluctuation in prey abundance (Zabel et al. 1996).

A variety of factors may regulate northern spotted owl population levels. These factors may be density-dependent (e.g., habitat quality, habitat abundance) or density-independent (e.g., climate). Interactions may occur among factors. For example, as habitat quality decreases, density-independent factors may have more influence on survival and reproduction, which tends to increase variation in the rate of growth (Franklin et al. 2000). Specifically, weather could have increased negative effects on northern spotted owl fitness for those owls occurring in relatively lower quality habitat (Franklin et al. 2000). A consequence of this pattern is that at some point, lower habitat quality may cause the population to be unregulated (have negative growth) and decline to extinction (Franklin et al. 2000).

Olson et al. (2005) used open population modeling of site occupancy that incorporated imperfect and variable detectability of northern spotted owls and allowed modeling of temporal variation in site occupancy, extinction, and colonization probabilities (at the site scale). The authors found that visit detection probabilities average less than 0.70 and were highly variable among study years and among their three study areas in Oregon. Pair site occupancy probabilities declined greatly on one study area and slightly on the other two areas. However, for all owls, including singles and pairs, site occupancy was mostly stable through time. Barred owl presence had a negative effect on these parameters (see barred owl discussion in the New Threats section below). However, there was enough temporal and spatial variability in detection rates to indicate that more visits would be needed in some years and in some areas, especially if establishing pair occupancy was the primary goal.

2.1.3 Threats

2.1.3.1 Reasons for Listing

The northern spotted owl was listed as threatened throughout its range "due to loss and adverse modification of suitable habitat as a result of timber harvesting and exacerbated by catastrophic events such as fire, volcanic eruption, and wind storms" (USDI FWS 1990a). More specifically, threats to the northern spotted owl included low populations, declining populations, limited habitat, declining habitat, inadequate distribution of habitat or populations, isolation of provinces, predation and competition, lack of coordinated conservation measures, and vulnerability to natural disturbance (USDI FWS 1992a). These threats were characterized for each of the 12 provinces within the range of the northern spotted owl as severe, moderate, low or unknown (USDI FWS 1992a; see Figure 1). Declining habitat was recognized as a severe or moderate threat to the northern spotted owl throughout its range, isolation of populations was identified as a severe or moderate threat in 11 provinces, and a decline in population was a severe or moderate threat in 10 provinces. Together, these three factors represented the greatest concerns about range-wide conservation of the northern spotted owl. Limited habitat was considered a severe or moderate threat in nine provinces, and low populations were a severe or moderate concern in eight provinces, suggesting that these factors were also a concern throughout the majority of the northern spotted owl's range. Vulnerability to natural disturbances was rated as low in five provinces.

The degree to which predation and competition might pose a threat to the northern spotted owl was unknown in more provinces than any of the other threats, indicating a need for additional information. Few empirical studies exist to confirm that habitat fragmentation contributes to increased levels of predation on northern spotted owls (Courtney et al. 2004). However, great horned owls (*Bubo virginianus*), an effective predator on northern spotted owls, are closely associated with fragmented forests, openings, and clearcuts (Johnson 1992, Laidig and Dobkin 1995). As mature forests are harvested, great horned owls may colonize fragmented forests, thereby increasing northern spotted owl vulnerability to predation.

2.1.3.2 New Threats

The Service conducted a 5-year review of the northern spotted owl in 2004 (USDI FWS 2004a), for which the Service prepared a scientific evaluation of the status of the northern spotted owl (Courtney et al. 2004). An analysis was conducted assessing how the threats described in 1990 might have changed by 2004. Some of the key threats identified in 2004 are:

- "Although we are certain that current harvest effects are reduced, and that past harvest is also probably having a reduced effect now as compared to 1990, we are still unable to fully evaluate the current levels of threat posed by harvest because of the potential for lag effects…In their questionnaire responses…6 of 8 panel member identified past habitat loss due to timber harvest as a current threat, but only 4 viewed current harvest as a present threat." (Courtney and Gutiérrez 2004)

- "Currently the primary source of habitat loss is catastrophic wildfire, although the total amount of habitat affected by wildfires has been small (a total of 2.3% of the range-wide habitat base over a 10-year period)." (Courtney and Gutiérrez 2004)

- "Although the panel had strong differences of opinion on the conclusiveness of some of the evidence suggesting [barred owl] displacement of [northern spotted owls], and the mechanisms by which this might be occurring, there was no disagreement that [barred owls] represented an operational threat. In the questionnaire, all 8 panel members identified [barred owls] as a current threat, and also expressed concern about future trends in [barred owl] populations." (Courtney and Gutiérrez 2004)

Barred Owls (Strix varia)

With its recent expansion to as far south as Marin County, California along the Coast Range and Kings Canyon National Park in the southern Sierra Nevada (Gutiérrez et al. 2004), the barred owl's range now completely overlaps that of the northern spotted owl. Barred owls may be affecting northern spotted owls through competition for resources, direct harm through aggressive behavior, and hybridization. Barred owls may be competing with northern spotted owls for prey (Hamer et al. 2001) or habitat (Hamer et al. 1989, Dunbar et al. 1991, Herter and Hicks 2000, Pearson and Livezey 2003). In addition, barred owls physically attack northern spotted owls (Pearson and Livezey 2003), and in at least one situation, a barred owl may have killed a northern spotted owl (Leskiw and Gutiérrez 1998). Evidence that barred owls are causing negative effects on northern spotted owls is largely indirect, based primarily on retrospective examination of long-term data collected on northern spotted owls (Kelly et al. 2003, Pearson and Livezey 2003, Olson et al. 2005). Recent research has shown that the two species of owls share similar habitats and are likely competing for food resources (Hamer et al. 2001, 2007; Singleton et al. 2010). Research on barred owls and their interactions with northern spotted owls is lacking, but necessary to determine the specific effects barred owls may have on northern spotted owls and their habitat. Because the effects of barred owls on northern spotted owls have been realized while solely conducting research and monitoring of northern spotted owls, the effects of barred owls are likely underestimated. Because there has been no research to quantitatively evaluate the strength of different types of competitive interactions, such as resource partitioning and competitive interference, the particular mechanism by which the two owl species may be competing is unknown.

Barred owls, though they are generalists, likely compete with northern spotted owls for prey resources (Hamer et al. 2001, 2007; Gutiérrez et al. 2007; Livezey and Fleming 2007). The only study comparing northern spotted owl and barred owl food habits in the Pacific Northwest indicated that barred owl diets overlap strongly (76 percent) with northern spotted owl diets (Hamer et al. 2001, 2007). Barred owl diets are more diverse than northern spotted owl diets and include species associated with riparian and other moist habitats (e.g. fish, invertebrates, frogs, and crayfish), along with more terrestrial and diurnal species (Smith et al. 1983; Mazur and James 2000; Hamer et al. 2001, 2007; Gronau 2005). Because barred owls took a much lower proportion of the four primary prey species taken by northern spotted owls (Hamer et al. 2001, 2007), barred owls may only be opportunistically taking northern spotted owl prey and not necessarily selecting for the same prey species (Gutiérrez et al. 2007). Even though barred owls may be taking northern spotted owls' primary prey only as a generalist, northern spotted owls may be affected by a sufficient reduction in the density of these prey items due to barred owls, leading to a depletion of prey to the extent that the northern spotted owl cannot find an adequate amount of food to sustain maintenance or reproduction (Gutiérrez et al. 2007, Livezey and Fleming 2007).

Barred owls were initially thought to be more closely associated with early successional forests than northern spotted owls, based on studies conducted on the west slope of the Cascades in Washington (Hamer 1988, Iverson 1993). However, recent studies conducted in the Pacific Northwest show that barred owls frequently use mature and old-growth forests (Pearson and Livezey 2003, Gremel 2005, Schmidt 2006). In the fire prone forests of eastern Washington, a telemetry study conducted on barred owls showed that barred owl home ranges were located on lower slopes or valley bottoms, in closed canopy, mature, Douglas-fir forest, while northern spotted owl sites were located on mid-elevation areas with southern or western exposure, characterized by closed canopy, mature, ponderosa pine or Douglas-fir forest (Singleton et al. 2005). More recently, Singleton et al. (2010) found that barred owls preferred multispecies, structurally diverse forests with high canopy closure dominated by large overstory trees similar to northern spotted owls, however, barred owls also showed a preference for lower topographical areas and gentler slopes not usually preferred by northern spotted owls. Additionally, the two species use the same types of nests (Devereux and Mosher 1984, Forsman et al. 1984, Hamer 1988, Postupalsky et al. 1997). Although there are no estimates for home range sizes of barred owls in Oregon or California (Gutiérrez et al. 2007), northern spotted owl home ranges in Washington can be up to eight times larger than those of barred owls (Singleton et al. 2010).

The presence of barred owls has been reported to reduce northern spotted owl site occupancy, reproduction, and survival. The occupancy of historical territories by northern spotted owls in Washington and Oregon was significantly lower ($p < 0.001$) after barred owls were detected within 0.5 miles of the territory center but was "only marginally lower" ($p = 0.06$) if barred owls were located more than 0.5 miles from the northern spotted owl territory center (Kelly et al. 2003). Pearson and Livezey (2003) found that there were significantly more barred owl site-centers in unoccupied northern spotted owl circles than occupied northern spotted owl circles (centered on historical northern spotted owl site-centers) with radii of 0.5 miles ($p = 0.001$), 1 mile ($p = 0.049$), and 1.8 miles ($p = 0.005$) in Gifford Pinchot National Forest. In Olympic National Park, Gremel (2005) found a significant decline ($p = 0.01$) in northern spotted owl pair occupancy at sites where barred owls had been detected, while pair occupancy remained stable at northern spotted owl sites without barred owls. Olson et al. (2005) found that the annual probability that a northern spotted owl territory would be occupied by a pair of northern spotted owls after barred owls were detected at the site declined by 5 percent in the HJ Andrews study area, 12 percent in the Coast Range study area, and 15 percent in the Tyee study area. Contrastingly, Bailey et al. (2009), when using a two-species occupancy model, showed no evidence that barred owls excluded northern spotted owls from territories in Oregon. Most recently, preliminary results from a barred owl and northern spotted owl radio-telemetry study in Washington reported two northern spotted owls fleeing their territories and traveling six and 15 miles, believed to be as a result of frequent direct encounters with barred owls (Irwin et al. 2010). Both northern spotted owls were subsequently found dead (Irwin et al. 2010).

Olson et al. (2004) found that the presence of barred owls had a significant negative effect on the reproduction of northern spotted owls in the central Coast Range of Oregon (in the Roseburg study area). The conclusion that barred owls had no significant effect on the reproduction of northern spotted owls in one study (Iverson 2004) was unfounded because of small sample sizes (Livezey 2005). It is likely that all of the above analyses underestimated the effects of barred owls on the reproduction of northern spotted owls because northern spotted owls often cannot be relocated after they are displaced by barred owls (E. Forsman, pers. comm., cited in USDI FWS 2008a). Anthony et al. (2006) found significant evidence for negative effects of barred owls on apparent survival of northern spotted owls in two of 14 study areas (Olympic and Wenatchee). They attributed the equivocal results for most of their study areas to the coarse nature of their barred owl covariate. When examining current literature, Gutiérrez et al. (2007) found that productivity of barred owls and northern spotted owls are similar where their ranges do not overlap, leading to the assumption that barred owls likely produce more young overall than northern spotted owls, or have a higher success rate. Barred owls in a 3-year study in western Washington (Hamer 1988) produced more young than a sympatric group of northern spotted owls.

[1] Best model included age and even-odd year effects, but a competing model had a negative time effect on productivity.
[2] Variable among years, but with a declining trend.
[3] Decreasing in early years, increase in last 5 years, stable overall.
[4] Gradual declines in fecundity and apparent survival, plus estimates of realized population change suggest a decline in last 8 years.

Figure 1. Physiographic provinces, northern spotted owl demographic study areas, and demographic trends (Anthony et al. 2006).

Barred owls and northern spotted owls occasionally hybridize and produce fertile young (Hamer et al. 1994, Kelly and Forsman 2004), although it is relatively uncommon (Gutiérrez et al. 2007). In a recent analysis of more than 9,000 banded northern spotted owls throughout their range, 47 hybrids were detected (Kelly and Forsman 2004). Hybridization with the barred owl is considered to be "an interesting biological phenomenon that is probably inconsequential, compared with the real threat—direct competition between the two species for food and space" (Kelly and Forsman 2004). However, because hybridization is often more prevalent when one species is rare or limiting or when one species is a recent invader of new habitat (Randler 2002), the likelihood of barred owls mating with northern spotted owls may become more likely, especially as barred owls become more common (Gutiérrez et al. 2007).

Monitoring and management of northern spotted owls has become more complicated due to their possible reduced detectability when barred owls are present (Kelly et al. 2003, Courtney et al. 2004, Olson et al. 2005, Crozier et al. 2006). Olson et al. (2005) found that the presence of barred owls had a significant negative effect on the detectability of northern spotted owls, and that the magnitude of this effect did not vary among years. In a study simulating presence of barred owls, Crozier et al. (2006) determined that the presence of barred owls might negatively affect responsiveness of northern spotted owls. Both northern spotted owls and California spotted owls responded less frequently in areas having high numbers of barred owls (Crozier et al. 2006). Lower response and calling of northern spotted owls could interfere with their ability to establish and defend territories. Evidence that northern spotted owls were responding less frequently during surveys led the Service and its many research partners to update the northern spotted owl survey protocol, with the updated draft protocol being released in February 2010. The changes were based on the probability of detecting northern spotted owls when barred owls are present (USDI FWS 2010a). No systematic surveys for barred owls have been conducted within the range of the northern spotted owl (Gutiérrez et al. 2007), but should be considered to determine the rate and extent of expansion and overlap with the northern spotted owl, and the interaction between the two species to aid in management (Livezey and Fleming 2007).

In areas where population sizes are extremely small, barred owls may pose an even larger threat. In British Columbia, Canada, relocation of barred owls has proven unsuccessful when one barred owl that was relocated 62 miles across three mountain ranges returned to the same location in which it was captured within one year (Pynn 2010). Biologists eventually lethally controlled 12 barred owls that represented competition to the remaining six northern spotted owls occurring in the wild after these relocation efforts were unsuccessful (Pynn 2010).

Evidence suggests that barred owls are exacerbating the northern spotted owl population decline, particularly in Washington, portions of Oregon, and the northern coast of California (Dark et al. 1998; Gutiérrez et al. 2004, 2007; Courtney et al. 2004; Olson et al. 2005). There is no evidence that the increasing trend in barred owls has stabilized in any portion of the northern spotted owl's range in the western United States, and "there are no grounds for optimistic views suggesting that barred owl impacts on northern spotted owls have been already fully realized" (Gutiérrez et al. 2004).

Wildfire

Studies indicate that the effects of wildfire on northern spotted owls and their habitat are variable, depending on fire intensity, severity and size. Within the fire-adapted forests of the northern spotted owl's range, northern spotted owls likely have adapted to withstand fires of variable sizes and severities. However, fire is often considered a primary threat to northern spotted owls because of its potential to rapidly alter habitat (Bond et al. 2009) and is a major cause of habitat loss on Federal lands (Courtney et al. 2004). Bond et al. (2002) examined the demography of the three spotted owl subspecies after wildfires, in which wildfire burned through spotted owl nest and roost sites in varying degrees of severity. Post-fire demography parameters for the three subspecies were similar or better than long-term demographic parameters for each of the three subspecies in those same areas (Bond et al. 2002). In a study of fire effects of seven radiomarked California spotted owls in the southern Sierra Nevada of California, Bond et al. (2009) found that most owls foraged in high-severity burned forest more than all other burn categories, and actually avoided unburned forest within one kilometer of the center of their foraging areas. In a preliminary study conducted by Anthony and Andrews (2004) in the Oregon Klamath Province, their sample of northern spotted owls appeared to be using a variety of habitats within the area of the Timbered Rock fire, including areas where burning had been moderate.

At the time of listing there was recognition that large-scale wildfire posed a threat to the northern spotted owl and its habitat (USDI FWS 1990b, 1992b). New information suggests fire may be more of a threat than previously thought. It has been estimated that the rate of habitat loss due to stand-replacing fire within Federal lands managed under the Northwest Forest Plan (NWFP; USDA FS and USDI BLM 1994b) was almost 140,000 acres between 1993-2004 (Moeur et al. 2005). Up until 2005, the overall total amount of habitat loss from wildfires was relatively small, estimated at approximately 1.2 percent on Federal lands (Lint 2005), but this estimation does not take into account habitat lost during the more recent large fires (i.e. 2007, 2008).

During the 2008 fire season, greater than one million acres burned in northern and central California. More than 2,700 individual fires were ignited, mostly due to lightning from a storm that passed through the state in mid-June. These fires encompassed 203,320 acres of the neighboring STNF in Trinity County, affecting approximately 100 northern spotted owl activity centers (USDI FWS unpubl. data). Within the Mendocino National Forest (MNF), nearly 100,000 acres burned in the Yolla Bolly Complex during the 2008 fire season. The MNF estimates that approximately 59,354 acres of the Yolla Bolly Wilderness adjacent to the project area burned, mostly at low intensity, but also included isolated patches of stand replacing fires, the two largest being 1,900 and 550 acres. Also within the MNF, the Soda Complex burned 9,100 acres during the 2008 fire season.

Several large fires burned in the eastern Cascade Range during the 1994 fire season, negatively affecting multiple northern spotted owl territories (Bevis et al. 1997, Gaines et al. 1997). In 1994, the Hatchery Complex fire burned 43,498 acres in the Wenatchee National Forest in Washington's eastern Cascades, affecting six northern spotted owl activity centers (Gaines et al. 1997). Northern spotted owl habitat within a 1.8-mile radius of the activity centers was reduced by eight to 45 percent (mean = 31 percent) as a result of the direct effects of the fire and by 10 to

85 percent (mean = 55 percent) as a result of delayed mortality of fire-damaged trees and insects. Direct mortality of northern spotted owls was assumed to have occurred at one site, and northern spotted owls were present at only one of the six sites one year after the fire. In 1994, two wildfires burned in the Yakama Indian Reservation in Washington's eastern Cascades, affecting the home ranges of two radio-tagged northern spotted owls (King et al. 1998). Although the amount of home ranges burned was not quantified, northern spotted owls were observed using areas that burned at low and medium intensities. No direct mortality of northern spotted owls was observed, even though thick smoke covered several northern spotted owl site-centers for a week. It appears that, at least in the short term, northern spotted owls may be resilient to the effects of wildfire—a process with which they have evolved. Hanson et al. (2009) believes northern spotted owls are actually suffering adverse consequences from a deficit of fire, which creates habitat necessary for an abundance of their key prey species. More research is needed to further understand the relationship between fire and northern spotted owl habitat use. In a recent paper, Hanson et al. (2009) propose that the fire risk was overestimated in the Recovery Plan, and the effects of fire and silvicultural treatment tools should be further researched.

West Nile Virus

West Nile virus (WNV), caused by a virus in the family Flaviviridae, has killed millions of wild birds in North America since it arrived in 1999 (Caffrey and Peterson 2003, Marra et al. 2004). Mosquitoes are the primary carriers (vectors) of the virus that causes encephalitis in humans, horses, and birds. Mammalian prey may also play a role in spreading WNV among predators, like northern spotted owls. WNV has caused high levels of mortality in North American hawks and owls (Hull et al. 2010). Owls and other predators of mice can contract the disease by eating infected prey (Garmendia et al. 2000, Komar et al. 2003), and possibly through feces (Kipp et al. 2006). One captive northern spotted owl in Ontario, Canada, is known to have contracted WNV and died (Gancz et al. 2004), but there are no documented cases of the virus in wild northern spotted owls. During a four year study to detect antibody response of California spotted owls, northern goshawk (*Accipter gentilis*), and great gray owl (*Strix nebulosa*) in the Sierra Nevada mountains, no antibody response to WNV was found even though 10-60% of the species' populations were sampled (Hull et al. 2010). This finding is attributed to either low exposure of WNV to these species in the study area or high mortality rates of the species to WNV (Hull et al. 2010).

Health officials expect that WNV eventually will spread throughout the entire range of the northern spotted owl (Blakesley et al. 2004), but it is unknown how the virus will ultimately affect northern spotted owl populations. Susceptibility to infection and the mortality rates of infected individuals vary among bird species (Blakesley et al. 2004), but most owls appear to be quite susceptible. For example, eastern screech-owls (*Otus asio*) breeding in Ohio that were exposed to WNV experienced 100 percent mortality (T. Grubb pers. comm. in Blakesley et al. 2004). In California, 23.1% of western screech owls (*Otus kennicottii*) randomly collected dead by the public, tested positive for WNV, while 12.5% of great horned owls tested positive for WNV (Wheeler et al. 2009). Barred owls, in contrast, showed lower susceptibility (B. Hunter pers. comm. in Blakesley et al. 2004).

Blakesley et al. (2004) offer two possible scenarios for the likely outcome of northern spotted owl populations being infected by WNV. One scenario is that a range-wide reduction in northern spotted owl population viability is unlikely because the risk of contracting WNV varies between regions. An alternative scenario is that WNV will cause unsustainable mortality, due to the frequency and/or magnitude of infection, thereby resulting in long-term population declines and extirpation from parts of the northern spotted owl's current range. WNV remains a potential threat of uncertain magnitude and effect (Blakesley et al. 2004).

Sudden Oak Death

Sudden oak death was recently identified as a potential threat to the northern spotted owl (Courtney et al. 2004). This disease is caused by the fungus-like pathogen, *Phytopthora ramorum* that was recently introduced from Europe and is rapidly spreading. The disease is now known to extend over 404 miles from south of Big Sur, California to Curry County, Oregon (Rizzo and Garbelotto 2003), and has reached epidemic proportions in oak (*Quercus* spp.) and tanoak (*Lithocarpus densiflorus*) forests along approximately 186 miles of the central and northern California coast (Rizzo et al. 2002). It has also been found near Brookings, Oregon, killing tanoak and causing dieback of closely associated wild rhododendron (*Rhododendron* spp.) and evergreen huckleberry (*Vaccinium ovatum*) (Goheen et al. 2002). It has been found in several different forest types and at elevations from sea level to over 2,625 feet. Sudden oak death poses a threat of uncertain proportion because of its potential impact on forest dynamics and alteration of key prey and northern spotted owl habitat components (e.g., hardwood trees, canopy closure and nest tree mortality), especially in the southern portion of the northern spotted owl's range (Courtney et al. 2004). During a study completed between 2001 and 2003 in California, one-third to one-half of the hikers present in the study area carried infected soil on their shoes (Davidson et al. 2005), creating the potential for rapid spread of the disease.

Inbreeding Depression, Genetic Isolation, and Reduced Genetic Diversity

Inbreeding and other genetic problems due to small population sizes were not considered an imminent threat to the northern spotted owl at the time of listing. Recent studies show no indication of reduced genetic variation and past bottlenecks in Washington, Oregon, or California (Barrowclough et al. 1999, Haig et al. 2004, Henke et al. unpublished data). However, in Canada in 2004, the breeding population was estimated to be less than 33 pairs and annual population decline as high as 35 percent (Harestad et al. 2004). Currently only six northern spotted owls are known to exist in the wild in British Columbia, where captive raising of young and captive breeding is currently being practiced to ensure the owl's survival (Pynn 2010). Canadian populations may be more adversely affected by issues related to small population size including inbreeding depression, genetic isolation, and reduced genetic diversity (Courtney et al. 2004). Low and persistently declining populations throughout the northern portion of the species range (see "Population Trends" below) may be at increased risk of losing genetic diversity.

Hybridization of northern spotted owls with California spotted owls and barred owls has been confirmed through genetic research (Hamer et al. 1994, Gutiérrez et al. 1995, Dark et al. 1998, Kelly 2001, Funk et al. 2008).

Climate change

The International Panel on Climate Change (IPCC), a scientific intergovernmental body established by the World Meteorological Organization and the United Nations Environment Programme to assess scientific information and consequences of climate change, concluded that climate change is occurring and is caused by human activities (Forster et al. 2007). The global average temperature has risen approximately 1.08 degrees Fahrenheit (°F) during the 20th Century (IPCC 2001). Within this time, the Pacific Northwest has seen annual average temperature increases of 1.08 to 3.06 °F (Parson et al. 2000). Snow-season length and depth of snowpack are very likely to decrease in most of North America (Christenson et al. 2007), and has already been shown in several studies (Mote et al. 2005 and Regonda et al. 2005 cited in Vicuna and Dracup 2007, Trenberth et al. 2007). Snowmelt-driven runoff is predicted to occur as much as two months earlier in the western United States (Rauscher et al. 2008).

California, in particular, will suffer significant consequences as a result of climate change [California Climate Action Team (CCAT) 2006]. Climate change is already affecting wildlife throughout California (Parmesan and Galbraith 2004), and its effects will continue to increase. Depending on the model and assumptions, scientists project the average annual temperature in California to rise between 4 and 10.5 °F above the current average temperature by the end of the century (Schneider and Kuntz-Duriseti 2002, Turman 2002, Hayhoe et al. 2004). The Grinnell Resurvey Project in Yosemite National Park and surrounding areas have already recorded a substantial increase in monthly minimum temperatures of more than 5.4 °F over 100 years, which is much greater than the average for the state of California (Moritz 2007). This temperature increase is also reflected in tree ring data and analyses of vegetation change (Millar et al. 2004). Seventeen species monitored in the Grinnell Resurvey Project showed range contractions (Moritz 2007). Most of these range contractions involved mid to high elevation taxa (Moritz 2007), coupled with the upward elevation movement of formerly low-elevation species (Moritz et al. 2008).

Climate change, a potential additional threat to northern spotted owl populations, is not explicitly addressed in the NWFP. Climate change could have direct and indirect effects on northern spotted owls and their prey. Based upon a global meta-analysis, Parmesan and Yohe (2003) discussed several potential implications of global climate change to biological systems, including terrestrial flora and fauna. Results indicated that 62 percent of species exhibited trends indicative of advancement of spring conditions. In bird species, trends were manifested in earlier nesting activities. Because the northern spotted owl exhibits a limited tolerance to heat relative to other bird species (Weathers et al. 2001), subtle changes in climate have the potential for significant negative effects. However, the direct effects of climate change to the species are unknown.

Climate change is expected to make unpredictable changes to many species' habitat. Changes in water availability to plants may affect tree growth and distribution of flora (Skinner 2007). Added stress, such as drought, to tree species and changes in the distribution of diseases and insects may make them more vulnerable, and may compound the susceptibility to high severity fire (Skinner 2007). The recent expansion of the mountain pine beetle (*Dendroctonus ponderosae Hopkins*) is an example of range expansion of insects that are affecting large amounts of North American forests (Skinner 2007). The dramatic increase in tree mortality due to these insects increases the potential for intense fires (Skinner 2007). Changes in the fire regime are expected to occur due to warmer temperatures increasing the probability of severe fire and length of fire season (Skinner 2007). Westerling et al. (2006) showed that large wildfire activity has increased suddenly since mid-1980's, with higher large-wildfire frequency, longer wildfire durations, and longer wildfire seasons. A greater number of fires with more fires escaping initial attack suppression are expected (Fried et al. 2004). However, Hanson et al. (2009) believe northern spotted owls are actually suffering adverse consequences from a deficit of fire, which creates habitat necessary for an abundance of their key prey species. Of all burn severity categories, Bond et al. (2009) found that California spotted owls mostly foraged in high-severity burned forest, actually avoiding unburned forest within one kilometer of the center of their foraging areas.

As shown by paleoecological record, dramatic changes in species distributions can take place over only a few decades to a century during periods of rapid climate variation (Peteet 2000, Davis and Shaw 2001). Current communities of plants are likely to dissolve and create new associations as species ranges adjust (Davis 1986, Whitlock 1992). The current assemblages are managed for favorable conditions for the northern spotted owl; however, the influence of a warming climate may make it more difficult to sustain appropriate habitat without considering climate (Skinner 2007). Winter precipitation was the most important climate variable based on northern spotted owl distribution models used by Carroll (in press), further suggesting that negative effects on survival and recruitment may occur due to climate change. Range shifts due to climate change may affect the effectiveness of reserves for northern spotted owls, increasing the importance of higher elevation reserves that were created before the NWFP (Carroll, in press).

Disturbance-Related Effects

The effects of noise on northern spotted owls are largely unknown, and whether noise is a concern has been a controversial issue. The effect of noise on birds is extremely difficult to determine due to the inability of most studies to quantify one or more of the following variables: 1) timing of the disturbance in relation to nesting chronology; 2) type, frequency, and proximity of human disturbance; 3) clutch size; 4) health of individual birds; 5) food supply; and 6) outcome of previous interactions between birds and humans (Knight and Skagan 1988). Additional factors that confound the issue of disturbance include the individual bird's tolerance level, ambient sound levels, physical parameters of sound and how it reacts with topographic characteristics and vegetation, and differences in how species perceive noise.

Although information specific to behavioral responses of northern spotted owls to disturbance is limited, research indicates that recreational activity can cause Mexican spotted owls to vacate otherwise suitable habitat (Swarthout and Steidl 2001) and helicopter overflights can reduce prey delivery rates to nests (Delaney et al. 1999). Additional effects from disturbance, including altered foraging behavior and decreases in nest attendance and reproductive success, have been reported for other raptors (White and Thurow 1985, Anderson et al. 1989, McGarigal et al. 1991).

Northern spotted owls may also respond physiologically to a disturbance without exhibiting a significant behavioral response. In response to environmental stressors, vertebrates secrete stress hormones called corticosteroids (Campbell 1990). Although these hormones are essential for survival, extended periods with elevated stress hormone levels may have negative effects on reproductive function, disease resistance, or physical condition (Carsia and Harvey 2000, Saplosky et al. 2000). In avian species, the secretion of corticosterone is the primary non-specific stress response (Carsia and Harvey 2000). The quantity of this hormone in feces can be used as a measure of physiological stress (Wasser et al. 1997). Recent studies of fecal corticosterone levels of northern spotted owls indicate that low intensity noise of short duration and minimal repetition does not elicit a physiological stress response (Tempel and Gutiérrez 2003, 2004). However, prolonged activities, such as those associated with timber harvest, may increase fecal corticosterone levels depending on their proximity to northern spotted owl core areas (Wasser et al. 1997, Tempel and Gutiérrez 2004).

Post-harvest fuels treatments may also create above-ambient smoke or heat. Although it has not been conclusively demonstrated, it is anticipated that nesting northern spotted owls may be disturbed by heat and smoke intrusion into the nest grove.

2.1.4 Conservation Needs of the Northern Spotted Owl

Based on the above assessment of threats, the northern spotted owl has the following habitat-specific and habitat-independent conservation (i.e., survival and recovery) needs:

2.1.4.1 Habitat-specific Needs

1. Large blocks of suitable habitat to support clusters or local population centers of northern spotted owls (i.e., 15 to 20 breeding pairs) throughout the owl's range;

2. Suitable habitat conditions and spacing between local northern spotted owl populations throughout its range to facilitate survival and movement;

3. Suitable habitat distributed across a variety of ecological conditions within the northern spotted owl's range to reduce risk of local or widespread extirpation;

4. A coordinated, adaptive management effort to reduce the loss of habitat due to catastrophic wildfire throughout the northern spotted owl's range, and a monitoring program to clarify whether these risk reduction methods are effective and to determine how owls use habitat treated to reduce fuels; and

5. In areas of significant population decline, sustain the full range of survival and recovery options for this species in light of significant uncertainty.

2.1.4.2 Habitat-independent Needs

1. A coordinated research and adaptive management effort to better understand and manage competitive interactions between spotted and barred owls; and

2. Monitoring to better understand the risk that WNV and sudden oak death pose to northern spotted owls and, for WNV, research into methods that may reduce the likelihood or severity of outbreaks in northern spotted owl populations.

2.1.4.3 Conservation Strategy

Since 1990, various efforts have addressed the conservation needs of the northern spotted owl and attempted to formulate conservation strategies based upon these needs. These efforts began with the Interagency Scientific Committee's (ISC's) Conservation Strategy (Thomas et al. 1990); they continued with the designation of critical habitat (USDI FWS 1992a), the Draft Recovery Plan (USDI FWS 1992b), and the Scientific Analysis Team report (Thomas et al. 1993), report of the Forest Ecosystem Management Assessment Team (Thomas and Raphael 1993); and they culminated with the NWFP (USDA FS and USDI BLM 1994a). Each conservation strategy was based upon the reserve design principles first articulated in the ISC's report, which are summarized as follows:

- Species that are well distributed across their range are less prone to extinction than species confined to small portions of their range.

- Large blocks of habitat, containing multiple pairs of the species, are superior to small blocks of habitat with only one to a few pairs.

- Blocks of habitat that are close together are better than blocks far apart.

- Habitat that occurs in contiguous blocks is better than habitat that is more fragmented.

- Habitat between blocks is more effective as dispersal habitat if it resembles suitable habitat.

2.1.4.4 Federal Contribution to Recovery

Since it was signed on April 13, 1994, the NWFP has guided the management of Federal forest lands within the range of the northern spotted owl (USDA FS and USDI BLM 1994a, 1994b). The NWFP was designed to protect large blocks of old growth forest and provide habitat for species that depend on those forests including the northern spotted owl, as well as to produce a predictable and sustainable level of timber sales. The NWFP included land use allocations which would provide for population clusters of northern spotted owls (i.e., demographic support) and maintain connectivity between population clusters. Certain land use allocations in the plan contribute to supporting population clusters: Late-Successional Reserves (LSRs), Managed Late-successional Areas (MLSAs), and Congressionally Reserved Areas (CRAs). Riparian Reserves (RRs), Adaptive Management Areas (AMAs) and Administratively Withdrawn Areas (AWAs) can provide both demographic support and connectivity/dispersal between the larger blocks, but were not necessarily designed for that purpose. Matrix areas were to support timber production while also retaining biological legacy components important to old-growth obligate species (i.e., 100-acre owl cores, 15 percent late-successional provision; USDA FS and USDI BLM 1994a, USDI FWS 1994b) which would persist into future managed timber stands.

The NWFP with its rangewide system of LSRs was based on work completed by three previous studies (Thomas et al. 2006): the 1990 ISC Report (Thomas et al. 1990), the 1991 report for the Conservation of Late-successional Forests and Aquatic Ecosystems (Johnson et. al. 1991), and the 1993 report of the Scientific Assessment Team (Thomas et al. 1993). In addition, the 1992 Draft Recovery Plan for the Northern Spotted Owl (USDI FWS 1992b) was based on the ISC report.

The Forest Ecosystem Management Assessment Team predicted, based on expert opinion, the northern spotted owl population would decline in the Matrix land use allocation over time, while the population would stabilize and eventually increase within LSRs as habitat conditions improved over the next 50 to 100 years (Thomas and Raphael 1993; USDA FS and USDI BLM 1994a, 1994b). Based on the results of the first decade of monitoring, Lint (2005) could not determine whether implementation of the NWFP would reverse the northern spotted owl's declining population trend because not enough time had passed to provide the necessary measure of certainty. However, the results from the first decade of monitoring do not provide any reason to depart from the objective of habitat maintenance and restoration as described in the NWFP (Lint 2005, Noon and Blakesley 2006). Bigley and Franklin (2004) suggested that more fuels treatments are needed in east-side forests to preclude large-scale losses of habitat to stand-replacing wildfires. Other stressors that occur in suitable habitat, such as the range expansion of the barred owl (already in action) and infection with WNV (which may or may not occur) may complicate the conservation of the northern spotted owl. Recent reports about the status of the northern spotted owl offer few management recommendations to deal with these emerging threats. The arrangement, distribution, and resilience of the NWFP land use allocation system may prove to be the most appropriate strategy in responding to these unexpected challenges (Bigley and Franklin 2004).

Under the NWFP, the agencies anticipated a decline of northern spotted owl populations during the first decade of implementation. Recent reports (Courtney et al. 2004, Anthony et al. 2006) identified greater than expected northern spotted owl declines in Washington and northern portions of Oregon, and more stationary populations in southern Oregon and northern California. The reports did not find a direct correlation between habitat conditions and changes in vital rates of northern spotted owls at the meta-population scale. However, at the territory scale, there is evidence of negative effects to northern spotted owl fitness due to reduced habitat quantity and quality. Also, there is no evidence to suggest that dispersal habitat is currently limiting (Courtney et al. 2004, Lint 2005). Even with the population decline, Courtney et al (2004) noted that there is little reason to doubt the effectiveness of the core principles underpinning the NWFP conservation strategy.

The current scientific information, including information showing northern spotted owl population declines, indicates that the northern spotted owl continues to meet the definition of a threatened species (USDI FWS 2004a). That is, populations are still relatively numerous over most of its historic range, which suggests that the threat of extinction is not imminent, and that the subspecies is not endangered, even though, in the northern part of its range population trend estimates are showing a decline.

In May, 2008, the Service published the 2008 Final Recovery Plan for the Northern Spotted Owl (USDI FWS 2008a). The recovery plan identified that competition with barred owls, ongoing loss of suitable habitat as a result of timber harvest and catastrophic fire, and loss of amount and distribution of suitable habitat as a result of past activities and disturbances are the most important range-wide threats to the northern spotted owl (USDI FWS 2008a). To address these threats, the recovery strategy had the following three essential elements: barred owl control, dry-forest landscape management strategy, and managed owl conservation areas (MOCAs) (USDI FWS 2008a). The recovery plan listed recovery actions that address research of the competition between spotted and barred owls, experimental control of barred owls to better understand the impact the species is having on northern spotted owls, and, if recommended by research, management of barred owls (USDI FWS 2008a). In addition, the recovery plan recommended a research and monitoring program be implemented to track progress toward recovery, inform changes in recovery strategy by a process of adaptive management, and ultimately determine when delisting is appropriate (USDI FWS 2008a). The three primary elements of this program included 1) the monitoring of northern spotted owl population trends, 2) an inventory of northern spotted owl distribution, and 3) a comprehensive program of barred owl research and monitoring (USDI FWS 2008a). The recovery plan estimated that recovery of the northern spotted owl could be achieved in approximately 30 years (USDI FWS 2008a).

In 2011, the Service published the Revised Recovery Plan for the Northern Spotted Owl (USDI FWS 2011b). The 2011 Revised Recovery Plan, like the 2008 Recovery Plan, identifies barred owls and habitat loss due to timber harvest and wildfire as major threats to the northern spotted owl. To address these threats, the present recovery strategy has the following four essential elements: completion and application of rangewide habitat modeling, habitat conservation and active forest management, barred owl management, and research and monitoring (USDI FWS 2011b). The revised recovery plan lists 34 recovery actions that address overall recovery through maintenance and restoration of suitable habitat for northern spotted owls, monitoring of avian diseases, development and implementation of a delisting monitoring plan, and management of the barred owl (USDI FWS 2011b). Implementation of the full suite of recovery actions will involve participation from the States, Federal agencies, non-Federal landowners, and the public. Recovery Actions 10 and 20 are especially reliant on the participation of private landowners and pertain to the FGS HCP. The intent of Recovery Action 10 is to conserve spotted owl sites and high value spotted owl habitat, regardless of land ownership. Recovery Action 20 requests the cooperation of CAL FIRE and individual stakeholders to evaluate the potential recovery role of spotted owl sites and high-quality habitat on nonfederal lands in California, and to evaluate and implement appropriate conservation tools, such as HCPs, to assist with supporting spotted owl recovery actions outlined in the recovery plan.

2.1.4.5 Conservation Efforts on Non-Federal Lands

In the report from the Interagency Scientific Committee (Thomas et al. 1990), the draft recovery plan (USDI FWS 1992b), and the report from the Forest Ecosystem Management Assessment Team (Thomas and Raphael 1993), it was noted that limited Federal ownership in some areas constrained the ability to form a network of old-forest reserves to meet the conservation needs of the northern spotted owl. In these areas in particular, non-Federal lands would be important to the range-wide goal of achieving conservation and recovery of the northern spotted owl. The Service's primary expectations for private lands are for their contributions to demographic support (pair or cluster protection) to Federal lands, or their connectivity with Federal lands. In addition, timber harvest within each state is governed by rules that provide protection of northern spotted owls or their habitat to varying degrees.

There are 17 current or completed HCPs that have incidental take permits issued for northern spotted owls—eight in Washington, three in Oregon, and four in California. The HCPs range in size from 40 acres to more than 1.6 million acres, although not all acres are included in the mitigation for northern spotted owls. In total, the HCPs cover approximately 2.9 million acres (9.1 percent) of the 32 million acres of non-Federal forest lands in the range of the northern spotted owl. The period of time that the HCPs will be in place ranges from 5 to 100 years; however, most of the HCPs are of fairly long duration. While each HCP is unique, there are several general approaches to mitigation of incidental take:

- Reserves of various sizes, some associated with adjacent Federal reserves
- Forest harvest that maintains or develops suitable habitat
- Forest management that maintains or develops dispersal habitat
- Deferral of harvest near specific sites

Washington. In 1996, the State Forest Practices Board adopted rules (Washington Forest Practices Board 1996) that would contribute to conserving the northern spotted owl and its habitat on non-Federal lands. In Spotted Owl Special Emphasis Areas, suitable owl habitat inside management circles established for territorial spotted owls is regulated under the default component of the Forest Practices Rules. Outside the Spotted Owl Special Emphasis Areas, the best 70 acres of habitat around the site center is protected from harvest during the nesting season. Outside the nesting season there are no owl-related protections that constrain harvest of suitable habitat in spotted owl management circles. Adoption of the rules was based in part on recommendations from a Science Advisory Group that identified important non-Federal lands and recommended roles for those lands in northern spotted owl conservation (Hanson et al. 1993, Buchanan et al. 1994). The 1996 rule package was developed by a stakeholder policy group and then reviewed and approved by the Forest Practices Board (Buchanan and Swedeen 2005). Northern spotted owl-related HCPs in Washington generally were intended to provide demographic or connectivity support (USDI FWS 1992b).

Oregon. The Oregon Forest Practices Act provides for protection of 70-acre core areas around sites occupied by an adult pair of northern spotted owls capable of breeding (as determined by recent protocol surveys), but it does not provide for protection of northern spotted owl habitat beyond these areas (Oregon Department of Forestry 2007). In general, no large-scale northern spotted owl habitat protection strategy or mechanism currently exists for non-Federal lands in Oregon. The three northern spotted owl-related HCPs currently in effect cover more than

300,000 acres of non-Federal lands. These HCPs are intended to provide some nesting habitat and connectivity over the next few decades.

California. The California Forest Practice Rules (CFPRs,) which govern timber harvest on private lands, require surveys for northern spotted owls in suitable habitat and provide protection around activity centers (CALFIRE 2007). Under the CFPRs, no timber harvest plan can be approved if it is likely to result in incidental take of federally listed species, unless the take is authorized by a Federal incidental take permit (CALFIRE 2007). The CDFG initially reviewed all THPs to ensure that take was not likely to occur. The Service took over that review function in 2000. In 2008, the Service handed over the THP review process to CALFIRE. Upon request, the Service may provide technical assistance to CALFIRE if deemed necessary.

The CFPRs requires private landowners to maintain 500 acres and 1,336 acres of suitable (nesting, roosting and foraging) northern spotted owl habitat within an activity center's 0.7- mile core and 1.3-mile home range, respectively. Additionally, within 500 feet of the active nest site or pair activity center, the characteristics of functional nesting habitat must be maintained. Harvest of suitable habitat is allowed if more than 500 acres and 1,336 acres within the 0.7-mile core and 1.3-mile home range, respectively, are currently present. Additionally, under the current CFPRs, if an activity center is determined to be unoccupied all habitat within the home range can be removed without compensatory mitigation.

There are several short-comings of the current CFPRs. The CFPRs define suitable northern spotted owl habitat based on CWHR classification system, which could lead to retention of relatively low quality habitat. For example, 4D is considered suitable nesting/roosting habitat, but encompasses a broad range of tree diameters (11 to 24 inches dbh) and canopy cover (60 to 100 percent). The CFPRs do not specify how much of the total northern spotted owl habitat within the core and home range should be maintained as nesting, roosting and foraging. Conceivably, most of the northern spotted owl habitat within the core and home range could be low quality foraging habitat and harvest could be allowed under the CFPRs. Furthermore, the CFPRs follow the guidance in the 1992 Protocol for Surveying Management Activities that May Impact Northern Spotted Owls for determining unoccupied status. According to that protocol, an historic activity center may be considered unoccupied if no responses have been obtained after three years of surveys. New research information available on northern spotted owl site occupancy indicates that sites may be unoccupied (or northern spotted owls fail to respond due to the presence of barred owls) for more than three years and then subsequently are utilized by nesting northern spotted owls.

The Service's experience with interior California THP review from 2000 to 2009 indicates that the CFPRs regulating timber harvest during the 1990s did not necessarily prevent significant effects to activity centers resulting from the continued reduction of habitat quality within northern spotted owl home ranges overlapping THPs. Extensive review has suggested that in many cases, the cumulative effects of repeated entries within northern spotted owl home ranges reduces habitat quality and leads to reduced occupancy rates and apparent site abandonment. In a large proportion of the Service's technical assistance letters to CALFIRE and industrial timberland owners during the past five years, the Service has noted the lack of northern spotted owl responses at historic territories and habitat conditions considered inadequate to support continued occupancy and reproduction following repeated entries within northern spotted owl home ranges under the CFPRs.

In 2008, the YFWO developed take avoidance guidance for CALFIRE which included documentation of the criteria and habitat thresholds currently used by the Service in making take evaluations for northern spotted owls on private lands in the interior region (USDI FWS 2008c). In 2009, in order to document the scientific rationale behind the Service guidelines, the YFWO issued a science support document titled "Regulatory and Scientific Basis for the U.S. Fish and Wildlife Service Guidance for Evaluation of Take for Northern Spotted Owls on Private Timberlands in California's Northern Interior Region." Generally, the guidelines describe the range of conditions associated with occupied northern spotted owl activity centers. The Service recommends maintenance of 250 acres of nesting/roosting and 150 acres of foraging habitat within the northern spotted owl territory (i.e., core area). The northern spotted owl territory is established by placing a 0.5 mile radius circle around a nest site, which equates to 502 acres. Additionally, maintenance of 935 acres of foraging habitat is recommended within the northern spotted owl outer ring of the home range (i.e., 0.5 to 1.3-mile radius around the nest site). The northern spotted owl home range is established by placing a 1.3 mile radius circle around a nest site which equates to 3,396 acres. The habitat thresholds and definitions in the Service guidance provide the quantity and quality of habitat associated with occupancy and reproduction at northern spotted owl cores. Although these new guidelines were developed by the Service and based upon the best scientific information available at the time, CALFIRE cannot mandate the use of a different standard than those described in the CFPRs.

Several large industrial owners operate under northern spotted owl management plans that have been reviewed by the Service and that specify basic measures for northern spotted owl protection. Four HCPs authorizing take of northern spotted owls have been approved; these HCPs cover more than 669,000 acres of non-Federal lands in California. Implementation of these plans is intended to provide for northern spotted owl demographic and connectivity support to NWFP lands.

2.1.5 Current Condition of the Northern Spotted Owl

The current condition of the species incorporates the effects of all past human activities and natural events that led to the present-day status of the species and its habitat (USDI FWS and USDC NMFS 1998).

2.1.5.1 Range-wide Habitat

The 1992 Draft Northern Spotted Owl Recovery Plan estimated approximately 8.3 million acres of northern spotted owl habitat remained range-wide (USDI FWS 1992b). However, reliable habitat baseline information for non-Federal lands is not available (Courtney et al. 2004). The Service has used information provided by the USFS, Bureau of Land Management, and National Park Service to update the habitat baseline conditions on Federal lands for northern spotted owls on several occasions since the northern spotted owl was listed in 1990. The estimate of 7.4 million acres used for the NWFP in 1994 (USDA FS and USDI BLM 1994a) was believed to be representative of the general amount of northern spotted owl habitat on these lands. This baseline has been used to track relative changes over time in subsequent analyses, including those presented here.

In 2005, a new map depicting suitable northern spotted owl habitat throughout the range of the northern spotted owl was produced as a result of the NWFP's effectiveness monitoring program (Lint 2005). However, the spatial resolution of this new habitat map currently makes it unsuitable for tracking habitat effects at the scale of individual projects. The Service is evaluating the map for future use in tracking habitat trends. Additionally, there continues to be no reliable estimates of northern spotted owl habitat on non-Federal lands; consequently, consulted-on acres by the Service can be tracked, but not evaluated in the context of change with respect to a reference condition on non-Federal lands. The production of the monitoring program habitat map does, however, provide an opportunity for future evaluations of trends in non-Federal habitat.

NWFP Lands Analysis 1994 – 2001

In 2001, the Service conducted an assessment of habitat baseline conditions, the first since implementation of the NWFP (USDI FWS 2001). This range-wide evaluation of habitat, compared to the Final Supplemental Environmental Impact Statement (FSEIS) (USDA FS and USDI BLM 1994b), was necessary to determine if the rate of potential change to northern spotted owl habitat was consistent with the change anticipated in the NWFP. In particular, the Service considered habitat effects that were documented through the Section 7 consultation process since 1994. In general, the analytical framework of these consultations focused on the reserve and connectivity goals established by the NWFP land-use allocations (USDA FS and USDI BLM 1994a), with effects expressed in terms of changes in suitable northern spotted owl habitat within those land-use allocations. The Service determined that actions and effects were consistent with the expectations for implementation of the NWFP from 1994 to June, 2001 (USDI FWS 2001).

Range-wide Analysis 1994 – March 30, 2011

This section updates the information considered in USDI FWS (2001), relying particularly on information in documents the Service produced pursuant to Section 7 of the ESA and information provided by NWFP agencies on habitat loss resulting from natural events (e.g., fires, windthrow, insects and disease). To track impacts to northern spotted owl habitat, the Service designed the Consultation on Effects Database which records impacts to northern spotted owls and their habitat at a variety of spatial and temporal scales. Data are entered into the Consulted on Effects Database under various categories including, land management agency, land-use allocation, physiographic province, and type of habitat affected.

In 1994, about 7.4 million acres of suitable northern spotted owl habitat were estimated to exist on Federal lands managed under the NWFP. As of March 30, 2011**,** the Service had consulted on the proposed removal/downgrading of approximately 188,971 acres (Table 2) or 2.6 percent of 7.4 million acres (Table 3) of northern spotted owl suitable habitat on Federal NWFP lands. Of the total Federal acres consulted on for removal/downgrading, approximately 160,566 acres or 2.2 percent of 7.4 million acres of northern spotted owl habitat were removed/downgraded as a result of timber harvest. These changes in suitable northern spotted owl habitat are consistent with the expectations for implementation of the NWFP (USDA FS and USDI BLM 1994a).

Habitat loss from Federal NWFP lands due to management activities has varied among the individual provinces with most of the impacts concentrated within the Non-Reserve relative to the Reserve land-use allocations (Table 3). When habitat loss is evaluated as a proportion of the affected acres range-wide, the most pronounced losses have occurred within Oregon (79%), especially within its Klamath Mountains (40%) and Cascades (East and West) (38%) Provinces (Table 3), followed by much smaller habitat losses in Washington (10%) and California (11%) (Table 3). When habitat loss is evaluated as a proportion of provincial baselines, the Oregon Klamath Mountains (20.3%), Cascades East (13%) and the California Cascades (5.5%) all have proportional losses greater than the range-wide mean (5.4%) (Table 3).

From 1994 through February 14, 2011, habitat lost due to natural events was estimated at approximately 207,262 acres range-wide (Table 3). This estimate doesn't include acres of habitat lost from the 2008 fires and a couple of 2009 fires on the Shasta-Trinity, Mendocino, and Six Rivers National Forests because emergency consultations have not been completed on these fires. About two-thirds of this loss was attributed to the Biscuit Fire that burned over 500,000 acres in southwest Oregon (Rogue River basin) and northern California in 2002. This fire resulted in a loss of approximately 113,451 acres of northern spotted owl habitat, including habitat within five LSRs (Table 3[7]). Approximately 18,630 acres of northern spotted owl habitat were lost due to the B&B Complex and Davis Fires in the East Cascades Province of Oregon in 2003 (Table 3[7]).

Because there is no comprehensive northern spotted owl habitat baseline for non-NWFP Federal lands and non-Federal lands, there is little available information regarding northern spotted owl habitat trends on these lands. Yet, we do know that Service consultations conducted since 1992, have documented the eventual loss of 472,772 acres (Table 2) of habitat on non-NWFP Federal lands and non-Federal lands. Approximately 63 percent of these losses have yet to be realized because they are part of large-scale, long-term HCPs/Safe Harbor Agreements (SHAs). Combining effects on Federal and non-Federal lands, the Service had consulted on the proposed removal of approximately 661,743 acres of northern spotted owl habitat range-wide, resulting from all management activities, as of March 30, 2011 (Table 2).

Table 2. Range-wide Aggregate of Changes to NRF[1] Habitat Acres from Activities Subject to Section 7 Consultations and Other Causes from 1994 to March 30, 2011.

Land Ownership	Consulted On Habitat Changes[2]		Other Habitat Changes[3]	
	Removed/ Downgraded	Maintained/ Improved	Removed/ Downgraded	Maintained/ Improved
NWFP (FS,BLM,NPS)	188,971	512,961	207,262	5,481
Bureau of Indian Affairs / Tribes	108,210	28,372	2,398	0
Habitat Conservation Plans/Safe Harbor Agreements	295,889	14,430	N/A	N/A
Other Federal, State, County, Private Lands	68,673	21,894	279	0
Total Changes	**661,743**	**577,657**	**209,939**	**5,481**

Notes:

1. Nesting, roosting, foraging (NRF) habitat. In California, suitable habitat is divided into two components; nesting - roosting (NR) habitat, and foraging (F) habitat. The NR component most closely resembles NRF habitat in Oregon and Washington. Due to differences in reporting methods, effects to suitable habitat compiled in this, and all subsequent tables include effects for nesting, roosting, and foraging (NRF) for 1994-6/26/2001. After 6/26/2001 suitable habitat includes NRF for Washington and Oregon but only nesting and roosting (NR) for California.
2. Includes both effects reported in USFWS 2001 and subsequent effects reported in the Northern Spotted Owl Consultation Effects Tracking System (web application and database.)
3. Includes effects to suitable NRF habitat (as generally documented through technical assistance, etc.) resulting from wildfires (not from suppression efforts), insect and disease outbreaks, and other natural causes, private timber harvest, and land exchanges not associated with consultation.

Table 3. Aggregate Results of All Adjusted, Suitable Habitat (NRF[1]) Acres Affected by Section 7 Consultation on NWFP Lands for the Northern Spotted Owl; Baseline and Summary of Effects by State, Physiographic Province and Land Use Function from 1994 to March 30, 2011.

Physiographic Province[2]		Evaluation Baseline[3]	Habitat Removed/Downgraded[4]					% Provincial Baseline Affected	% Range-wide Effects
			Land Use Allocations			Habitat Loss to Natural Events[7]	Total

Total		**7,397,098**	**18,437**	**170,534**	**188,971**	**207,262**	**396,233**	**5.36**	**100**

Notes:

1. Nesting, roosting, foraging (NRF) habitat. In California, suitable habitat is divided into two components; nesting - roosting (NR) habitat, and foraging (F) habitat. The NR component most closely resembles NRF habitat in Oregon and Washington. Due to differences in reporting methods, effects to suitable habitat compiled in this, and all subsequent tables include effects for nesting, roosting, and foraging (NRF) for 1994-6/26/2001. After 6/26/2001 suitable habitat includes NRF for Washington and Oregon but only nesting and roosting (NR) for California.

2. Defined by the NWFP as the 12 physiographic provinces, as presented in Figure 3&4-1 on page 3&4-16 of the FSEIS. The WA Western Lowlands and OR Willamette Valley provinces are not listed as they are not expected to contribute to recovery.
3. 1994 FSEIS baseline (USDA FS and USDI BLM 1994b).
4. Includes both effects reported in USDI FWS (2001) and subsequent effects reported in the Northern Spotted Owl Consultation Effects Tracking System (web application and database.)
5. Land-use allocations intended to provide large blocks of habitat to support clusters of breeding pairs. (LSR, MLSA, CRA)
6. Land-use allocations intended to provide habitat to support movement of spotted owls among reserves. (AWA, AMA, MX)
7. Acres for all physiographic provinces, except the Oregon Klamath Mountains, are from the Scientific Evaluation of the Status of the Northern Spotted Owl (Courtney et al. 2004) and subsequent effects entered into the Northern Spotted Owl Consultation Effects Tracking System. Acres for the Oregon Klamath Mountains province are from the biological assessment entitled: Fiscal year 2006-2008 programmatic consultation: re-initiation on activities that may affect listed species in the Rogue-River/South Coast Basin, Medford BLM, and Rogue-Siskiyou National Forest and from subsequent effects entered into the Northern Spotted Owl Consultation Effects Tracking System.

Other Habitat Trend Assessments

In 2005, the Washington Department of Wildlife released the report, "An Assessment of Northern Spotted Owl Habitat on Non-Federal Lands in Washington between 1996 and 2004" (Pierce et al. 2005). This study estimates the amount of northern spotted owl habitat in 2004 on lands affected by State and private forest practices. The study area is a subset of the total Washington forest practice lands, and statistically-based estimates of existing habitat and habitat loss due to fire and timber harvest are provided. In the 3.2-million acre study area, Pierce et al. (2005) estimated there was 816,000 acres of suitable northern spotted owl habitat in 2004, or about 25 percent of their study area. Based on their results, Pierce et al. (2005) estimated there were less than 2.8 million acres of northern spotted owl habitat in Washington on all ownerships in 2004. Most of the suitable owl habitat in 2004 (56%) occurred on Federal lands, and lesser amounts were present on State-local lands (21%), private lands (22%) and tribal lands (1%). Most of the harvested northern spotted owl habitat was on private (77%) and State-local (15%) lands. A total of 172,000 acres of timber harvest occurred in the 3.2 million-acre study area, including harvest of 56,400 acres of suitable northern spotted owl habitat. This represented a loss of about 6 percent of the owl habitat in the study area distributed across all ownerships (Pierce et al. 2005). Approximately 77 percent of the harvested habitat occurred on private lands and about 15 percent occurred on State lands. Pierce and others (2005) also evaluated suitable habitat levels in 450 northern spotted owl management circles (based on the provincial annual median northern spotted owl home range). Across their study area, they found that owl circles averaged about 26 percent suitable habitat in the circle across all landscapes. Values in the study ranged from an average of 7 percent in southwest Washington to an average of 31 percent in the east Cascades, suggesting that many owl territories in Washington are significantly below the 40 percent suitable habitat threshold used by the State as a viability indicator for northern spotted owl territories (Pierce et al. 2005).

Moeur et al. (2005) estimated an increase of approximately 1.25 to 1.5 million acres of medium and large older forest (greater than 20 inches dbh, single and multi-storied canopies) on Federal lands in the NWFP area between 1994 and 2003. The increase occurred primarily in the lower end of the diameter range for older forest. The net area in the greater than 30 inch dbh size class increased by only an estimated 102,000 to 127,000 acres. The estimates were based on change-detection layers for losses due to harvest and fire and remeasured inventory plot data for increases due to ingrowth. Transition into and out of medium and large older forest over the 10-year period was extrapolated from inventory plot data on a subpopulation of Forest Service land types and applied to all Federal lands. Because size class and general canopy layer descriptions do not necessarily account for the complex forest structure often associated with northern spotted owl habitat, the significance of these acres to northern spotted owl conservation remains unknown.

2.1.5.2 Northern spotted Owl Numbers, Distribution, and Reproduction Trends

There are no estimates of the size of the northern spotted owl population prior to settlement by Europeans. Northern spotted owls are believed to have inhabited most old-growth forests or stands throughout the Pacific Northwest, including northwestern California, prior to beginning of modern settlement in the mid-1800s (USDI FWS 1989). According to the final rule listing the northern spotted owl as threatened (USDI FWS 1990a), approximately 90 percent of the roughly 2,000 known northern spotted owl breeding pairs were located on federally managed lands, 1.4 percent on State lands, and 6.2 percent on private lands; the percent of northern spotted owls on private lands in northern California was slightly higher (Forsman et al. 1984, USDI FWS 1989, Thomas et al. 1990).

The current range of the northern spotted owl extends from southwest British Columbia through the Cascade Mountains, coastal ranges, and intervening forested lands in Washington, Oregon, and California, as far south as Marin County (USDI FWS 1990a). The range of the northern spotted owl is partitioned into 12 physiographic provinces (Figure 1) based on recognized landscape subdivisions exhibiting different physical and environmental features (Thomas et al. 1993). The northern spotted owl has become rare in certain areas, such as British Columbia, southwestern Washington, and the northern coastal ranges of Oregon.

There are few northern spotted owls remaining in British Columbia. Chutter et al. (2004) suggested immediate action was required to improve the likelihood of recovering the northern spotted owl population in British Columbia. As a result, in 2007, personnel in British Columbia captured and brought into captivity 16 wild northern spotted owls (USDI FWS 2008a). Prior to initiating the captive-breeding program, the population of northern spotted owls in Canada was declining by as much as 10.4 percent per year (Chutter et al. 2004). Currently, only six northern spotted owls are known to exist in the wild in British Columbia (Pynn 2010). Biologists plan to capture two of the remaining single males for their captive breeding program (Pynn 2010). The other four northern spotted owls comprise two pairs and will continue to remain in the wild, with any offspring removed for captive breeding. Provincial biologists have lethally controlled 12 barred owls that represented competition for the last remaining northern spotted owls. The amount of previous interaction between northern spotted owls in Canada and the United States is unknown.

As of July 1, 1994, there were 5,431 known site-centers of northern spotted owl pairs or resident singles: 851 sites (16 percent) in Washington, 2,893 sites (53 percent) in Oregon, and 1,687 sites (31 percent) in California (USDI FWS 1995). By June 2004, the number of territorial northern spotted owl sites recognized by Washington Department of Fish and Wildlife was 1,044 (Buchanan and Swedeen 2005). The actual number of currently occupied northern spotted owl locations across the range is unknown because many areas remain unsurveyed (USDI FWS 1992a, Thomas et al. 1993). In addition, many historical sites are no longer occupied because northern spotted owls have been displaced by barred owls, timber harvest, or severe fires, and it is possible that some new sites have been established due to reduced timber harvest on Federal lands since 1994. The totals in USDI FWS (1995) represent the cumulative number of locations recorded in the three States, not population estimates.

Because the existing survey coverage and effort are insufficient to produce reliable range-wide estimates of population size, demographic data are used to evaluate trends in northern spotted owl populations. Analysis of demographic data can provide an estimate of the finite rate of population change (λ) (lambda), which provides information on the direction and magnitude of population change. A λ of 1.0 indicates a stationary population, meaning the population is neither increasing nor decreasing. A λ of less than 1.0 indicates a decreasing population, and a λ

of greater than 1.0 indicates a growing population. Demographic data, derived from studies initiated as early as 1985, have been analyzed periodically (Anderson and Burnham 1992, Burnham et al. 1994, Forsman et al. 1996, Anthony et al. 2006) to estimate trends in the populations of the northern spotted owl.

In January 2009, two meta-analyses by Forsman et al. (2011) modeled rates of population change for up to 24 years using the re-parameterized Jolly-Seber method (λ_{RJS}). One meta-analysis modeled the 11 long-term study areas (Table 4), while the other modeled the eight study areas that are part of the effectiveness monitoring program of the NWFP (Forsman et al. 2011).

Table 4. Northern spotted owl demographic study areas (adapted from Forsman et al. 2011).

Study Area	Fecundity	Apparent Survival[1]	λ_{RJS}	Population change[2]
Cle Elum	Declining	Declining	0.937	Declining
Rainier	Increasing	Declining	0.929	Declining
Olympic	Stable	Declining	0.957	Declining
Coast Ranges	Increasing	Declining since 1998	0.966	Declining
HJ Andrews	Increasing	Declining since 1997	0.977	Declining
Tyee	Stable	Declining since 2000	0.996	Stationary
Klamath	Declining	Stable	0.990	Stationary
Southern Cascades	Declining	Declining since 2000	0.982	Stationary
NW California	Declining	Declining	0.983	Declining
Hoopa	Stable	Declining since 2004	0.989	Stationary
Green Diamond	Declining	Declining	0.972	Declining

[1]Apparent survival calculations are based on model average.
[2]Population trends are based on estimates of realized population change.

Point estimates of λ_{RJS} were all below 1.0 and ranged from 0.929 to 0.996 for the 11 long-term study areas. There was strong evidence that populations declined on seven of the 11 areas (Forsman et al. 2011), these areas included Rainier, Olympic, Cle Elum, Coast Range, HJ Andrews, Northwest California and Green Diamond. On other four areas (Tyee, Klamath, Southern Cascades, and Hoopa), populations were either stable, or the precision of the estimates was not sufficient to detect declines.

The weighted mean λ_{RJS} for all of the 11 study areas was 0.971 (standard error [SE] = 0.007, 95 percent confidence interval [CI] = 0.960 to 0.983), which indicated an average population decline of 2.9 percent per year from 1985 to 2006. This is a lower rate of decline than the 3.7 percent reported by Anthony et al. (2006), but the rates are not directly comparable because Anthony et al. (2006) examined a different series of years and because two of the study areas in their analysis were discontinued and not included in Forsman et al. (2011). Forsman et al. (2011) explains that the indication populations were declining was based on the fact that the 95 percent confidence intervals around the estimate of mean lambda did not overlap 1.0 (stable) or barely included 1.0.

The mean λ_{RJS} for the eight demographic monitoring areas (Cle Elum, Olympic, Coast Range, HJ Andrews, Tyee, Klamath, Southern Cascades and Northwest California) that are part of the effectiveness monitoring program of the NWFP was 0.972 (SE = 0.006, 95 percent CI = 0.958 to 0.985), which indicated an estimated decline of 2.8 percent per year on Federal lands with the range of the northern spotted owl (Forsman et al. 2011). The weighted mean estimate λ_{RJS} for the other three study areas (Rainier, Hoopa and Green Diamond) was 0.969 (SE = 0.016, 95 percent CI = 0.938 to 1.000), yielding an estimated average decline of 3.1 percent per year (Forsman et al. 2011). These data suggest that demographic rates for northern spotted owl populations on Federal lands were somewhat better than elsewhere; however, this comparison is confounded by the interspersion of non-Federal land in study areas and the likelihood that northern spotted owls use habitat on multiple ownerships in some demography study areas.

The number of populations that declined and the rate at which they have declined are noteworthy, particularly the precipitous declines in the Olympic, Cle Elum, and Rainier study areas in Washington and the Coast Range study area in Oregon. Estimates of population declines in these areas ranged from 40 to 60 percent during the study period through 2006 (Forsman et al. 2011). Northern spotted owl populations on the HJ Andrews, Northwest California, and Green Diamond study areas declined by 20-30 percent whereas the Tyee, Klamath, Southern Cascades, and Hoopa study areas showed declines of 5 to 15 percent.

Decreases in adult apparent survival rates were an important factor contributing to decreasing population trends. Forsman et al. (2011) found apparent survival rates were declining on 10 of the study area with the Klamath study area in Oregon being the exception. Estimated declines in adult survival were most precipitous in Washington where apparent survival rates were less than 80 percent in recent years, a rate that may not allow for sustainable populations (Forsman et al. 2011). In addition, declines in adult survival for study areas in Oregon have occurred predominately within the last five years and were not observed in the previous analysis by Anthony et al. 2006. Forsman et al. (2011) express concerns by the collective declines in adult survival across the subspecies range because northern spotted owl populations are most sensitive to changes in adult survival.

2.2 Fisher

2.2.1 Legal Status

In 2004, the U.S. Fish and Wildlife Service (Service) concluded a 12-month finding (USDI FWS 2004b) for a petition to list the West Coast (Washington, Oregon, and California) population of the fisher (*Martes pennanti*). The finding determined that West Coast fishers constitute a distinct population segment (DPS) and that their listing is warranted but precluded by higher priority listing actions.

2.2.2 Life History

2.2.2.1 Taxonomy

The fisher is a member of the order *Carnivora*, family *Mustelidae* (weasels), subfamily *Mustelinae*, genus *Martes* (martens, fishers, and sables), subgenus *Pekania* (Anderson 1994). It is the largest member of the genus *Martes* and is the only extant species in the subgenus *Pekania* (Anderson 1994). The fisher's range overlaps extensively with that of the American marten (*M. americana*), which is the only other North American member of the genus *Martes* (Anderson 1994).

Three subspecies of fisher have been recognized in the literature: *M. p. pennanti* in eastern and central North America, *M. p. columbiana* in central and western Canada and the Rocky Mountains of the United States, and *M. p. pacifica* on the West Coast of North America (Goldman 1935, Hall 1981). A morphological analysis of specimens from across the range of the fisher, however, did not support recognition of separate subspecies (Hagmeier 1959). Genetic studies have found patterns of population subdivision similar to the 3 subspecies but have not determined whether the subspecies designations are taxonomically valid (Kyle et al. 2001; Drew et al. 2003) or have rejected the subspecies designations (Knaus et al. 2011).

2.2.2.2 Physical Description

The fisher has a long body, short legs, a long bushy tail, and a pointed face with forward eyes and rounded ears (Powell and Zielinski 1994). Fishers are usually deep brown to black and the face, neck, and shoulders are often grizzled with gray, silver, or gold (Powell 1993). The chest and abdomen typically have irregular white or cream markings. Fishers often have a sleeker appearance during their fall molt than during other seasons (Powell and Zielinski 1994). The species is commonly confused with the American marten, which is smaller and lighter in color and has more pointed ears and a shorter tail relative to the length of the body (Lofroth et al. 2010).

Male fishers are approximately 20% longer and 50 to 100% heavier than females (Lofroth et al. 2010). Adult males are 35 to 47 inches long and weigh 7.7 to 12.1 pounds, while adult females are 29 to 37 inches long and weigh 3.3 to 5.5 pounds (USDI FWS 2004b). Fishers also exhibit regional variation in body mass. Fishers in western North America typically weigh less than those in the eastern United States (USDI FWS 2004b). Individuals in the northern portions of western North America are typically heavier than those in the southern portions (Aubry and Lewis 2003, Lofroth et al. 2010).

2.2.2.3 Current and Historical Range

At the time of European settlement, the fisher's range extended across the northern forests of North America and south along the Appalachian, Rocky, and Pacific Coast mountains (Powell and Zielinski 1994; Figure 2). The range of the West Coast population of fishers included the Hozameen, Okanagan, and Cascade Ranges of British Columbia; the Cascade and Coast Ranges of Washington, Oregon, and northern California; the Klamath-Siskiyou Mountains of Oregon and California; and the Sierra Nevada of California (Powell and Zielinski 1994).

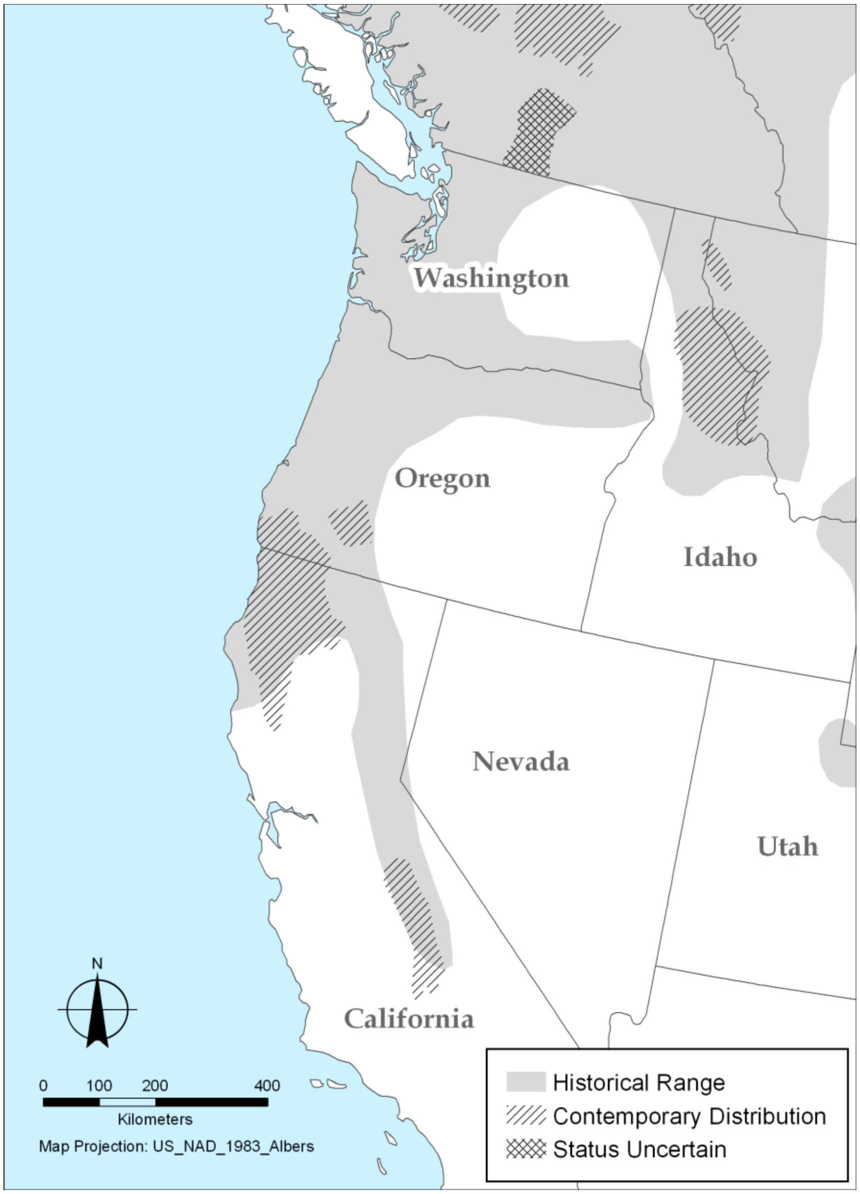

Figure 2. Contemporary distribution of fisher in the western United States and southern British Columbia compared to the historical distribution as depicted by Gibilisco (1994). Figure adapted from Lofroth et al. (2010).

Trapping, predator control, and habitat destruction during the late 1800s and early 1900s extirpated fishers from large portions of their range in the United States and eastern Canada (Douglas and Strickland 1987, Powell and Zielinski 1994). Within the Pacific Coast region, fishers were extirpated from Washington and portions of British Columbia, Oregon, and California (Lofroth et al. 2010).

Fishers are still absent from portions of their historical range (e.g., the southern Appalachian Mountains) but regrowth of forests, reduced trapping, and reintroduction programs have facilitated population recoveries in some areas (Powell and Zielinski 1994, Lofroth et al. 2010). The fisher's range and distribution in the Pacific Coast region have been substantially reduced. Fishers native to Washington are currently rare or extinct. Fishers have been reintroduced to the Olympic Peninsula but successful establishment of the population has not yet been verified (Lewis et al. 2010, Washington Department of Fish and Wildlife 2011). Oregon currently has 2 genetically isolated populations: a native population in the Siskiyou Mountains and a reintroduced population in the Cascade Range (Aubry and Lewis 2003). California has 2 disjunct native populations: one in the southern Sierra Nevada and one in the northwestern part of the State (Powell and Zielinski 1994, Zielinski et al. 1995). Fishers in southwestern Oregon and northwestern California occur as a series of interconnected local populations (USDI FWS 2010b); hereafter, these are collectively referred to as the southwestern Oregon/northwestern California population. Fishers have been translocated to the northern Sierra Nevada but successful establishment of the population has not yet been verified (CDFG 2011).

2.2.2.4 Behavior

Locomotion

Fishers have 5 toes on each of their large feet (Powell and Zielinski 1994). They walk with either their whole foot or just their toes and have an undulating, weasel-like, gait (Powell 1993). Deep snow can restrict fishers' movements and possibly influences their habitat associations, distribution, and reproduction (Powell and Zielinski 1994, Krohn et al. 2004).

The fisher's partially retractable claws and slightly specialized anatomy enable them to climb trees and descend head-first (Powell 1993, Lofroth et al. 2010). Fishers climb trees to access cavities or prey and have been observed traveling from tree to tree (Coulter 1966). However, the species is less arboreal than is commonly thought (Powell 1993, Powell and Zielinski 1994).

Daily Activity Pattern

Fishers have 1 to 3 activity periods per day (Powell 1993). They are active during daytime or nighttime, but are least active during mid-day and often have peaks in activity near sunrise and sunset (Arthur and Krohn 1991, Powell 1993). Fisher activity patterns appear to be influenced by a variety of factors beyond time of day, such as gender, breeding status, development of offspring, ambient temperature, and snow conditions (Leonard 1980, Arthur and Krohn 1991, Weir and Corbould 2007).

Fishers use snags, logs, and other structures for resting when they are not foraging or traveling (Lofroth et al. 2010). Individuals typically remain inactive at a rest site for several hours to several days at a time (Powell and Zielinski 1994).

Fishers are able to rapidly move long distances but travel an average of approximately 3 to 4 miles per day (Powell 1993). As with activity patterns, the mobility of fishers is influenced by season, offspring development, and other factors (Powell 1993).

Agonistic Behavior and Territoriality

Fishers are solitary except when mating, defending their territory, or rearing kits (Powell 1993). Fishers are territorial toward members of the same sex. Home ranges do not generally overlap for members of the same sex but the large home ranges of males often overlap those of multiple females (Powell 1993). Fishers appear to primarily maintain their territories through scent marking (Powell and Zielinski 1994). Agonism has rarely been documented for fishers (Powell and Zielinski 1994). However, kits are often aggressive toward each other at about 3 months of age and mothers often become aggressive toward their kits after they are about 4 months old (Coulter 1966, Powell 1993). Indirect evidence suggests that adult males occasionally fight during the breeding season, when many males trespass into neighboring territories to find estrous females (Leonard 1986, Powell 1993). Male fishers appear to select between 2 reproductive strategies. Some males maintain their territories during the breeding season, perhaps in order to defend access to females within them, while others abandon their territories and roam in search of estrous females (Aubry et al. 2004).

2.2.2.5 Habitat Relationships

Home Range Size

Rigorous comparisons of fisher home range estimates are not possible due to differences in sampling efforts and analytical methods among studies. General comparisons, however, may still be of interest. Mean fisher home range sizes across North America varied from 3,954 to 30,147 acres for males and from 988 to 13,096 acres for females (USDI FWS 2004b). Mean home range sizes for fishers in western North America closely resembled these (Lofroth et al. 2010). Throughout North America, the home ranges of males are, on average, nearly 3 times larger than those of females (Powell and Zielinski 1994, Lofroth et al. 2010). Mean home range sizes from 7 study areas in California ranged from 1,829 to 14,357 acres for males and from 420 to 5,807 acres for females (Lofroth et al. 2010).

Habitat Relationships

Denning and Resting Sites

Dens and rest sites likely provide fishers with protection from predators and weather, access to foraging areas, and a place to safely consume prey (Powell 1993, USDI FWS 2004b, Lofroth et al. 2010). Fishers typically use 3 dens per litter of kits (Arthur and Krohn 1991, Paragi et al. 1996, Higley and Matthews 2006) and only occasionally reuse rest sites (Powell and Zielinski 1994). Thus, a well distributed network of suitable denning and resting sites is a key feature of fisher home ranges (USDI FWS 2004b). Suitable dens and rest sites are likely more limiting than foraging habitat for fishers (Powell 1993, Powell and Zielinski 1994).

All natal dens are located in cavities in trees or snags, but platforms in trees (e.g., mistletoe brooms or rodent nests), the interiors of hollow logs, and spaces under woody debris may be used for maternal dens (Powell and Zielinski 1994, Lofroth et al. 2010). Fishers also use a variety of structures for resting, including cavities in trees or snags, large branches, hollow logs, mistletoe clumps, platform nests, rocks, holes in the ground, and slash and brush piles (Powell and Zielinski 1994, Lofroth et al. 2010). Fishers rested primarily in live trees and secondarily in snags and coarse down wood (Lofroth et al. 2010). Fishers on managed timberlands in northwestern California primarily rested on mistletoe brooms but also used large lateral branches, mammal nests, and tree cavities (Self and Kerns 2001, Simpson Resource Company 2003).

Fishers in western North America use both conifers and hardwoods for denning but appear to favor hardwoods (Lofroth et al. 2010). Black oaks (*Quercus kelloggii*) are often used for denning in California (Lofroth et al. 2010). Most (91%) hardwoods used for denning in western North America are alive, whereas live and dead conifers are used almost equally (Lofroth et al. 2010). Fishers in the southern Sierra Nevada usually rested in black oaks and other hardwoods; fishers near the northern California coast primarily used Douglas-firs; and fishers in the Klamath Mountains mostly rested in hardwoods, followed by conifers, snags, and logs (Zielinski et al. 2004b, Higley and Matthews 2006).

Trees used for denning and resting are typically large. The average diameter at breast height (dbh) of trees used for denning and resting in western North America ranged between 18 and 73 inches and 22 and 46 inches, respectively (Lofroth et al. 2010). Conifer trees used for denning and resting are usually larger than hardwoods used (Lofroth et al. 2010). In California, conifers, conifer snags, and hardwoods used for denning averaged 46, 46, and 25 inches dbh, respectively (Truex et al. 1998). The sizes of trees used for resting in California were similar to those used for denning (46, 47, and 27 inches dbh for conifers, conifer snags, and hardwoods; Zielinski et al. 2004b). The diameters of trees used for denning and resting in western North America were, on average, 1.7 to 2.8 and 1.5 to 1.7 times larger, respectively, than those of other nearby trees (Lofroth et al. 2010). Logs used for denning and resting in western North America were also generally large; ranges of means among studies were 22 to 65 inches for dens and 16 to 52 inches for resting (Lofroth et al. 2010).

Areas immediately surrounding fisher denning and resting locations in western North America are generally characterized by the presence of large trees and snags, large-diameter hardwoods, coarse woody debris, dense multi-layered canopies, and steep slopes near water (USDI FWS 2004b, Lofroth et al. 2010). Rest sites in western North America usually had denser canopies, larger trees, more large trees and snags, and a greater abundance of coarse woody debris than was generally available (Lofroth et al. 2010). Fishers in California also tended to rest at sites with more hardwoods than were generally available.

Habitats Used by Active Fishers and Prey

Habitats used for foraging, traveling, and other activities resemble denning and resting habitat but include a broader range of conditions (USDI FWS 2004b, Lofroth et al. 2010). Throughout their range, fishers generally favor areas with dense canopy cover and avoid open or sparsely-canopied areas (Powell 1993, Powell and Zielinski 1994, Lofroth et al. 2010). Fishers also occur in areas with sparse canopy cover, particularly on managed lands in northern California, but their population performance in these areas is unknown (Powell and Zielinski 1994). Rosenberg and

Raphael (1986) characterized fishers in northern California as sensitive to the sizes of forest stands. Survey stations at which fishers were detected in both northern and southern California have generally been located in more structurally complex forests than those at which fishers were not detected (Lofroth et al. 2010). Fishers in northern California were also more likely to be detected at sites with a greater component of hardwoods, greater shrub or overstory tree cover, and greater densities of snags and coarse woody debris (Lofroth et al. 2010). Fishers in the southern Sierra Nevada were usually detected in areas with greater canopy cover, a component of hardwoods and large trees (greater than about 24 inches), and close proximity to a stream (Green 2007).

Fishers have broad diets that include prey species with a wide variety of habitat associations. Nonetheless, certain habitat elements are important to many of the fisher's prey: (1) large conifers and hardwoods are the primary sources of seeds for many birds and small mammals; (2) many of the fisher's prey rely on shrubs for food, cover, or nest sites, and shrubs and other understory plants provide fruit for fishers; (3) snags and coarse woody debris are used by many birds and small mammals for cover, foraging, caching food, nesting, and other functions, and large, well-decayed logs are often important to truffles (a key food resource for many small mammals); and (4) interconnected, multi-layered canopies are important for arboreal mammals and many bird species (Lofroth et al. 2010).

Landscape Composition

Home ranges and landscapes occupied by fishers typically consist of a mosaic of vegetation types and structural stages, but with a large component of mid- to late-successional forest (Powell and Zielinski 1994, Lofroth et al. 2010). Fishers in western North America appear to generally avoid landscapes with large amounts of non-forest (Lofroth et al. 2010). The home ranges of fishers in California contained a variety of vegetation types and structural stages but were mostly composed of conifer or conifer-hardwood forest with dense canopy cover and mid- to late-successional structure (Zielinski et al. 2004a).

Abiotic Habitat Features

Studies have identified a variety of abiotic features associated with the presence or absence of fishers, including elevation, terrain ruggedness, solar insolation, slope angle or position, and proximity to streams or roads (Powell and Zielinski 1994, Lofroth et al. 2010, Zielinski et al. 2010). It is often unclear whether these features directly influence habitat use by fishers or are simply associated with other important variables, such as vegetation conditions or prey availability.

Fishers are generally found at low- to mid-elevations in the Pacific States (e.g., less than about 5,000 feet; Powell 1993, Powell and Zielinski 1994, Lofroth et al. 2010). Elevation is likely a proxy for the distribution of snow depth and suitable vegetation conditions, rather than a direct influence on fisher-habitat relationships (Powell and Zielinski 1994, Lofroth et al. 2010). Throughout its range, the fisher appears to avoid higher elevations and other areas with deep snow, which is thought to restrict the species' movements (Powell and Zielinski 1994). In areas with intermediate snow depths, fishers may partly favor densely-canopied forests for their interception of snow (Powell and Zielinski 1994, Weir 1995). Elevation also influences the distribution of vegetation composition and structure in western mountains. For example, major vegetation types in the Klamath Mountains and Sierra Nevada of California tend to occur as lateral bands distributed according to elevational controls on climate and natural disturbance regimes (Sawyer 2006, Fites-Kaufmann et al. 2007).

Numerous studies have found that fishers favor riparian areas or other areas near streams (Powell and Zielinski 1994, Lofroth et al. 2010). In areas where they differ from uplands, riparian areas provide important habitat for many birds and small mammals due to the presence of shrubs, herbs, hardwoods, and other moisture- or disturbance-associated plants and their function as corridors for movement for some species (Doyle 1990, Knopf and Samson 1994, Boyce and Payne 1997, Anthony et al. 2003). Riparian areas may also function as corridors for movements by fishers (Powell and Zielinski 1994). In some landscapes, large proportions of suitable denning and resting structures and habitat may be located in riparian areas (Lofroth et al. 2010).

2.2.2.6 Reproductive Biology

The fisher's breeding season extends from February through April but can occur as early as January and as late as May (Powell and Zielinski 1994). Fishers usually give birth between mid-March and early April, although parturition can also occur a month earlier or later than this (Powell 1993). Females become estrous for about 1 week 3 to 9 days after giving birth (Powell 1993). Males become more active early in the breeding season and often foray into other males' territories in search of estrous females (Arthur and Krohn 1991, Powell 1993). Due to delayed implantation, fishers give birth nearly 1 year after conception (Powell 1993). The average litter size for fishers is 2 to 3 kits (Powell 1993). Males do not assist females with care of the offspring and may even pose a threat to young fishers (Powell 1993).

Fishers use cavities in trees or snags to give birth (Powell 1993, Lofroth et al. 2010). Kits are born blind and have tightly closed ears and sparse hair (Coulter 1966). Mothers may move kits to multiple den locations before weaning them at approximately 10 weeks old (Arthur and Krohn 1991, Powell 1993). After weaning, mothers and kits become more mobile but often use the same den for 2 or more days at a time (Arthur and Krohn 1991, Paragi et al. 1996, Aubry and Raley 2006). Kits typically establish their own home ranges by about 1 year of age (Powell 1993).

Male fishers produce sperm at 1 year of age but do not appear to be effective breeders until after their first year (Powell 1993). Females can breed at 1 year of age but do not produce a litter until at least their second year due to delayed implantation (Powell and Zielinski 1994). Older females may breed more frequently than younger females (Weir and Corbould 2008).

2.2.2.7 Natal Dispersal

Juvenile fishers usually disperse from their natal areas during their first fall or winter (Lofroth et al. 2010). Fishers are capable of moving long distances but appear to have relatively poor dispersal abilities (Lofroth et al. 2010). The duration of dispersal by fishers is influenced by multiple factors, including gender and the availability of unoccupied, suitable habitat (Lofroth et al. 2010). Inferences about dispersal by fishers, however, are generally limited by small sample sizes.

Juvenile fishers may disperse shorter distances in areas with high mortality and a low density of other fishers (Arthur et al. 1993). In Maine, which has high trapping mortality and a low density, the mean minimum distance moved by dispersing fishers was 7 miles (Arthur et al. 1993). In contrast, fishers in a higher-density population in Massachusetts dispersed a mean minimum distance of 20 miles (York 1996).

Juvenile dispersal appears to be male-biased in western North America (Lofroth et al. 2010). For example, in the Oregon Cascades, the average dispersal distance for males (18 miles) was nearly 5 times that of females (3.7 miles) (Aubry and Raley 2006).

2.2.2.8 Food Habits

Fishers are opportunistic, generalist predators (Powell and Zielinski 1994, Lofroth et al. 2010). Fisher diets typically include birds, mammals, reptiles, insects, fruit, and carrion (Powell and Zielinski 1994, Lofroth et al. 2010). Porcupines (*Erethizon dorsatum*) and snowshoe hares (*Lepus americanus*) are key contributors to fisher diets in much of North America but appear to be absent from the diet in California (Zielinski et al. 1999, Golightly et al. 2006). Fishers in California tend to have more diverse diets than do other western fishers (Zielinski et al. 1999, Golightly et al. 2006). Small and medium size mammals, including carnivores, rodents, and insectivores, were most often present in the scats of fishers in California (Zielinski et al. 1999, Golightly et al. 2006). Birds, reptiles, insects, truffles, and ungulate carrion also appeared to be important components of fisher diets in the State (Zielinski et al. 1999, Golightly et al. 2006).

Seasonal changes in fisher diets are generally minor (Powell and Zielinski 1994), although ungulate carrion was present in substantially more scats during winter than during other seasons in the southern Sierra Nevada (Zielinski et al. 1999). Sexual differences in the diets of fishers also appear to be weak (Powell and Zielinski 1994). However, males, which are larger, may capture larger mammalian prey more frequently than do females (Lofroth et al. 2010). Perhaps due to their poorer hunting ability, juvenile fishers in the eastern United States ate more fruits than did adults (Giuliano et al. 1989).

2.2.2.9 Population Biology

Fishers have low annual reproductive capacity and reproductive rates can strongly fluctuate among years (Lofroth et al. 2010). The annual reproductive rate of adult female fishers (proportion that denned) in western North America averaged 64% and ranged between 39 and 89% (Lofroth et al. 2010). The annual reproductive rates in a study on managed timberlands in northern California were 22 and 80% during 2 breeding seasons (51% for both years combined; Reno et al. 2008). Only a portion of breeding females successfully wean kits. For example, the annual reproductive rate in a northern California study was 85% but only 68% of females successfully weaned 1 or more kits (Higley and Matthews 2006). Annual fluctuations in reproduction could be influenced by a variety of factors, including snow depths or the age structure of the population’s females (Powell and Zielinski 1994, Weir and Corbould 2008).

Trapping and other human activities are the primary causes (68%) of mortality in some eastern North American populations, whereas natural factors cause the majority (54%) of mortalities in western North America (Lofroth et al. 2010). Predation is the primary natural source of mortality in western North America (Lofroth et al. 2010); bobcats, large carnivores, and raptors are the fisher's main predators (Powell and Zielinski 1994, Higley and Matthews 2009). Starvation, choking on food, injuries received from prey or conspecifics, are also sources of natural mortality for fishers (Powell and Zielinski 1994, Lofroth et al. 2010). Anthropogenic factors that contribute to individual fisher mortality and fitness include; contaminants, pest control programs, non-target poisoning, collision with vehicles, and accidental trapping in manmade structures (Folliard 1997, Truex et al. 1998, Gabriel et al. 2011, Sweitzer et al. 2011). Diseases and parasites are thought to be uncommon in fishers (Powell 1993, Powell and Zielinski 1994, Lofroth et al. 2010). A recent study in northern California, however, found exposure by fishers to several diseases including canine distemper virus and parvovirus (Brown et al. 2008). Although the full ecology of canine distemper virus and parvovirus in fishers is not fully understood, both viruses have caused mortality and morbidity in fishers and many other susceptible mustelids (Gabriel 2010). In 2009, in an insular population of fishers in the southern Sierra Nevada Mountains in California, an epizootic of distemper virus caused four mortalities within a short period of time (Gabriel 2010). Some of the reported diseases suppress immune function in other species and thus, could act synergistically with other factors to cause mortality of fishers. For example, the protozoan *Toxoplasma gondii* has been documented as a cause of mortality as well as an immunosuppressive pathogen in fishers (Gabriel 2010).

An emerging conservation concern is how the widespread use of anticoagulant rodenticides may be affecting fishers. Prevalence of exposure to anticoagulant rodenticides in fishers from California and Washington is quite high, with 80% of 71 sampled fishers testing positive (Gabriel 2012). It is unknown at this time whether exposure to these toxicants has an additive sublethal or chronic effect on an individual fisher or population; however, four fisher mortalities from California were directly attributed to anticoagulant rodenticides toxocosis (Gabriel 2012). To date, no direct consumption of anticoagulant rodenticides has been detected in fisher stomach contents, thus suggesting that exposure to these toxicants may be from secondary poisoning from consumption of prey or carrion exposed to anticoagulant rodenticides (Gabriel 2012).

The life expectancy of fishers is approximately 10 years but individuals as old as 12 have been reported (Powell 1993, Lofroth et al. 2010). Nonetheless, only a small proportion of fishers in wild, unharvested populations are more than 6 or 7 years-old (Lofroth et al. 2010). Studies in 2 areas of northern California found that 45 and 55% of individuals were not yet of reproductive age (i.e., less than 2 years-old), 52 and 35% were 2 to 6 years-old, 3% and 10% were 7 or 8 years-old, and no individuals were older than 8 years (Brown et al. 2006, Reno et al. 2008). It is possible, however, that these studies' use of live-trapping to determine fishers' ages biased their results toward younger animals (Lofroth et al. 2010). The age structures of fisher populations likely fluctuate among years in response to a variety of factors, including age-specific survivorship, population density, and prey availability (Powell and Zielinski 1994, Lofroth et al. 2010).

Estimates of annual survivorship, sex ratios, and age structure vary across the fisher's range and are closely associated with the occurrence of commercial trapping (Powell and Zielinski 1994, Lofroth et al. 2010). Mean annual survivorship was 0.82 for males and 0.74 for females in 3 untrapped populations in western North America (Lofroth et al. 2010). In contrast, male survivorship was, on average, 34% lower than that of females in commercially trapped populations in eastern North America. Age-specific survivorship also appears to be sensitive to commercial trapping (Lofroth et al. 2010). In Maine, juvenile survivorship during the trapping period was nearly half that of the nontrapping period (38 vs. 72%; Krohn et al. 1994).

Powell and Zielinski (1994) hypothesized that populations of fishers and other mustelids are characterized by episodes of local extinction and recolonization. If true, small population sizes and geographic isolation could prevent recolonization of depopulated areas (see section 2.2.3).

2.2.3 Threats

2.2.3.1 Reasons for Legal Status

The Service's 12-month finding for a petition to list the West Coast DPS concluded that listing was warranted but precluded by pending proposals for other species with higher listing priorities (USDI FWS 2004b). The Service determined that listing was warranted due to multiple past and present threats to the DPS, including: (1) over-trapping and incidental captures; (2) loss and fragmentation of habitat; (3) other problems associated with spread of roads and other human developments, such as vehicle collisions and behavioral disturbance; (4) disease and predation; and (5) small, isolated populations. The Service considered the combined magnitude of these threats to be non-imminent but high. The remainder of this section summarizes relevant sections of the Service's 12-month finding.

Commercial trapping, particularly during the late 1800s and early 1900s, contributed to dramatic declines in the fisher's abundance, distribution, and range. Trapping continues to be a primary cause of fisher mortality in areas where it is still legal. Commercial trapping has been prohibited in California, Oregon, and Washington since the 1930s and 1940s. However, fishers are sometimes incidentally captured in traps set for other species. Incidental captures often maim or kill fishers. Even small numbers of mortalities from trapping could prevent local recovery of populations or recolonization of historically occupied areas.

Historical logging was a primary cause of the fisher's decline and harvesting continues to threaten the species in some parts of its range. Depending on how and where it occurs, logging can alter fisher habitat by fragmenting or reducing forests or by modifying forest composition and structure. Fishers are generally associated with dense canopy cover, large and deformed trees, and large snags and logs. These features, along with understory cover, are also important to the fisher's prey communities. The impacts of logging on fishers partly depend on the degree to which these structural characteristics are reduced. Habitat fragmentation and loss might also negatively affect fishers by creating barriers to dispersal and other movements.

Fire suppression, together with logging, livestock grazing, and other factors, has facilitated increased forest densities in drier, more fire-prone portions of the fisher's range. Increased canopy cover and greater abundances of dead woody materials in these forests might benefit some fishers. However, increased forest densities have substantially heightened the risk of large, stand-replacing wildfires. Large, stand-replacing fires could threaten large areas of fisher habitat.

Although not discussed in the 12-month finding, it is also important to note that increased forest densities have contributed to declines in oaks and other shade-intolerant hardwoods in some areas of California (Sugihara et al. 2006). Loss or reduction of hardwoods could negatively affect some populations by reducing denning and resting structures for fishers and mast for prey. Additionally, increased densities of small and medium size trees have accelerated declines of large conifers in some forests (Dolph et al. 1995, Smith et al. 2005, Ritchie et al. 2008).

The 12-month finding concluded that outbreaks of insects and diseases that affect trees are probably not a major threat to fisher habitat on the West Coast. However, at uncharacteristic high levels, insects and disease can cause broad-scale loss of overstory trees and vegetation diversity that may fragment or remove forested environments capable of supporting fishers. Sudden Oak Death, for example, could pose a significant future threat to fisher populations strongly associated with oaks and other hardwoods (e.g., the southwestern Oregon/northern California population).

Increases in the number and distribution of residential areas, roads, and other human developments likely strongly contributed to the fisher's extirpation from, and failure to recolonize, the central and northern Sierra Nevada. Expanding human populations are projected to result in increased land conversion in forested areas of the West Coast. Increased roads and other human developments could reduce and fragment fisher habitat, disrupt fisher movements, and bring the species into greater contact with vehicles, recreationists, and trapping. Collisions with vehicles are a major cause of fisher mortality in some areas and vehicles or recreationists may alter the behavior or distribution of fishers. Additionally, several fishers have been found dead in water storage tanks associated with human developments.

Major outbreaks of disease have not been documented for fisher populations but fishers are susceptible to diseases that have strongly impacted other mustelids. Predation appears to be a primary source of mortality for some fisher populations. Disease and predation potentially threaten West Coast fishers due to their occurrence as small, isolated populations.

West Coast fishers are at risk of extinction due to small population size and associated factors, such as isolation, low reproductive capacity, and demographic and environmental stochasticity. California and southwestern Oregon have the only known native populations of fishers on the West Coast. Native fishers are currently rare or absent in Washington and most of Oregon. Fishers were reintroduced to the southern Cascades of Oregon but the population is small and isolated. Fishers were reintroduced to the Olympic Peninsula of Washington and northern Sierra Nevada of California subsequent to the 12-month finding but their status is still being determined (Lewis et al. 2010, Washington Department of Fish and Wildlife 2011, CDFG 2011).

2.2.3.2 Additional Threats

Climate Change

Projected climate changes and their general effects are described in sections 1.4.5.1 (Changed Circumstances) and 2.1.3.2 (New Threats). Projected effects that could influence West Coast fisher populations include changes to forest composition and structure, prey communities, snow packs, and natural disturbance regimes. The effects of projected changes are difficult to predict for fishers because they would likely affect the species in complex and synergistic ways (Safford 2007). Some projected changes could benefit fishers. For example, reduced, earlier-melting snow packs might enable fishers to travel more easily or exploit higher-elevation areas. Projected increases in the abundance and distribution of oaks and other hardwoods in California's mountains could also benefit fishers by increasing denning and resting structures and mast for prey. Other projected changes could negatively affect West Coast fishers. For example, increased occurrence of catastrophic wildfires in some forests could reduce or fragment habitat for fishers. Climate change is also expected to cause the extinction of many wildlife species. Extinctions, along with species-specific responses to climate change, would likely have complex, unpredictable effects on the composition and abundance of the fisher's prey communities.

2.2.4 Conservation Needs of the Fisher

2.2.4.1 Habitat Needs

1. Large blocks of suitable habitat to support clusters of fisher (i.e., greater than 20 females) throughout the fisher's range;

2. Suitable habitat conditions and spacing between clusters of fisher populations throughout its range to facilitate survival and movement;

3. Suitable habitat distributed across a variety of ecological conditions within the fishers' range to reduce risk of local or widespread extirpation;

4. A coordinated, adaptive management effort to reduce the loss of habitat due to catastrophic wildfire throughout the fisher's range, and a monitoring program to clarify whether these risk reduction methods are effective and to determine how fishers use habitats treated to reduce fuels; and

5. Monitoring and coordinated research to better understand the risk of how uncharacteristically high levels of insect and disease (e.g., sudden oak death) affect fisher habitat.

2.2.4.2 Habitat-independent Needs

1. A coordinated adaptive management effort is needed to ameliorate threats and overcome the fundamental challenges posed by relatively, small isolated populations. These efforts will differ by geographic region because the type, number, and potential synergistic effects of threat

interactions are complex and varied;

2. A coordinated research and adaptive management effort to better understand and manage for the competitive and predatory interactions between fishers and their predators.

3. A coordinated research and monitoring effort to better understand the risk that disease and toxins pose to fishers and methods that may reduce the likelihood or severity of outbreaks and exposure in fisher populations.

2.2.4.3 Conservation Strategy

Region 8 of the Service completed an action plan for the West Coast DPS of the fisher (USDI FWS 2010c). The plan identified the following actions to maintain or improve the West Coast fisher's current status from 2010 to 2014:

1. Develop conservation strategies among Federal, State, and local agencies, as well as private land owners.

2. Develop a systematic survey and monitoring program for fishers throughout their historical range in the Pacific States and ensure that it has long-term institutional support.

3. Conduct research to assist in recovery and conservation planning.

4. Augment existing populations or reintroduce extirpated populations in suitable habitat within the species' historical range.

The Service's action plan acknowledged that 5 years was likely insufficient for demonstrating satisfactory improvements in the numbers or distribution of fishers. Large amounts of time and money from multiple Federal and State agencies will be required to demonstrate growth of existing populations and/or establishment of new populations. The Service did, however, expect to initiate the required programs during the 5-year period.

2.2.4.4 Federal Contribution to Recovery

As described above in section 2.1.4.4, the NWFP was adopted in 1994 to guide the management of 24 million acres of Federal lands in portions of western Washington and Oregon, and northwestern California (USDA Forest Service and USDI Bureau of Land Management 1994a, b). The NWFP represents a 100-year strategy for conservation of the northern spotted owl (*Strix occidentalis caurina*) and other species associated with late-successional and old-growth forests on Federal lands. The NWFP is intended to ultimately provide a network of large block reserves of late-successional habitat, connected through riparian reserves, and surrounded by a matrix of younger more intensively managed forest. As the forests mature the plan could lead to a substantial improvement in current habitat conditions for fishers on Federal lands within the reserve network. However, the assessment of NWFP implementation on fishers within the Plan Area projected only a 63% likelihood of achieving an outcome in which habitat is of sufficient quality, distribution, and abundance to allow the fisher population to stabilize and be well distributed across Federal lands (FEMAT 1V-173). Habitat modeling by Zielinski et al. (2006) suggested that areas of high predicted value for fishers poorly overlap with the current NWFP Late-Successional Reserve system; particularly in the eastern portion of the Klamath Province, where relatively little high value habitat currently occurs.

The Sierra Nevada Forest Plan Amendment (SNFPA) was adopted in 2001 and a Final Record of Decision (ROD) was issued in 2004 (USDA FS 2000a, 2001, 2004). The final ROD provides the framework guidance and policy document for managing 11 National Forests and about 11 million acres of California's National Forest lands in the Sierra Nevada and Modoc Plateau. The SNFPA includes measures expected to lead to an increase over time of late-successional forest; retention of important wildlife structures such as large-diameter snags and coarse woody debris; and management of about 40% of the Plan Area as old forest emphasis areas. The SNFPA also established a Southern Sierra Fisher Conservation Area with additional requirements intended to maintain and expand the fisher population in the southern Sierra Nevada. Conservation measures for the fisher conservation area include maintaining at least 60% of each watershed in mid-to-late successional forest (at least 11-inch mean dbh) with an average canopy cover of at least 50%. The plan also includes protections for known fisher den sites. However, this measure has limited conservation value in many areas due to the difficulty of locating fisher den sites without radio-telemetry. As part of the ROD, the USFS initiated a regional fisher monitoring program in 2002 to track population trends throughout the southern Sierra Nevada. The primary objective of the program is to use sampling to detect a 20% decline in relative abundance of the population with 80% statistical power.

The USDA Forest Service (USFS) Sensitive Species Policy and the USDI Bureau of Land Management (BLM) manual call for both National Forests and BLM districts to assist and coordinate with other Federal agencies and States to conserve species with viability concerns. The fisher has been identified as a sensitive species by the USFS Pacific Southwest and Pacific Northwest Regions (Regions 5 and 6, respectively) and the Oregon-Washington and California BLM.

Each National Forest operates under a Land and Resource Management Plan (LRMP) and each BLM district operates under a Resource Management Plan (RMP). The NWFP standards and guidelines apply to National Forests and BLM districts within the range of the northern spotted owl except when the standards and guidelines of LRMPs or RMPs are more restrictive or provide greater benefits to species associated with late-successional forest. Most individual Forest LRMPs and BLM district RMPs do not provide any additional protections to fishers or fisher habitat. Therefore, the above discussion regarding the NWFP and SNFPA summarizes the primary regulatory mechanisms in place on National Forest and BLM lands within the range of the West Coast DPS.

Land management plans for the National Parks within the range of the West Coast DPS do not contain specific measures to protect fishers. Nonetheless, areas not developed specifically for recreation or camping are managed toward natural ecosystem composition and function and are expected to maintain fisher habitat. Hunting and trapping are not allowed in the parks. Fisher habitat occurs in National Parks within the range of the West Coast DPS but many of the parks contain large areas at higher elevations than those at which fishers and their habitat generally occur. The Olympic National Park, Olympic National Forest, and the Washington Department of Fish and Wildlife are currently cooperating and implementing a reintroduction of fishers to suitable lands in the Olympic National Park (Lewis et al. 2010, Washington Department of Fish and Wildlife 2011).

2.2.4.5 Conservation Efforts on Non-Federal Lands

Washington. The State of Washington listed the fisher as endangered (WAC 232-12-297) in 1998. This status provides protection in the form of more stringent fines for poaching and a process for environmental analysis of projects that may affect the species. There are no special regulations to protect habitat for fishers or to conduct surveys for this species prior to obtaining forest activity permits.

The State Forest Practice Rules are the primary regulatory mechanism on non-Federal forest lands in Washington (Title 222 of the Washington Administrative Code). These rules apply to all commercial timber growing, harvesting, or processing activities on non-Federal lands, and give direction on how to implement the Forest Practice Act (Title 76.09 Revised Code of Washington), and Stewardship of Non-Industrial Forests and Woodlands (Title 76.13 RCW). Washington's Forest Practice Rules do not specifically address the fisher's habitat requirements but may provide limited benefit to the species through protection of important habitat elements (e.g., dead woody materials, canopy cover) in some areas.

The Washington Department of Fish and Wildlife (WDFW), in cooperation with the Olympic National Park, US Geological Survey, and others, began to reintroduce fishers onto Park Service lands on the Olympic Peninsula in Washington in January 2008 (Lewis et al. 2010). Three years of planned reintroductions were complete at the end of the 2010 trapping season with a total of 90 fishers (40 males and 50 females) relocated from British Columbia to the park. These fishers will be monitored for a number of years to determine both the extent of their distribution and success in establishing a reproducing population of fishers on the Olympic Peninsula. Successful establishment of this population will not be known for several years.

Oregon. Oregon designated the fisher a protected non-game species and a sensitive species (critical category; Oregon Department of Fish and Wildlife 2008). The Oregon Department of Fish and Wildlife does not allow 'take' (i.e., kill or obtain possession or control) of fishers, but some fishers may be injured or killed by traps set for other species. Training and testing is required of applicants for trapping licenses in order to minimize take of non-target species such as fishers.

The two management plans for Oregon's State Forests generally appear to be of little benefit to fishers. Both plans include provisions to protect some forest reserves, but these are not likely to benefit fishers because of the fragmented nature of the lands.

The Forest Practice Administrative Rules and Forest Practices Act (Oregon Department of Forestry 2000) regulates forest activities on all State, county, and private lands in Oregon. Interim procedures for protecting sensitive resource sites apply only to threatened and endangered species, and to bird species listed as "sensitive" in the rules, and currently do not apply to fishers. While Oregon's rules governing forest management on non-Federal lands do not directly protect the fisher or its habitat, they may provide some protection for habitat elements important to the species.

California. The State of California classifies the fisher as a furbearing mammal that is protected from commercial harvest. On April 8, 2009, the California Fish and Game Commission accepted a petition initiating a 12-month review of the status of fisher by the CDFG, pursuant to Fish and Game Code Section 2074.6. At its June 23, 2010 meeting, the California Fish and Game Commission determined that listing was not warranted as suggested by CDFG in the "Report to the Fish and Game Commission, A Status Review of the Fisher (*Martes pennanti*) in California", (CDFG 2010).

The California Environmental Quality Act (CEQA) provides regulatory protections for critical habitat and habitat required by federally listed species (e.g., northern spotted owls, marbled murrelets [*Brachyramphus marmoratus*], anadromous salmonids) on state and private lands in California. These protections may provide limited benefits to fishers.

Timber management activities on commercial forestlands in the State are guided by the CFPRs (California Department of Forestry and Fire Protection 2011). The Forest Practice Rules provide protections for species listed as threatened or endangered under the Endangered Species Act or CESA and for species identified by the California Board of Forestry as sensitive, but the fisher is not currently on any of these lists. The Forest Practice Rules also include intent language about reducing significant impacts to non-listed species and maintaining functional wildlife habitat. However, this language is not associated with specific enforceable measures. The CFPRs may provide limited benefit to fishers in some areas; for example, by protecting habitat elements for spotted owls and other species associated with late-successional forests.

The CDFG, in cooperation with the Service and Sierra Pacific Industries, began to translocate fishers to the northern Sierra Nevada in December, 2009. Three years of planned translocations (Callas and Figura 2008) were complete in December of 2011, with a total of 40 fishers (16 males and 24 females) relocated from northwestern California to the northern Sierra Nevada. These fishers will be monitored for seven years to determine both the extent of their distribution and success in establishing a reproducing population of fishers in the northern Sierra Nevada. Successful establishment of this population will not be known for several years.

Tribal. Tribal lands within the range of the West Coast DPS manage their forests under a variety of management plans. Some of these forest management plans (e.g., Warm Springs Reservation of the Confederated Tribes, The Coquille Tribe of Oregon, and The Confederated Tribes and Bands of the Yakama Nation) contain guidelines and habitat protection measures for spotted owls, riparian areas, and dead woody materials that will, at a minimum, provide some of the habitat components important to fishers and their prey. The forest management plan for the Hoopa Valley Indian Reservation in northwestern California includes setting aside habitat and no-harvest reserves and specifically acknowledges needs for conservation and research of fishers on the Reservation.

Habitat Conservation Plans. Some non-Federal lands are managed under Habitat Conservation Plans (HCPs) with strategies that conserve habitat for a variety of species. These HCPs may provide some incidental benefit to fishers. A few HCPs cover areas within the historical range of the fisher, particularly in western Washington and northwestern California. Although the fisher is a covered species in 7 HCPs within Washington and California, the species is currently known to be present only on lands under 2 California HCPs. In most HCPs, areas where late-successional habitat will be protected or allowed to develop are mostly in riparian buffers and smaller blocks of remnant old forest.

2.2.5 Current Condition of the West Coast DPS of the Fisher

2.2.5.1 Current Range and Distribution

The current range and distribution of West Coast fishers is described in section 2.2.2.3 (also see Lofroth et al. 2010).

2.2.5.2 Habitat Trends and Current Conditions

West Coast fishers favor areas containing mid- to late-successional conifer or conifer-hardwood forest, with relatively dense canopy cover, large-diameter trees, snags, and logs, and complex structure, including understory vegetation and down wood (USDI FWS 2004b). The current abundance of these conditions in the Pacific States is substantially lower than during historical periods. Bolsinger and Waddell (1993) found a 31% reduction of old-growth forests in evaluated portions of California, Oregon, and Washington compared to the early 20th century. The Forest Ecosystem Management Assessment Team (1993) reported that: (1) heavy logging has eliminated most late-successional and old-growth forest in the western Washington lowlands and northern Oregon Coast Range; (2) public lands in the Olympic Peninsula, southern Oregon Coast Range, and western Washington and Oregon Cascades still contain substantial amounts of late-successional or old-growth forest but much of it has been highly fragmented by logging; and (3) the Oregon and California Klamath Provinces and the California Cascades also have substantial amounts of late-successional and old-growth forest but it is highly fragmented by logging and natural factors. Franklin and Fites-Kauffman (1996) found that only about 14% of evaluated polygons (landscape units on public lands that were relatively uniform in type and distribution of vegetation patches) in the Sierra Nevada and southern Cascades of California are currently dominated by late-successional or old-growth forest structure and function.

Several recent models have used fisher detection locations and habitat associations to predict the distribution of habitat suitability for the species in California and southwestern Oregon (Carroll et al. 1999; Zielinski et al. 2006, 2010; Davis et al. 2007; Spencer et al. 2011). These models showed that large proportions of northwestern California currently consist of predicted medium- and high-suitability habitat for fishers; that is, areas in which there is a moderate or high probability of detecting the species (Carroll et al. 1999; Zielinski et al. 2006, 2010; Davis et al. 2007). The models have differed somewhat, however, in their projections of habitat suitability in the western versus eastern portions of the Klamath Province. Carroll et al. (1999) showed that most of the high-suitability fisher habitat in the Oregon and California Klamath Provinces is located relatively close to the coast. In contrast, Davis et al. (2007) projected greater amounts of high-suitability fisher habitat in the central, northern, and eastern portions of the California Klamath Province than in the western portion. Zielinski et al. (2010) did not model fisher habitat near the coast but did project greater concentrations of medium- and high-suitability fisher habitat in the western portion of the California Klamath Province than in the eastern portion. Models indicated that the southern Sierra Nevada currently contains a band of medium- and high-suitability fisher habitat on the range's western slope (Davis et al. 2007, Spencer et al. 2011). Pockets of medium- and high-suitability habitat likely also occur in rugged forested canyons in the northern Sierra Nevada but they are distant from the southern Sierra Nevada fisher population relative to fisher dispersal distances (Davis et al. 2007).

2.2.5.3 Population Densities and Abundances

Estimates of fisher densities and abundances vary among studies and geographic areas. Fisher populations are primarily influenced by the availability of habitat and prey (Powell 1993, Powell and Zielinski 1994). Population estimates for the species are often inaccurate due to large sampling errors and should be cautiously evaluated (Powell 1993, Powell and Zielinski 1994).

In British Columbia, densities of fishers in the highest-suitability habitats were estimated to be between 1.0 and 1.5 fishers per 38.6 mile^2 (Weir 2003). Estimated densities on an industrial forest in the province ranged between 0.8 and 1.3 fishers per 38.6 mile^2 (Weir and Corbould 2006). The late-winter population in British Columbia was conservatively estimated to be between 1,113 and 2,759 individuals (Weir 2003).

Native fishers are absent or rare in Washington. Ninety fishers were relocated from British Columbia to the Olympic Peninsula during 2008 through 2010 (Washington Department of Fish and Wildlife 2011). Monitoring during the coming years will determine whether or not fishers successfully establish themselves in this area.

Fishers were relocated from British Columbia and Minnesota to the southern Oregon Cascades in 1961 and from 1977 to 1981 (Aubry and Lewis 2003, Drew et al. 2003). The population has persisted but there have been no rigorous efforts to estimate its size (Lofroth et al. 2010).

Several density estimates are available for California portions of the southwestern Oregon/northern California fisher population. A density of about 5 females per 38.6 mile^2 was estimated for a study area on the Six Rivers and Shasta-Trinity National Forests (Zielinski et al. 2004a). On the Hoopa Valley Indian Reservation, densities of 52 and 14 fishers (male and female) per 38.6 mile^2 were estimated for 1998 and 2005, respectively (Matthews et al. 2011). The population was not monitored during the period between these years, so the cause of the apparent decline is unknown; however, the rebounding population appears to be stable or increasing based on lambda estimates and age structure shifts (Higley and Matthews 2009). Surveys on adjacent Green Diamond Resource Company lands during a similar period did not detect any major declines, suggesting that the decline on Hoopa lands was localized (Callas and Figura 2008). The density of fishers on Green Diamond lands was estimated to be between 7 and 11 fishers (male and female) per 38.6 mile^2) during 2002 and 2003 (Thompson 2008). Self et al. (2008) estimated that the entire southwestern Oregon/northern California population consists of 4,616 fishers. In a personal communication to the CDFG, C. Carroll estimated that the population consists of between 1,000 and 3,000 individuals (CDFG 2010).

Density and population estimates are also available for the southern Sierra Nevada. Roughly 8 females per 38.6 mile^2) were estimated to occur on the Sequoia National Forest (Zielinski et al. 2004a). Fishers on the Sierra National Forest were estimated to have a density of 9.5 to 13.4 individuals (male and female) per 38.6 mile^2) (Jordan 2007). Spencer et al. (2008) used 3 different approaches to estimate a population of between 160 and 350 fishers (55 to 120 adult females) in the southern Sierra Nevada. Using 2 approaches, Self et al. (2008) estimated that either 548 or 598 fishers occur in the southern Sierra Nevada. A third paper used expert opinion to estimate a population of between 100 and 500 fishers in the area (Lamberson et al. 2000). In 2002, the Forest Service initiated a monitoring program to track population trends in the Sierra Nevada. The population trend has not yet been analyzed but there was little change in the index of abundance during the program's first 5 years (Truex et al. 2009).

Native fishers appear to be rare or extirpated from the central and northern Sierra Nevada. A program is currently underway (2009 through 2011) to reintroduce a total of 40 fishers to the northern Sierra Nevada and southern Cascades of California (CDFG 2010). The translocated animals will be monitored for 7 years to determine the program's success (Callas and Figura 2008).

3.0 ENVIRONMENTAL BASELINE

Regulations implementing the ESA (50 CFR §402.02) define the environmental baseline as including the past and present impacts of all Federal, State, or private actions and other human activities in the Action Area, the anticipated impacts of all proposed Federal projects in the Action Area that have already undergone formal or early section 7 consultation, and the impact of State or private actions which are contemporaneous with the consultation process. Such activities include, but are not limited to, previous timber harvests and other land management activities.

The environmental baseline encompasses the effects of past and ongoing human and natural factors leading to the current status of the species, its habitat (including designated critical habitat), and ecosystem, within the Action Area. The environmental baseline is a "snapshot" of a species' health at a specified point in time.

3.1 Factors Affecting Species Environment within the Action Area

This analysis describes factors affecting the environment of the northern spotted owl and fisher in the Action Area. The baseline includes State, tribal, local, private and natural factors affecting the species or that will occur contemporaneously with the consultation in progress. Unrelated Federal actions affecting the species or critical habitat that have completed formal or informal consultation are also part of the environmental baseline, as are Federal and other actions within the Action Area that may benefit listed species or their critical habitat.

Existing conditions in the Action Area are largely the result of past management practices and natural disturbance regimes. Many factors have combined to alter the present environment from conditions that existed prior to Anglo-American settlement of the Klamath and Scott River basins. Human-induced changes related to terrestrial habitat have been the result of timber operations, mining, and grazing. Other factors that have influenced the current conditions related to terrestrial habitat within the Action Area include geology and the past fire regime. The historical vegetative condition is described briefly to provide context. Much of this information was drawn from the Beaver Creek (USDA FS 1996a), Horse Creek (USDA FS 2002), Callahan (USDA FS 1997), and Lower Scott (USDA FS 2000b) ecosystem analyses.

3.1.1 Land Management Activities

3.1.1.1 Timber Operations

Repeated timber operations, mining, grazing, and other land management activities over the past century have left the landscape deficit in late-successional and old-growth forested habitat essential to northern spotted owls for nesting and roosting, and fisher for resting and denning. Through 1971, timber harvest concentrated on old-growth stands. Requirements for logging included snag removal and stream cleaning, which removed denning and nest cavities and reduced canopy cover, thereby hampering the ability of the forest to provide a moderate microclimate for thermoregulation. Large sugar pine and ponderosa pine were the preferred logs because they were easy to mill, and mills were designed to accommodate logs more than 20 inches in diameter. During the 1950s, mills were refurbished to cut dimensional lumber and fir trees became desirable. Since passage of the Forest Practices Act in 1972, timber management has focused on younger, more productive forests. Mandatory protective measures for natural resources have been implemented, including designated stream protection zones, canopy retention standards, stream crossing standards, and other protective best management practices. Despite these protective measures, much of the landscape is still lacking suitable spotted owl and fisher habitat because forest stands have yet to develop the necessary habitat features to provide nesting and roosting sites for owls, and resting and denning sites for fisher.

3.1.1.2 Roads

Early logging operations used steam donkeys (steam powered hoists), log chutes, horses, and other less invasive methods to transport logs. Steam donkeys were eventually replaced with steam engines and railroad track, allowing logs to be transported longer distances. By the late 1930s and 1940s, railroad logging declined and railroad grades were converted to road systems for logging trucks. Extensive new road development and reconstruction of existing roads began in the late 1950s and continued to the mid-1980s by private timber companies and the USFS, primarily for timber harvest.

Throughout the drainages that contain the Plan Area, nearly 4,500 miles of roads have been identified, but only about one-third (about 1,350 miles) of these roads are on FGS lands. The remaining 3,150 miles of road are on lands controlled by the USFS, other governmental agencies, or private interests. FGS is solely responsible for maintenance of more than 1,100 miles of road in the Plan Area. About 250 miles of road on FGS lands are maintained under cooperative road agreements with USFS (co-op roads). Only the approximately 1,100 miles of road for which FGS is solely responsible for maintenance are covered under this HCP.

The density of roads in the individual drainages ranges from 0.6 to 5.9 miles per square mile (mi/mi^2). On the FGS ownership, road density generally ranges from 4 to 7 mi/mi^2 depending on the watershed. The highest road densities are in the Doggett and Lumgrey Creek watersheds in the Klamath River Management Unit, and the Mill and Pat Ford watersheds in the Scott Valley Management Unit, where road densities exceed 7 mi/mi^2. Overall road density on the FGS ownership is 5.4 mi/mi^2.

For roads solely maintained and covered under the FGS HCP, there are approximately 781 miles classified as local or secondary roads and 219 miles classified as arterial main lines. For the purposes of this BO, a local or secondary road will average 12 feet in width, while an arterial main line will average 24 feet in width. Based on this assumption, roads solely maintained by FGS have removed approximately 1,773 acres of habitat. While it cannot be determined from this estimate the quantity or quality of northern spotted owl and fisher habitat that was removed for road construction, it does provide an estimate of habitat no longer available to these species.

3.1.1.3 Mining

Gold mining within the Klamath and Scott watersheds was the primary resource for extraction from the mid-1850s through the 1930s. Hydraulic mining began in the area sometime after 1850, and operations were often concurrent with hard-rock and dredge mining. Giant “monitors” were used to wash away entire hillsides. This form of mining may have existed into the 1930s along with dredge and small-scale, depression-era placer mining. Large-scale dredge mining, however, continued in the upper reaches and tributaries of the Scott River until the 1950s (USDA FS 1997).

Hydraulic mining diverted creeks to supply water to high pressure nozzles that leveled entire hillsides and rearranged much of the riparian areas in the basin. Sluicing and hydraulic mining destroyed riparian areas. Deforestation associated with mining destabilized hillslopes, and increased erosion, flooding, and fires. Deforestation, erosion, and degradation of riparian areas caused by years of mining downgraded and removed habitat used by spotted owls, fisher and their prey species.

3.1.1.4 Grazing

Domestic livestock were brought to northern California more than 150 years ago. Miners and homesteaders raised livestock to supply food for local residents and for transportation to distant markets. As the Scott Valley area became settled and ranches were established, cattle and sheep were moved into the adjacent mountains to forage. In the early 1900s, grazing was largely unregulated, and livestock numbers were as much as five times higher than what is currently permitted on the KNF (USDA FS 1996a, 2000b, 2002). In the past, the longer grazing seasons of February through December (compared to the present April to October grazing season) allowed animals to graze plants in the more sensitive times of spring and early winter. Continued high use of the mountain rangelands created degraded conditions in some areas, and forage production was reduced, potentially reducing habitats used by some spotted owl and fisher prey species. The land affected by grazing today is a much smaller portion of the KNF (USDA FS 1996a, 2000b, 2002).

3.1.2 Vegetation

Few forested regions have experienced fires as frequently and with such high variability in severity as those in the Klamath Mountains (Taylor and Skinner 1998). The fire regime prior to European settlement (1850) within the Klamath area can be described as having frequent fires with return intervals of 1 to 25 years. Lightning and intentional burning by American Indians were the predominant causes of ignition (USDA FS 1996a, 1997, 2000b, 2002). The pre-European fire regime can be described as having mostly low- to moderate-intensity fires, with only small areas burning at high intensity. Fire return intervals were shorter on exposed sites and longer on sheltered sites. The steepness of the slopes and vegetation that had adapted to a history of frequent fires contributed to the varying intensities. Fire worked as both a thinning agent and an agent of decomposition. Although most vegetation (mixed conifers) promoted lower intensities when burned at frequent intervals, stand-replacing events occurred in some areas. Aspect, stand diameter, elevation, and topography are all factors that influence fire intensity within the Klamath region (Taylor and Skinner 1998, Fry and Stephens 2006, Alexander et al. 2006).

Prior to European settlement, much of the Action Area was maintained in an open mixed conifer forest. Ponderosa pine was the dominant conifer species found in open lower elevation stands on south and west aspects. Douglas fir was most prevalent on moister sites, especially on north and east aspects (USDA FS 1996a, 2002). Due to the historic fire regime, north and east aspects supported denser stands than south and west, but were less dense than current stands (USDA FS 1996a, 2002). True fir was found on colder sites above 5,000 feet elevation, and the mixed conifer forest blended into hardwoods on drier sites below 3,000 feet. Under the historical fire regime, brush fields within the Action Area were periodically replaced, but fire suppression has resulted in much denser and larger vegetation here as well. Depending on the level and types of human activities conducted, these vegetation communities have been altered to varying degrees.

Fire frequency, intensity, and size occurring within the Action Area have changed since the fire-suppression era (1950 to present) (Fry and Stephens 2006). Prior to the fire-suppression era, fires occurred frequently. In most of the vegetation assemblages covering large portions of the Klamath Mountains, they were of generally low to moderate and mixed severity (Skinner et al. 2006). Fires occurring in the fire-suppression era are less frequent and have greater intensity, resulting in a more homogeneous effect on the habitat by damaging and removing all vegetation (Fry and Stephens 2006). Fire suppression has allowed dense conifer stands to develop, and more litter and downed woody material accumulation than that under the historical fire regime (USDA FS 1996a, 2002). The lack of fire favors regeneration of Douglas fir and white fir over pine species. Currently, dense stands of Douglas fir and white fir are found in some areas that were historically open, pine-dominated stands. Although this shift in species composition to favor Douglas fir may be beneficial to spotted owls because they are most highly associated with this tree species, the increase in brush and stand density resulting from years of fire suppression may decrease the owl's foraging ability in some areas. Fisher hunt for a variety of prey species that occupy various forest vegetation types and successional stages, but typically avoid non-forested environments and early successional forest stands that lack dense canopy cover (Lofroth et al. 2010). More importantly, the increase in fire frequency and severity due to fire suppression has increased the risk of uncharacteristically severe wildfire, which removes habitat for both spotted owls and fishers and creates more homogenous forest conditions compared to what would occur historically in the naturally mosaic landscape.

The following vegetation characteristics (e.g., tree size [dbh], canopy coverage) within the Action Area are described using the vegetation classification system described in the CWHR system (Mayer and Laudenslayer 1988).

3.1.2.1 Upland Forest

The forest communities of FGS's Klamath River and Scott Valley Management Units are dominated by second-growth mixed evergreen forests consisting of three or more species of conifers. Conifer species of the mixed evergreen forest include Douglas-fir, incense-cedar (*Calocedrus decurrens*), white fir, ponderosa pine, and sugar pine. The proportion of these species represented in the overstory depends on site-specific conditions (such as elevation, aspect, precipitation, soils, microclimate conditions, and past management). Small stands consisting of a single species (typically Douglas-fir or ponderosa pine), are scattered throughout the predominately mixed conifer forest landscape. Hardwood species such as canyon live oak (*Quercus chrysolepis*), Pacific madrone (*Arbutus menziesii*), California black oak (*Quercus kelloggii*), and Oregon white oak (*Quercus garryana*) are common in the understory. Forested areas within the Action Area tend to be naturally fragmented due to the diverse geology, topography, and dry conditions that result in areas dominated by hardwoods or chaparral species.

Three major forest types occur in FGS's Grass Lake Management Unit: Sierran Montane Forest, Upper Montane Forest, and Northern Yellow Pine Forest (Kuchler 1988). Sierran and Upper Montane Forest types occur at higher elevations, and Northern Yellow Pine forest at lower elevations. The Northern Yellow Pine forest type, dominated by ponderosa pine and white fir, is the most common forest type in FGS's Grass Lake Management Unit. As a result of fire suppression, stands of white fir have developed in some locations previously dominated by ponderosa pine. In contrast to the forests of FGS's Klamath River and Scott Valley Management Units, hardwood species are largely absent from FGS's Grass Lake Management Unit.

Approximately 11 percent of the ownership is not considered commercial forest land, consisting of either non-stocked forest land (brush and non-commercial species) or non-forest land (bare ground, meadows, rock). The greatest percentage of non-commercial land is in the Scott Valley Management Unit (15.1 percent, primarily non-stocked forest land) followed by Grass Lake (14.3 percent) and the Klamath River (6.7 percent) Management Units.

Forests in the Action Area have been managed for commercial timber production since the early 1900s. Consequently, forests are relatively young (less than 80 years old) with only small, isolated patches of older stands. Prior to the start of large-scale commercial logging, much of the conifer forests in the Action Area and vicinity were older, on average, than current forest stands. However, because this region is fire-prone, it is likely that a mosaic of age classes, including a high percentage of late-seral stages, developed and persisted prior to the advent of commercial logging. Currently, less than 1 percent of the forested area in FGS's Klamath River, Scott Valley, and Grass Lake Management Units (65, 21, and 29 acres in each management unit, respectively) are in CWHR size class 5 (> 24 inches dbh) and may be considered late-seral stage. From 79 to 93 percent of commercial forest stands are considered mid-seral, with average tree sizes of 6 to 24 inches dbh (CWHR size classes 3 and 4).

3.1.2.2 Riparian Forest

The plant species composition and structure of riparian forest habitat currently occurring along streams in the Action Area varies in relation to factors such as stream characteristics, topography, elevation, and past management. Close to the valley floor, hardwoods (such as willows [*Salix spp.*] and cottonwoods [*Populus spp.*]) predominate. In some of the valley floor areas, the riparian zone composed of hardwoods forms a plant community that is distinct from drier upland areas that support chaparral species. At higher elevations, the riparian zone is characterized as a mix of conifer and hardwood species. The conifer component is similar to adjacent upslope areas; the hardwood component consists of red alders (*Alnus rubra*) and big leaf maple (*Acer macrophyllum*) along the immediate margins of the stream. Along many streams on FGS lands, particularly higher-gradient streams, riparian forest composition is largely indistinguishable from the adjacent upland mixed conifer forest.

Site-specific riparian inventories have not been conducted along all streams in the Plan Area. To provide a general indication of the condition of riparian stands, the FGS hydrology (stream) layer was buffered according to CDFG Coho Recovery Plan specifications (150-foot buffers along Class I streams, 75- to 125-foot buffers along Class II streams, and 25- to 50-foot buffers along Class III streams) and overlain on the FGS 2004 Forest Inventory using Geographic Information System (GIS). The range of buffer width within a given class was dependent on percent slope of adjacent hillsides. Results of this analysis are presented in Tables 4-9 through 4-11 of the HCP, which summarize the number of trees per acre in various size classes in riparian stands along Class I[5], Class II, and Class III streams, respectively.

3.1.3 Climate

The climate in FGS's Klamath River Management Unit can be characterized as temperate Mediterranean, with hot, dry summers and cool, moist winters. Precipitation in the Klamath River watershed varies greatly, from around 20 inches per year in the upper watershed to as much as 100 inches per year near the coast. FGS's Klamath River Management Unit lies near the middle of this range; precipitation increases with elevation within the unit. Precipitation in the Klamath River Management Unit ranges from an average of around 30 inches per year in the lower elevations near the Klamath River to about 75 inches per year at the highest elevations, with approximately 90 percent falling between October and May (USDA FS 1996a, 2002). Summer precipitation occurs primarily during thunderstorm activity; high-intensity, short-duration thunderstorms are common (USFS 1996a, 2002). Below 3,500 feet in elevation, most precipitation is rainfall; above 4,000 feet, winter precipitation is predominately snowfall. Higher-elevation terrain in the Klamath River watershed receives large winter and spring snowpacks, and can be associated with high amounts of runoff during warm winter storms (CETFKRB 2004).

The Scott River watershed also has hot, dry summers and cool, wet winters characteristic of Mediterranean climates. Rainfall is somewhat less than along the Klamath River. Approximately 90 percent of precipitation falls between October and May; peak precipitation occurs in December and January. Although most precipitation occurs winter through spring, there may be short periods of locally intense rainfall from summer thunderstorms (USDA FS 1997, 2000b). In the valleys, precipitation is significantly lower than in the surrounding mountains. Average annual precipitation ranges from below 20 inches at the lowest elevations along the Scott River, to more than 60 inches at the highest elevations at the western and southern extents of the watershed (North Coast RWQCB 2005). Winter precipitation is mostly rain at the lower elevations, below about 4,000 feet, with a rain-snow transition zone between about 4,000 feet and 5,000 feet. Snow typically accumulates in the rain-snow transition zone, but is frequently melted by midwinter rains. The higher elevations, especially above 6,000 feet, have short summers and relatively long winters with deep snowpacks.

The topographic characteristics of the basin make the Scott River watershed particularly susceptible to severe flooding caused by rain-on-snow events. A significant portion of the basin is between 4,500 and 5,500 feet in elevation, which is the range of elevation most susceptible to rain-on-snow events (North Coast RWQCB 2005). The largest floods on record (1861, 1955, 1964, 1974, and 1997) were associated with this type of event (USDA FS 2000b).

The Grass Lake Management Unit receives considerably less precipitation than the Klamath River and Scott Valley Management Units. In the western portions of the Action Area, annual precipitation averages about 30 to 35 inches, whereas precipitation in the eastern portions averages 20 inches or less per year (Ruffner 1978).

3.1.4 Land Ownership

FGS's Hilt/Siskiyou ownership is intermixed with Federal and other private lands. The KNF accounts for the largest proportion of adjacent Federal land; although a small portion of FGS lands are bordered by lands managed by the Bureau of Land Management (BLM). Much of FGS's Klamath River Management Unit is in "checkerboard" ownership; land in alternating sections typical of lands granted to the railroad in the nineteenth century, with USFS lands and other private landowners. FGS's Scott Valley and Grass Lake Management Units generally consist of larger, more contiguous blocks surrounded by USFS lands or private landowners. Adjoining privately owned lands are managed for commercial timber harvest in a manner similar to the FGS ownership, or are agricultural lands with rural residential use.

Federal lands of the KNF are managed for multiple uses including recreation, fish and wildlife habitat, timber harvest, and visual resources under the KNF Land and Resource Management Plan (LRMP) (USDA FS 1994). The LRMP was largely based on the NWFP (USDA FS and USDI BLM 1994a). Under the LRMP, the USFS will manage about 22 percent of the KNF as LSRs, with the objective of providing for the viability needs of late-successional species using an ecosystem-based approach. About 35 percent of the KNF is considered matrix lands that are managed for multiple-use purposes, including timber harvest, fish and wildlife resources, recreation, and visual resources. The remaining 43 percent of the KNF consists of other CRAs and AWAs. Many of these areas (such as wilderness areas, backcountry areas, RRs, cultural areas, and research natural areas) will be managed in a manner consistent with achieving late seral conditions (USDA FS 1994).

Riparian Reserves on the KNF are designated primarily along perennial and intermittent streams, lakes, ponds, seeps, springs, and wetlands. They are also designated in unstable and potentially unstable non-riparian areas that are primary contributors of sediment and wood to aquatic systems. In riparian reserves, riparian-dependent resources are of primary concern, with management standards and guidelines applied to maintain or restore riparian functions. In keeping with the ROD, riparian reserves are at least 300 feet wide along fishbearing (Class I)[5] streams, and at least 150 feet wide along perennial, non-fishbearing (Class II) streams. Along intermittent streams and around unstable or potentially unstable areas, riparian reserves are at least 100 feet wide. Timber harvest is generally prohibited in riparian reserves unless it is consistent with or necessary to achieve the Aquatic Conservation Strategy (ACS) objectives set forth in the NWFP. Other land uses, such as grazing and mineral operations, are similarly restricted in that they must be conducted in a manner compatible with the ACS objectives. Riparian reserves encompass an estimated 458,000 acres (27 percent) of KNF (USDA FS 1994).

3.2 Status of Northern Spotted Owl in the Action Area

The Action Area is defined to mean "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action (50 CFR §402.02)." For the purposes of this consultation, the Action Area consists of a 1.3-mile radius around the FGS ownership, reflective of the local owl population that could be directly or indirectly affected by the HCP. The 1.3-mile distance criterion is based on the average home range size of the northern spotted owl within the California Klamath and California Cascades Provinces (USDI FWS 2005). The activity center typically consists of a roost or nest site, and is considered the center of an owl's home range. The total area within the Action Area is approximately 545,030 acres. This 1.3-mile radius around the FGS ownership is termed "Area of Impact" in the FGS HCP for the purposes of characterizing environmental baseline conditions and describing effects of the covered activities on the northern spotted owl.

The northern spotted owl population in the Action Area is divided by two ecological provinces: the California Klamath Province and the California Cascades Province. The environmental baseline is described separately for these two provinces within the Action Area because they are distinct in terms of population demographics and trends, threats, and quantity and quality of northern spotted owl habitat.

The following description of owl population status and habitat both range-wide and within the Action Area is based on published and unpublished information, and stand inventories and protocol-level owl surveys within the Plan Area and adjacent Federal lands.

[5] Stream classes used in the HCP are those defined in the California Forest Practice Rules (CAL FIRE 2008)

3.2.1 Environmental Baseline in the California Klamath Province Action Area

The following section describes local environmental baseline conditions for the portion of the Action Area within the California Klamath Province, including a discussion of the northern spotted owl population, amount and quality of habitat on the FGS ownership and adjacent Federal lands, and current threats. Fruit Growers Supply's Scott Valley and Klamath River Management Units occur within the California Klamath Province.

Northern Spotted Owl Population in the Klamath Action Area

Comprehensive surveys for spotted owls were not conducted for the purposes of developing the FGS HCP. The Service relied on the CDFG Northern Spotted Owl Database to estimate the number of spotted owls occupying the Action Area using records dating from 1987 through 2007. The owl population baseline is based on a compilation of northern spotted owl sightings from the database within the Action Area, including results of incidental sightings as well as protocol-level owl surveys on FGS lands and adjacent private and public lands. Information on fecundity and survivorship in the Action Area is not available, as no mark-recapture programs for owls have been conducted on FGS's ownership in the California Klamath Province.

For the period from 1987 through 2007, the CDFG database contains records of 87 activity centers on or within 1.3-miles of FGS's ownership in the California Klamath Province. Of these, 13 sites were determined by the Service to be invalid because they did not meet the Service's criteria for designation as an activity center (i.e, inadequate number of detections for residency status) and/or were extremely lacking in amounts of suitable habitat (i.e., habitat was removed by a stand-replacing fire in a significant portion of the core) during development of the HCP. Since FGS did not conduct comprehensive surveys of all the historic activity centers to determine current occupancy status, the remaining 74 activity centers were considered occupied at their highest historic status (Table 5) for the purposes of HCP development. Using this conservative approach, a total of 143 northern spotted owls were estimated to occur within the California Klamath Province portion of the Action Area (containing FGS's Scott Valley and Klamath River Management Units); 18 of these historic activity centers are located on FGS land.

There is some uncertainty as to the exact number of currently occupied activity centers within this area because some activity centers may no longer be active. A substantial number of the remaining 74 historic activity centers are unlikely to support occupancy by spotted owls, particularly reproducing pairs. Many of the historic activity centers have not been surveyed during the past five to 10 years, others have been surveyed to varying degrees with no detections, and most of the historic activity centers have received substantial timber harvest within their core areas and home ranges. It is unlikely that there are additional undetected activity centers on FGS ownership given the low amounts of suitable habitat and extensive survey effort over time on the property.

Because the size and distribution of the spotted owl population within the Action Area was uncertain, the Service augmented the above-described survey information with results from a predictive model developed by Zabel et al. (2003). The model was used to evaluate the likelihood of additional activity centers occurring within the California Klamath Province portion of the Action Area over the permit term. The model predicts probability of occupancy based on habitat conditions within a 500-acre (0.5-mile radius) circular window; this spatial scale corresponds to 'core areas' that receive disproportionate use by nesting and foraging spotted owls in the Klamath region (Bingham and Noon 1997) and where differences between use and availability of habitat tend to be most pronounced (USDI FWS 2011b, Appendix C). The Service evaluated the broad-scale patterns of habitat suitability on and within 1.3 miles of the FGS ownership by decade and determined that establishment of additional activity centers (i.e larger population size) beyond the owl population baseline within the Klamath Action Area is unlikely over the permit term.

Table 5. Quantification of Northern Spotted Owls by Reproductive Status in the California Klamath Province Portion of the Action Area

Status (1987-2007)[a]	Sites[b]	Owls
Reproductive pair with young	50	100
Nesting pair	19	38
Territorial single	5	5
Not valid activity center	13	0
Total activity centers	87	143
Total valid activity centers	74	143

[b] For the purpose of the effects analysis, each site is considered an activity center

Northern Spotted Owl Habitat in the Klamath Action Area

In addition to landscape and topographic features, vegetation and structural elements are important factors determining northern spotted owl habitat suitability (57 FR 1796). The structure and composition of coniferous vegetation within the Action Area is naturally diverse and fragmented due to variation in topography and soil type, the relatively dry climate, and stochastic events such as fire. Timber harvest and fuels management have contributed to the habitat mosaic. Because the HCP area is an industrial forest landscape, forest stands within the HCP area have experienced a long history of intensive management. Many attributes important to northern spotted owls (i.e., dense stands of large old trees, snags, logs) are lacking in most stands.

As part of the HCP development process, FGS worked with the Service to produce a GIS layer that represents current northern spotted owl habitat in the Action Area and the region. Using a combination of local data sources and models, a habitat data layer was derived for the area encompassing FGS ownership and surrounding 20-mile buffer, which includes portions of Siskiyou, Shasta, and Trinity counties in California and Jackson, Josephine, and Klamath counties in Oregon. This derived data layer represents the most current depiction of northern spotted owl habitat for this region. The habitat definitions used in the database are based on mean values and minimum standards for stand structural variables; this fact, combined with the long history of intensive timber management of FGS lands, suggests that the habitat layer likely represents an overestimate of actual habitat quality. A description of the 2005 northern spotted owl baseline habitat layer, including data sources and methods can be found in Appendix A of the FGS HCP (2009).

Based on the owl habitat layer, there are 70,034 acres of foraging habitat, 42,045 acres of nesting habitat, and 227,464 acres of unsuitable habitat within the 339,543-acre Klamath portion of the Action Area (Table 6). Table 7 shows the acreage and ownership of northern spotted owl habitat within the core and home range of each activity center within the Klamath Action Area. Habitat on Federal and private non-FGS land over the term of the ITP is represented by the owl habitat layer to avoid speculating on the types of changes that may occur on these lands over time.

Northern Spotted Owl Critical Habitat in the Klamath Action Area

On August 13, 2008, the Service released the Final Revised Designation of Critical Habitat for the Northern Spotted Owl (USDI FWS 2008b). This rule became effective on September 12, 2008, and designated 5,312,300 acres of Federal lands in California, Oregon, and Washington as northern spotted owl critical habitat. Under regulations, the Service is required to identify the known physical and biological features [Primary Constituent Elements (PCEs)] essential to the conservation of the northern spotted owl. All areas designated as revised critical habitat for the northern spotted owl are within the geographic area occupied by the species at the time of listing and contain the appropriate forest type (PCE 1) and at least one other PCE. The Service determined that the PCEs for northern spotted owl are 1) forest types that support the northern spotted owl across its geographic range, 2) nesting, roosting, and foraging habitat, and 3) dispersal habitat. Nesting, roosting, foraging, and dispersal habitat, as well as the forest types associated with northern spotted owls, are described in section 2.1.2.5 (Habitat Relationships).

Northern spotted owl critical habitat has not been designated for private lands, and therefore, critical habitat does not occur on FGS lands. However, designated northern spotted owl critical habitat is located on Federal lands within the Action Area of the FGS HCP. The selection of FGS HCP mitigation sites was based on proximity to northern spotted owl critical habitat. The FGS HCP Conservation Strategy is designed to provide demographic support to northern spotted owls inhabiting lands in the Federal Reserve System by providing CSAs on FGS's ownership to provide habitat for activity centers that are centered on or are in close proximity to federal lands designated as northern spotted owl critical habitat. The following information characterizes the status of northern spotted owls and habitat within CHUs and LSRs within the California Klamath Province portion of the Action Area to describe the baseline condition of the Federal Reserve System upon which the FGS HCP Conservation Strategy is based.

Five CHU subunits overlap with the California Klamath Province portion of the Action Area: subunits CA-29 and OR-19 in the Klamath Intra-Province CHU; subunit OR-18 in the Southern Cascades CHU; and subunits CA-28 and CA-31 in the Scott and Salmon Mountains CHU. Four of these subunits overlap with four designated LSRs. A summary of the habitat conditions in the LSRs that overlap the CHUs is described below and is based on the KNF LSR Assessment conducted by Dix et al. (1999). Information on the status of the LSRs was used because considerably more information is available on conditions in the LSRs than for individual CHUs and subunits, and because there is an 83 percent overlap in acreage between current subunit designations and the 1994 LSRs. Northern spotted owl pair goals for the newly designated CHUs and their subunits are under development by the Service but have not been finalized. However, because the distribution and total acres of the 2008 designated subunits do not differ significantly from the 1992 critical habitat designation within the Action Area, it is reasonable to assume that pair goals will be comparable. Therefore, for the purpose of this document, the 1992 pair goals will be used as a surrogate for the 2008 designated subunits.

Seiad LSR (353)/Scott and Salmon Mountains CHU Subunits CA 28 and CA-30.
The Seiad LSR is approximately 101,200 acres in size, making it the largest LSR within the KNF. It contains approximately 26,240 acres of nesting/roosting habitat and 23,490 acres of foraging habitat, for a total of 49,730 acres of suitable northern spotted owl habitat. An

additional 24,910 acres have the potential to provide northern spotted owl habitat. The combined habitat within the Seiad LSR and the adjacent Marble Mountain Wilderness enables this area to function as a large refugium for northern spotted owls. The amount of nesting/roosting and foraging habitat is within 10 percent of the expected range of suitable northern spotted owl habitat for the Seiad LSR (Dix et al. 1999).

Twenty-five activity centers have been located within the Seiad LSR boundary (21 pairs and 4 territorial singles); however, at least 40 percent of the LSR has not been adequately surveyed. The southern portion of the Seiad LSR overlaps considerably with subunit CA-30 (which is outside of the FGS Action Area) and the northern portion of this LSR overlaps considerably with the western portion of subunit CA-28. The eastern portion of CA-28 overlaps with the Klamath portion of the Johnny O'Neil LSR. In the northern portion of the Seiad LSR that overlaps with CA-28, three pairs and 4 territorial singles have been reported. In the Klamath portion of the Johnny O'Neil LSR that overlaps with CA-28, 16 pairs and one territorial single have been reported. The total of 19 owl pairs within the portions of the Seiad and Johnny O'Neil LSRs that overlap with subunit CA-28 nearly meets the pair goal of 22 for this subunit. Overall, the Seiad LSR, in combination with the Johnny O'Neil LSR, performs all the intended functions for subunit CA-28. There are some portions of critical habitat that fall outside of the LSR boundary, but overall, the population goals of the critical habitat designation is exceeded by the LSR.

Johnny O'Neil LSR (354)/ Scott and Salmon Mountains CHU Subunit CA-28.
The Johnny O'Neil LSR is approximately 46,840 acres in size, with 27,900 acres located on the KNF and the remainder on the Rogue National Forest. This LSR contains approximately 20,420 acres of nesting/roosting habitat and 7,370 acres of foraging habitat, for a total of 27,790 acres of suitable northern spotted owl habitat. An additional 8,850 acres have the potential to provide owl habitat. There are large, continuous parcels of late-successional and old growth (LSOG) habitat throughout most portions of the Johnny O'Neil LSR, including the Horse Creek drainage in the southeast, much of the northeast portion, and a 2-mile-wide band in the northwest that runs along the Siskiyou Crest and north. The amount of nesting/roosting and foraging habitat is within the expected range of suitable northern spotted owl habitat, and the acres of LSOG forest are above the expected functioning range for the Klamath portion, but below for the Rogue portion. Overall, Johnny O'Neil was ranked at the high end of moderate for habitat connectivity, due in part to moderate amounts of mid-successional forest.

As described previously, the Klamath portion of the Johnny O'Neil LSR overlaps with the eastern portion of subunit CA-28. A total of 21 northern spotted owl activity centers have been located within the Johnny O'Neil LSR boundary, 17 of which overlap with subunit CA-28. However, approximately 20 percent of the Klamath portion has not been surveyed. Sixteen northern spotted owl pairs and one territorial single were recorded in the Klamath portion of the Johnny O'Neil LSR. The total of 19 owl pairs within the portions of the Seiad and Johnny O'Neil LSRs that overlap with subunit CA-28 nearly meets the pair goal of 22 for this subunit. There are some portions of critical habitat that fall outside of the LSR boundary, but overall, the population goals of the critical habitat designation is met by the LSR.

Collins Baldy LSR (355)/ Scott and Salmon Mountains Subunit CA-31.
The Collins Baldy LSR is approximately 14,670 acres in size, and supports approximately 4,600 acres of nesting/roosting habitat and 4,500 acres of foraging habitat, for a total of 9,100 acres of suitable northern spotted owl habitat. An additional 2,930 acres have the potential to provide northern spotted owl habitat. The habitat is fairly discontinuous because of the checkerboard ownership of private and Federal lands. Late-successional habitat is currently lacking within the Collins Baldy LSR and accounts for only 1,630 acres (13 percent) of the capable ground. Relative to other LSRs, it ranks low and moderate for the proportion of LSOG habitat and combined mid-successional/LSOG habitat, respectively.

A total of 12 northern spotted owl activity centers supporting 12 owl pairs have been located within the Collins Baldy LSR. The entire LSR has been surveyed for northern spotted owls. The Collins Baldy LSR overlaps almost entirely with subunit CA-31. The 12 known owl pairs within the Collins Baldy LSR exceed the pair goal of 5 for subunit CA-31.

Overall, the Collins Baldy LSR performs the intended function of subunit CA-31 in that it extends protected habitat east toward subunit CA-61 in the Southern Cascades Unit and exceeds the CHU pair goal.

Mt. Ashland LSR (248)/Klamath Intra-Province Subunits OR-19 and CA-29.
The Mt. Ashland LSR is approximately 51,512 acres in size and provides approximately 30,169 acres of suitable northern spotted owl habitat, or 58 percent of the total LSR land base. Late-successional habitat (greater than 24 inch dbh) accounts for 14,981 acres (29 percent) of the LSR and mostly occurs below 5,000 feet elevation. Another 29 percent is less optimal habitat (mid-successional stands from 17 to 24 inch dbh). This LSR is extensively fragmented by a checkerboard ownership pattern and past land use.

A total of 26 activity centers have been located within the Mt. Ashland LSR. Thirteen northern spotted owl pairs and two territorial singles were recorded in the northern portion of the LSR, while nine pairs and two territorial singles were located in the southern zone, for a total of 22 pairs and four resident singles. Complete protocol surveys have covered almost all suitable habitat within the LSR boundary. The home ranges of two activity centers in the northern portion of the LSR have less than 40 percent suitable habitat, and four activity centers south of the crest are below this minimum habitat threshold. The Mt. Ashland LSR overlaps with the subunits OR-19 and CA-29 of the Klamath Intra-Province CHU. The CHU objectives include maintaining a link between California and Oregon, and providing habitat for 20 northern spotted owl pairs. The 22 owl pairs in the Mt. Ashland LSR exceed the pair goals for subunits OR-19 and CA-29.

Threats to the Northern Spotted Owl in the California Klamath Province

Threats to the northern spotted owl in this region include habitat loss due to fires, Federal and private management activities, displacement by barred owls, forest health (insect outbreaks and disease), and potential for avian disease. Northern spotted owl nesting/roosting and dispersal habitat both decreased by one percent on Federal lands as a result of management activities from 1994 to 2007 in the California Klamath Province; nesting/roosting and dispersal habitat on

Federal lands was reduced by 1.05 percent and 1.03 percent, respectively, as a result of natural disturbances from 1994 to 2007 in this province (Davis, in press). The total reduction in nesting/roosting habitat was 5.2 percent and the net gain of dispersal habitat was 5.4 percent on Federal lands from land management activities and natural disturbances during this timeframe.

Fire

Fire continues to modify the quality and quantity of northern spotted owl habitat within this region. The Revised Recovery Plan for the Northern Spotted Owl (USDI FWS 2011b) reported a reduction of 71,600 acres from 1994 to 2007 on Federal lands in the California Klamath Province attributable to fire, and 1,600 acres lost from insects and disease during the same time period. However, Agee (2007) disputed these estimates, reporting that from 1994 through 2003, this region experienced the Dillon fire (27,000 acres), Megram/Onion (125,000 acres), Jones and Happy Camp Complex (1,670 acres and 6,800 acres, respectively), and many smaller fires. He concluded that while not all acres burned with high severity, probably 30 percent of this habitat was seriously altered or destroyed as owl habitat, resulting in a loss of 48,141 acres from 1994 through 2003. An additional 170,000 acres burned in 2006. While not all of the 2006 fires burned with high severity, using an estimate of 30 percent loss, it was estimated that an additional 51,042 acres of habitat was lost to fire in this province (Agee 2007). Although there is some uncertainty as to the extent of northern spotted owl habitat loss due to fire, both estimates clearly demonstrate that fire is a threat to owls.

Historically, lands within the California Klamath Province experienced frequent (1 to 25 years) low- to moderate-intensity surface fires, while the current regime is characterized as infrequent (25 to 100 years) high-intensity fires. The extent of the recent high-severity burns appears to be different than historic burn patterns, with more area burning at high intensity (Skinner et al. 2006). Before fire suppression, fires of higher spatial complexity created openings of variable size within a matrix of forest that was generally more open than today (Taylor and Skinner 1998, as referenced in Skinner et al. 2006). This heterogeneous pattern has been replaced by a more homogeneous pattern of smaller openings in a matrix of denser forest, thus reducing spatial complexity (Skinner 1995, as referenced in Skinner et al. 2006). Studies suggest that vegetation patterns and conditions generated by pre-fire suppression fire regimes may be advantageous for the northern spotted owl (Franklin et al. 2000). The incidence of catastrophic wildfire on Federal Reserve lands (e.g., CHUs, LSRs) may have increased from historical occurrences as a result of recent fire suppression policies, but this effect has been strongly debated by various researchers (Hanson et al. 2009).

Forest Health

Information on forest health is primarily based on the KNF LSR Assessment conducted by Dix et al. (1999). Mortality caused by insects and disease in the Seiad and Johnny O'Neil LSRs was localized to the southern portion of the LSRs. At upper elevations, the fir engraver beetle has been responsible for ponderosa pine and Douglas fir mortality. At lower elevations, the western pine beetle and pine engraver beetle have been primarily responsible for ponderosa pine and Douglas-fir mortality. The Johnny O'Neil LSR is at risk for future insect outbreaks due to early and midseral stand stocking levels.

Barred Owls

Barred owls are present within the California Klamath Province, and have recently been detected in the Action Area. Barred owls were reported in southern Jackson County, Oregon as early as 1990 (Kelly 2001), and records from the Rogue-Siskiyou National Forest and Medford BLM indicate that numerous barred owl locations have been reported in that area through 2007. Five pairs of barred owls were detected in the Oregon portion of the Mt. Ashland LSR (subunit OR-19 of the Klamath Intra-Province CHU) during 2005-2006 (USDI FWS unpublished data); however, annual surveys of subunit CA-29 of the Klamath Intra-Province CHU, and subunits CA-28, CA-31, and CA-30 of the Scott and Salmon Mountains CHU did not detect barred owls until 2006. In 2006 and 2007, barred owls were detected at six locations in and adjacent to these CHUs (USDI FWS unpublished data). Based on these reports, combined with the rate and pattern of colonization observed in the California Cascades Province, barred owls are predicted to become established in the Action Area within 5 years (USDI FWS unpublished data).

West Nile Virus

West Nile virus is the primary disease of concern for the northern spotted owl (USDI FWS 2008a). The virus has not been detected in the California Klamath Province; however, it is now within the range of the northern spotted owl in northwestern California (Courtney et al. 2004).

3.2.2 Environmental Baseline in the California Cascade Province Action Area

The following section describes environmental baseline conditions for the portion of the Action Area within the California Cascades Province, including a discussion of the northern spotted owl population, amount and quality of habitat on the FGS ownership and adjacent Federal lands, and current threats. Fruit Growers Supply's Grass Lake Management Unit occurs within the California Cascades Province.

Northern Spotted Owl Population in the Cascades Action Area

The northern spotted owl population in the California Cascades Province has been identified as providing an important link between the California spotted owl and northern spotted owl and resides in the Shasta-McCloud Area of Special Concern (Thomas et al. 1990). Unlike the California Klamath Province, the amount of northern spotted owl habitat in the California Cascades Province is limited and protocol-level owl surveys have been conducted in the last 10 years on the majority of lands within the province that could potentially support owls. Anthony et al. (2006) did not include the California Cascades Province in their demographic studies because northern spotted owl populations in this province are too low to make demographic studies of this type possible. Information on fecundity and survivorship in this portion of the Action Area is not currently available, as no mark-recapture programs for owls have been conducted on FGS's ownership in the California Cascades Province.

The Service considers the CDFG Northern Spotted Owl Database the best source for documenting the number of owls in this province. For the period from 1987 through 2007, the

CDFG database contains records of 10 activity centers within 1.3 miles of FGS's ownership in the California Cascades Province. Of these, two sites were determined by the Service to be invalid because they typically did not meet the Service's criteria for designation as an activity center (i.e, inadequate number of detections for residency status) and/or were extremely lacking in amounts of suitable habitat (i.e., habitat was removed by a stand-replacing fire in a significant portion of the core). Therefore, eight historic activity centers supporting a total of up to 15 northern spotted owls are estimated to occur within the California Cascades Province portion of the Action Area. A quantification of northern spotted owls by reproductive status in the Cascades Action Area is presented in Table 8. There is some uncertainty as to the exact number of currently occupied activity centers within this area because some activity centers may no longer be active. It is unlikely that there are additional undetected activity centers on FGS ownership given the low amounts of suitable habitat and extensive survey effort over time on the property.

Table 8. Quantification of Northern Spotted Owls by Reproductive Status in the California Cascades Province Portion of the Action Area.

Northern Spotted Owl Habitat in the Cascades Action Area

Based on the 2005 owl habitat layer, there are 22,728 acres of suitable foraging habitat, 7,349 acres of suitable nesting habitat, and 154,865 acres of unsuitable habitat within the entire 184,942-acre Cascades Province portion of the Action Area (Table 9). Table 10 shows the acreage and ownership of northern spotted owl habitat within the core and home range of each activity center within the Cascades Action Area.

Table 9. Northern Spotted Owl Habitat and Land Ownership within the California Cascades Province Portion of the Action Area.

Northern Spotted Owl Critical Habitat in the Cascades Action Area

As described above, the Revised Designation of Critical Habitat for the Northern Spotted Owl; Final Rule (FR 73 47326, USDI FWS 2008b) revised the designation of critical habitat into larger critical habitat units (e.g., Western Klamath-Siskiyou Mountains) with designated subunits that roughly correspond with the original CHU designations. Northern spotted owl critical habitat does not occur on FGS lands; however, the following section characterizes the status of northern spotted owls and habitat within CHUs and LSRs to describe the baseline condition of the Federal Reserve System upon which the FGS HCP Conservation Strategy is based. The analysis below is based on LSR Assessment for the Goosenest LSR #RC-363 (USDA FS 1996b) but uses the revised subunit numbers for critical habitat from the revised designation. Information on the status of the LSRs was used because considerably more information is available on conditions in the LSRs than for individual CHUs and subunits, and because there is an 83 percent overlap in acreage between current subunit designations and the 1994 LSRs. Owl pair objectives for the new subunits have not been established by the Service; however, since the distribution and total acres of the newly designated subunits do not significantly differ from the 1992 critical habitat designation within the Action Area, pair objectives from the 1992 critical habitat designation were used for the evaluation below.

Two subunits (CA-61 and CA-66) in the Southern Cascades CHU are within the California Cascades portion of the Action Area. Subunit CA-61 overlaps with the Goosenest LSR. A very small portion (200 of approximately 3,000 acres) of subunit CA-66 is within the California Cascades Province portion of the Action Area.

Goosenest LSR (363)/ Southern Cascades CHU Subunits CA-61 and CA-66. The Goosenest LSR is approximately 39,770 acres in size. Habitats considered suitable for breeding and/or foraging by northern spotted owls (dense late-successional, open late-successional, and dense mid-successional) occupy 14,097 acres, or about 35 percent, of the LSR area (USDA FS 1996b). Low precipitation and temperatures, and high elevation reduce the overall potential of lands within the California Cascades Province to support dense late-successional habitat suitable for northern spotted owls (USDA FS 1996b). The majority of northern spotted owl home ranges in the Goosenest LSR are functioning poorly in terms of long-term sustainability (USDA FS 2005). Home ranges contain overly dense forest with suppressed understory dominated by white fir and lack large trees, particularly Douglas fir. The habitat in these home ranges is at moderate to high risk of insect attack, with subsequent increased wildfire hazard. At such high densities, stand development is unlikely to attain old-growth characteristics in the absence of fire or active management.

A total of 14 northern spotted owl activity centers have been located within the Goosenest LSR. The Goosenest LSR overlaps considerably with subunit CA-61. The 14 known activity centers (12 pairs and 2 territorial singles) within the Goosenest LSR exceed the recovery pair goal of 6 for subunit CA-61 (USDA FS 1996b).

Threats to the Northern Spotted Owl in the California Cascades Province

Threats to the northern spotted owl in this region include habitat loss due to Federal and private management activities, forest health issues (including overstocking, insect infestations, and forest disease), fire, and displacement by barred owls. Northern spotted owl nesting/roosting and dispersal habitat decreased by 1.03 percent and 1.02 percent, respectively, on Federal lands as a result of management activities from 1994 to 2007 in the California Cascades Province; nesting/roosting and dispersal habitat both decreased by 1.01 percent on Federal lands as a result of natural disturbances from 1994 to 2007 in this province (Davis, in press). Bigley and Franklin (2004) reported a 5.77 percent reduction in northern spotted owl habitat on Federal lands as a result of management activities from 1994 to 2003 in the California Cascades Province. Habitat was unchanged by natural disturbances from 1994 to 2002 in the California Cascade Province (USDI FWS 2008a). The total reduction in nesting/roosting habitat was 4.0 percent and the net gain of dispersal habitat was 8.1 percent on Federal lands from land management activities and natural disturbances during this timeframe.

Barred owls currently pose a significant threat to northern spotted owls in the California Cascades Province. While numerous detections of barred owls were reported in the southern Oregon Cascades during the early 1990s, this species was not detected in the California Cascades Province until 1996. From 1996 to 2003, single barred owls were detected at two locations within subunit CA-61 of the Southern Cascades CHU. Surveys in 2004 detected barred owl pairs at three locations, all within northern spotted owl territories. Single barred owls were detected at three additional locations in and adjacent to CHU CA-61, and two locations were reported on the McCloud Ranger District of the STNF, immediately to the south of subunit CA-61. Between 2004 and 2007, the numbers of barred owls detected in the California Cascades Province has increased steadily (USDI FWS unpublished data). As of 2007, barred owls have been detected at 11 locations, and three of 12 northern spotted owl territories (within subunit CA-61) have been displaced by barred owls.

West Nile virus is the primary disease of concern for the northern spotted owl (USDI FWS 2008a). The virus has not been detected in the California Cascades Province; however, it is within the range of the northern spotted owl in northwestern California (Alan Franklin, John Marzluff, pers. comm., as reported in Courtney et al. 2004).

3.3 Status of Fishers in the Action Area

For the purposes of this consultation, the Service is analyzing the environmental baseline for fisher populations and habitat within the California Klamath Province and California Cascades Province portions of the Action Area. The environmental baseline is described separately for these two provinces because they are distinct in terms of their ecology, the availability and quality of information for fishers, and the apparent abundances of fishers and their habitat. The Action Area for fishers consists of FGS ownership with a surrounding 1.6-mile buffer (Figure 3). The 1.6-mile buffer was based on the radius of an estimated circular home range for female fishers in the Klamath Province (7.7 $mile^2$: Appendix E of the HCP). Female fisher home range size was used because females are considered the reproductive unit and presumably establish their home ranges based on the availability of resources. Male fisher home ranges are larger and may in part establish their home ranges based on the location of female home ranges. The Action Area includes the portion of the fisher population that could be directly or indirectly affected by the proposed HCP and ITP.

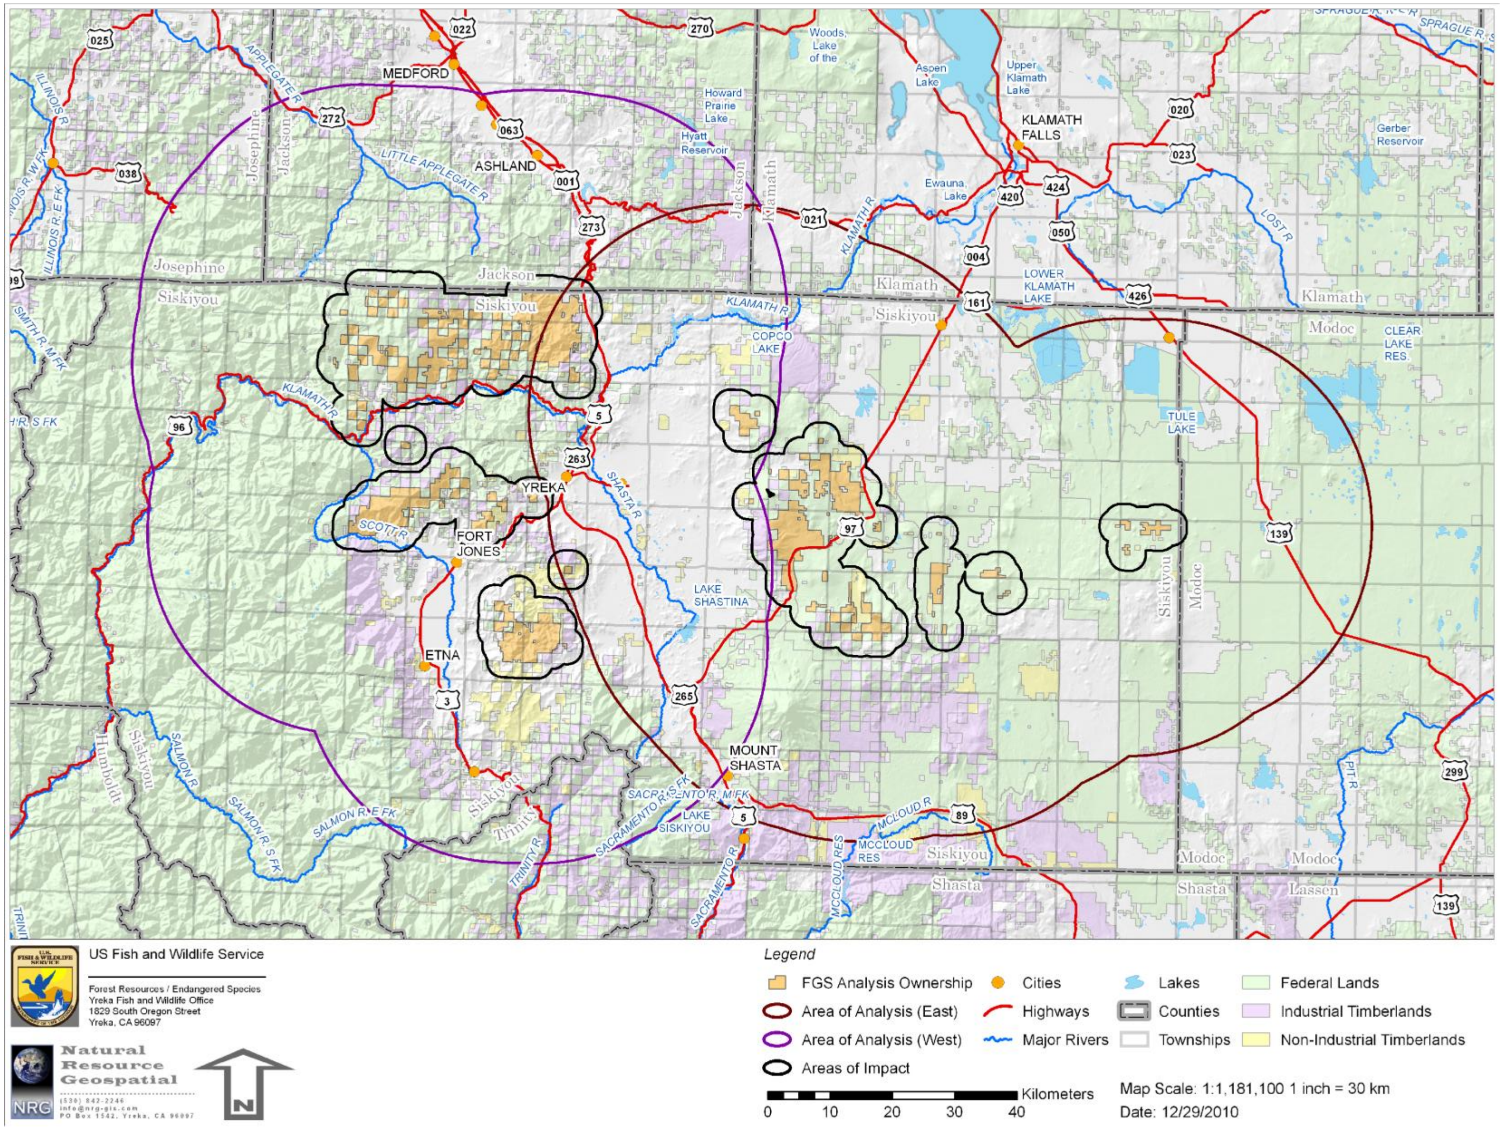

Figure 3. California Klamath and California Cascades regional “Area of Analysis” and local “Area of Impact” within a 20-mile and 1.6-mile radius, respectively, of Fruit Growers Supply Company’s ownership.

3.3.1 Environmental Baseline in the California Klamath Province Action Area

The California Klamath Province portion of the Action Area for fishers contains approximately 350,800 acres. About 29% of this area is owned by FGS, 38% is federally owned, 33% is held by other private land owners, and less than 1% is owned by the State of California.

Fisher Habitat in the Klamath Action Area

Zielinski et al. (2010) used survey data to develop a model that predicts the probability of detecting fishers throughout the California Klamath Region. The final model included the following variables (see Zielinski et al. 2010 for definitions): amount of dense forest, percent hardwood, medium and large trees, structurally complex forest, elevation, solar insolation, and predicted abundance of mammalian prey. Other biotic and abiotic habitat variables may also be important to fishers and were included in candidate models. However, the final model (a composite of the 4 best candidate models) better classified fisher detection locations in the region than did any of the candidate models. The model correctly classified fisher detection and non-detection locations 84% and 70% of the time, respectively.

The Service modified the Zielinski et al. (2010) model by using FGS forest inventory data in place of the original model's vegetation data for FGS lands to provide an estimate of the current amount of modeled habitat for fishers in the California Klamath Province portion of the Action Area. The model predicts the probability of detection of fishers across the landscape, and assumes that areas with a higher probability of detection fulfill a greater number of, or higher quality of, life-requisite needs for fishers (e.g., food, shelter). The probability of detecting fishers may be used as an index of relative habitat suitability for fishers. The Service selected modeled values greater than or equal to 0.41 as a threshold to represent preferred habitat (hereafter 'suitable habitat') using the FGS fisher model (see "Fisher Spatial Analysis" in Appendix E of the HCP for more details on the modeling process used for the Klamath Action Area). To represent the minimum area for supporting a hypothetical female home range, the Service excluded from some calculations isolated patches of modeled habitat smaller than 7.7 mi^2 (20 km^2). This provided a conservative approach to quantifying areas that have a greater likelihood of providing sufficient habitat for the species to meet its life history needs and a spatially explicit method for analyzing how changes in the amount and spatial configuration of habitat may impact fishers under the Proposed Action.

The California Klamath Province portion of the Action Area for fishers consists of approximately 350,800 acres. As predicted by the FGS model, 39% of this area (137,163 acres) currently consists of suitable fisher habitat, with 36% (125,937 acres) existing in large (greater than 7.7 mi^2) patches that contain the minimum area to support a hypothetical female fisher home range (Figure 4). Federal and private (e.g., FGS, other private industrial timberland owners, some non-capable agriculture and urban land) lands account for similar proportions of suitable habitat that occurs in large patches (Figure 4). However, relative to their total acreage within this portion of the Action Area, Federal lands disproportionately contribute to the total amount of suitable fisher habitat that occurs in large patches compared to private lands (Figure 4). State lands account for a negligible (0.4%) proportion of the Klamath Action Area, and do not contain suitable habitat for fisher. Of the FGS ownership within the Klamath Action Area, approximately 34% currently consists of suitable habitat for fishers, mostly (31%) in large blocks. Fruit Growers Supply Company contributes about 10% of the suitable habitat and about 9% of the suitable habitat that occurs in large blocks; therefore, FGS's potential impact on fisher habitat within the Klamath Action Area is limited (Figure 4).

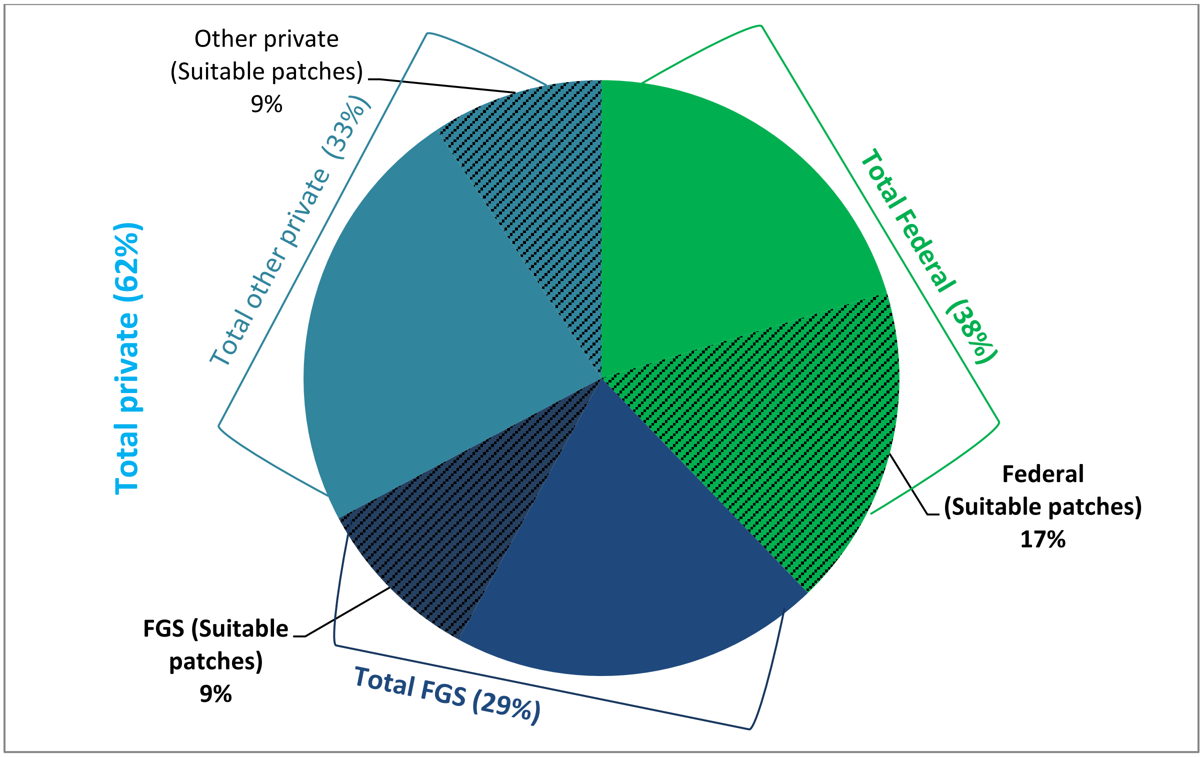

Figure 4. Percentage of total ownership and large patches (>7.7 mi^2) of fisher habitat within the California Klamath Province portion of the Action Area showing suitable habitat by ownership at baseline conditions.

Fisher Population in the Klamath Action Area

Fishers within the California Klamath Province portion of the Action Area are part of the native southwestern Oregon/northern California population, which consists of a series of interconnected local populations that extend west to the Pacific Ocean, south to Lake County, and north into southern Oregon (USDI FWS 2010b). A USFS database query conducted on January 24, 2011 reported verified fisher detections throughout much of the northern and central portions of the Klamath Action Area (Figure 5). Relatively few surveys have been conducted in the vicinity of Moffet Creek in the southernmost portion of the Klamath Action Area; however, one fisher was detected in this area in October, 2011 (Callas 2011).

Additional information on fisher numbers was available for a portion of the Klamath Action Area. In 2006, a fisher monitoring study began in the eastern Klamath Mountains of California. The northern half of this 200-mile^2 study area occurs within the Action Area, overlapping the Beaver Creek drainage of FGS's Klamath River Management Unit. This study uses DNA extracted from fisher hair samples to "mark" and "recapture" individuals. This methodology can be used to estimate population size, demographic structure, and immigration/emigration for each year. DNA samples were collected from 52 different fishers (22 females and 30 males) during 2006 through 2009. Preliminary population estimates for the study area were 25, 53, and 47 individuals during years 2007, 2008, and 2009, respectively (Swiers and Powell 2010).

Comprehensive surveys have not been conducted within the California Klamath Province portion of the Action Area to determine actual fisher population size within this area; however, the modified Zielinski et al. (2010) model indicated that current conditions could support approximately 25 hypothetical female home ranges within the Klamath Action Area (Appendix E of the HCP).

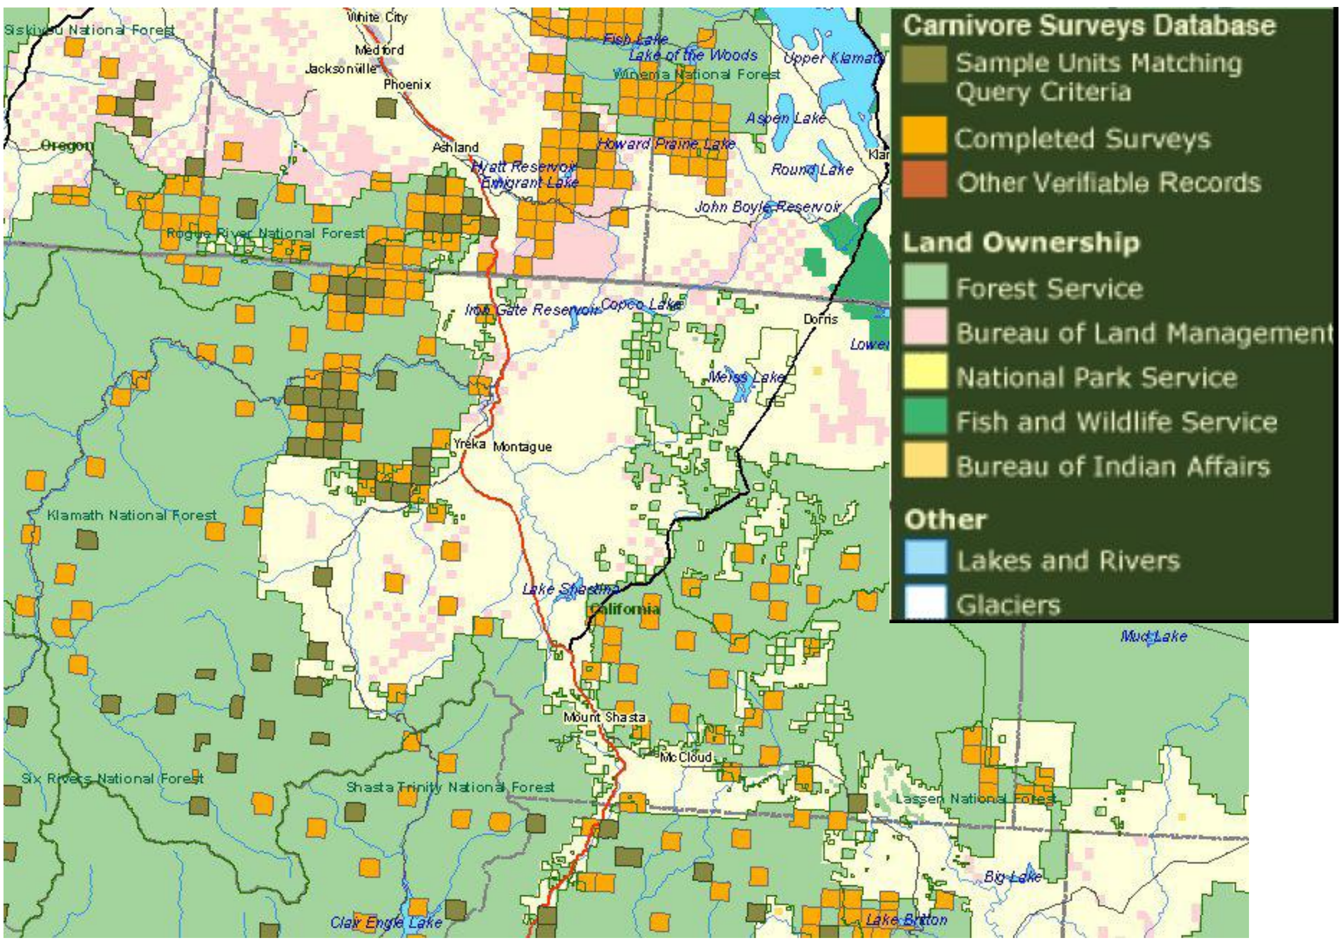

Figure 5. Graphical results of January 24, 2011 query of the USFS Forest Carnivore Surveys in the Pacific States website [http://maps.fs.fed.us/carnivore//Modules/application/home.html]. Orange squares [ ] represent completed surveys within 4-mi^2 sample units based on the Public Land Survey System. Dark green squares [ ] match query parameters that included: Carnivores: "Fisher", Range of Years from: "1995" to "2010", and detection Sources: "All Sources".

Threats to the Fisher in the California Klamath Province

Threats to fishers in the Klamath Province are similar those that threaten the West Coast DPS as a whole (see section 2.2.3). Threats in the Klamath Province include loss, deterioration, and fragmentation of habitat from past and current forest management practices and the potential for catastrophic wildfire. Disturbances that reduce canopy cover or the availability of large trees, snags, and down wood can negatively affect fishers by degrading habitat for them and their prey. Other potential threats, such as vehicle traffic, disease, or predation could work synergistically with habitat modification to further threaten fishers. See section 3.2.2 for more information on management-induced changes to natural disturbance regimes and habitat in the California Klamath Province.

3.3.2 Environmental Baseline in the California Cascades Province Action Area

The total area within the California Cascades Province portion of the Action Area for fishers is 255,100 acres. About 19% of this area is owned by FGS, 60% is federally owned, 20% is held by other private land owners, and less than 1% is owned by the State of California.

Fisher Habitat in the Cascades Action Area

The Zielinski et al. (2010) habitat model could not be applied to the California Cascades Province because it was developed specifically for the Klamath region. Furthermore, the number of fisher detections in the California Cascades Province is currently insufficient for an adequate evaluation of model performance.

Davis et al. (2007) developed and compared multiple habitat models for fishers in California. The model that was developed with detection locations from northern California (as opposed to the southern Sierra Nevada or Statewide) predicted only small, isolated areas of modeled habitat in the California Cascades portion of the Action Area.

Although some of their life history requirements differ, fishers and northern spotted owls have overlapping habitat associations. For example, both species generally gravitate toward relatively old, densely-canopied, multi-layered forests with large trees and dead woody materials. Sixteen percent of the Cascades Action Area currently consists of suitable foraging, nesting, or roosting northern spotted owl habitat on FGS ownership (Table 9). Section 3.2.3 describes the distribution of foraging, nesting, and roosting habitat for northern spotted owls by ownership within the Cascades Action Area.

Fisher Population in the Cascades Action Area

A January 24, 2011 query of the USFS Forest Carnivore Surveys in the Pacific States showed no records of fisher detections within the California Cascades Province portion of the Action Area. However, survey effort in this area is relatively low compared to the Klamath Province. One verified detection of a fisher south of Mount Shasta approximately 9 miles south-southwest of the Cascades Action Area is known to have occurred in 2003 (Lindstrand 2008). Except for the one verified location, fishers appear to be either not present or sufficiently low in numbers to avoid detection. The close proximity of this detection relative to fisher movements, combined with the relatively low survey effort in the region, suggest that fishers may occur in the Cascades Action Area.

As described above in the “Fisher Habitat in the Cascades Action Area” section, the Zielinski et al. (2010) model could not be used to model habitat within the California Cascades Province; therefore, the number of hypothetical female home ranges under current conditions within the California Cascades Province portion of the Action Area could not be estimated.

Threats to Fishers in the California Cascades Province

Threats to fishers in the California Cascades Province include habitat loss and modification due to management activities (e.g., timber harvesting, fire suppression) and the potential for catastrophic wildfire. The Forest Ecosystem Management Assessment Team (1993) described forests in the California Cascades as highly fragmented due to harvest activities and natural factors.

4.0 EFFECTS OF THE ACTION

In general, implementation of the FGS HCP Covered Activities consists of the following: timber harvest (e.g., felling and bucking of timber, yarding timber, salvage and transport of timber), silviculture (e.g., clearcutting, commercial thinning, biomass thinning, seedtree/shelterwood removal, selection/group selection, or combination of these), stand regeneration and improvement (e.g., site preparation, prescribed burning, slash treatment, tree planting, vegetation management), minor forest products (e.g., Christmas tree cutting, firewood cutting, fence post cutting), and fire prevention (e.g., vegetation management, fuel break construction) and suppression (e.g., fuel break construction, application of aerial fire suppressants, falling trees or snags, water drafting). Each of these Covered Activities has the potential to result in adverse effects to the northern spotted owl, fisher, and their habitat through a number of mechanisms (e.g., habitat modification, noise disturbance, direct injury, and mortality), which are described in detail in the following sections. This section presents an analysis of the direct and indirect effects of the FGS HCP, including interrelated and interdependent actions, on the northern spotted owl and fisher.

4.1 Northern Spotted Owl

The degree to which the Covered Activities listed above are likely to directly and indirectly affect the northern spotted owl within the Action Area are discussed below. These effects are then evaluated with consideration of the conservation needs of the owl within the larger conservation strategy established for the northern spotted owl by the NWFP and Revised Recovery Plan, including: 1) protection of large blocks of habitat to provide for clusters of breeding pairs of northern spotted owls; 2) suitable habitat distributed across a variety of ecological conditions; and, 3) reserves connected by habitat within the intervening matrix to support survival and movement across the landscape.

Forest management is the primary activity in the Plan Area, occurring on 152,178 acres. Not all forest management activities and their effects have the potential to cause 'take' of northern spotted owls. The modification of forest stand conditions through timber harvest has the greatest potential to affect (adversely or beneficially) northern spotted owls because of the immediate and long-term effects it has on habitat conditions and prey availability. Silvicultural treatments such as thinning may benefit northern spotted owls by accelerating the development of northern spotted owl habitat and dense prey populations, and reducing the risk of catastrophic wildfire. Silvicultural activities associated with stand regeneration (e.g., site prep and tree planting) are unlikely to affect habitat conditions for northern spotted owls, but have the potential to adversely affect northern spotted owls by increasing noise and activity levels. Other Covered Activities related to timber harvesting (e.g., harvesting minor forest products, fire prevention, and watershed management) could result in varying levels of habitat modification and disturbance.

4.1.1 Direct Effects

4.1.1.1 Disturbance-Related Effects

Timber harvesting, timber hauling, plantation establishment and maintenance, road management (road building, road decommissioning), and fuels work will require use of heavy equipment, power tools, chainsaws, and large vehicles, all of which introduce an increased level of sound and human activity into the environment. The effect of sight- and sound-related disturbance on northern spotted owls is not well studied. Further, the effects of noise on birds can be difficult to establish due to difficulties associated with quantifying and qualifying characteristics of disturbance (i.e., type, frequency, proximity) and appropriate response variables (i.e., behavior, reproductive success, survival). Additional factors increase the complexity of evaluating effects of disturbance such as the individual bird's tolerance level, ambient sound levels, physical parameters of sound and how it reacts with topographic characteristics and vegetation, and differences in how species perceive noise.

In spite of these challenges, research conducted on a variety of bird species does suggest that disturbance can have a negative effect on reproductive success (Tremblay and Ellison 1979, Anderson et al. 1989, Belanger and Bedard 1989, Piatt et al. 1990, Henson and Grant 1991). Such studies have shown that disturbance can affect productivity in a number of ways including: interference of courtship (Bednarz and Hayden 1988), nest abandonment (White and Thurow 1985), egg and hatchling mortality due to exposure and predation (Drent 1972, Swensen 1979), and altered parental care (Fyfe and Olendorrf 1976, Bortolotti et al. 1984). Disturbance can also have an effect prior to incubation by influencing the choice of a nesting site (Long and Ralph 1998). The few studies that have examined spotted owl responses to several types of disturbance (e.g., helicopters, small chainsaw, hikers) determined that owl behavior was disrupted by such stimuli, as demonstrated by flushing, altered prey delivery rates, and decreased prey handling behavior (Delaney et al. 1999; Delaney and Grubb 2001; Swarthout and Steidl 2001, 2003). However, whether or not the owls responded to the disturbance, and to what extent, depended on several factors, including time of year, noise level, and proximity to stimulus.

Disturbances that cause exposure of adult or juvenile northern spotted owls may increase predation risks. Causing a northern spotted owl to fly off the nest may increase the likelihood of predation or injury through the advertisement of the nest's location, advertisement of the adult and juvenile, or premature departure of a nestling from a nest. Predation is presumed the largest cause of northern spotted owl mortality, particularly of juveniles, due to raptors, other owls, and corvids (Forsman et al. 1984, Laymon 1985, Verner et al. 1992). Human presence alone appears to attract predators, such as corvids. For example, Forsman et al. (1984) recorded an incident in which ravens attempted to predate a nest after survey efforts called the female out of the nest cavity during the day.

As described under "Disturbance-Related Effects" in section 2.1.3.2 (Threats), spotted owls may have elevated stress hormone levels in response to a disturbance without exhibiting a change in behavior which, over extended periods, may have negative effects on reproductive function, disease resistance, or physical condition (Carsia and Harvey 2000, Saplosky et al. 2000). Prolonged activities, such as those associated with timber harvest, may increase stress hormone levels depending on their proximity to northern spotted owl core areas (Wasser et al. 1997, Tempel and Gutiérrez 2004). Gender differences found in fecal glucocortoid concentrations over time from owls in Washington and Oregon suggest that timber practices and other prolonged disturbances may have disproportional negative effects to female owls (Wasser et al. 1997). However, not surprisingly, these studies also indicate that owl sensitivity varies with stimulus distance, location (aerial or ground), type, and timing, as well as individual tolerance (Delaney et al. 1999; Delaney and Grubb 2001; Swarthout and Steidl 2001, 2003; Tempel and Gutiérrez 2003).

Post-harvest fuels treatments may also create above-ambient smoke or heat. Although it has not been conclusively demonstrated, it is anticipated that nesting northern spotted owls may be negatively affected by heat and smoke intrusion into the nest grove. Smoke and heat may serve as a disturbance to nesting owls or their young by causing them to avoid important foraging areas or fleeing the nest area prematurely, thereby reducing fitness.

Fruit Growers Supply's Covered Activities have the potential to cause direct disturbance to northern spotted owls when they are present within a treatment area. Noise or visual disturbance created by the use of heavy machinery, logging trucks, or other noise producing equipment used within treatment areas or along access roads to carry out FGS' Covered Activities has the potential to disrupt nesting, roosting, and foraging behaviors of northern spotted owls. Prescribed burning or burning of brush/scrap piles may also disrupt northern spotted owls nesting, roosting, and foraging behaviors. Noise, smoke, or visual disturbance can cause nesting northern spotted owls to temporarily flush from nest sites leaving eggs or hatchlings exposed to temperature changes or predation. More severe disturbances can cause the abandonment of the nest by adults or early abandonment of the nest by young. Roosting northern spotted owls exposed to noise, smoke, or visual disturbance can be subject to predation if forced off their roost site. If forced to move into an area with a less favorable microclimate and habitat, it could ultimately reduce their fitness (i.e., survival and reproduction). Additionally, owls that are forced out of their normal foraging areas may be subject to move into areas that have less prey availability or where they are less efficient in capturing prey.

While roosting and foraging northern spotted owls can be disturbed during any time of the year, noise, smoke, or visual disturbances generally have the greatest effect on them during the breeding, nesting, or rearing periods. To minimize direct disturbance to northern spotted owls during breeding, nesting, or rearing periods, FGS will implement a Limited Operating Period (LOP) from February 1 to August 31 for activities within 0.25 mile of known active nest sites. Fruit Growers Supply Company will implement protocol surveys according to the "Protocol for Surveying Proposed Management Activities that May Impact Northern Spotted Owls" (USDI FWS 2011a) or current northern spotted owl survey protocols approved by the Service prior to project implementation to determine the status of historic activity centers and determine if new activity centers have been established within 0.25 mile of any proposed treatment units.

4.1.1.2 Injury or Mortality

Forest management activities can result in direct mortality of adults, eggs, or young. Such cases are rare, but direct mortality due to tree-felling has been documented (Forsman et al. 2002). The potential for northern spotted owls to be struck and killed or injured by falling trees during harvesting or exposed to high levels of smoke during prescribed burning is confined to the area relatively close to the nest tree. During timber harvest or prescribed burning, individual adult northern spotted owls can reasonably be expected to move from the area and avoid injury. However, nesting adult northern spotted owls tending to reproductive activities such as incubation or brooding young may be reluctant to leave the area (Delaney et al. 1999), and therefore may be vulnerable to such injury. Foraging owls are not expected to be affected directly, as they will likely avoid areas with disturbance.

Young-of-the-year, whether in or out of the nest, may also be vulnerable to the effects of tree falling or smoke inhalation, or might disperse prematurely in response to the disturbance and thus be subject to predation, starvation, or injury outside of the nest or nest grove. Because young must be constantly brooded by an adult post hatching for up to two weeks, parental abandonment of the nest could lead to mortality of the young. Potential effects to eggs range from the implications of parental abandonment (Drent 1972, Swensen 1979, White and Thurow 1985) to destruction during tree falling. These types of direct effects are most likely to occur in nesting/roosting habitat during the breeding season when active breeding activities are underway.

As stated in the Take Minimization Objective in section 5.3.1.4 of the FGS HCP, FGS will not conduct timber operations or create a noise or smoke disturbance in conducting Covered Activities (minus fire suppression) within 0.25 mile of active northern spotted owl nest sites during the breeding, nesting, or rearing season beginning February 1 and ending August 31 (i.e., the LOP). "Active northern spotted owl nest site" is defined as the nest tree of a pair of nesting northern spotted owls. Road use and maintenance within 0.25 mile of an active northern spotted owl nest site may occur during the breeding season, but will require evaluation and approval by the Service. With implementation of the LOP, the likelihood of direct injury or mortality of owls is very unlikely and thus discountable.

Emergency fire suppression by FGS could potentially lead to incidental take of northern spotted owls. Since wildfire can occur during the northern spotted owl breeding season, there is a small probability that an adult owl or dependent young could be injured or killed as a result of dozer line construction, lighting backfires, applying aerial fire suppressants, and falling trees or snags. While individual adult northern spotted owls can reasonably be expected to move from an area of disturbance, nesting northern spotted owls tenaciously tending to reproductive activities such as incubation or brooding young may be reluctant to leave the area (Delaney et al. 1999), and therefore may be vulnerable to injury or death. Northern spotted owl eggs or nest dependent young have a higher probability of mortality from fire suppression activities that affect nest groves since they would be unable to move away from the disturbance.

4.1.2 Indirect Effects

4.1.2.1 Habitat Modification

The FGS HCP proposes timber harvest through different types of silviculture, road construction and maintenance, stand regeneration and improvement, minor forest product harvest, fire prevention and suppression, and other activities collectively referred to as Covered Activities. Forest management activities can alter suitable northern spotted owl habitat to varying degrees, leading to direct and indirect effects to northern spotted owls at both site-specific and landscape scales.

Site-Specific Effects

Currently, FGS has approximately 43,757 acres of suitable northern spotted owl habitat across its ownership within the entire Action Area, 9,029 acres of which are nesting/roosting and 34,728 acres of which are foraging habitat. Within the California Klamath Province Action Area there are 8,410 acres of nesting/roosting and 30,548 acres of foraging habitat. Within the California Cascades Province Action Area there are 619 acres of nesting/roosting and 4,180 acres of foraging habitat. Nearly all of the currently suitable habitat available for northern spotted owl in the Action Area could be harvested over the term of the ITP, with the exception of approximately 7,131 acres which have been identified by FGS as habitat commitments in CSAs. Of these 7,131 acres in CSAs, 115 acres are targeted for nesting/roosting, 3,721 acres for high-quality foraging, and 3,294 acres for low-quality foraging habitat. Northern spotted owls will benefit from an additional 5,648 acres that will be protected outside of the CSAs in WLPZs under the Aquatic Conservation Strategy, 5,017 acres of which will be in the California Klamath Province and 631 acres of which will be in the California Cascades Province. It is anticipated that the majority of timber harvest of currently suitable northern spotted owl habitat within the Action Area will occur in the first ten years of the HCP, accounting for modification of approximately 18,640 acres of suitable northern spotted owl habitat. Of the 18,640 acres of suitable northern spotted owl habitat that is likely to be harvested in the first decade, it is estimated that 34 percent (approximately 6,347 acres) will be reduced to non-habitat. The remaining acres will provide some level of dispersal or foraging capability.

Timber harvesting can result in the direct loss of suitable habitat important for northern spotted owl nesting, roosting or foraging. As a result, northern spotted owls may abandon a territory and seek out habitat elsewhere that may be marginal or occupied by other northern spotted owls or barred owls that compete for the same resources. Timber harvest can adversely affect northern spotted owls by reducing the total amount of suitable habitat within a northern spotted owl’s home range. The result may be that the northern spotted owls continue to persist at the territory in the short-term, but marginal habitat conditions in the territory compromise the northern spotted owls’ long-term survival and ability to successfully reproduce.

Forest management activities, whether intended to address silvicultural needs or to facilitate other actions (e.g., road construction, wildfire prevention, recreation) have the potential to reduce availability of nest and roost sites and foraging and dispersal habitat for the northern spotted owl. Northern spotted owls do not construct their own nests, but depend upon existing structures such as cavities in snags and live trees, broken tree tops, and mistletoe brooms; characteristics associated with stands in later seral stages of development. Silvicultural prescriptions (e.g. regeneration and overstory removal prescriptions) or management activities that specifically target the oldest, most decadent trees in the stand for economic purposes, or require removal of hazard trees and snags to address human safety concerns, are likely to result in loss of nesting opportunities for northern spotted owls by removing the trees that contain those structures (Blakesley et al. 1992). In studying tree dimension data from trees harvested in the 1960s, Hummel (2009) found that crown morphologies of large, young trees were not the same as their similarly sized older counterparts; therefore younger stands with old-growth characteristics may not provide as favorable nesting habitat as actual old growth. Further, prescriptions designed to reduce or remove ladder fuels or release co-dominant individuals can simplify vertical structure in the forest understory, where northern spotted owls perch for hunting or roosting (Forsman et al. 1984).

Intermediate timber harvest and fuels reduction activities can contribute to changes in structure, diversity, and habitat microclimate by reducing overall canopy closure within a stand. Northern spotted owls prefer to nest and roost in older, multi-storied forests (USDI FWS 1990a, Thomas et al. 1990, Blakesley et al. 1992, Verner et al. 1992, Andrews et al. 2005) presumably because they provide protection under most weather conditions (Forsman et al. 1984, North et al. 2000). During periods of rain, snow, or cold, Forsman et al. (1984) found northern spotted owls roosting significantly higher in the forest overstory than during hot weather when northern spotted owls were commonly found roosting low in the forest understory (Barrows and Barrows 1978). Weathers et al. (2001) documents physiological limitations that corroborate results of laboratory work and field studies which determined low heat tolerance of northern spotted owls compared to other birds.

Various forestry activities that remove large trees, snags, shrubs, and downed wood can affect prey composition and/or availability by altering characteristics of the habitat upon which prey species depend. Because the amount of standing dead (i.e., snags) and down material present on the forest floor is positively correlated with densities of some northern spotted owl prey species, removing these materials or temporarily disturbing material on the forest floor may contribute to declines in northern spotted owl prey, at least on a localized, short-term basis (Williams et al. 1992, Bevis et al. 1997). It may also be possible for prey species to be adversely affected by incidental loss of hardwoods, hazard trees, or snags during harvest.

In the southern portion of their range, where woodrats are a major component of their diet, northern spotted owls are more likely to use a variety of stands, including younger stands, brushy openings in older stands, and edges between forest types in response to higher prey density in some of these areas (Solis 1983, Sakai and Noon 1993, 1997, Carey et al. 1999, Franklin et al. 2000). Density of dusky-footed woodrats appears to be highest in sapling/bushy poletimber 15 to 40 years old and in older forests that have openings with abundant bushy understory (Raphael

1988, Sakai and Noon 1993, Hamm 1995, Carey et al. 1999, Hamm and Diller 2009). Hamm and Diller (2009) hypothesize that dusky-footed woodrats (*Neotoma fuscipes*) in northern California are likely directly tied to understory plant species diversity, vegetation density, and sites suitable for constructing houses rather than presence or absence of overstory conifer trees. Many other researchers (e.g. Carey et al. 1999, Innes et al. 2007) recognize the importance of large logs, stumps, shrubs, and materials for houses to woodrat density. Because of the importance of snags, downed logs, and mistletoe to woodrats, Lehmkuhl et al. (2006a) found that management to reduce woody fuels and restore low-intensity high frequency fire into ponderosa pine and Douglas fir forests will likely reduce bushy-tailed woodrat (*Neotoma cinerea occidentalis*) populations.

Dusky-footed woodrats prefer forested habitats with a brushy understory and suitable nest building materials. Houses are built of sticks and leaves at the base of, or in a tree, around a shrub, or at the base of a hill. Silvicultural treatments and prescribed burning could negatively affect dusky-footed woodrat habitat by destroying shrub cover and burning stick nests. However, it has been noted that opening up the canopy and having patchy openings throughout a stand may provide for the growth of shrubs, thereby increasing habitat availability to dusky-footed woodrats. Lehmkuhl et al. (2006b) determined that bushy-tailed woodrats can be abundant in dry interior forests where rock is scarce and snags, logs, and mistletoe provide cover. Large snags, mistletoe, and large logs are important cover elements that are positively correlated with bushy-tailed woodrat habitat value (Maser et al. 1984, Carey 1991, Smith 1997, Verts and Carraway 1998). Management to reduce woody fuels and restore low-intensity high-frequency fire regimes in ponderosa pine and dry Douglas-fir forest will likely reduce bushy-tailed woodrat populations (Lehmkuhl et al. 2006b). Cover provided by downed logs and mistletoe trees, whose dense brooms close to the ground torch easily in ground fires (Hessburg et al. 1994), would be mostly consumed by prescribed fire (Lehmkuhl et al. 2006b). Additionally, existing large snags with defects and old woodpecker cavities that provide woodrat nest sites (Carey 1991) also would be at risk of destruction by prescribed fire (Lehmkuhl et al. 2006b). Stand simplification, such as removal of tree height diversity or understory shrubbery, commonly resulting from timber harvest and prescribed burning, create less favorable foraging conditions for northern spotted owls. Because availability of large prey species, particularly dusky-footed woodrat and northern flying squirrels, has been shown to be important for northern spotted owl reproductive success (Barrows 1985, 1987; Zabel et al. 1995), activities that reduce prey populations could lower northern spotted owl recruitment and individual fitness, especially during breeding season.

Populations of small mammals vary widely in response to habitat availability and food resources. Silvicultural and fuel reduction treatments affect species differently depending on their life history needs. Northern flying squirrels, western red-backed voles, and bushy-tailed woodrats are usually negatively affected by silvicultural (thinning, shelterwood) and fuel reduction treatments in the short-term and may not start to recover until several years after treatments. On the other hand, many species such as ground dwelling squirrels and chipmunks increase almost immediately (1 to 2 years) after treatments. Loss of foraging habitat or silvicultural activities that lead to a short-term (1 to 5 years) reduction in prey availability may cause northern spotted owls to forage in other, less-familiar areas, leading to an increased probability of competitive interactions with barred owls or other northern spotted owls that may be in the area, as well as an increased probability of predation.

Fruit Growers Supply Company will employ various silvicultural treatments across its ownership. The most pronounced effect to suitable northern spotted owl habitat within the Plan Area will be from the use and implementation of even-aged regeneration methods. Even-aged regeneration occurs on a 50- to 80-year rotation and produces stands that will remain in young seral stages for 20 to 50 years depending on site potential and stocking retained. These units are generally small, from 10 to 30 acres, and scattered on the landscape. Additionally, based on FGS's MSP analysis and as stated on page 2-18 of the Final EIS, the HCP is expected to result in an increase in what the Service considers foraging habitat (i.e., CWHR habitat categories 4M and 4D) over time and a decrease in clearcutting and other even-aged management practices.

In most cases, even-aged regeneration targets marginally stocked and/or deteriorating stands to improve their long-term productivity. Harvest methods include seed tree, shelterwood, and clearcutting methods. Regeneration occurs artificially through planting nursery-grown seedlings, or naturally by seed trees retained within harvest units. Stands that are 50 to 80 years old generally support dispersal and foraging habitat for northern spotted owl. Harvesting by seed tree, shelterwood, and clearcutting methods will generally render the stands unsuitable to the northern spotted owl for nesting, roosting, foraging, and potentially dispersal.

Even-aged thinning units are intermediate treatments of mid-seral even-aged stands designed to accelerate growth of trees. Generally, mid-seral even-aged stands may provide dispersal and foraging opportunities for northern spotted owls, although these stands are generally dense with limited below-canopy roosting or perching opportunities. Thinning of these stands would likely improve an owl's ability to disperse through the stand by providing more space in the subcanopy to maneuver and fly through.

Uneven-aged silviculture is used to harvest trees individually or in small groups with the goal of developing or maintaining a variety of age classes within a stand. Typically, sites are restocked through natural regeneration and, where necessary, supplemented by planting seedlings obtained from a nursery. Uneven-aged silviculture will generally maintain the function of northern spotted owl habitat, although degradation of habitat components will typically occur.

Clearcutting

The clearcutting regeneration method involves the removal of a stand in one harvest. These clearcutting units are generally 20 to 30 acres, but may be up to 40 acres in size. Clearcutting occurs on FGS ownership within stands that are generally 50 to 80 years old. These stands typically provide foraging and dispersal habitat for northern spotted owls. In rare circumstances, a 70 to 80 year old stand may provide isolated patches of nesting/roosting habitat for northern spotted owls under optimum conditions (i.e., high site class mixed conifer or Douglas fir, proper elevation, aspect, slope position) which include older trees or snags that provide nesting opportunities. Clearcut timber harvest will adversely affect northern spotted owl habitat by completely removing the forest stand and rendering the harvested area unsuitable for northern spotted owl nesting, roosting, foraging, or dispersal for the life of the 50-year ITP. However, based on FGS's MSP analysis and as stated on page 2-18 of the Final EIS, the HCP is expected to result in an increase in what the Service considers foraging habitat (i.e., CWHR habitat categories 4M and 4D) over time and a decrease in clearcutting and other even-aged management practices (see section 4.1.3.2).

Commercial Thin

Commercial thinning is the removal of trees in a forest stand to maintain or increase the average diameter of the remaining trees, promote timber growth, and/or improve forest health. Commercial thinning is used as a tool to extend the "life" of some stands before using a regeneration harvest to better balance age class distributions across the forest. Commercial thinning is used to improve stand health and growth in relatively healthy, well-stocked stands of trees large enough to be harvested for lumber (> 10 inches dbh) that exceed target stocking requirements. Commercial thinning is typically conducted in northern spotted foraging or dispersal habitat. Commercial thinning reduces current canopy closure and has the potential to reduce tree height diversity when used within an uneven-aged stand of trees. Removal of forest cover increases solar radiation at the surface and in the understory, elevating daytime air temperatures (Heithecker and Halpern 2006). Rambo and North (2009) found that understory thinning units had significantly more extreme summer daily ranges of temperature and vapor pressure deficit than untreated control units. After thinning, northern spotted owls may avoid the area and move to adjacent suitable habitat areas (Forsman et al. 1984). Northern spotted owls prefer to roost in older forests due to their thermoregulatory properties, and early to middle stage forests have been shown to be used less than expected based on their availability, even in areas where old forest is scarce (Carey et al. 1990). Owls flew long distances to reach older stands, even bypassing younger and mature forests (Carey et al. 1990). Treated stands will likely be less favorable to northern spotted owls in the short-term (i.e., 30 to 50 years) for roosting due to a reduction in thermoregulatory properties, overstory canopy, and a reduction in understory perch trees that the owls use during hot summer days. Additionally, thinning treatments have the potential to damage residual trees, make residual trees more susceptible to windthrow, and allow increased wind speeds through the stand, which in turn could affect fire behavior. Therefore, while these stands will still maintain the characteristics of foraging and dispersal habitat, they may be less desirable to the northern spotted owl as a result of thinning activities.

Depending on the magnitude and severity, commercial thinning within northern spotted owl home ranges has the potential to cause site abandonment of resident owls or cause a reduction in owl fitness and recruitment. In a radiotelemetry study of northern spotted owls in hemlock/Douglas-fir forest in Oregon, timber harvest was the principal cause of site abandonment (Forsman et al. 1984), although it should be noted that sample size was small and the results were not based on an experimental design. In areas that experienced heavy thinning where canopy closure was reduced to less than 50 percent, northern spotted owls either completely disappeared or moved to adjacent unharvested old growth stands (Forsman et al. 1984).

The effects of commercial thinning on northern spotted owl in the more diverse Klamath forest types where the Action Area is located are less conclusive. The limited available literature from the Coast, West Cascades and Klamath Physiographic Provinces in Oregon appears to support the concept that spotted owl habitat can be thinned, to some degree (i.e., lightly), and retain its biological function post-treatment. Solis (1983), using radio-telemetry, found that northern spotted owl pairs infrequently used recently thinned pole/medium stands that retained 70 percent canopy closure post-thinning. Irwin et al. (1989) reported that many private forest managers in northern California observed owl pairs nesting successfully following partial harvest that retained relatively continuous forest canopies and important structures believed to influence owls and/or their prey. Kerns (1989) monitored three spotted owls during the breeding season and found that one of the owls used a thinned, relatively more open stand. King (1993) found that spotted owls used sites within selectively harvested (uneven-aged management) forests that retained higher canopy cover in the Yakama Indian Reservation. Hicks et al. (1999) documented through telemetry work on 14 northern spotted owls that the owls occasionally roosted in stands that had recently been managed, either through selective harvest or pre-commercial thinning. In both cases the owls were found in the managed stand within six months after ground operations. Irwin et al. (2005) evaluated spotted owl fidelity to home ranges following thinning and partial harvest treatments in young stands that retained at least 60 percent canopy. The authors found that no spotted owls vacated their home ranges after treatments were applied, and spotted owl use of stands pre- and post-treatment remained similar. Meiman et al. (2003) tracked the response of a single male spotted owl following relatively heavy commercial thinning in young (second-growth, 70-80 years old) Douglas-fir stands in the Oregon Coast Range. The authors recorded 13 percent of the male's locations in the thinned area prior to harvest and 3.8 percent of the locations in the thinned area following harvest. Use of the thinned stand was statistically significantly greater before than after harvest.

Thinning reduces the number of snags, downed woody material, shrubs, forbs, grasses, and fungi which provide key components of foraging and denning for northern spotted owl prey species. Shrub, down wood, and snags provide important cover from predators, so loss of these habitat elements may negatively affect some small mammals (Chambers 2002). Although small mammals seem to recolonize disturbed areas soon after disturbance, diversity and species dominance differ as succession progresses. Small mammals that prefer high canopy closure and/or woody debris may be adversely affected by thinning. Additionally, thinning has short-term negative effects on understory plants (mechanical destruction) and below-ground fungi (death of host trees and mechanical destruction) (Courtney et al. 2004). Loss of these habitat components can lead to decreased prey availability and less favorable habitat conditions (i.e., reduced snags, tree height diversity, less thermoregulatory buffering properties) resulting in possible avoidance of use by northern spotted owls and a reduction of overall fitness. Logging methods that minimize ground disturbing activities could minimize detrimental impacts to prey habitat and food resources. Variable-density thinning, as opposed to conventional thinning prescriptions holds promise for acceleration of the development of spotted owl habitat and dense prey populations (Carey 1995, 2001) especially when appropriate attention is paid to decadence (snags, cavity trees, and coarse woody debris) (Bunnell et al. 1999; Carey et al. 2002).

<u>Biomass Thin</u>

This intermediate treatment is used to thin younger, overstocked, submerchantable-sized stands to improve stand health and growth. It is predominantly used in young ponderosa pine stands and in mixed conifer stands with a heavy pine component. Although some saw logs are harvested, the main product is hog fuel (an unprocessed mix of barks and wood fiber) or paper chips from trees ranging from 4 to 10 inches dbh. Biomass thinning has been periodically used in the Grass Lake Management Unit to improve stand condition. It is also a valuable tool to reduce wildfire potential.

Biomass thinning would typically occur in northern spotted owl dispersal habitat or unsuitable habitat due to the age of the stands being thinned. Biomass stands are typically overstocked and are difficult for owls to forage or disperse through. Thinning these stands would generally improve the dispersal capability of northern spotted owls within the stands and potentially provide improved foraging capability. Although some saw logs may be removed, biomass thinning will generally improve current habitat conditions and allow the faster development of foraging and nesting/roosting habitat into the future.

<u>Seedtree</u>

The seed tree regeneration method involves the removal of a stand in one harvest except for well distributed seed trees of desired species which are left singly or in groups to restock the harvested area. The CFPRs require that retention trees are at least 18 inches dbh and that 15 ft^2/ac on site I, II and III (see Table 11; Site Classification) lands and 12 ft^2/ac on site IV and V lands per acre must be retained. The seed step is utilized to promote natural reproduction from seed and to initiate the establishment of an even-aged stand. The removal step may be utilized to remove the seed trees after a fully stocked stand of reproduction has become established.

Table 11. CFPR Site Classification (CALFIRE 2010)

	Ponderosa Pine, Jeffrey Pine, Mixed Conifer and True Fir[1]	
Site Class	**Site Index**[2] feet@100 years	**Site Index**[3] feet@300 years
I	≥114	≥163
II	93-113	138-162
III	75-92	113-137
IV	60-74	88-112
V	<60	<88

[1] Dunning 1942. Site index based on average tree height of dominant trees at age 100 and 300 years.
[2] Average total height in feet of dominant trees at 100 years of age.
[3] Average total height in feet of dominant trees at 300 years of age.

Seed tree regeneration harvest will typically occur in northern spotted owl nesting/roosting or foraging habitat. The initial harvest (seed step) will eliminate key components of northern spotted owl suitable habitat. Canopy closure and tree height diversity will be substantially reduced by the removal of the majority of trees within the stand. The removal of trees would likely include the removal of nest or potential nest trees that have various deformities (large cavities, broken tops, mistletoe infections, and other evidence of decadence) as these trees are less desirable to provide a viable seed source to restock the stand. Additionally, snags may be reduced and downed woody material would be reduced to prepare the stand for natural seeding. The reduction in these key components of northern spotted owl suitable habitat would render the harvested area unsuitable for northern spotted owl nesting/roosting, foraging, or dispersal as the remaining seed trees would be incapable of providing sufficient canopy closure needed by the northern spotted owl. The retention of seed trees throughout the stand could potentially provide nest trees in the future if not harvested through the removal step; however, these trees will remain unusable until the surrounding stand provides key components of nesting/roosting or foraging habitat.

Shelterwood Removal (Even-aged)

The shelterwood regeneration method reproduces a stand via a series of harvests (preparatory, seed, and removal). The preparatory step is utilized to improve the crown development, seed production capacity and wind firmness of designated seed trees. The seed step is utilized to promote natural reproduction from seed. The removal step is utilized when a fully stocked stand of reproduction has become established, and this step includes the removal of the protective overstory trees. The shelterwood regeneration method is normally utilized when some shade canopy is considered desirable for the establishment of regeneration.

In the shelterwood preparatory step, the CFPRs require that seed trees that are at least 18 inches dbh must be retained at a minimum of 30 ft^2/ac on site I, II, and III lands and 24 ft^2/ac on site IV and V lands. Overall, at least 125 ft^2/ac on site I lands, 75 ft^2/ac on site II and III lands, and 50 ft^2/ac on site IV and V lands must be retained. In the shelterwood seed step, the CFPRs require that seed trees that are at least 18 inches dbh must be retained at a minimum of 30 ft^2/ac on site I, II, and III lands and 24 ft^2/ac on site IV and V lands. Once the minimum stocking requirements have been met, as required by the CFPRs, then the shelterwood removal step may be utilized.

Shelterwood regeneration harvest will typically occur in northern spotted owl nesting/roosting or foraging habitat. The initial harvest (preparatory step) will eliminate key components of northern spotted owl suitable habitat, although not to the extent of a seed tree regeneration harvest, since additional basal area must be maintained within the stand. Canopy closure and tree height diversity will be reduced by the removal of overstory and mid-story trees within the stand. The removal of trees would likely include the removal of nest or potential nest trees that have various deformities (large cavities, broken tops, mistletoe infections, and other evidence of decadence) as these trees are less desirable to provide a viable seed source to restock the stand. Trees in the understory that provide perching opportunities for northern spotted owls and snags and downed woody material that provide shelter for northern spotted owl prey species would also be reduced. Based on the CFPRs retention standards, site I, II and III lands would likely maintain some characteristics of northern spotted owl foraging and/or dispersal habitat. Site IV lands would likely be reduced to northern spotted owl dispersal habitat. Once the shelterwood seed step was implemented, only the remaining overstory seed trees would be maintained. The remaining seed trees would be incapable of providing sufficient canopy closure needed by the northern spotted owl, thus rendering the harvested area unsuitable for northern spotted owl foraging or dispersal. The retention of seed trees throughout the stand could potentially provide nest trees in the future if not harvested through the removal step; however, these trees will remain unusable until the surrounding stand provides key components of nesting/roosting or foraging habitat.

Selection/Group Selection (Uneven-aged)

This silvicultural method is used in heavily stocked, relatively healthy stands that have an uneven-aged structure. Merchantable trees are harvested from all size classes present. The intent is to maintain an uneven-aged structure, maintain stand health, and generate a harvest return. Harvest entries occur every 10 to 20 years. Selection harvest has also been applied to other stands throughout FGS ownership on the Hilt/Siskiyou forest, including those in watercourse protection zones and on potentially unstable slopes, including inner gorges and shallow, unstable soils.

Under the selection regeneration method, the trees are removed individually or in small groups sized from 0.25 acres to 2.5 acres. The CFPRs state that stocking should not be reduced below the following standards post-harvest: on site I lands at least 100 ft^2/ac shall be retained, on site II and III lands at least 75 ft^2/ac shall be retained, and on site IV and V lands at least 50 ft^2/ac of basal area shall be retained.

Selection harvest will typically occur in northern spotted owl nesting/roosting and foraging habitat. Selection harvest, whether individual or group selection, will reduce overall canopy closure but maintain a level of tree height diversity throughout the stand. Additionally, snags and downed woody material will be reduced. Overall, current nesting/roosting habitat for the northern spotted owl would be reduced to foraging or dispersal habitat and current foraging habitat would either be maintained at foraging or reduced to dispersal habitat, depending on site class and amount of timber removed.

Alternative Prescriptions

A number of alternative prescriptions are commonly used by FGS in its silvicultural management. All alternative prescriptions are analyzed and approved during the THP review process. In most cases where alternative prescriptions are employed, past management and timber harvest have created an irregular condition in stand structure and/or stocking. Standard silvicultural prescriptions as specified in the rules are difficult to apply in these irregular stands. FGS's management scheme is to maintain stand health and generate a periodic and economical harvest in these stands through the use of alternative prescriptions over the first one to four years, gradually building up inventory to a point when standard silvicultural prescriptions can be applied. These alternative prescriptions include, but are not limited to:

- Seedtree/shelterwood removal (uneven-aged)
- Modified selection
- Combination shelterwood removal/biomass thin

- Modified commercial thin
- Combination shelterwood removal/commercial thin

Alternative prescriptions are likely to degrade, downgrade, or remove northern spotted owl habitat within stands being treated. Without a definitive THP, it is difficult to determine actual effects, but effects would be a composite of the silvicultural treatments discussed previously.

Salvage Logging

Dead, dying, and downed trees are periodically salvaged. Salvage is primarily related to road maintenance, fire damage, insect damage, or storm damage. Generally the economics and logistics involved in the potential harvest determine the feasibility of salvage operations. Salvage operations are feasible when damaged or weakened trees occur adjacent to ongoing logging operations, or are in heavy enough concentrations over a large enough area to justify sending in a salvage logger. It is typically not feasible to harvest individual occurrences of one or two trees, or trees that have been dead for more than two years. Salvage operations typically occur in isolated locations throughout the Plan Area, and consist of harvesting dead and dying conifers as individuals or in small groups.

Patches of dead, dying and downed trees typically provide high quality foraging habitat for northern spotted owls, especially when these patches are interspersed within larger areas of suitable nesting/roosting and foraging habitat. The abundance of standing snags and downed logs provide quality habitat for northern spotted owl prey species and northern spotted owls typically have high foraging success within and adjacent to these patches. In vast expanses of tree mortality, northern spotted owls may avoid foraging in the center of these areas if canopy closure is absent and the potential for predation is high. Additionally, standing dead and dying trees provide nest sites for northern spotted owls. In summary, the removal of dead, dying and downed trees may remove northern spotted nest sites or potential nest sites, foraging habitat, and prey habitat and subsequently have adverse effects to northern spotted owls.

Road Construction and Maintenance

Implementation of the HCP is expected to result in less than one mile of new road construction per year and will mainly serve as temporary spurs to access isolated patches of timber. Construction of new roads in connection with timber management, including clearing vegetation from road rights-of-way, removing trees, grubbing (removing stumps and surface organics), grading, and compaction will remove suitable northern spotted owl habitat if present. In addition, new road construction will remove habitat for northern spotted owl prey species.

Maintenance of existing roads typically will not affect northern spotted owl habitat unless snags or hazard trees that provide nesting opportunities for the owl are removed for safety concerns. Removal of snags, hazard trees, or removal of brush along existing roads will likely have some negative impact on northern spotted owl prey species, which in turn may indirectly affect northern spotted owl foraging success.

Closure of roads, temporary (abandoned) or permanently (decommissioned), will have a net positive effect on northern spotted owl as noise disturbance from vehicle traffic will be eliminated and vegetation will be allowed to reestablish and grow. Decommission of seasonal roads under the HCP is estimated to be approximately one mile per year. Over half of FGS's permanent roads (not coop) are subject to seasonal closure and many are opened only during operations (approximately 500 miles are gated, 250 miles of which are gated year-round).

Stand Regeneration and Improvement

Timber stand regeneration and improvement includes activities necessary to establish, grow, and achieve the desired species composition, spacing, and rate of growth of forest stands on the ownership. Activities may include site preparation, prescribed burning, slash treatment, tree planting, vegetation management, and silvicultural thinning (includes biomass, pre-commercial thinning, and commercial thinning). Silvicultural thinning was described previously and will not be discussed here. Site preparation, prescribed burning, slash treatment, tree planting, and vegetation management will have no effect on existing suitable northern spotted owl habitat. However, these activities are likely to negatively affect northern spotted owl prey species, which in turn may indirectly affect northern spotted owl foraging success along the edges of the stand. A LOP for noise and smoke disturbance will be implemented around known northern spotted owl nest sites to reduce disturbance during the critical nesting period.

Minor Forest Product Harvest

Minor forest products include, but are not limited to, Christmas trees and bows, mistletoe, firewood, fence posts, poles, yew bark, stumps, root wads, and mushrooms. These are all very minor components of FGS's Covered Activities and are not considered a major contribution to habitat loss for the northern spotted owl; however, firewood cutting has the potential to reduce prey habitat by removing snags or downed wood on a local scale.

Fire Prevention and Suppression

Wildfire prevention involves vegetation management and the construction of fuel breaks strategically located throughout the Plan Area. These activities are designed and implemented by the area forester on a local basis, and are therefore generally limited in scale. The prescription typically includes thinning for shaded fuel breaks along property lines or between watersheds where FGS deems it beneficial.

Fuel break construction typically involves the retention of overstory trees and the removal of understory trees and shrubs, snags, and downed woody material. As a result, overstory canopy typically remains the same or may be slightly reduced; vertical structure, shrubs, and downed wood are reduced; and snags are eliminated. Typically this type of vegetation management will degrade or downgrade suitable northern spotted owl habitat and reduce the amount of suitable habitat available to prey species. In areas of non-suitable northern spotted owl habitat, habitat manipulation that reduces brush and downed woody material may have a negative effect on the local prey population, thereby reducing northern spotted owl foraging success along edges of suitable habitat.

Wildfire suppression is typically under the authority of local, State, or Federal agencies. In cases of escaped prescribed burns where local, State, or Federal agencies are not involved, or for initial responses until responsible agencies have arrived, FGS employs emergency fire suppression activities, such as construction of fuel breaks by hand or bulldozer, lighting backfires, applying aerial fire suppressants, falling trees or snags, and water drafting for fire suppression.

Construction of fuel breaks or the falling of trees or snags during emergency fire suppression can have substantial effects to suitable northern spotted owl habitat. Hand lines are created by crews using hand tools. The focus of hand crews is to create a line at the ground level. The vegetation is either scraped or cut away with hand tools, such as shovels and chainsaws, to create a bare ground strip to prevent ground fire from spreading. Ladder fuels that are close to the line may be cut away to prevent the fire from jumping into the higher canopy. Dozer lines vary in width and can be anywhere from eight to 20 feet. Dozer lines require the total removal of all vegetation including the overstory. Lighting backfires can have a substantial effect on existing northern spotted owl habitat by burning up habitat components (e.g., understory trees, snags, downed wood) and killing larger trees.

Activities that remove large trees, snags, shrubs, and downed wood, such as fireline construction, felling of snags and trees, and lighting backfires, can affect habitat by directly removing or damaging nesting and/or roosting and perching trees, and affect prey composition and/or availability by altering characteristics of the habitat upon which prey species depend. The effects of removing standing dead and down material on northern spotted owl prey species is described above. It may also be possible for prey species to be adversely affected by incidental loss of hardwoods, hazard trees, or snags during burning, felling, or fireline construction.

Applying aerial fire suppressants is unlikely to affect suitable northern spotted owl habitat, but could potentially kill a northern spotted owl if directly hit by the suppressant. This is discussed in the direct mortality section above.

Other Activities

Other activities that may occur on FGS lands include those activities that are consistent with the zoning of FGS's lands as a Timber Production Zone. These activities may include watershed management, fish and wildlife habitat improvement, use of roads, landings, and log decks. These activities are not anticipated to affect suitable northern spotted owl habitat.

Rock quarrying activities would be covered under the HCP. Fruit Growers Supply Company quarries rocks from a number of locations on its ownership for the purpose of obtaining material for road surfacing. FGS has four primary rock quarries on the ownership that are each less than two acres in size. These existing rock quarries will not affect suitable northern spotted owl habitat and will be subject to a LOP to minimize noise disturbance during the breeding season if within 0.25-mile of an active nest site. Typically, up to five or more local rock sources commonly referred to as "borrow pits," are developed as needed for road upgrades associated with THPs. Each local rock source is rarely larger than 0.5 acres in size and is most often located in the upper portions of watersheds away from Class 1 streams. There is the possibility that these borrow pits may remove northern spotted owl habitat; however, it is anticipated that borrow pits will be located in areas with minimal vegetation.

Landscape Level Effects

Any individual or suite of site-specific effects discussed above could change the habitat function that a forested stand provides for owls. For the purpose of the following discussion, the degree of change to habitat function has been categorized using the following terms: removal, downgrade, and degrade. The term *removal* represents a complete loss of habitat function following an effect (i.e., an area that functioned as nesting/roosting, foraging, or dispersal habitat for northern spotted owls before the effect, no longer provides any habitat function for northern spotted owls after the effect). *Downgrade*, a subset of the term *removal*, refers to a reduction in the function of habitat (i.e., an area that functions as nesting/roosting habitat before an effect, provides only foraging or dispersal habitat following the effect). This term could be used also to signify a change in function from foraging to dispersal as well. *Degrade*, to be distinguished from *downgrade*, indicates a reduction in habitat quality, but not habitat function following the effect (i.e., an area that functioned as foraging habitat prior to the effect, still provides such function after the effect, but perhaps is more limited due to a temporary reduction in prey base).

Landscape-level changes in habitat availability, distribution, and configuration have implications to individual northern spotted owl survival and productivity, as well as to northern spotted owl population dynamics. For example, removal or downgrading of habitat within home ranges, and especially close to the nest site, can be expected to have negative effects on northern spotted owls. Bart (1995) reported a linear reduction in northern spotted owl productivity and survivorship as the amount of suitable habitat within a northern spotted owl home range declined. In addition, many researchers have stressed the importance of habitat availability within a 0.5-mile radius core area around the nest site (Hunter et al. 1995, Bingham and Noon 1997, Meyer et al. 1998, Wagner and Anthony 1999, Franklin et al. 2000, Zabel et al. 2003). In northwestern California, Franklin et al. (2000) found that survivorship of adult owls was higher where greater amounts of older forest were present around the activity center, but also found increased reproductive success where the amount of edge between older and younger forest was relatively high. Based on analysis of radio-telemetry data, Bingham and Noon (1997) reported that a sample of northern spotted owls in northern California focused their activities in heavily-used core areas that ranged in size from about 167 to 454 ac, with a mean of about 409 ac. These core areas, which included 60 to 70 percent of the owl telemetry locations during the breeding season, typically comprised only 20 percent of the area of the wider home range, and survivability of the owls was affected by the amount of habitat available within these core areas. Meyer et al. (1998) evaluated habitat available within a 2-mile circle around the nest site and found habitat within the 0.5-mile radius, or core, was profoundly different from that in the remainder of the home range, suggesting that owls are most strongly affected by landscape characteristics within the 0.5-mile core. These studies suggest that habitat removal within core areas could have disproportionate effects to owls.

Landscape-level, large scale timber harvest that produces relatively open stands (less than 40 percent canopy closure) or patch clear-cuts can fragment forest stands, creating more forest edge, and reducing the area of interior old forest habitat (Lehmkuhl et al. 1991). Habitat fragmentation has the potential to isolate individual owls or populations of owls by increasing distances between suitable habitat patches and reducing habitat connectivity. Such isolation decreases the likelihood of successful dispersal of juvenile owls (Miller 1989), which in turn could reduce opportunities for genetic exchange between owl populations (Barrowclough and Coats 1985).

Currently there is little empirical data confirming that habitat fragmentation contributes to increased levels of predation on northern spotted owls. However, great horned owls, an effective predator on northern spotted owls, are known to be closely associated with fragmented forest habitats (Johnson 1992). As mature forests are harvested, it is possible that great horned owls could colonize the fragmented forest and possibly increase northern spotted owl vulnerability to predation events.

Recent studies indicate that barred owls are capable of utilizing a broader range of habitat types than northern spotted owls (Hamer 1988, Kelly et al. 2003). Thus, activities that modify suitable northern spotted owl habitat could benefit barred owls. Barred owls may be negatively affecting northern spotted owls through competition for resources, direct harm through aggressive behavior, and hybridization, and may also directly attack northern spotted owls. However, it is unclear whether forest management has an effect on the outcome of interactions between barred owls and the northern spotted owl (Gutiérrez et al. 2004).

Many recent silvicultural projects focus on managing fire behavior and severity to avoid loss of timber stands to high severity fire; however, some silvicultural activities have been shown to negatively affect fire behavior and severity. Odion et al. (2004) tested for modern human effects on the fire regime and severity and found that multi-aged, closed forests burned with much lower severity than open forest and shrubby non-forest vegetation. In addition, tree plantations experienced twice as much severe fire as multi-aged forests (Odion et al. 2004). Odion et al. (2004) hypothesize that coupled with a warming climate, tree plantations that now occur on one-third of the roaded landscape within their study area in the Klamath-Siskiyou region of northern California and southwestern Oregon may increase the size and severity of future fires. On the Shasta-Trinity National Forest, evidence of increasing fire severity in plantations and adjacent stands was noted after the 2008 fires (USDI FWS 2009). Although the risk of high severity fire is expected to decrease due to the reduction in clearcutting and other even-aged management practices under the FGS HCP, tree plantations will be created and continue to pose a potential fire threat.

Landscape level changes in habitat availability, distribution, and configuration have implications to individual northern spotted owl survival and productivity as well as to northern spotted owl population dynamics. Northern spotted owls are known to disperse through many kinds of forested areas including over and around roads, clear-cuts, burned areas, and non-forested areas (Forsman et al. 2002). Dispersing juveniles have been observed using a wide variety of conifer forests ranging from harvested areas to open sapling stands to mature and old-growth stands (Miller et al. 1997). Implementation of the FGS HCP has the potential to improve the dispersal ability of northern spotted owls within the Action Area with the reduction in clearcutting, seed tree and shelterwood harvesting, and other even-aged management practices across FGS's ownership. However, dispersal patterns may be disrupted by the fragmented landscape that is typical of heavily managed forests.

Plantation establishment, as a result of clearcutting, seed tree harvest, and shelterwood harvest within the Plan Area has the potential to affect northern spotted owls by changing and/or increasing fire severity within the area and surrounding areas, potentially leading to further habitat loss and disturbance in the Action Area and on adjacent Federal, private and State lands. Tree plantations have been found to experience twice as much severe fire as multi-aged forests, and multi-aged closed forests burn with much lower severity than open forest and shrubby non-forest vegetation (Odion et al. 2004). When viewing areas within the Shasta-Trinity National Forest after the 2008 fires, it was evident in the areas visited that even-aged stands and stands adjacent to plantations also experienced higher fire severity than those that were not (USDI FWS 2009). Creation of new plantations within the fire-prone California Klamath Province is not recommended (SEI 2008). The creation of new plantations within the Plan Area could potentially change and/or increase fire severity within adjacent Federal lands, leading to habitat loss and disturbance in these areas that we assume are contributing to the conservation of the northern spotted owl. However, based on FGS's MSP analysis and as stated on page 2-18 of the Final EIS, the HCP is expected to result in an increase in what the Service considers foraging habitat (i.e., CWHR habitat categories 4M and 4D) over time and a decrease in clearcutting and other even-aged management practices. Additionally, thinning and maintenance of existing plantations within the Plan Area would help balance the effects on fire severity. The fire tolerance of existing plantations can be increased by actively manipulating species composition, reducing density, promoting spatial heterogeneity in forest structure (avoiding large areas of homogeneously fire-prone plantations), treating surface fuels, and favoring the development of large, fire tolerant trees (SEI 2008).

4.1.3 Description of Effects to Northern Spotted Owls in the Action Area

4.1.3.1 Northern Spotted Owl Activity Centers in the Action Area

The population within the Action Area includes all northern spotted owls that could be directly or indirectly affected by FGS's operations. It encompasses the known northern spotted owl activity centers within 1.3 miles of FGS ownership, which is the average radius of northern spotted owl home ranges within the California Klamath and California Cascades Provinces (USDI FWS 1992b). Eighty-two historic activity centers supporting a total of up to 158 individual northern spotted owls were estimated to occur within the Action Area during development of the HCP. As described in section 3.2.2, northern spotted owls have been detected at these historic activity centers at some point since the owl was listed; however, in most cases the current status is unknown and many home ranges contain high amounts of low quality habitat due to repeated timber harvest entries and wildfire. Based on the distribution of the current population and habitat available, there is a very low probability of additional undetected activity centers within the Action Area.

The northern spotted owl population in the Action Area is divided by two ecological provinces: the California Klamath Province and the California Cascades Province. The effects analysis is conducted separately for these two provinces within the Action Area because they are distinct in terms of population demographics and trends, threats, and quantity and quality of northern spotted owl habitat.

California Klamath Province

Seventy-four of the 82 total activity centers in the Action Area are located in the California Klamath Province (see section 3.2.2). During HCP development, the Service identified 31 of these 74 activity centers where incidental take of owls is not likely. Implementation of Covered Activities within the home ranges of 11 of these activity centers is not expected to result in incidental take of owls because FGS has limited ownership in the core and/or home range (i.e., less than ten percent) and therefore has little potential to reduce the amount and distribution of habitat to the point that take will occur. For example, out of these 11 activity centers, FGS has suitable northern spotted owl habitat within only one activity center core (SK379). The core has 0.02 acres of suitable northern spotted owl nesting/roosting habitat on FGS's lands. It is not anticipated that removal or downgrading of this habitat would impact the ability of the core to support occupancy by northern spotted owls because of the negligible amount of habitat and since the core would still be within the range of habitat conditions described in the Service Take Avoidance Guidance (USDI FWS 2008c). All other suitable habitat within this core is managed by the USFS.

At the home range scale, FGS has suitable northern spotted owl habitat in nine of the 11 outer ring home ranges. Eight of these are currently within the range of habitat conditions described in the Service guidelines to support occupancy by owls (USDI FWS 2008c). Given current restrictions on timber harvest on other ownerships, if FGS harvested all suitable habitat within these eight outer ring home ranges, the outer ring home ranges would still retain adequate amounts of habitat to support northern spotted owl occupancy. It is unlikely that FGS' removal of habitat within the outer home ranges of these activity centers will result in take of spotted owls. Fruit Growers Supply Company's activities are not likely to impact the ability of the other activity center (SK537) to support occupancy by northern spotted owls because the activity center has a low likelihood of occupancy due to an inadequate amount of suitable habitat in both the core and outer ring home range. This activity center may be deemed abandoned with the appropriate level of protocol surveys determined by the Service.

Incidental take of owls is not expected to occur at an additional 20 activity centers within the California Klamath portion of the Action Area because adequate habitat within their home ranges will be retained as CSAs on FGS's ownership throughout the 50-year permit term to support occupancy. Fruit Growers Supply Company will adhere to habitat commitments for each CSA identified in Appendix D of the FGS HCP in addition to maintaining or creating general habitat conditions and features identified in the demographic support objective of the Terrestrial Species Conservation Program in section 5.3.1.1 of the FGS HCP. While FGS may be allowed to harvest suitable habitat within CSAs not specifically identified as part of their habitat commitments, FGS must first meet its habitat commitments and, in general, the activity centers must exceed the FGS HCP habitat standards, regardless of ownership. Any Covered Activities occurring in CSAs must be approved by the Service. These conservation measures will provide demographic support to northern spotted owls associated with these 20 activity centers located within 1.3 miles of the FGS ownership and whose home ranges overlap with CHUs in the Klamath portion of the Action Area. None of the actual activity centers occur on FGS lands; 22 occur on the KNF and two occur on other private lands.

The habitat targets that must be maintained in the CSAs under the FGS HCP have a higher threshold than those used to determine take of other northern spotted owl activity centers on private lands (i.e., CFPRs or the 2008 Service Take Avoidance Guidance – Interior Region, USDI FWS 2008c). The habitat commitments in the core remain the same as the 2008 Service Take Avoidance Guidance; 250 acres of nesting/roosting and 150 acres of foraging must be maintained in the 502-acre core. Additionally, all existing substrate for northern spotted owl nest structures (tree deformities, mistletoe brooms, tree cavities) will be maintained within the 502-acre core area where it does not create a hazard for public safety. Within the outer ring home range (2,894 acres), the minimum habitat that must be maintained is 350 acres of nesting/roosting habitat and 900 acres of foraging habitat, which provides greater retention of habitat than the 2008 Service Take Avoidance Guidance (USDI FWS 2008c).

Out of the 20 mitigation activity centers in the Klamath portion of the Action Area, habitat in the core of six and in the outer ring home range of 15 are currently above the HCP habitat targets. Table 12 shows both the cumulative current acres of habitat and amount of habitat FGS has committed to grow and/or maintain on its ownership within the 20 mitigation activity center cores and outer ring home ranges over the 50-year permit term. The habitat commitments would provide a cumulative decrease of 59 acres of nesting/roosting habitat and an increase of 396 acres of foraging habitat in the core areas, and a cumulative decrease of 1,134 acres of nesting/roosting habitat and an increase of 351 acres of foraging habitat in the outer ring home ranges compared to current levels on FGS ownership over the permit term. The reduction in nesting/roosting habitat is due to 1) harvest in the core of mitigation sites that currently or will (with ingrowth of habitat) exceed the HCP habitat targets specified in section 5.3.1.1 of the FGS HCP, and 2) harvest of small patches that do not function as nesting/roosting habitat due to their size and/or distance to the core. The exceptions to these reasons are the harvest of habitat in the outer ring home range of SK040, SK262b, and SK503 because of current conditions of vegetation (i.e., low potential to grow additional high-quality habitat) and planned timber projects as negotiated with the Service.

Table 12. Cumulative Current and Target Non-Overlapping Acres of Northern Spotted Owl Habitat on Fruit Growers Supply Company Ownership within the 20 Mitigation Sites in the Klamath Province portion of the Action Area.

	Current Habitat		**Target Habitat**	
Habitat	**502-acre Core**	**2,894-acre Outer Ring**	**502-acre Core**	**2,894-acre Outer Ring**
Foraging	481	3,484	877	3,835
Nesting/Roosting	119	1,183	60	49
Total	**600**	**4,667**	**937**	**3,884**

Currently, there are only six mitigation activity centers where both the core and outer ring home range are above threshold when nesting/roosting habitat is used as a surrogate for foraging. However, none of the activity centers meet the threshold according to the conditions identified in section 5.3.1.1 of the FGS HCP. To the degree that mitigation sites are currently below the HCP habitat targets, sufficient ingrowth of habitat will need to occur before FGS can harvest suitable habitat.

Harvest by FGS within the home ranges of mitigation sites will maintain sufficient amounts and distribution of habitat to support occupancy and reproduction of owls, as determined by the Service. Any Covered Activities occurring in CSAs must be approved by the Service and are reliant upon FGS conducting protocol level surveys and implementing a LOP within 0.25-mile of active northern spotted owl nest sites where operations would not be authorized during the breeding season to avoid disturbance to nesting owls and their young. Any Covered Activities that occur within the home ranges of the 31 activity centers where incidental take of owls is not likely, or newly identified activity centers within the California Klamath Province, must undergo a review and approval process by the Service prior to any Covered Activities being implemented. Approval would be based on a rigorous evaluation of the quantity and quality of existing habitat, field reviews, and other criteria to insure that sufficient amounts and distribution of habitat to support occupancy and reproduction by owls is maintained.

The northern spotted owl conservation strategy in the FGS HCP is based on the conservative assumption that habitat at 43 historic activity centers that are not designated as mitigation or 'no take' sites would be harvested to the extent that take of up to 83 individual owls would occur as a result of FGS implementing Covered Activities under the HCP. Generally, take would occur indirectly from the loss or degradation of habitat within northern spotted owl cores and home ranges.

As described in section 3.2.2, this estimate of the potential for incidental take represents a worst-case scenario because it assumes that each of the activity centers supports northern spotted owls at their highest historical reproductive status and that modification of habitat would lead to the incidental take of all individual northern spotted owls occupying those activity centers. However, not all activity centers may be currently occupied and some activity centers are not likely to be occupied at their highest historic reproductive status.

This conservative approach is appropriate for landscape-level analysis and development of the conservation strategy in the HCP. However, in determining the amount and impact of take under section 7 of the Act, the Service must use the best scientific information available to evaluate as closely as possible the likelihood of significant impairment of feeding, breeding and sheltering behavior (take) of spotted owls. Determination of the likelihood of take is based primarily on 1) the rate, intensity, and extent of habitat modification potentially influencing the species and 2) the probability of individuals being present where habitat-modifying activities occur. In particular, because the 43 'take' sites were established based on a wide range of historical survey records, the Service conducted an evaluation of the probability of occupancy at the 43 sites where harvest would likely occur. Because updated surveys have not been conducted at the 43 sites where take could potentially occur, the Service determined the likelihood of take based on the combination of: 1) existing survey records, 2) results of habitat modeling (Zabel et al. 2003), and 3) evaluation of the amount and distribution of suitable habitat.

1) Evaluation of survey results

The amount, quality, and vintage of survey records at some of the 43 historic activity centers were not adequate to support classification of all of the sites into 'occupied' and 'not occupied' status. Because some surveys did not fully conform with the recommended Service survey protocols for the spotted owl, negative results (i.e., survey was conducted and owls were not detected) did not always result in a determination of 'unoccupied'. However, since development of the HCP, additional survey information is available because FGS has continued to survey historic activity centers associated with THPs. In cases where spotted owls were recently detected (2007-2011) or there were no detections during the past five years of protocol surveys, this information was used to determine occupancy status for the purposes of the BO. Using this information, the Service classified eight activity centers as currently occupied and 12 activity centers as likely not occupied (Table 13). The remaining activity centers have varying potential for occupancy.

Table 13. Likelihood of Occupancy for the 43 'Take' Activity Centers in the California Klamath Province portion of the Action Area.

Code	Category	Criteria	Activity Center	# Sites
1	Currently occupied	Spotted owl(s) detected during 2007-2011 surveys	SK205, SK262, SK322, SK370, SK380, SK450, SK467, SK500	8
2	Likely occupied	Spotted owl(s) detected prior to 2007, recent surveys lacking	SK020, SK046, SK065, SK130, SK310, SK359, SK454, SK469, SK472, SK477	10
3	Potentially occupied	Spotted owl(s) not detected 2007-2011, survey effort not to protocol but substantial	SK239, SK309, SK334, SK336, SK360, SK363, SK364, SK369, SK387, SK388, SK389, SK474, SK533	13
4	Likely not occupied	Spotted owl(s) not detected during >3 years protocol surveys	SK318, SK321, SK333, SK335, SK358, SK361, SK365, SK368, SK391, SK473, SK475, SK534	12

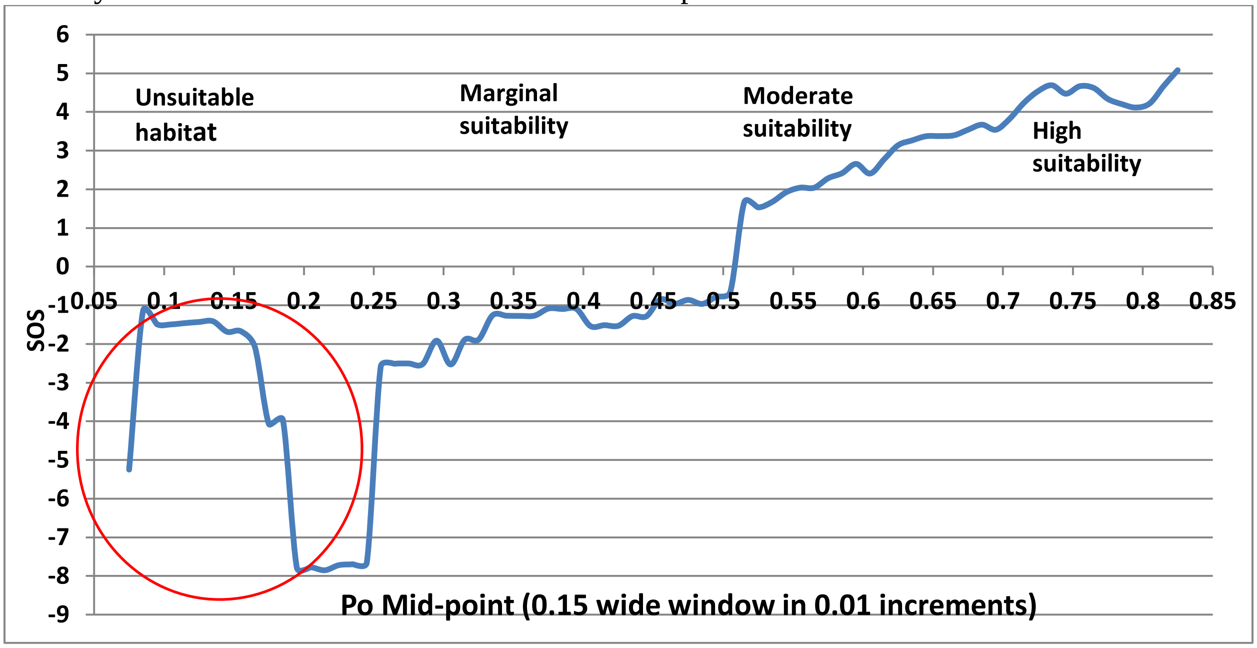
2) Relative habitat suitability modeling

Species distributional models are used to evaluate species-habitat relationships, evaluate an area's suitability for the species, and to predict a species' presence (Elith and Leathwick 2009). These models, also called environmental (or ecological) niche models, correlate environmental conditions with species distribution and thereby predict the relative suitability of habitat within some geographic area (Warren and Seifert 2011). In this context, we defined relative habitat suitability (RHS) as the relative similarity of environmental conditions (forest composition and structure) at spotted owl sites to the distribution of those conditions across the landscape. When translated into maps depicting the spatial distribution of predicted habitat suitability, these models have great utility for evaluating conservation reserve design and function (Zabel et al. 2003, Carroll and Johnson 2008, Carroll et al. 2010).

The spotted owl distribution model described by Zabel et al. (2003) was used in the development of the FGS HCP, and provided the Service with a useful method to evaluate the habitat quality at historic activity centers in the project's Action Area. As described in the Environmental Baseline section, the Zabel model predicts probability of occupancy based on habitat conditions within a 500-acre (0.5-mile radius) circular window. This spatial scale corresponds to 'core areas' that receive disproportionate use by nesting and foraging spotted owls in the Klamath region (Bingham and Noon 1997) and where differences between use and availability of habitat tend to be most pronounced (USDI FWS 2011b, Appendix C). This approach is appropriate for mapping broad-scale patterns of habitat suitability, but because spotted owls depend on a larger 'home range' area for resources, may not provide a reliable method for evaluating the quality of individual territories (Buchanan et al. 1998). To account for this, we analyzed the Zabel model results using a 'focal mean' method that incorporates a larger area (1-mile radius, or approximately 2,011 acres) into estimation of RHS at an activity center, while still emphasizing conditions within the core area. This larger area corresponds to the mean home range size (95% Fixed Kernel method) of spotted owls in the Klamath region (Irwin et al. 2007, Timber Products Company 2007).

The Service used a 'Strength of Selection' (SOS) approach to compare the distribution of RHS values at spotted owl territories to the overall landscape, and establish cutoff points for categories of habitat suitability (unsuitable, marginal suitability, moderate suitability, and high suitability). The observed use that areas with various RHS values receive (by nesting spotted owls in our case) were plotted relative to the abundance of such areas within the FGS HCP Action Area. For example, areas with a mid-point RHS less than 0.25 were used eight times less than expected based on their availability within the Action Area. Similarly, areas with RHS values greater than 0.75 were used about 4.5 times more than expected. Figure 6 shows the degree of selection by spotted owls for RHS values ranging from 0 to 100, and the four RHS categories used to inform our estimation of the likelihood of take. The portion of the curve circled in red exhibits an anomaly caused by the large proportion of the FGS Action Area occurring in the lowest RHS values and a very small sample of spotted owl records in low RHS value areas.

Figure 6. 'Strength of Selection' (SOS) and Relative Habitat Suitability for the 43 'Take' Activity Centers in the California Klamath Province portion of the Action Area.



To quantify habitat conditions and the subsequent likelihood of occupancy at each of the 43 historic spotted owl sites, we evaluated the distribution of RHS values in three categories (Table 14).

Table 14. Likelihood of Occupancy based on Relative Habitat Suitability (RHS) Values for the 43 'Take' Activity Centers in the California Klamath Province portion of the Action Area.

Code	Likelihood of Occupancy	Criteria	Activity Center	# Sites
1	High	Core and home range contain high proportions of moderate to high suitability habitat (RHS > 60%)	SK020, SK046, SK130, SK205, SK239, SK262, SK322, SK335, SK360, SK361, SK364, SK380, SK389, SK391, SK450, SK469, SK472	17
2	Moderate	Core and home range contain intermediate proportions of moderate to high suitability habitat (RHS = 51% to 60%)	SK065, SK310, SK318, SK336, SK359, SK363, SK365, SK368, SK370, SK387, SK477, SK500, SK534	13
3	Low	Core and home range contain high proportions of marginal and unsuitable habitat (RHS < 51%)	SK309, SK321, SK333, SK334, SK358, SK369, SK388, SK454, SK467, SK473, SK474, SK475, SK533	13

Evaluation of RHS at spotted owl core areas and home ranges provided a useful method for describing the likelihood of occupancy by spotted owls at the 43 historic sites. However, in a number of cases the model outputs were unreliable due to changes in habitat condition (e.g., fires, timber harvest) that occurred after the model's underlying vegetation layer was developed or other inconsistencies in the habitat typing used in the modeling. To ensure that our determinations were based on the best site-specific information available, we verified the model results at each site by assessing the amount and distribution of habitat by comparing with 2009 digital orthophoto quadrangles (DOQs; see below).

3) Amount and distribution of suitable habitat

To provide a more site-specific evaluation of the likelihood of take, we augmented the habitat modeling results with a visual assessment of the amount and distribution of spotted owl habitat within the core areas and home ranges of the 43 historic activity centers. We used DOQs and maps generated from the 2005 northern spotted owl baseline habitat layer to estimate 1) the overall amount of nesting/roosting and foraging habitat and 2) the proportion of suitable habitat occurring on lands managed by FGS (and therefore likely to be harvested under the HCP) versus habitat on adjacent USFS land.

Table 8 (section 3.2.2) shows amount and distribution of suitable spotted owl habitat by ownership at each activity center within the Klamath Province portion of the Action Area. Compared to the Service Take Avoidance Guidance thresholds of 400 acres of suitable habitat (250 acres nesting/roosting and 150 acres foraging habitat) in the 502-acre core and 935 acres suitable habitat in the 2,894-acre outer ring of the home range (USDI FWS 2008c), out of the 43 'take' activity center cores, three are currently above the habitat thresholds and the remaining 40 activity centers are currently below. Of the 40 activity centers that are below, three are above threshold in total amount of suitable habitat, but are deficit in the amount of nesting/roosting habitat. Out of the 43 'take' activity center outer ring home ranges, 28 are currently above threshold and the remaining 15 activity centers are currently below threshold. Only three activity centers (SK239, SK380, and SK469) currently have both the core and home range above threshold. Table 15 shows the results of the Service's evaluation of the likelihood of occupancy at the 43 'take' activity centers based on amounts of nesting/roosting and foraging habitat within the core and home range.

Table 15. Likelihood of Occupancy based on Amounts of Nesting/Roosting and Foraging Habitat within the Core and Home Range of the 43 'Take' Activity Centers in the California Klamath Province portion of the Action Area.

Code	Likelihood of Occupancy	Criteria	Activity Center	# Sites
1	High	Core and home range contain adequate amounts of nesting/roosting and foraging habitat	SK239, SK380, SK469	3
2	Moderate	Core or home range is deficient in nesting/roosting or foraging habitat	SK046, SK065, SK130, SK205, SK262, SK321, SK322, SK333, SK334, SK335, SK336, SK358, SK359, SK360, SK361, SK364, SK365, SK368, SK370, SK388, SK391, SK450, SK472, SK477, SK500	25
3	Low	Core and home range contain insufficient amounts of nesting/roosting and foraging habitat	SK020, SK309, SK310, SK318, SK363, SK369, SK387, SK389, SK454, SK467, SK473, SK474, SK475, SK533, SK534	15

This evaluation focuses on quantification of the amounts of nesting/roosting habitat and foraging habitat at both the core area and home range scales, but also the distribution, patch size and other features that influence the suitability of an area for spotted owls. Because forest habitats in the vicinity of many of the historic spotted owl sites have been modified by wildfires and repeated harvest entries, current vegetation databases and habitat classification maps required verification by visual examination of DOQs. In a number of cases, the quantity and quality of habitat observed on DOQs differed substantially from amounts described in step 2 above. In these cases the likelihood of occupancy was revised to reflect current conditions.

4) Evaluation of extent of impacts to spotted owl territories

The Service evaluated the potential for FGS's Covered Activities to result in take based on the proportion of existing suitable habitat located on FGS's ownership within the core and home range of the 43 'take' activity centers. The Service used the habitat amounts in the core and outer ring of the home range from Table 7 (section 3.2.2) to calculate the proportion of suitable habitat on FGS's ownership. Table 16 shows the potential impact of FGS's activities on the currently suitable habitat for each 'take' site. Fruit Grower's activities have a low likelihood of taking spotted owls, if present, at 15 sites where FGS has a "low" potential for impact. However, in a number of cases the results are unreliable due to changes in habitat condition (e.g., fires, timber harvest) that occurred after the vegetation layer was developed or other inconsistencies in the habitat typing. As described in step 3 (above) in these cases the observed quantity and quality of habitat as observed on aerial photographs was used to revise the estimation of likelihood of take.

Table 16. Potential Impact on Suitable Habitat based on Proportion of FGS's Ownership in the Core and Outer Ring of the Home Range of the 43 'Take' Activity Centers in the California Klamath Province portion of the Action Area.

Code	Potential Impact	Criteria	Activity Center	# Sites
1	Low	FGS owns < 20% suitable habitat in core and/or home range	SK020, SK310, SK318, SK359, SK365, SK387, SK388, SK389, SK391, SK454, SK469, SK474, SK477, SK500, SK533	15
2	Moderate	FGS owns 20% to 40% suitable habitat in core and/or home range	SK065, SK130, SK205, SK239, SK309, SK321, SK334, SK335, SK368, SK472, SK473, SK534	12
3	High	FGS owns > 40% suitable habitat in core and/or home range	SK046, SK262, SK322, SK333, SK336, SK358, SK360, SK361, SK363, SK364, SK369, SK370, SK380, SK450, SK467, SK475	16

Summary

In total, of the 74 activity centers within the Klamath portion of the Action Area, incidental take of owls is not likely to occur at 43 activity centers (Figure 7). Eleven activity centers are not likely to be occupied by spotted owls based on more recent protocol survey results and a rigorous evaluation of the amount and distribution of suitable habitat using 2009 digital orthophoto quadrangles (DOQs), habitat maps generated from the 2005 northern spotted owl baseline habitat layer (see 2009 FGS HCP, Appendix A), and a Relative Habitat Suitability (RHS) model (Zabel et al. 2003). Spotted owls have not been detected at these 11 activity centers during protocol surveys within the last five years, and/or the core and/or home ranges contain high proportions of marginal and unsuitable habitat (RHS < 51 percent) and amounts of nesting/roosting and foraging habitat the Service considers insufficient to support occupancy and reproduction (USDI FWS 2008c). Incidental take of owls is also not likely to occur at the 20 mitigation sites, at the 11 activity centers that have low overlap with FGS ownership, and the one activity center (SK310) where only three percent of the suitable habitat in its home range is on FGS's ownership.

Based on the evaluation of survey records, habitat suitability models, habitat mapping, and evaluation of potential impacts of FGS activities, the Service identified 31 activity centers where incidental take of owls resulting from FGS's operations could reasonably occur over the course of the 50-year permit term (Table 17). Suitable habitat with the home ranges of these 31 activity centers is scheduled to be harvested to the extent that incidental take of up to 61 individual owls could reasonably occur as a result of FGS implementing Covered Activities under the HCP. Generally, take would occur indirectly from the loss or degradation of habitat within northern spotted owl cores and home ranges. Eleven of these 31 activity centers occur on FGS lands, 17 occur on KNF, and three occur on other private lands.

Table 17. Likelihood of Actual Take based on the Service's Evaluation for the 43 'Take' Activity Centers in the California Klamath Province Portion of the Action Area.

Code	Likelihood of Take	Criteria	Activity Center	# Sites
1	High	Detections within past 5 years, high Relative Habitat Suitability, high amounts of suitable habitat, and/or high potential impact of FGS's activities on existing suitable habitat.	SK130, SK239, SK262, SK322, SK370, SK380, SK450, SK467, SK469, SK500	10
2	Moderate/Low	Spotted owls(s) detected prior to 2007 and recent surveys lacking or inconclusive, moderate Relative Habitat Suitability, moderate amounts of suitable habitat, and/or moderate potential impact of FGS's activities on existing suitable habitat.	SK020, SK046, SK065, SK205, SK334, SK336, SK359, SK360, SK363, SK364, SK369, SK388, SK389, SK454, SK472, SK474, SK477	17
3	Very Low	Spotted owl(s) not detected during >3 years protocol surveys, low Relative Habitat Suitability, low amounts of suitable habitat, and/or low potential impact of FGS's activities on existing suitable habitat.	SK321, SK333, SK475, SK534	4
4	None	Spotted owl(s) not detected during >5 years protocol surveys, very low Relative Habitat Suitability, very low amounts of suitable habitat, and/or very low potential impact of FGS's activities on existing suitable habitat.	SK309, SK310, SK318, SK335, SK358, SK361, SK365, SK368, SK387, SK391, SK473, SK533	12

California Cascades Province

Eight of the activity centers in the Action Area are located in the California Cascades Province (see section 3.2.3). Incidental take of owls at these eight activity centers is not likely (Figure 8). Implementation of Covered Activities within the home ranges of four of these activity centers is not expected to result in incidental take of owls because FGS has limited ownership in the core and/or home range (i.e., less than ten percent) and therefore has little potential to reduce the amount and distribution of habitat to the point that take will occur. For example, FGS owns land that does not have any suitable northern spotted owl habitat available within either the core or outer ring home range of SK194 and SK442; therefore, incidental take due to FGS's activities will not occur. None of the four actual activity centers occur on FGS lands; three occur on the KNF and one occurs on other private lands.

Incidental take of owls will not occur at an additional four activity centers (SK153, SK284, SK428, SK462) within the California Cascades portion of the Action Area because habitat within their home ranges will be retained as CSAs on FGS's ownership throughout the 50-year permit term. Fruit Growers Supply Company will adhere to habitat commitments for each CSA identified in Appendix D of the FGS HCP in addition to maintaining or creating general habitat conditions and features identified in the demographic support objective of the Terrestrial Species Conservation Program in section 5.3.1.1 of the FGS HCP. While FGS will be allowed to harvest suitable habitat within CSAs not specifically identified as part of their habitat commitments, FGS must first meet its habitat commitments and, in general, the mitigation activity centers must exceed the FGS HCP habitat targets, regardless of ownership. As described below, any Covered Activities occurring in CSAs must be approved by the Service. These conservation measures will provide demographic support to northern spotted owls associated with these four activity centers located within 1.3 miles of the FGS ownership and whose home ranges overlap with CHUs in the Cascades portion of the Action Area. None of the actual activity centers occur on FGS lands; all occur on the KNF.

All four mitigation activity center cores and outer ring home ranges in the Cascades portion of the Action Area are currently below the HCP habitat targets. Table 18 shows both the cumulative current acres of habitat and amount of habitat FGS has committed to grow and/or maintain on its ownership within the four mitigation activity center cores and outer ring home ranges over the 50-year permit term. The habitat commitments would maintain the same amount of nesting/roosting habitat and provide a cumulative increase of 226 acres of foraging habitat in the core areas, and a cumulative decrease of 12 acres of nesting/roosting habitat and an increase of 883 acres of foraging habitat in the outer ring home ranges compared to current levels on FGS ownership over the permit term. The reduction in nesting/roosting habitat is due to 1) harvest in the outer ring home range of mitigation sites that currently or will (with ingrowth of habitat) exceed the HCP habitat targets specified in section 5.3.1.1 of the FGS HCP, and 2) harvest of small patches that do not function as nesting/roosting habitat due to their size and/or distance to the core. The exception to these reasons is the harvest of habitat in the outer ring home range of SK428 because of current conditions of vegetation (i.e., low potential to grow additional high-quality habitat) and planned timber projects as negotiated with the Service.

Table 18. Cumulative Current and Target Non-Overlapping Acres of Northern Spotted Owl Habitat on Fruit Growers Supply Company Ownership within the Four Mitigation Sites in the Cascades Province portion of the Action Area.

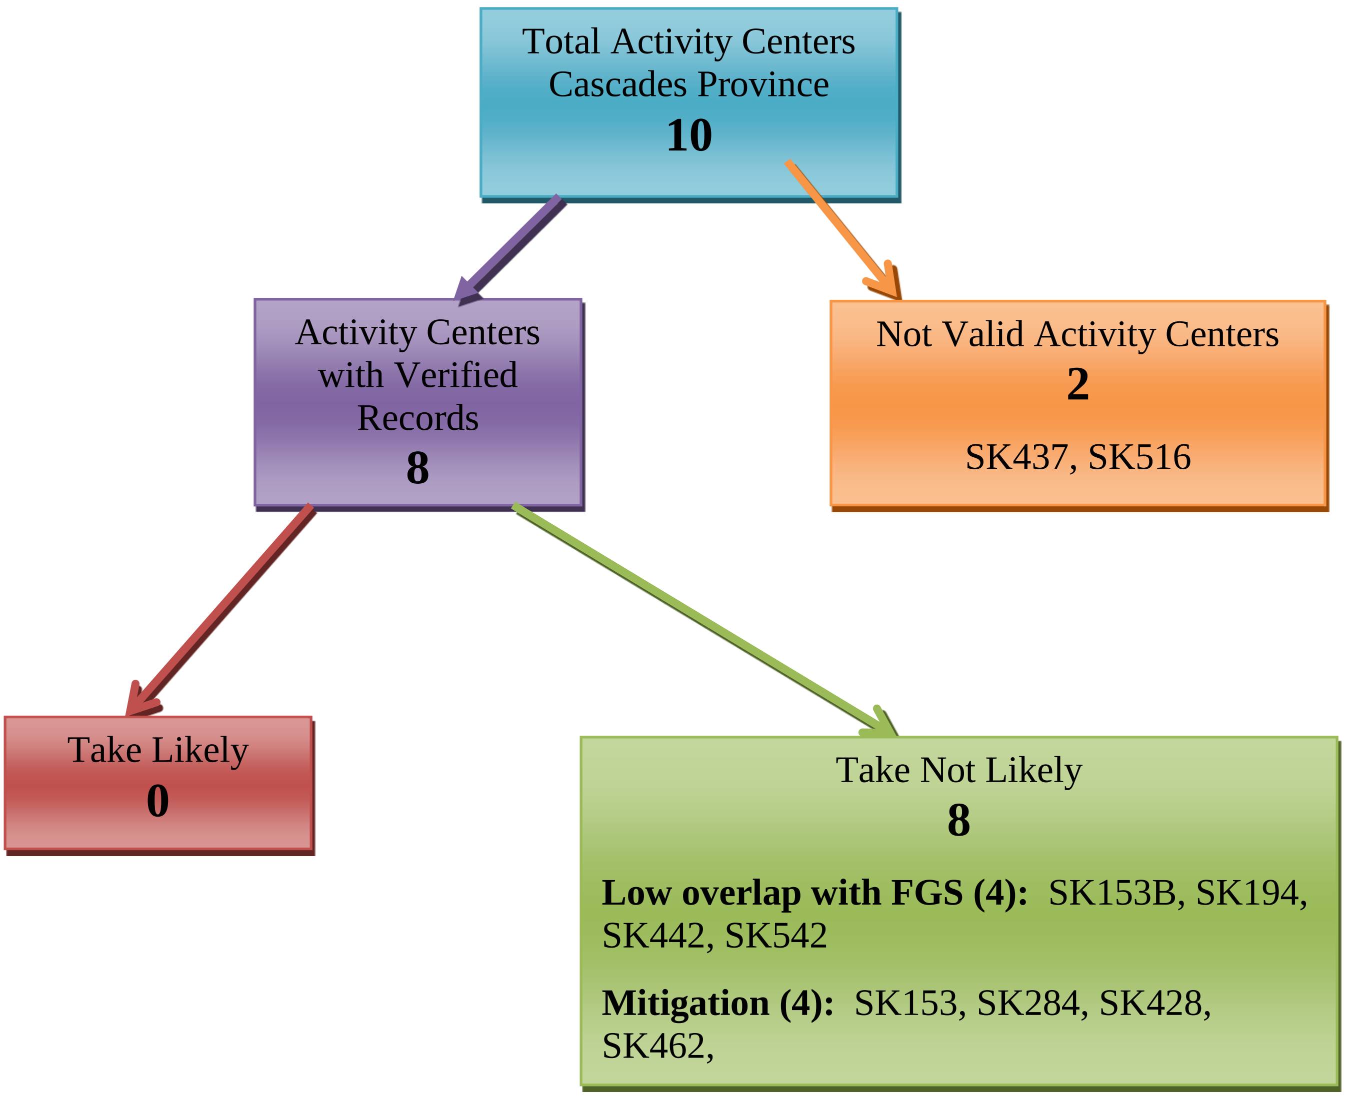
	Current Habitat		**Target Habitat**	
Habitat	**502-acre Core**	**2,894-acre Outer Ring**	**502-acre Core**	**2,894-acre Outer Ring**
Foraging	193	1,001	419	1,884
Nesting/Roosting	6	12	6	0
Total	**199**	**1,013**	**425**	**1,884**

Currently, none of the mitigation activity centers in the Cascades portion of the Action Area are above threshold in both the core and outer ring home range when nesting/roosting habitat is used as a surrogate for foraging. To the degree that mitigation sites are currently below the HCP habitat targets, sufficient ingrowth of habitat will need to occur before FGS can harvest suitable habitat.

Harvest by FGS within the home ranges of mitigation sites will maintain sufficient amounts and distribution of habitat to support occupancy and reproduction of owls, as determined by the Service. Any Covered Activities occurring in CSAs must be approved by the Service and are reliant upon FGS conducting protocol level surveys within 1.3 miles of the treatment units and implementing a LOP within 0.25-mile of active northern spotted owl nest sites where operations would not be authorized during the breeding season to avoid disturbance to nesting owls and their young. Any Covered Activities that occur within the home ranges of the eight activity centers where incidental take of owls is not likely, or newly identified activity centers within the California Cascades Province, must undergo a review and approval process by the Service prior to any Covered Activities being implemented. Approval would be based on a rigorous evaluation of the quantity and quality of existing habitat, field reviews, and other criteria to insure that sufficient amounts and distribution of habitat to support occupancy and reproduction by owls is maintained.

.

Figure 8. Northern Spotted Owl Activity Centers within the California Cascades Province portion of the Action Area.



4.1.3.2 Northern Spotted Owl Habitat in the Action Area

Based on the 2005 owl habitat layer, there are 92,762 acres of suitable foraging habitat, 49,394 acres of suitable nesting habitat, and 382,329 acres of unsuitable habitat within the entire 524,484-acre Action Area (Tables 6 and 9). Thirty-one percent of the total amount of suitable northern spotted owl habitat within the Action Area is likely to be affected by FGS's activities over the term of the ITP. Of the suitable habitat likely to be affected, it is anticipated that approximately 44 percent (19,340 acres) will be reduced to non-habitat on FGS's land at some point over the 50-year permit term. The remaining 51 percent on FGS's lands is not scheduled to be converted to plantation, and will continue to function as foraging or dispersal habitat. The quality of nesting/roosting and foraging habitat on FGS ownership has been degraded due to repeated timber harvest entries, and to a substantial degree does not support reliable occupancy or reproduction by spotted owls; higher-quality habitats are retained in CSAs. Spotted owl habitat on adjacent federally managed lands is much more likely to contain important habitat elements and support spotted owl occupancy.

An important aspect of the HCP is the ownership-wide increase in foraging and dispersal habitat that is predicted to occur due to changes in FGS's management practices. According to FGS's Maximum Sustainable Production (MSP) analysis and as stated on page 2-18 of the Final EIS, the HCP is expected to result in an increase in what the Service considers foraging habitat (i.e., CWHR habitat categories 4M and 4D) over time and a decrease in clearcutting and other even-aged management practices across the FGS ownership. Under the ITP, FGS would be allowed to harvest more of the currently suitable northern spotted owl habitat on its ownership within the home ranges of 'take' sites. Areas of suitable owl habitat generally have more and larger trees and provide more timber volume per acre than non-habitat areas. Fruit Growers Supply Company has indicated that this would reduce the amount of even-aged regeneration harvest necessary to meet financial targets. A reduction in clearcutting of moderate-complexity stands would allow these and other stands to grow into suitable northern spotted owl habitat over the duration of the permit. According to FGS's MSP analysis, it is anticipated that there would be about a 10 percent decrease in acres harvested each decade under the FGS HCP, including as much as a 25 percent decrease in even-age regeneration harvest compared to timber management under current regulations. As shown in Table 19, the amount of early- and mid-seral forest with high canopy coverage (CWHR classes 2M, 2D, 3M, and 3D) would decrease by up to 20 percent during the first three decades under the HCP compared to conditions under current regulations. The acreage of mid-to late-seral stands with low canopy coverage (CWHR classes 4S and 4P) would decrease over the 50-year permit term to levels less than 10 percent of the acreage in these stand types under current regulations as these stands are allowed to grow and increase in canopy coverage. Thus, the acreage in mid- to late-seral stands with high canopy coverage (CWHR classes 4M and 4D) would be nearly twice as high as under current regulations by the end of the permit term. The amount of late-seral forest in size class 5 would remain essentially the same as currently exists (near zero).

Table 19. Projected Acres in each CWHR Size/Canopy Cover Class Under the FGS HCP.

CWHR Class	**2007**	**Decade 1**	**2**	**3**	**4**	**5**

4.1.4 Relative Effects on Survival and Recovery of Northern Spotted Owl

Evaluation of the relative effects of the FGS HCP on the survival and recovery of the northern spotted owl is based on several factors, including:

- The estimated changes in number of spotted owls and their habitat that are likely to occur with implementation of the FGS HCP
- The current and future condition of the FGS landscape and its ability to support spotted owl survival and recovery
- The conservation and mitigation strategy employed in the HCP and its contribution to spotted owl recovery
- The adequacy of existing regulatory mechanisms to conserve spotted owls and habitat currently existing on FGS lands.

The importance of each of these factors, and the relative significance of effects, vary with the scale of analysis. For this consultation, the Service evaluated the relative effects at three spatial scales; the Action Area, Region (local population scale) and rangewide.

4.1.4.1 Effects to Northern Spotted Owls within Action Area

Effects to Northern Spotted Owl Population within Action Area

Fruit Growers Supply Company has requested incidental take of up to 83 owls within the Action Area. While the Service based its take evaluation (section 4.1.3.1) on potential impacts to owls at 43 activity centers within the Action Area, the analysis strongly indicates that 11 of these 43 historic activity centers (representing 20 owls) are no longer occupied because the home ranges of these 11 activity centers contain extremely low amounts of suitable habitat due to repeated timber harvest entries and wildfire, and several consecutive years of protocol surveys have not detected owls at most of these sites. Fruit Growers Supply Company is also not likely to incidentally take the two owls associated with one activity center (SK310) because the company owns only three percent of the remaining suitable habitat in the home range. Therefore, 61 owls are likely to be incidentally taken over the permit term during HCP implementation. The take authorization of the 22 additional owls, for a total of 83 owls under the proposed ITP, is based on uncertainty regarding the potential displacement and movement of owls in response to Covered Activities within the Action Area during the 50-year permit term. Based on analysis of owl activity centers and habitat suitability, the Service concludes that authorization of take of an additional 22 owls would, at most, likely have a minor impact to the species' survival and recovery because 11 of the activity centers used in the estimate of the baseline population are of low quality and are not likely to support owls now or perhaps in the future, and because FGS has very low potential to reduce the habitat quality in the home range of SK310. Habitat loss expected to occur within the home ranges of the 22 owls has already been identified and evaluated in the habitat sections of this BO.

Based on the take evaluation (section 4.1.3.1) and as described above, the Service anticipates that incidental take of up to 61 northern spotted owls resulting from FGS's Covered Activities within the Action Area could reasonably occur as a result of implementation of the FGS HCP over the 50-year permit term. This number corresponds to 44% of the individual owls the Service considers potentially occupying the Action Area. However, as described in section 3.2.2, actual take is not likely to be this high because historic activity centers may not be currently occupied or occupied by owl pairs.

The significance of the loss of 61 owls is strongly influenced by the current condition of forest habitats on FGS ownership; in particular the amount and quality of habitat within spotted owl home ranges and core areas. Spotted owl activity centers on and immediately adjacent to FGS ownership have received multiple timber harvest entries during the past 25 years, and most of these activity centers are considered deficit in nesting/roosting and foraging habitat. Repeated harvest entries have removed or reduced important habitat elements such as high canopy cover, snags and large, defective trees, resulting in degraded habitat conditions even in stands classified as nesting/roosting or foraging. These conditions, combined with the Service's review of survey records for many of the historic activity centers, were the bases for the Service's conclusion that occupancy rates at many of these sites are low and that over time the observed pattern of site abandonment will continue regardless of whether an HCP is implemented.

Given the above conditions, existing regulatory mechanisms will be unlikely to conserve activity centers that are strongly influenced by FGS ownership. Under the current CFPRs and Section 9 of the ESA, take is deemed unlikely if an activity center is determined to be abandoned; subsequently all habitat within the home range can be removed without compensatory mitigation. Because occupancy rates at many of the historic activity centers on FGS ownership are low, take of spotted owls as a result of habitat removal and degradation at these sites is expected to be low. This circumstance acts to further reduce both the extent and the effects of the potential take estimated under the HCP.

Estimation and description of the local or population-level effects of proposed take is based on the significance of the take to survival and recovery of the listed species as a whole. Northern spotted owl populations encompass large regions (physiographic provinces), and owls within the FGS Action Area constitute a very small portion of two, much larger, widespread populations in two physiographic provinces. For the northern spotted owl, the significance of impacts is most strongly influenced by losses of owl pairs occupying sites likely to support long-term occupancy and reproductive success; these sites contribute disproportionately to population stability and recovery. Low-quality sites supporting territorial singles or low rates of occupancy and reproduction by owl pairs contribute substantially less to the conservation of the species, but may provide habitat for dispersing spotted owls and occasional occupancy and even reproduction. Because some of the activity centers proposed to be lost or degraded currently support owl pairs and some reproduction, implementation of the FGS HCP is likely to result in a measurable reduction in the numbers and distribution of spotted owls within the Action Area; however, as discussed below in "Relative Effects to Northern Spotted Owl across its Range" (section 4.1.4.3), the effect of this loss on the survival and the recovery of spotted owls across the species range is minor and insignificant. Even when the impact of the anticipated take is considered within the Action Area, the significance of this impact is reduced substantially by the low occupancy and reproductive rates of many territories anticipated to be lost, and the low likelihood that these activity centers would persist through time via existing regulatory mechanisms. For this reason, the Service concludes that implementation of the FGS HCP is likely to have a measurable impact on occupancy, survival, and reproduction of individual spotted owls within the Action Area. However, as described in the following sections, this impact is insignificant at the scale of regional or provincial populations.

Relative Effects to Northern Spotted Owl Habitat within Action Area

<u>California Klamath Province</u>

Within the California Klamath Province portion of the Action Area there are 339,543 acres of land, of which FGS manages 104,493 acres (31 percent). In addition, 30 percent (103,608 acres) of the total Action Area in this province is managed by other private landowners. Thirty-nine percent (130,895 acres) is administered by Federal agencies, approximately 29,663 acres (23 percent) of which are in federally designated CHUs. Approximately 33 percent of the Klamath

Action Area (112,078 acres) is considered suitable northern spotted owl habitat; 42,045 acres of nesting/roosting and 70,033 acres of foraging habitat. Currently, 38,958 acres of the suitable northern spotted owl habitat (35 percent) is located on the FGS ownership; 8,410 acres of nesting/roosting and 30,548 acres of foraging habitat. Approximately 4,771 acres have been identified by FGS as habitat commitments in CSAs, of which 109 acres are targeted as nesting/roosting, 2,850 acres as high-quality foraging, and 1,812 acres as low-quality foraging habitat. Northern spotted owls will benefit from an additional 5,017 acres that will be protected outside of the CSAs in WLPZs under the Aquatic Species Conservation Program. The majority of suitable habitat outside of the habitat commitments made for CSAs and WLPZs on FGS's lands in this province are likely to be harvested over the term of the ITP, which equates to 34,954 acres. Of these 34,954 acres of suitable habitat planned for harvest, 7,118 acres are currently nesting/roosting and 27,836 acres are foraging habitat.

Implementation of the FGS HCP is anticipated to result in a 17 percent reduction in spotted owl nesting/roosting habitat and 31 percent reduction in foraging habitat from current levels within the California Klamath Action Area. Much of this reduction will occur within the spotted owl activity centers (described in 4.2.1.1, above) where take is anticipated. As described above, the quality of nesting/roosting and foraging habitat on FGS ownership has been degraded due to repeated timber harvest entries, and to a substantial degree does not support reliable occupancy or reproduction by spotted owls; higher-quality habitats are retained in CSAs. Spotted owl habitat on adjacent federally managed lands is much more likely to contain important habitat elements and support spotted owl occupancy. However, in the short term (five to 25 years), the FGS habitat could be used by single territorial owls, dispersing owls, and some pairs. The loss of this habitat is therefore anticipated to have a negative impact on numbers and distribution of spotted owls within the Action Area. The significance of this impact over longer time periods (>25 years) is reduced by the increase in foraging habitat expected to occur across FGS ownership, as modeled by the company's MSP analysis.

California Cascades Province

Within the California Cascades Province portion of the Action Area there are 184,942 acres of land, of which FGS manages 42,967 acres (23 percent). Currently, 21 percent (38,785 acres) of the total Action Area in this province is managed by other private landowners and 56 percent (103,190 acres) is administered by Federal agencies. Approximately 13,054 acres (13 percent) of the Federal lands are in federally designated CHUs for the northern spotted owl. Approximately 16 percent of the Cascades Action Area (30,077 acres) is considered suitable northern spotted owl habitat; 7,349 acres of nesting/roosting and 22,728 acres of foraging habitat. Currently, 4,799 acres of the suitable northern spotted owl habitat (16 percent) is located on the FGS ownership; 619 acres of nesting/roosting and 4,180 acres of foraging habitat. Approximately 2,359 acres have been identified by FGS as habitat commitments in CSAs, of which six acres are targeted as nesting/roosting, 871 acres as high-quality foraging, and 1,482 acres as low-quality foraging habitat. Northern spotted owls will benefit from an additional 631 acres that will be protected outside of the CSAs in WLPZs under the Aquatic Species Conservation Program. The majority of suitable habitat outside of the habitat commitments made for CSAs and WLPZs on FGS's lands in this province are likely to be harvested over the term of the ITP, which equates to 4,605 acres. Of these 4,605 acres of suitable habitat planned for harvest, 609 acres are currently nesting/roosting and 3,996 acres are foraging habitat.

Implementation of the FGS HCP is anticipated to result in an eight percent reduction in spotted owl nesting/roosting habitat and an 18 percent reduction in foraging habitat from current levels within the California Cascades Action Area. Because spotted owl activity centers are located primarily on federal lands adjacent to FGS ownership, and because home ranges that overlap FGS ownership are managed in CSAs, this degree of habitat loss is not anticipated to have a significant negative impact on survival and recovery of spotted owls within the California Cascades Action Area.

4.1.4.2 Relative Effects to Northern Spotted Owl within Region

Relative Effects to Northern Spotted Owl Population within Region

The Service analyzed the relative impacts of the proposed take of northern spotted owls within a 20-mile buffer surrounding FGS ownership (see section 6.2.1.3 of the FGS HCP). This area, termed the Area of Analysis, is intended to represent the regional population or subpopulation of owls. The Area of Analysis encompasses 3,304,840 acres and represents 35 percent of the 6-million acre California Klamath Province and 46 percent of the 2.5-million acre California Cascades Province. The Service evaluated relative impacts at the regional rather than provincial scale because it provides a more meaningful analysis of potential impacts of FGS's operations that are reasonably expected to affect dispersal and long-term distribution of owls over the 50-year permit term. Additionally, information about northern spotted owl population size and distribution is not available at the larger provincial scale. Even though the number of currently active owl sites is unknown at the regional scale, there is even greater uncertainty with using data at the provincial level.

The Service estimated the baseline population for the California Klamath Province Area of Analysis using a predictive model (probability of occupancy model; Zabel et al. 2003). A detailed description of this process can be found in section 4.9.1.3 of the FGS HCP (2009). Results of the modeling indicated that approximately 186 activity centers (372 owls) may be supported within the California Klamath Province Area of Analysis. The Service was unable to apply the Klamath model to the California Cascades Area of Analysis, so instead used a 2008 query of the CDFG Northern Spotted Owl Database to estimate the potential number of spotted owl activity centers there. There are records for 54 northern spotted owl activity centers (108 owls) within the California Cascades Area of Analysis. The Service estimated that there are 240 activity centers potentially supporting 480 northern spotted owls within the combined Areas of Analysis.

The Service estimates that up to 61 northern spotted owls within the Action Area may be taken as a result of implementation of the FGS HCP. This would represent a 13 percent reduction in the number of individual owls within the regional population (Area of Analysis). Incidental take authorization of the additional 22 owls requested by FGS constitutes, at most, a minor additional impact to the species' survival and recovery at the regional and provincial scales because the Service concluded that the habitat within the home ranges of these owls is of low quality and is unlikely to support owls over the permit term, and FGS has very low potential to affect the habitat quality in the home range of the additional site.

As described under the Action Area (4.2.1.1, above), the relative impact of this loss on survival and recovery of the species at the regional and provincial levels is substantially reduced by the poor quality and low occupancy rates at many of the spotted owl activity centers that could reasonably be lost or degraded during HCP operations. Because spotted owl population performance is largely driven by survival and reproduction of owls occupying high-quality territories, activity centers on federally managed lands surrounding FGS ownership contribute disproportionately to the regional population. These federal lands constitute about 60 percent of the Area of Analysis and support a large majority of the owls estimated to occur there. Spotted owl activity centers located on FGS lands constitute a very small proportion of the regional population, and due to their low quality contribute little to reproductive output and population stability.

Conservation measures within the FGS HCP act to further mitigate the negative impacts associated with take of owls. The HCP's Terrestrial Species Conservation Program takes into account the wide variation in quality and conservation value among spotted owl activity centers within the Action Area, retaining higher-value activity centers supported by CSAs. The conservation value of the 'take' versus mitigation activity centers has an important influence on the relative impact of the anticipated take at the broader population scales. As part of the HCP development process, the Service identified 24 activity centers within the HCP area that contain or can grow sufficient amounts of suitable habitat to support occupancy by breeding pairs, and are in close proximity to federally designated CHUs. These activity centers were designated mitigation sites to offset the loss of owls associated with the lower quality take activity centers and to provide demographic support to the Federal conservation strategy. Fruit Growers has committed to maintaining habitat within the home ranges of the 24 mitigation sites to support occupancy by reproductive owls throughout the 50-year permit term.

The mitigation sites have some of the highest conservation value because in general they:

- Are in close proximity to a CHU
- Contain high amounts of federal land in the core and home range
- Have consistent occupancy and productivity
- Contain relatively high quality habitat

Conservation values were derived for each activity center in the Action Area using the above four factors (section 6.2.1.3 of the FGS HCP). The 24 mitigation activity centers have some of the highest conservation values; all are generally greater than 40 on a scale of 0 to 111. Seventeen of the mitigation sites have a conservation value greater than 60, 19 have a conservation value greater than 40, and five have a conservation value less than 40. Of the 15 activity centers where take is not likely because of low overlap with FGS's ownership, eight have a relatively high conservation value of greater than 60; the remaining seven activity centers have a conservation value ranging from 0 to 37. All take activity centers have conservation values less than 42, with the majority having values less than 20 (see Figure 6-6 of the FGS HCP). Almost half of the take sites have conservation values less than 10 on a scale of 0 to 111. Therefore, the mitigation sites are those with the highest likelihood of contributing significantly to the conservation and recovery of the northern spotted owl.

If take of 83 owls were to occur across the landscape, which as discussed above, the Service considers very unlikely, there would be a corresponding reduction of 18 percent of the total conservation value of activity centers in the Action Area because most of the activity centers where incidental take is likely to occur under the HCP provide a minimal contribution to the conservation strategy outlined in the Recovery Plan. The 24 mitigation activity centers and the 15 activity centers in which incidental take is unlikely because of low overlap with FGS's ownership represent 55 percent and 27 percent of the total conservation value of activity centers in the Action Area, respectively, for a combined total of 82 percent.

The vast majority of activity centers within the Area of Analysis are located within high quality habitat on Federal lands, and the FGS ownership contains relatively poor habitat for spotted owls due to repeated timber harvest entries into owl home ranges. At many of the 'take' sites on FGS's lands, the amount and distribution of existing suitable habitat is not sufficient to support owls currently or in the long-term due to the lack of high quality habitat that is essential for nesting and roosting. The take sites that do not contain adequate amounts of suitable habitat, particularly nesting/roosting sites, provide little contribution to the overall population in the region because they are not likely to support owls, especially once they are determined to be unoccupied or abandoned. For these reasons, and because the activity centers most likely to contribute to spotted owl occupancy, survival and reproduction within the Action Area receive protection with CSAs, the relative impact resulting from implementation of the FGS HCP is expected to have a measurable but small negative impact on the survival and recovery of northern spotted owls within the Area of Analysis. Because the Klamath and Cascades provinces encompass much larger areas and owl populations, potential effects would be even less.

Relative Effects to Northern Spotted Owl Habitat within Region

California Klamath Province

The majority of the FGS HCP is located within the Klamath Province, a large expanse of federally administered land managed under the NWFP. Within the Klamath Province, there are approximately 3 million acres of high-quality (nesting/roosting) spotted owl habitat, 2.5 million acres of which are Federal. Approximately half of the acres on Federal lands are within Federal Reserves such as Wilderness and Late-successional Reserves (Davis, in press).

Within the California Klamath Province portion of the Area of Analysis (the FGS ownership plus an approximate 20-mile radius area around the ownership) there are 2,157,945 acres of land, of which FGS manages 109,370 acres (5 percent). Currently, 35 percent (748,477 acres) of the total Area of Analysis in this province is managed by other private landowners and 60 percent (1,292,400 acres) is administered by Federal agencies. Approximately 291,000 acres (22 percent) of the Federal lands are in federally designated CHUs for the northern spotted owl. Approximately 27 percent of the Area of Analysis (572,460 acres) in this province is considered suitable northern spotted owl habitat; 286,335 acres of nesting/roosting and 286,125 acres of foraging habitat. Currently, 40,443 acres of the suitable northern spotted owl habitat (7 percent) is located on the FGS ownership; 9,413 acres of nesting/roosting and 31,030 acres of foraging habitat. Of the 40,443 acres of suitable habitat, 38,958 acres are covered under the HCP; the remaining 1,485 acres are located in Oregon and are not included in the HCP. Of those lands covered under the HCP, there are a total of 8,410 acres of nesting/roosting and 30,548 acres of foraging habitat that could potentially be affected by FGS's Covered Activities.

Approximately three percent of the total nesting/roosting habitat and 11 percent of the total foraging habitat available within the Klamath Area of Analysis may potentially be affected by implementation of the FGS HCP. However, accounting for FGS habitat commitments within CSAs and WLPZs, the percentage of suitable habitat potentially affected would also be three percent for nesting/roosting habitat, but less (eight percent) for foraging habitat. As described under 4.2.1.2, above, the quality of nesting/roosting and foraging habitat on FGS ownership has been degraded due to repeated timber harvest entries, and to a substantial degree does not support reliable occupancy or reproduction by spotted owls; higher-quality habitats are retained in CSAs. Spotted owl habitat on adjacent federally managed lands is much more likely to contain important habitat elements and support spotted owl occupancy. Relative to the quantity and quality of spotted owl habitat on adjacent federally managed lands and protected within CSAs, habitat expected to be removed or downgraded on FGS lands contributes little to spotted owl survival and reproduction. The significance of this habitat loss over longer time periods (>25 years) is further reduced by the increase in foraging habitat expected to occur across FGS's ownership, as modeled by the company's MSP analysis. In addition, forest stands that are considered unsuitable or dispersal habitat, and nesting/roosting and foraging habitat that is not removed but downgraded or degraded by FGS's Covered Activities, will be allowed to grow and mature across the ownership in the Klamath Area of Analysis over the term of the ITP, thereby offsetting some of the initial approximately 17,588 acres of habitat removed during the first decade of the HCP.

Because the large majority of high-quality spotted owl habitat, particularly habitat within spotted owl sites likely to be occupied, occurs on federally managed lands within the Area of Analysis, the Service concludes that the small proportions of lower-quality nesting/roosting and foraging habitat (3 percent and 11 percent, respectively) likely to be affected by implementation of the FGS HCP does not constitute a significant effect to survival and recovery of spotted owls within the regional population.

California Cascades Province

Within the California Cascades Province portion of the Area of Analysis there are 1,146,898 acres of land, of which FGS manages 42,967 acres (4 percent). Currently, 47 percent (540,116 acres) of the total Area of Analysis in this province is managed by other private landowners and 49 percent (563,185 acres) is administered by Federal agencies. Approximately 85,948 acres (15 percent) of the Federal lands are in federally designated CHUs for the northern spotted owl. Approximately 15 percent of the Area of Analysis (168,623 acres) in this province is considered suitable northern spotted owl habitat; 50,309 acres of nesting/roosting and 118,314 acres of foraging habitat. Currently, 4,799 acres of the suitable northern spotted owl habitat (3 percent) is located on the FGS ownership; 619 acres of nesting/roosting and 4,180 acres of foraging habitat.

The total potentially affected suitable habitat accounts for one percent of the total nesting/roosting habitat and four percent of the total foraging habitat available within the Cascades Area of Analysis. However, accounting for FGS habitat commitments within CSAs and WLPZs, the percentage of suitable habitat potentially affected would also be one percent for nesting/roosting habitat, but less (one percent) for foraging habitat. As described under 4.2.1.2, above, the quality of nesting/roosting and foraging habitat on FGS ownership has been degraded due to repeated timber harvest entries, and to a substantial degree does not support reliable occupancy or reproduction by spotted owls; higher-quality habitats are retained in CSAs. Spotted owl habitat on adjacent federally managed lands is much more likely to contain important habitat elements and support spotted owl occupancy. Relative to the quantity and quality of spotted owl habitat on adjacent federally managed lands and protected within CSAs, the habitat expected to be removed or downgraded on FGS lands contributes little to spotted owl survival and reproduction. The Service concludes that the loss of small amounts of spotted owl habitat expected to result from implementation of the FGS HCP will have an insignificant effect on survival and recovery of the species in the California Cascades Area of Analysis.

4.1.4.3 Relative Effects to Northern Spotted Owl across its Range

The range of the northern spotted owl encompasses roughly 50 million acres distributed across three states and several physiographic provinces. Rangewide population estimates are unavailable, but recent population modeling suggested that roughly 5,000 to 6,000 owl sites may currently exist (USDI FWS 2011b). Against this backdrop, the significance of the estimated potential take of 61 owls and modification of 39,000 acres of low-quality habitat resulting from issuance of an ITP to FGS is considered not significant. However, additional population factors such as demographic trends and isolated populations or genetic units are evaluated below to determine whether the estimated take may have a disproportionate effect on the species.

Estimates from demographic studies suggest the rangewide population declined by three percent per year from 1985 to 2006. The most precipitous declines in northern spotted owl populations have occurred in the Olympic, Cle Elum, and Rainier study areas in Washington and the Coast Range study area in Oregon. Estimates of population declines in these areas ranged from 40 to 60 percent during the 21 year study period (Forsman et al. 2011). Northern spotted owl populations on the HJ Andrews, Northwest California, and Green Diamond study areas declined by 20-30 percent, whereas the Tyee, Klamath, Southern Cascades, and Hoopa study areas showed declines of five to 15 percent. Two of the three demographic study areas (DSAs) closest to the HCP area support stationary populations (Klamath and South Cascades DSAs) and one (Northwestern California) is marginally declining (Forsman et al. 2011).

Genetic analyses have confirmed genetic mixing between the northern and California spotted owls, especially in the eastern Klamath region. Most gene flow is directional from the California spotted owl northward into the historical range of the northern spotted owl in the Klamath region of northern California and southern Oregon (Barrowclough et al. 1999; Haig et al. 2001, 2004). Mitochondrial DNA sequence analysis by Haig et al. (2004) of 213 owls demonstrated California spotted owl gene flow into the traditional geographic range of the northern spotted owl (15 or 11.5% of 131 owls). When the analysis was limited to the Klamath region, this value went up to 12 or 20.3% of 59 birds, suggesting most of the genetic overlap is in the area surrounding the zone of contact between the two subspecies.

The FGS HCP area is located within a region which supports a fairly large, well-distributed, and genetically robust population of northern spotted owls. Demographic monitoring within the Klamath and southern Cascades regions indicates that spotted owl populations are stable or slightly decreasing. This information suggests that the estimated potential loss of 61 owls over a 50 year period will not occur within a small, isolated population area, or contribute significantly to genetic isolation or population vulnerability within a significant portion of the species' range.

As described in section 4.1.4.1, FGS has requested incidental take authorization for 22 owls in addition to the 61 owls of which FWS expects take to reasonably occur over the permit term. The Service has determined that habitat within the home ranges of 20 of these owls is unlikely to support occupancy by spotted owls. This determination is based on extremely low amounts of suitable habitat due to repeated timber harvest entries and wildfire within the home ranges of these owls, as well as several consecutive years of protocol surveys with no owl detections. At one additional site (SK310), only three percent of suitable habitat occurs on FGS ownership. Due to the fact that the habitat within the home ranges of 20 of these owls is of low quality and is unlikely to support owls over the permit term, and FGS has very low potential to reduce the habitat quality in the home range of SK310, the Service concludes that the take authorization of the additional 22 owls constitutes at most a minor, discountable impact to the species' survival and recovery across its range. Habitat loss expected to occur within the home ranges of the 22 owls has already been included in the habitat sections of this BO.

In 1994, it was estimated that there was 7,400,000 acres of suitable nesting/roosting habitat on NWFP lands within the range of the northern spotted owl. There is no range-wide estimate on the amount of suitable nesting/roosting habitat on non-NWFP lands. Additionally, there are no range-wide estimates for suitable foraging habitat on NWFP lands or non-NWFP lands since foraging habitat characteristics vary widely across the range of the northern spotted owl. The Service has tracked nesting/roosting habitat removed or downgraded since the northern spotted owl was listed through the Section 7 process and technical assistance documents. As of March 30, 2011, the Service has documented the removal or downgrading of 188,971 acres of nesting/roosting habitat as a result of management activities on NWFP lands. Additionally, the Service has documented the removal or downgrading of 472,772 acres of nesting/roosting habitat associated with Tribal lands, HCPs/SHAs, other Federal, State, county, and private lands. The Service also tracks the amount of nesting/roosting habitat removed or downgraded as a result of natural disturbances (e.g., wildfire, insect infestations, windthrow). The Service has documented the removal or downgrading of 207,262 acres of nesting/roosting habitat on NWFP lands, although this figure does not take into account the habitat lost due to the 2008 wildfires that occurred in northern California. Those figures are still being calculated through the emergency consultation process and technical assistance. The Service recognizes the need to develop a new range-wide habitat baseline for the northern spotted owl. The current (1994) habitat baseline that is being used to track changes to available suitable habitat through management actions and natural events does not take into account habitat that has developed since the baseline was established. That is to say, the Service does not know the amount of non-habitat, dispersal habitat or foraging habitat that has grown into suitable dispersal, foraging or nesting/roosting habitat since the 1994 baseline was established.

As a result of issuing an ITP to FGS, the HCP would result in the potential modification of 7,727 acres of suitable nesting/roosting habitat and 31,832 acres of foraging habitat through harvest operations. Of this, approximately 49% or 19,340 acres (4,159 acres nesting/roosting and 15,182 acres foraging habitat) are scheduled for regeneration harvests over the term of the ITP. Regeneration harvests result in plantations, which may provide dispersal and potentially foraging habitat at various stages of their rotation during the permit term, but are not expected to become nesting/roosting habitat because of the even-aged structure and density. The modification of approximately 39,559 acres of low-quality habitat is considered minor with respect to the available suitable habitat range-wide for the northern spotted owl. This relative impact is substantially reduced by 1) the generally low quality of habitat within the FGS HCP area as a result of repeated timber harvest entries and subsequent low rates of occupancy by spotted owls, and 2) predicted increases in foraging habitat across FGS's ownership, as modeled by the company's MSP analysis. Based on this analysis, the Service concludes that the loss of spotted owl habitat expected to occur with implementation of the FGS HCP will not significantly impact the species' survival and recovery across its range.

4.1.4.4 Consistency with Objectives of Northern Spotted Owl Recovery Plan

The Revised Recovery Plan for the Northern Spotted Owl (USDI FWS 2011b; RRP) acknowledges the important role that State, private, and Tribal lands can play toward recovering the northern spotted owl. Contributions from non-Federal lands are recognized as important to the range-wide goal of achieving conservation and recovery of the spotted owl. While the RRP recommends retention of all occupied sites and unoccupied, high quality northern spotted owl habitat on all lands to the greatest extent feasible, the Service recognized that this goal will be especially difficult to meet on non-Federal lands.

Recovery Action 14 in the RRP states: *Encourage applicants to develop Habitat Conservation Plans/Safe Harbor Agreements that are consistent with the recovery objectives.* Habitat Conservation Plans (HCPs) and Safe Harbor Agreements (SHAs) are important tools that non-Federal landowners can voluntarily use to assist in the recovery of the spotted owl. Although HCPs authorize take of listed species, the conservation measures developed to mitigate the impact of the taking must be consistent with the recovery plan objectives. Although HCPs do not require recovery standards, voluntary Recovery Actions included in an HCP can promote recovery. The Service estimates that 71 activity centers may currently be occupied within the FGS HCP Action Area; the Service has determined that take is unlikely at 40 sites because 1) FGS identified 24 activity centers where CSAs will be established to provide demographic support to the recovery of northern spotted owl under the HCP, and 2) the home ranges of 16 activity centers have low overlap with FGS's ownership or remaining suitable habitat on FGS's ownership.

The RRP suggests that spotted owl recovery will require conservation of occupied and high quality owl habitat to ameliorate impacts from barred owls and buffer potential declines in habitat due to climate change. This strategy is described in Recovery Action 10 – *Conserve spotted owl sites and high value habitat to provide additional demographic support to the spotted owl population.* This recovery action focuses on retention of high quality habitat and long-term occupancy and reproduction at spotted owl sites in order to bolster demographic rates in the larger landscape. Because the CSAs in the FGS HCP are intended to support higher-quality spotted owl activity centers that are associated with existing conservation reserve networks (Critical Habitat Units), and because the majority of activity centers where take is likely to occur exhibit low occupancy rates and poor overall habitat quality, the HCP is generally consistent with this objective.

Recovery Acton 32 is intended to reduce negative impacts of barred owls and other stressors on spotted owls by maintaining and restoring high-quality habitat that can serve as refugia where such habitat is limited. High-quality habitat is described as stands with large-diameter trees, high canopy cover, and decadence components such as broken-topped live trees, mistletoe, cavities, large snags, and fallen trees. Because of the long history of intensive timber management on FGS lands, stands meeting this description are limited to a few spotted owl nest stands and patches of riparian habitat. Some of the existing RA32 habitat will be conserved with CSAs; whereas an unknown quantity will be harvested at the spotted owl activity centers where take is authorized. Stands meeting the RA 32 definition of habitat must be identified in the field on a case by case basis and are not mapped at a broad-scale resolution. Because RA32 stands have not been identified on FGS lands, the degree to which effective RA32 habitat may be removed by implementation of the FGS HCP is unknown.

In the RRP, the Service recognizes the threat posed by the barred owl to spotted owl recovery, and proposes nine Recovery Actions focused on better understanding and ameliorating this threat. The objectives of Recovery Action 30 – *Manage to reduce the negative effects of barred owls on spotted owls so that Recovery Criterion 1 can be met* and Recovery Action 31 – *Develop mechanisms for landowners and land managers to support barred owl management using a collaborative process* – are both addressed in the FGS HCP. In the HCP, the Company is required to survey for barred owls, report detections of barred owls to the Service, and facilitate removal of barred owls from FGS lands if and when a Migratory Bird Treaty Act Permit is obtained.

Although the bulk of conservation and recovery activities described in the RRP are focused on Federal lands, the above-listed Recovery Actions pertain to management of private timberlands and are to varying degrees incorporated into the FGS HCP. The FGS HCP does not detract from the broader objectives of the RRP; it does not result in significant losses of high-quality spotted owl sites with consistent occupancy and reproduction or high-quality habitat, it contains provisions that facilitate conservation of existing higher-quality spotted owl sites associated with Critical Habitat, and it facilitates the potential control of barred owls. The Service therefore concludes that the FGS HCP is consistent with the above-described provisions of the RRP and with recovery of the northern spotted owl.

4.2 Fisher

4.2.1 Biological Requirements of the Fisher

Section 2.2.2 describes the fisher's life history, including its home range sizes, habitat associations, food habits, and dispersal distances (also see Powell 1993, Powell and Zielinski

1994, and Lofroth et al. 2010). Relationships between these factors and the individual fitness or population performance of fishers have not been rigorously established. Nonetheless, the large body of literature concerning fishers suggests that they have the following biological requirements:

1. Home range and density estimates vary substantially among studies and geographic areas but fishers generally have large spatial requirements (100s to 10,000s of acres each).

2. Although they are capable of moving long distances, fishers appear to have limited dispersal abilities and thus, require habitat that is well connected at landscape scales.

3. Fisher home ranges often consist of a mosaic of vegetation types and structural stages but typically contain a large component of mid- to late-successional forest. Thus, suitable landscapes for fishers likewise contain a large component of mid- to late-successional forest.

4. Fishers require a well-distributed network of suitable denning and resting sites within their home ranges. Fishers favor relatively dense, old, decadent forest conditions for denning and resting. Suitable denning and resting sites often include dense, multi-layered canopies, large-diameter trees, snags, and logs, or defective trees (e.g., with cavities or mistletoe brooms). Oaks and other hardwoods are often favored for denning or resting when available.

5. Fishers use a wider variety of conditions when active than when denning or resting but still generally favor areas with relatively complex structure, dense canopy cover, large trees, snags, and logs, and a component of hardwoods.

6. Fishers are associated with several abiotic habitat features. Perhaps most important among these are lower to middle elevations at which relatively dense conifer or conifer-hardwood forests and low to moderate snowfall occur, and riparian areas, where denser forest and prey may be concentrated.

7. Fishers have broad diets that include prey with a wide variety of habitat associations. Nonetheless, many of their primary prey species are associated with structures and resources that are also favored by fishers, such as multi-layered canopies, hardwoods, and large-diameter trees, snags, and logs.

4.2.2 Potential Effects of Habitat Modification

Given that the habitat associations of fishers and northern spotted owls overlap substantially, many of the effects of the Covered Activities on northern spotted owls as described above in section 4.1 are also likely to impact fishers. Forest management is the primary activity in the Plan Area and will be conducted in a variety of ways and settings and could, therefore, have a variety of short- and long-term effects on fishers. For example, depending on the setting and prescription, forest thinning could remove structures important to fishers and their prey or could result in their accelerated development or prevent their loss to severe natural disturbances.

Timber harvest practices that clearly degrade habitat for fishers or their prey (e.g., by excessively reducing canopy cover, structural complexity, large or deformed trees, or dead woody materials) have the most obvious potential to negatively affect the species. Fishers could also be accidentally killed or injured if they are struck by vehicles associated with management operations or if their den or rest trees are felled while in use. Covered Activities other than timber harvesting include harvesting minor forest products, fire prevention, and watershed management. These activities could result in varying levels of habitat modification and disturbance for fishers.

4.2.3 Habitat Model

The Service modified the Zielinski et al. (2010) model by using FGS forest inventory data in place of the original model's vegetation data for FGS lands (section 3.3.1.1; also see "Fisher Spatial Analysis" in Appendix E of the HCP) to quantify changes to both the total amount of modeled habitat suitable for fishers and the amount of modeled habitat in large (female home range-size) blocks (7.7 $mile^2$) in the Klamath Province. The Service selected modeled values greater than or equal to 0.41 as a threshold to represent preferred habitat (hereafter 'suitable habitat') using the FGS fisher model. To quantify changes to modeled habitat suitability under the Proposed Action, the Service compared the current predicted amount of suitable habitat to amounts at five subsequent 10-year time steps. Analysis of changes to female home range-size blocks of suitable habitat provided a spatially explicit means of analyzing habitat changes over this period. This approach does not provide an absolute estimate of the size of the area's fisher population but, rather, serves as a reasonable index for changes to the number of female fishers that the area can support over time under the Proposed Action.

Appendix E of the HCP describes some limitations to the application and interpretation of the FGS fisher model. First, the Service only applied the model to the California Klamath Province. The Zielinski et al. (2010) model was developed specifically for fishers in the Klamath Province and thus, might not have accurately predicted habitat suitability in the California Cascades Province. Furthermore, few fisher detection locations were available for testing the model's validity in the California Cascades Province. Second, the FGS inventory data used to build the modified model were spatially coarse compared with those used for non-FGS ownerships (EVEG: USDA FS 2011). It is unknown whether or how this difference in vegetation data influenced the modeling results. Third, the resolution of the habitat suitability model, regardless of the vegetation data used, is too coarse to detect changes to the availability of important fine-scale habitat elements (e.g., structures and sites suitable for denning and resting).

Despite its limitations, the modeling effort used the best available science to describe fisher habitat in the Klamath Province. This model represents the most current description of fisher habitat in the Klamath Action Area and provides the best estimate of potential changes to habitat under the Proposed Action.

4.2.4 Summary of Effects to Fisher in the Action Area

The Action Area occurs in two ecological provinces: the California Klamath Province and the California Cascades Province. The Service is providing separate effects analyses for these provinces because they are distinct in terms of their ecology, the availability and quality of information for fishers, and the apparent abundances of fishers and their habitat. The Action Area encompasses the local fisher population on FGS ownership that could be directly affected by FGS's operations (FGS ownership with a 1.6-mile buffer).

Effects to Fisher in Klamath Action Area

Table 20 describes changes to the predicted amount of suitable fisher habitat in the California Klamath Province portion of the Action Area (both total and in large blocks), as well as the number of hypothetical female home ranges. The amount of suitable habitat was projected to increase by nearly 17% with large a block increase of 21% during the 50-year permit term. Projected increases in large blocks of suitable habitat and the number of hypothetical female home ranges suggest that the Proposed Action will lead to a slight increase in the number of fishers that the Klamath Action Area can support. Fishers would also benefit from the increases in habitat from the northern spotted owl and aquatic conservation measures, and increases in habitat over the ownership with the expected reduction of even-aged management practices. However, at a finer scale, timber harvest activities at northern spotted owl take sites are expected to reduce habitat suitability, forest complexity, and the availability of structures that are essential to fishers for resting and denning at these locations. Overall, the adverse and beneficial effects of the FGS HCP on fisher are expected to be less than significant.

Table 20. Changes to the amount of suitable fisher habitat (total and in blocks of at least 7.7 mile^2) and the number of hypothetical female home ranges in the Klamath Action Area under the Proposed Action.

	Total		Large Blocks		Hypothetical Female
Time Step	**Acres**	**% Change**	**Acres**	**% Change**	**Home Ranges**
Current	137,163	–	126,036	–	25.5
Decade 1	141,205	2.95%	126,468	0.34%	25.6
Decade 2	157,751	11.72%	144,032	13.89%	29.1
Decade 3	160,143	1.52%	150,798	4.70%	30.5
Decade 4	166,832	4.18%	152,545	1.16%	30.9
Decade 5	160,113	-4.03%	152,251	-0.19%	30.8

Effects to Fisher in Cascades Action Area

The Service was unable to model changes in habitat suitability for fishers in the California Cascades Province. However, given that the habitat associations of fishers and northern spotted owls overlap substantially, many of the effects of the Covered Activities on northern spotted owls (see section 4.1) are also likely to impact fishers. It is important to acknowledge, however, that protections of northern spotted owls provided by the CFPRs do not apply to fishers. Fishers may incidentally benefit from spatial or temporal restrictions on activities near northern spotted owl nests but some areas important to fishers may be unprotected.

5.0 CUMULATIVE EFFECTS

Cumulative effects are those effects of future State, tribal, and private actions that are reasonably certain to occur within the Action Area. Future Federal actions will be subject to the consultation requirements established in section 7 of the ESA and, therefore, are not considered cumulative to the Proposed Action.

Approximately 152,178 acres within the Action Area is owned by FGS. The effects of the proposed Covered Activities on northern spotted owl and fisher are evaluated elsewhere in this BO and therefore are not included in this section.

In 1990, CFPRs, which govern timber harvest on private lands, were amended to require surveys for northern spotted owls in suitable habitat and to provide protection around activity centers (CALFIRE 2001). Under the CFPRs, no timber harvest plan can be approved if it is likely to result in incidental take of federally listed species, unless the take is authorized, for example, under an HCP or Safe Harbor Agreement. The CFPRs do not contain specific provisions for fishers other than including intent language about reducing significant impacts to non-listed species and maintaining functional wildlife habitat. However, this language is not associated with specific enforceable measures. Fishers may incidentally benefit from the CFPRs' spatial and temporal restrictions on activities near northern spotted owl nests; however, some areas important to fishers may be unprotected.

Other private lands account for 142,393 acres within the Action Area. Of these lands, 116,745 acres are currently unsuitable northern spotted owl habitat; suitable habitat includes 8,192 acres of nesting/roosting habitat and 17,456 acres of foraging habitat. These adjoining other private lands are typically managed for commercial timber harvest, or are agricultural lands with rural residential use. The majority of agricultural lands are not suitable northern spotted owl or fisher habitat due to their location on the landscape (i.e., meadows, valleys, grasslands); therefore, they will not provide northern spotted owl or fisher habitat even in the absence of agricultural practices. Commercial timberlands in the Action Area have been actively managed since the early 1900s, and it can be expected that commercial timber harvest on other private lands will continue in the future.

The Service anticipates that FGS's Covered Activities will remove habitat to the extent that incidental take of up to 83 owls is likely over the 50-year permit term. The take prohibition of the CFPRs will still apply to other private landowners who want to harvest suitable habitat within the home ranges of these take sites. Before harvest of additional habitat can occur, other private landowners will be required to survey for owls at these sites. However, the Service has found that the effects of repeated entries within northern spotted owl home ranges reduces habitat quality and leads to reduced occupancy rates and apparent site abandonment. If the Service issues a letter of non-occupancy after making the determination that the activity center is no longer occupied (i.e., abandoned) and doesn't contain sufficient amounts of habitat to support owls, suitable habitat on other private lands within the home ranges of owl sites may be harvested, further reducing suitable owl and fisher habitat available within the Action Area. Because we have no information that actions on private lands will occur during the 50-year term of the permit and we have no information that the rate of non-occupancy will change, we assume that at least the present rate of apparent northern spotted owl site abandonment will continue for the 50-year term of the permit. Likewise we have no information that any other activities likely to affect fishers are reasonably certain to occur in the Action Area.

State Lands account for 686 acres within the Action Area; 644 acres which are currently unsuitable and 42 acres of foraging owl habitat. It is not anticipated that suitable owl or fisher habitat on State lands would change considerably over the term of the ITP. There are no tribal lands within the Action Area.

The Service does not have information to support analysis of the effects of specific actions that are expected to occur on state and private lands within the Action Area; however, activities reasonably certain to occur include the continued harvesting of some proportion of forest habitat suitable for fisher and northern spotted owl. After nearly a century of intensive timber management, the current condition of these forests does not contribute substantially to the survival and recovery of these species, and activity centers on private lands in the Action Area generally exhibit low occupancy rates. For these reasons, the Service concludes that the loss of habitat expected to occur with implementation of FGS HCP, in combination with activities reasonably certain to occur on other private and State lands within the Action Area, will not have a significant negative cumulative effect on the survival and recovery of the northern spotted owl or be likely to jeopardize the continued existence of the West Coast DPS of fishers.

6.0 CONCLUSION

Under Section 7(a)(2) of the ESA, Federal agencies must ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of any listed species or result in the destruction or adverse modification of critical habitat. Regulations implementing this Section of the ESA define "jeopardize the continued existence of" as: "to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species" (FR §402.02).

6.1 Northern Spotted Owl

After reviewing the current status of the northern spotted owl, the environmental baseline, the effects of the Proposed Action, and the cumulative effects, it is the Service's biological opinion that implementation of the FGS HCP discussed herein is not likely to jeopardize the continued existence of the northern spotted owl or impede its recovery, and will not destroy or adversely modify designated critical habitat. The bases for this determination are as follows.

Relative Impacts to Populations

Action Area:

- Although the Service analyzed the potential impact of incidental take of up to 61 northern spotted owls within the Action Area as a result of implementation of the FGS HCP over the 50-year permit term, actual take is likely to be lower because historic activity centers may not be currently occupied or occupied by owl pairs. Thus the Service concludes the level of take and impact of that take is likely to be substantially lower due to the low occupancy and reproductive rates of many of the territories.

- Authorization of incidental take under the FGS HCP of an additional 22 northern spotted owls, for a total of 83 owls, as requested by FGS, constitutes at most a minor additional impact at the Action Area scale because the Service has determined that habitat within the home ranges of 20 of these owls is of low quality and not likely to support owls now or perhaps in the future, and FGS has very low potential to reduce the habitat quality in the home range of SK310.
- The Service concluded that population growth beyond the owl population baseline within the Klamath Action Area is unlikely over the permit term based on an evaluation of current conditions and habitat suitability modeled (Zabel et al. 2003) by decade.

Regional scale:

- Incidental take of up to 61 northern spotted owls represents a 13 percent reduction in the number of individual owls within the regional population, as defined by a 20-mile buffer surrounding FGS ownership (Area of Analysis). Spotted owl activity centers located on FGS lands constitute a very small proportion of the regional population and, due to their low quality, contribute little to reproductive output and population stability. In contrast, federal lands constitute about 60 percent of the Area of Analysis and support the majority of high-quality territories that contribute disproportionately to the local population. Therefore, the relative impact resulting from implementation of the FGS HCP is expected to have a measurable but small negative impact on the regional population. However, the potential adverse effects will not impede the survival and recovery of the northern spotted owl, and the establishment of CSAs on FGS's ownership to support existing higher-quality spotted owl sites associated with CHUs is consistent with the Revised Recovery Plan's strategy to conserve occupied and high quality owl habitat.

Provincial scale:

- The FGS HCP area is located within two physiographic provinces that support a fairly large, well-distributed, and genetically robust population of northern spotted owls. The estimated take of owls will not occur within a small, isolated population area, or contribute significantly to genetic isolation.

Rangewide:

- Given that recent population modeling suggests that roughly 5,000 to 6,000 owl sites may currently exist (USDI FWS 2011b) across the species range, the estimated incidental take of up to 61 owls resulting from issuance of an ITP to FGS is not likely to jeopardize the continued existence or impede recovery of the northern spotted owl across its range because it represents a less than one percent reduction in activity centers range-wide. Additionally, the majority of activity centers where take is likely to occur do not substantially contribute to the Federal conservation strategy outlined in the Revised Recovery Plan because the sites exhibit low occupancy rates, poor overall habitat quality, and/or are not in close proximity to the Federal conservation reserve network. In contrast, most of the activity centers designated as mitigation sites contribute disproportionately to overall population stability and recovery because they are more likely to support long-term occupancy and reproductive success by owl pairs, in accordance with the Revised Recovery Plan.

Relative Impact of Habitat Modification

- Implementation of the FGS HCP is anticipated to result in a 17 percent reduction in spotted owl nesting/roosting habitat and 31 percent reduction in foraging habitat from current levels within the California Klamath portion of the Action Area, and an eight percent reduction in spotted owl nesting/roosting habitat and an 18 percent reduction in foraging habitat from current levels within the California Cascades portion of the Action Area. The degree of this impact over longer time periods (>25 years) is reduced by the increase in foraging habitat expected to occur across FGS ownership, as modeled by the company's MSP analysis.
- Approximately three percent of the total nesting/roosting habitat and 11 percent of the total foraging habitat available within the Klamath portion of the Area of Analysis, and one percent of the total nesting/roosting habitat and four percent of the total foraging habitat available within the Cascades portion of the Area of Analysis may potentially be affected by implementation of the FGS HCP. Relative to the quantity and quality of spotted owl habitat on adjacent federally managed lands and protected within CSAs, habitat expected to be removed or downgraded on FGS lands contributes little in terms of quantity or quality to spotted owl survival and reproduction. The significance of this habitat loss over longer time periods (>25 years) is further reduced by the increase in foraging habitat expected to occur across FGS's ownership, as modeled by the company's MSP analysis.
- Given that the range of the northern spotted owl encompasses roughly 50 million acres distributed across three states and several physiographic provinces, the Service considers the estimated modification of 39,000 acres of lower quality habitat resulting from issuance of an ITP to FGS to be insignificant. The relative impact is substantially reduced by the generally low quality of habitat within the FGS HCP area as a result of repeated timber harvest entries and subsequent low rates of occupancy by spotted owls, and predicted increases in foraging habitat across FGS's ownership over the permit term, as modeled by the company's MSP analysis.

Conservation Planning and Mitigation

- If take of 83 owls were to occur across the landscape, there would be a corresponding reduction of 18 percent of the total conservation value of activity centers in the Action Area. Most of the activity centers where incidental take is likely to occur under the HCP provide a minimal contribution to the recovery of northern spotted owls under the federal conservation strategy outlined in the Revised Recovery Plan (USDI FWS 2011b). The 24 mitigation activity centers and the 15 activity centers in which incidental take is unlikely because of low overlap with FGS's ownership represent 55 percent and 27 percent of the total conservation value of activity centers in the Action Area, respectively, for a combined total of 82 percent.

- Existing regulatory mechanisms will be unlikely to conserve activity centers that are strongly influenced by FGS ownership, which acts to further reduce the relative impact of the estimated taking because under the current CFPRs, if an activity center is determined to be unoccupied or abandoned, all habitat within the home range can be removed without compensatory mitigation. For this reason, the HCP would provide more certainty that habitat would be conserved thru time than would existing regulatory mechanisms because habitat within CSAs would be maintained throughout the 50-year permit term, regardless of occupancy.
- The FGS HCP is consistent with the provisions of the Revised Recovery Plan (USDI FWS 2011b) because it does not result in significant losses of high-quality spotted owl sites with consistent occupancy and reproduction or high-quality habitat, it contains provisions that facilitate conservation of existing higher-quality spotted owl sites associated with Critical Habitat, and it facilitates the potential control of barred owls.

Impacts to Northern Spotted Owl Critical Habitat

- Critical habitat for the northern spotted owl has been designated on federal lands only; no direct destruction or adverse modification of critical habitat is anticipated due to implementation of the FGS HCP because modification of habitat will occur solely on FGS's private ownership.
- The Service considered whether implementation of the FGS HCP would indirectly affect critical habitat by creating fragmentation and 'edge effects' along the boundaries of FGS lands and adjacent critical habitat, potentially reducing the quality of critical habitat along those edges. Because of the long history of intensive timber management on FGS lands, there currently is a high degree of contrast between forest conditions on FGS's ownership and adjacent critical habitat on Federal lands. While Covered Activities may increase edge contrast in some limited areas, overall the Service anticipates that implementation of the FGS HCP will reduce this contrast during the 50-year permit term as stands develop as forecasted in the MSP modeling. In addition, the diversity of naturally occurring and anthropogenic habitat types in the project area, combined with the association of spotted owls with edge habitat in the Klamath Province (USDI FWS 2011b) suggest that any changes in edge characteristics will not have a significant negative effect on critical habitat. Therefore, the Service does not expect any indirect effects to critical habitat to result from implementation of the FGS HCP.

6.2 Fisher

After reviewing the current status of the fisher, the environmental baseline for the Action Area, the effects of implementing the proposed action and the cumulative effects, it is the Service's conference opinion that the FGS HCP, as proposed, is not likely to jeopardize the continued existence of the fisher within the West Coast DPS. No critical habitat has been designated for this species; therefore, none will be destroyed or adversely modified. The Service reached the non-jeopardy conclusion based on the following factors:

- Where modeled, the amount of suitable fisher habitat was estimated to increase during the 50-year permit term. Although the resolution of the fisher habitat suitability model was too coarse to detect changes to the availability of important fine-scale habitat elements (e.g., structures and sites suitable for denning and resting) and portions of FGS's lands associated with owl takes sites will likely be downgraded, the modeling results suggest an increasing trend in the amount of suitable fisher habitat at the landscape scale.
- The fisher habitat model also projected a slight increase in the number of fishers that the area can support.

INCIDENTAL TAKE STATEMENT

Section 9 of the ESA and Federal regulation pursuant to Section 4(d) of the ESA prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harm is further defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. Harass is defined by the Service as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered to be prohibited taking under the ESA provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement. Sections 7(b)(4) and 7(o)(2) of the ESA do not apply to listed plant species.

Amount or Extent of Take

Loss and fragmentation of habitat, together with the legacy of past harvesting on this landscape, may result in reduced resources such as prey and cover, increased predation, and exacerbate competition with barred owls and other spotted owls and therefore reduce the ability of spotted owls to survive and reproduce successfully within the Action Area. Given that many of the activity centers in the Action Area currently have less habitat than what is currently understood to be the minimum required to avoid take, the Service has determined that issuance of an ITP will create a likelihood of injury to owls by harming them to such an extent as to significantly disrupt their normal behavioral patterns such as breeding, feeding, or sheltering. The Service does not anticipate that incidental take of northern spotted owl in the form of harassment will occur because protocol surveys and restrictions on operations during the breeding season should act to avoid or adequately minimize disturbance to owls at occupied sites.

Based on review of survey records, habitat suitability models, habitat mapping, and evaluation of potential impacts of FGS activities on existing suitable habitat, the Service anticipates take, in the form of harm, of up to 61 northern spotted owls within the Action Area to occur over the course of the 50-year permit term as a result of FGS's Covered Activities (Table 16). Under the proposed ITP, the Service would authorize take of an additional 22 northern spotted owls for a total of 83 individual owls. However, the Service's evaluation (see section 3.2.2) indicates that take of this additional 22 owls is unlikely because negative survey results and/or lack of sufficient amounts of suitable habitat suggest the owls are not likely to occupy the Action Area now or throughout the permit term. The authorization of take of these 22 owls, *in addition to* the 61 owls deemed likely to be taken, reflects the total number of historic activity centers within the Action Area that could be adversely affected by timber harvest and other Covered Activities during the permit term, including activity centers that have little possibility of occupancy during the permit term due to deficient habitat conditions. However, because it is possible that owls might occupy these areas over the permit term, and because the proposed habitat conservation plan includes conservation measures to minimize and mitigate take of up to 83 owls, based on the number of historical activity centers, we have conservatively authorized take of up to 83 owls over the life of the permit. Estimating take based on impacts to historical activity centers also accounts for potential displacement of owls by Covered Activities and subsequent movement to alternate activity centers within the Action Area during the permit term.

The Service based its estimation of take on an analysis of historic activity centers, current habitat conditions, and modeled future conditions. Based on this analysis, the Service concludes that it is unlikely that there are additional undetected activity centers on FGS ownership given the low amounts of suitable habitat and extensive survey efforts that have been undertaken over time on the property. The Service also concluded that population growth beyond the current owl population baseline within the Klamath Action Area is unlikely over the permit term. However, because the future location of spotted owl habitat and activity centers within the Action Area cannot be predicted with certainty, the Service recognizes that the take of owls will occur across the Action Area over the permit term and not be based solely on the current activity centers. The Service will continue to provide technical assistance to FGS and will monitor the timing and extent of take throughout the permit term.

Effect of the Take

For the reasons stated in the analyses of the proposed project's effects, the Service determined that the anticipated incidental take of up to 61 northern spotted owls, in combination with the unlikely take of up to 22 additional individuals associated with low-quality habitat, is not likely to jeopardize the continued existence of or impede the recovery of the threatened northern spotted owl across its range. The Service has also determined that the proposed action is not likely to jeopardize the continued existence of the federal candidate West Coast DPS of fisher.

Reasonable and Prudent Measures and Terms and Conditions

The FGS HCP and accompanying documents identify anticipated adverse effects to the northern spotted owl likely to result from the proposed taking, and the specific measures and levels of species and habitat protection that are necessary and appropriate to minimize those adverse effects. All conservation measures described in the proposed HCP, together with the terms and conditions described in the associated Implementing Agreement and any section 10(a)(1)(B) permits issued with respect to the proposed HCP are hereby incorporated by reference as reasonable and prudent measures and terms and conditions within this Incidental Take Statement pursuant to 50 CFR 402.14(I). Such terms and conditions are non-discretionary and must be undertaken for the exemptions under section 10(a)(1)(B) and section 7(o)(2) of the ESA to apply. If FGS fails to adhere to these terms and conditions, the protective coverage of the section 10(a)(1)(B) permit and section 7(o)(2) may lapse. The Service finds that no further measures are necessary beyond those specified in the FGS HCP, Implementing Agreement, and any section 10(a)(1)(B) permit or permits issued with respect to the proposed HCP Because the Service will provide technical assistance to FGS throughout the term of the ITP, the Service will be in a position to monitor and influence how the HCP is implemented. In order to monitor the impact of incidental take, FGS must report the progress of the action and its impact on the species to the Service as specified below.

Reporting Requirements

As described in Chapter 7 of the HCP and Section 8 of the IA, FGS will submit periodic reports describing its activities and results of the compliance and effectiveness monitoring programs implemented by FGS during the prior calendar year. By January 1st of each calendar year during the Permit Term, and following the adoption of FGS's budget by its Board of Directors, FGS will also provide the Service with a Yearly Expenditure Report (YER). The YER will identify all HCP obligations undertaken the prior year, and the funds expended to implement those obligations. The YER will also identify: (1) all HCP-required obligations FGS will implement in the upcoming calendar year (e.g., monitoring, surveying, road work), (2) the funds budgeted for those purposes, (3) whether the budgeted funds are THP-related or not, and 4) all out-of-pocket expenditures required to carry out the obligations (e.g., hiring of outside specialists). Fruit Growers Supply Company will provide, within 30 days of being requested by the Service, any additional information in its possession or control related to implementation of the HCP that is requested by the Service for the purpose of assessing whether the terms and conditions of the permit and the HCP are being fully implemented. Fruit Growers Supply Company shall notify the Service of any transfer of ownership of real property or harvesting rights therein subject to the IA at the time of transfer of ownership, except where prior notification occurs pursuant to section 10. Such notice shall describe the lands to be transferred with particularity, identify the name and address of the transferee and include a detailed map showing the transferred lands.

Disposition of Sick, Injured, or Dead Specimens

Any dead or injured northern spotted owl must be reported to the Service's Law Enforcement Division (916-414-6660) as soon as possible, and turned over to the Law Enforcement Division or to a game warden or biologist of the CDFG for care or analysis. Care should be taken in handling sick or injured specimens to ensure effective treatment and care or handling of dead specimens to preserve biological material in the best possible state for later analysis of cause of death. In conjunction with the care of any sick or injured northern spotted owl or preservation of biological materials from a dead animal, the finder has the responsibility to carry out instructions provided by Law Enforcement to ensure that evidence intrinsic to the specimen is not unnecessarily disturbed. The Service is to be notified in writing within three working days of the accidental death of, or injury to, a northern spotted owl, or of the finding of any dead or injured northern spotted owl during implementation of the proposed action. Notification must include the date, time, and location of the incident or discovery of a dead or injured northern spotted owl, as well as any pertinent information on circumstances surrounding the incident or discovery. The Service contact for this written information is the Field Supervisor at (530) 842-5763.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the ESA directs Federal agencies to utilize their authorities to further the purposes of the ESA by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. In this case, the conservation measures of the project are sufficient to minimize take of northern spotted owl; therefore, the Service finds that no further measures are necessary beyond those specified in the FGS HCP, IA, and the conditions of the Permit.

REINITIATION-CLOSING STATEMENT

This concludes formal consultation on the issuance of the ITP to implement the FGS HCP. As provided in 50 CFR §402.16, reinitiation of consultation shall be required if: (1) the amount or extent of incidental take of northern spotted owl is exceeded; (2) new information reveals effects of the action that may affect northern spotted owl in a manner or to an extent not considered in this biological opinion or affect northern spotted owl critical habitat; (3) the action is subsequently modified in a manner that causes an effect to the species that was not considered in this biological opinion or to critical habitat; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation.

Appendix A. Gemmill Thin Project – Shasta-Trinity National Forest

STATUS OF THE SPECIES

1.0 STATUS OF THE NORTHERN SPOTTED OWL

1.1 Legal Status

The spotted owl was listed as threatened on June 26, 1990 due to widespread loss and adverse modification of suitable habitat across the owl's entire range and the inadequacy of existing regulatory mechanisms to conserve the owl (USDI FWS 1990a, p. 26114). The northern spotted owl was originally listed with a recovery priority number of 3C, but that number was changed to 6C in 2004 during the 5-year review of the species (USDI FWS 2004, p. 55). Priority numbers are assigned on a scale of 1C (highest) to 18 (lowest). This number reflects a high degree of threat, a low potential for recovery, and the owl's taxonomic status as a subspecies (USDI FWS 1983b, p. 51895). The "C" reflects conflict with development, construction, or other economic activity (USDI FWS 1983a, p. 43104). The most recent five year status review was completed on September 29, 2011, and did not propose changes to the listing status or introduce any new threats (USDI FWS 2011a).

1.2 Life History

1.2.1 Taxonomy

The northern spotted owl is one of three subspecies of spotted owls currently recognized by the American Ornithologists' Union. The taxonomic separation of these three subspecies is supported by genetic (Barrowclough and Gutiérrez 1990, pp.741-742; Barrowclough et al. 1999, p. 928; Haig et al. 2004, p. 1354), morphological (Gutiérrez et al. 1995, p. 2), and biogeographic information (Barrowclough and Gutiérrez 1990, p.741-742). The distribution of the Mexican subspecies (*S. o. lucida*) is separate from those of the northern and California (*S. o. occidentalis*) subspecies (Gutiérrez et al. 1995, p.2). Recent studies analyzing mitochondrial DNA sequences (Haig et al. 2004, p. 1354; Chi et al. 2004, p. 3; Barrowclough et al. 2005, p. 1117) and microsatellites (Henke et al., unpubl. data, p. 15) confirmed the validity of the current subspecies designations for northern and California spotted owls. The narrow hybrid zone between these two subspecies, which is located in the southern Cascades and northern Sierra Nevada, appears to be stable (Barrowclough et al. 2005, p. 1116).

Funk et al. (2008, pp. 1-11) tested the validity of the three current recognized subspecies of spotted owls and found them to be valid. During this genetics study, bi-directional hybridization and dispersal between northern spotted owls and California spotted owls centered in southern Oregon and northern California was discovered. In addition, a discovery of intro-regression of

Mexican spotted owls into the northernmost parts of the northern spotted owl populations in Washington was made, indicating long-distance dispersal of Mexican spotted owls into the northern spotted owl range (Funk et al. 2008, pp. 1-11). Some hybridization of northern spotted owls with barred owls has been recorded (Hamer et al. 1994, pp. 487-491; Dark et al. 1998, pp. 50-56; Kelly 2001, pp. 33, 38).

1.2.2 Physical Description

The northern spotted owl is a medium-sized owl and is the largest of the three subspecies of spotted owls (Gutiérrez et al. 1995, p. 2). It is approximately 46 to 48 centimeters (18 inches to 19 inches) long and the sexes are dimorphic, with males averaging about 13 percent smaller than females. The mean mass of 971 males taken during 1,108 captures was 580.4 grams (1.28 pounds) (out of a range 430.0 to 690.0 grams) (0.95 pound to 1.52 pounds), and the mean mass of 874 females taken during 1,016 captures was 664.5 grams (1.46 pounds) (out of a range 490.0 to 885.0 grams) (1.1 pounds to 1.95 pounds) (P. Loschl and E. Forsman, pers. comm. cited in USDI FWS 2011b, p. A-1). The northern spotted owl is dark brown with a barred tail and white spots on its head and breast, and it has dark brown eyes surrounded by prominent facial disks. Four age classes can be distinguished on the basis of plumage characteristics (Forsman 1981; Moen et al. 1991, p. 493). The northern spotted owl superficially resembles the barred owl, a species with which it occasionally hybridizes (Kelly and Forsman 2004, p. 807). Hybrids exhibit physical and vocal characteristics of both species (Hamer et al. 1994, p. 488).

1.2.3 Current and Historical Range

The current range of the spotted owl extends from southwest British Columbia through the Cascade Mountains, coastal ranges, and intervening forested lands in Washington, Oregon, and California, as far south as Marin County (USDI FWS 1990a, p. 26115). The range of the spotted owl is partitioned into 12 physiographic provinces (see Figure 1) based on recognized landscape subdivisions exhibiting different physical and environmental features (USDI FWS 2011b, p. III-1; Thomas et al. 1993). These provinces are distributed across the species' range as follows:

- Four provinces in Washington: Eastern Washington Cascades, Olympic Peninsula, Western Washington Cascades, Western Washington Lowlands

- Five provinces in Oregon: Oregon Coast Range, Willamette Valley, Western Oregon Cascades, Eastern Oregon Cascades, Oregon Klamath

- Three provinces in California: California Coast, California Klamath, California Cascades

The spotted owl is extirpated or uncommon in certain areas such as southwestern Washington and British Columbia. Timber harvest activities have eliminated, reduced or fragmented spotted owl habitat sufficiently to decrease overall population densities across its range, particularly within the coastal provinces where habitat reduction has been concentrated (USDI FWS 2011b, pp. B-1 to B-4; Thomas and Raphael 1993).

[1] Best model included age and even-odd year effects, but a competing model had a negative time effect on productivity.
[2] Variable among years, but with a declining trend.
[3] Decreasing in early years, increase in last 5 years, stable overall.
[4] Gradual declines in fecundity and apparent survival, plus estimates of realized population change suggest a decline in last 8 years.

Figure 1. Physiographic provinces, northern spotted owl demographic study areas, and demographic trends (Anthony et al. 2006).

1.2.4 Behavior

Northern spotted owls are primarily nocturnal (Forsman et al. 1984, pp. 51-52) and spend virtually their entire lives beneath the forest canopy (Courtney et al. 2004, p. 2-5). They are adapted to maneuverability beneath the forest canopy rather than strong, sustained flight (Gutiérrez et al. 1995, p. 9). They forage between dusk and dawn and sleep during the day with peak activity occurring during the two hours after sunset and the two hours prior to sunrise (Gutiérrez et al. 1995, p. 5; Delaney et al. 1999a, p. 44). They will sometimes take advantage of vulnerable prey near their roosts during the day (Layman 1991, pp. 138-140; Sovern et al. 1994, p. 202).

Northern spotted owls seek sheltered roosts to avoid inclement weather, summer heat, and predation (Forsman 1975, pp. 105-106; Barrows and Barrows 1978; Barrows 1981; Forsman et al. 1984, pp. 29-30). Northern spotted owls become stressed at temperatures above 28°C, but there is no evidence to indicate that they have been directly killed by temperature because of their ability to thermoregulate by seeking out shady roosts in the forest understory on hot days (Barrows and Barrows 1978; Forsman et al. 1984, pp. 29-30, 54; Weathers et al. 2001, pp. 678, 684). During warm weather, spotted owls seek roosts in shady recesses of understory trees and occasionally will even roost on the ground (Barrows and Barrows 1978, pp. 3, 7-8; Barrows 1981, pp. 302-306, 308; Forsman et al. 1984, pp. 29-30, 54; Gutiérrez et al. 1995, p. 7). Glenn et al. (2010, p. 2549) found that population growth was negatively associated with hot summer temperatures at their southernmost study area in the southern Oregon Cascades, indicating that warm temperatures may still have an effect on the species. Both adults and juveniles have been observed drinking water, primarily during the summer, which is thought to be associated with thermoregulation (Gutiérrez et al. 1995, p. 7).

Spotted owls are territorial; however, home ranges of adjacent pairs overlap (Forsman et al. 1984, p. 22; Solis and Gutiérrez 1990, p. 746) suggesting that the area defended is smaller than the area used for foraging. They will actively defend their nests and young from predators (Forsman 1975, p. 15; Gutiérrez et al. 1995, p. 11). Territorial defense is primarily effected by hooting, barking and whistle type calls. Some spotted owls are not territorial but either remain as residents within the territory of a pair or move among territories (Gutiérrez 1996, p. 4). These birds are referred to as “floaters.” Floaters have special significance in spotted owl populations because they may buffer the territorial population from decline (Franklin 1992, p. 822). Little is known about floaters other than that they exist and typically do not respond to calls as vigorously as territorial birds (Gutiérrez 1996, p. 4).

Spotted owls are monogamous and usually form long-term pair bonds. “Divorces” occur but are relatively uncommon. There are no known examples of polygyny in this owl, although associations of three or more birds have been reported (Gutiérrez et al. 1995, p. 10).

1.2.5 Habitat Relationships

<u>1.2.5.1 Home Range</u>

Home-range sizes vary geographically, generally increasing from south to north, which is likely a response to differences in habitat quality (USDI FWS 1990a, p. 26117). Estimates of median size of their annual home range (the area traversed by an individual or pair during their normal activities (Thomas and Raphael 1993, pp. IX-15)) vary by province and range from 2,955 acres in the Oregon Cascades (Thomas et al. 1990, p. 194) to 14,211 acres on the Olympic Peninsula (USDI FWS 1994a, p. 3). Zabel et al. (1995, p. 436) showed that these provincial home ranges are larger where flying squirrels are the predominant prey and smaller where wood rats are the predominant prey. Home ranges of adjacent pairs overlap (Forsman et al. 1984, p. 22; Solis and Gutiérrez 1990, p. 746), suggesting that the defended area is smaller than the area used for foraging. Within the home range there is a smaller area of concentrated use during the breeding season (approximately 20 percent of the home range), often referred to as the core area (Bingham and Noon 1997, pp. 133-135). Spotted owl core areas vary in size geographically and provide habitat elements that are important for the reproductive efficacy of the territory, such as the nest tree, roost sites and foraging areas (Bingham and Noon 1997, p. 134). Spotted owls use smaller home ranges during the breeding season and often dramatically increase their home range size during fall and winter (Forsman et al. 1984, pp. 21-22; Sisco 1990, p. iii).

Although differences exist in natural stand characteristics that influence home range size, habitat loss and forest fragmentation effectively reduce habitat quality in the home range. A reduction in the amount of suitable habitat reduces spotted owl abundance and nesting success (Bart and Forsman 1992, pp. 98-99; Bart 1995, p. 944).

1.2.5.2 Habitat Use and Selection

Forsman et al. (1984, pp.15-16) reported that spotted owls have been observed in the following forest types: Douglas-fir (*Pseudotsuga menziesii*), western hemlock (*Tsuga heterophylla*), grand fir (*Abies grandis*), white fir (*Abies concolor*), ponderosa pine (*Pinus ponderosa*), Shasta red fir (*Abies magnifica shastensis*), mixed evergreen, mixed conifer hardwood (Klamath montane), and redwood (*Sequoia sempervirens*). The upper elevation limit at which spotted owls occur corresponds to the transition to subalpine forest, which is characterized by relatively simple structure and severe winter weather (Forsman 1975, p. 27; Forsman et al. 1984, pp. 15-16).

Spotted owls generally rely on older forested habitats because such forests contain the structures and characteristics required for nesting, roosting, and foraging. Features that support nesting and roosting typically include a moderate to high canopy closure (60 to 90 percent); a multi-layered, multi-species canopy with large overstory trees (with diameter at breast height [dbh] of greater than 30 inches); a high incidence of large trees with various deformities (large cavities, broken tops, mistletoe infections, and other evidence of decadence); large snags; large accumulations of fallen trees and other woody debris on the ground; and sufficient open space below the canopy for spotted owls to fly (Thomas et al. 1990, p. 19). Forested stands with high canopy closure also provide thermal cover (Weathers et al. 2001, p. 686) and protection from predators (Franklin et al. 2000, p. 578).

Spotted owls nest almost exclusively in trees. Like roosts, nest sites are found in forests having complex structure dominated by large diameter trees (Forsman et al. 1984, p. 30; Hershey et al. 1998, p. 1402). Even in forests that have been previously logged, spotted owls select forests having a structure (i.e., larger trees, greater canopy closure) different than forests generally available to them (Folliard 1993, p. 40; Buchanan et al. 1995, p. 1402; Hershey et al. 1998, p. 1404).

Roost sites selected by spotted owls have more complex vegetation structure than forests generally available to them (Barrows and Barrows 1978, p. 3; Forsman et al. 1984, pp. 29-30; Solis and Gutiérrez 1990, pp. 742-743). These habitats are usually multi-layered forests having high canopy closure and large diameter trees in the overstory.

Foraging habitat is the most variable of all habitats used by territorial spotted owls (Thomas et al. 1990; USDI FWS 2011b, p. G-2). Descriptions of foraging habitat have ranged from complex structure (Solis and Gutiérrez 1990, pp. 742-744) to forests with lower canopy closure and smaller trees than forests containing nests or roosts (Gutiérrez 1996, p. 5). Foraging habitat for northern spotted owls provides a food supply for survival and reproduction. Foraging activity is positively associated with tree height diversity (North et al. 1999, p. 524), canopy closure (Irwin et al. 2000, p. 180; Courtney et al. 2004, pp. 5-15), snag volume, density of snags greater than 20 in (50 cm) dbh (North et al. 1999, p. 524; Irwin et al. 2000, pp. 179-180; Courtney et al. 2004, pp. 5-15), density of trees greater than or equal to 31 in (80 cm) dbh (North et al. 1999, p. 524), volume of woody debris (Irwin et al. 2000, pp. 179-180), and young forests with some structural characteristics of old forests (Carey et al.1992, pp. 245-247; Irwin et al. 2000, pp. 178-179). Northern spotted owls select old forests for foraging in greater proportion than their availability at the landscape scale (Carey et al. 1992, pp. 236-237; Carey and Peeler 1995, p. 235; Forsman et al. 2004, pp. 372-373), but will forage in younger stands with high prey densities and access to prey (Carey et al. 1992, p. 247; Rosenberg and Anthony 1992, p. 165; Thome et al. 1999, pp. 56-57).

Dispersal habitat is essential to maintaining stable populations by filling territorial vacancies when resident northern spotted owls die or leave their territories, and to providing adequate gene flow across the range of the species. Dispersal habitat, at a minimum, consists of stands with adequate tree size and canopy closure to provide protection from avian predators and at least minimal foraging opportunities (USDI FWS 2011b, p. G-1). Dispersal habitat may include younger and less diverse forest stands than foraging habitat, such as even-aged, pole-sized stands, but such stands should contain some roosting structures and foraging habitat to allow for temporary resting and feeding for dispersing juveniles (USDI FWS 2011b, p. G-1). Forsman et al. (2002, p. 22) found that spotted owls could disperse through highly fragmented forest landscapes. However, the stand-level and landscape-level attributes of forests needed to facilitate successful dispersal have not been thoroughly evaluated (Buchanan 2004, p. 1341).

Spotted owls may be found in younger forest stands that have the structural characteristics of older forests or retained structural elements from the previous forest. In redwood forests and mixed conifer-hardwood forests along the coast of northwestern California, considerable numbers of spotted owls also occur in younger forest stands, particularly in areas where hardwoods provide a multi-layered structure at an early age (Thomas et al. 1990, p. 158; Diller and Thome 1999, p. 275). In mixed conifer forests in the eastern Cascades in Washington, 27 percent of nest sites were in old-growth forests, 57 percent were in the understory reinitiation phase of stand development, and 17 percent were in the stem exclusion phase (Buchanan et al.

1995, p. 304). In the western Cascades of Oregon, 50 percent of spotted owl nests were in late-seral/old-growth stands (greater than 80 years old), and none were found in stands of less than 40 years old (Irwin et al. 2000, p. 41).

In the Western Washington Cascades, spotted owls roosted in mature forests dominated by trees greater than 50 centimeters (19.7 inches) dbh with greater than 60 percent canopy closure more often than expected for roosting during the non-breeding season. Spotted owls also used young forest (trees of 20 to 50 centimeters (7.9 inches to 19.7 inches) dbh with greater than 60 percent canopy closure) less often than expected based on this habitat's availability (Herter et al. 2002, p. 437).

In the Coast Ranges, Western Oregon Cascades and the Olympic Peninsula, radio-marked spotted owls selected for old-growth and mature forests for foraging and roosting and used young forests less than predicted based on availability (Forsman et al. 1984, pp. 24-25; Carey et al. 1990, pp. 14-15; Thomas et al. 1990; Forsman et al. 2005, pp. 372-373). Glenn et al. (2004, pp. 46-47) studied spotted owls in young forests in western Oregon and found little preference among age classes of young forest.

Habitat use is influenced by prey availability. Ward (1990, p. 62) found that spotted owls foraged in areas with lower variance in prey densities (that is, where the occurrence of prey was more predictable) within older forests and near ecotones of old forest and brush seral stages. Zabel et al. (1995, p. 436) showed that spotted owl home ranges are larger where flying squirrels (*Glaucomys sabrinus*) are the predominant prey and smaller where wood rats (*Neotoma* spp.) are the predominant prey.

Recent landscape-level analyses in portions of Oregon Coast and California Klamath provinces suggest that a mosaic of late-successional habitat interspersed with other seral conditions may benefit spotted owls more than large, homogeneous expanses of older forests (Zabel et al. 2003, p. 1038; Franklin et al. 2000, pp. 573-579; Meyer et al. 1998, p. 43). In Oregon Klamath and Western Oregon Cascade provinces, Dugger et al. (2005, p. 876) found that apparent survival and reproduction was positively associated with the proportion of older forest near the territory center (within 730 meters) (2,395 feet). Survival decreased dramatically when the amount of non-habitat (non-forest areas, sapling stands, etc.) exceeded approximately 50 percent of the home range (Dugger et al. 2005, pp. 873-874). The authors concluded that they found no support for either a positive or negative direct effect of intermediate-aged forest—that is, all forest stages between sapling and mature, with total canopy cover greater than 40 percent—on either the survival or reproduction of spotted owls. It is unknown how these results were affected by the low habitat fitness potential in their study area, which Dugger et al. (2005, p. 876) stated was generally much lower than those in Franklin et al. (2000) and Olson et al. (2004), and the low reproductive rate and survival in their study area, which they reported were generally lower than those studied by Anthony et al. (2006). Olson et al. (2004, pp. 1050-1051) found that reproductive rates fluctuated biennially and were positively related to the amount of edge between late-seral and mid-seral forests and other habitat classes in the central Oregon Coast Range. Olson et al. (2004, pp. 1049-1050) concluded that their results indicate that while mid-seral and late-seral forests are important to spotted owls, a mixture of these forest types with younger forest and non-forest may be best for spotted owl survival and reproduction in their study area. In a large-scale demography modeling study, Forsman et al. (2011, pp. 1-2) found a positive correlation between the amount of suitable habitat and recruitment of young.

1.2.6 Reproductive Biology

The spotted owl is relatively long-lived, has a long reproductive life span, invests significantly in parental care, and exhibits high adult survivorship relative to other North American owls (Forsman et al. 1984; Gutiérrez et al. 1995, p. 5). Spotted owls are sexually mature at 1 year of age, but rarely breed until they are 2 to 5 years of age (Miller et al. 1985, p. 93; Franklin 1992, p. 821; Forsman et al. 2002, p. 17). Breeding females lay one to four eggs per clutch, with the average clutch size being two eggs; however, most spotted owl pairs do not nest every year, nor are nesting pairs successful every year (USDI FWS 1990b; Forsman et al. 1984, pp. 32-34; Anthony et al. 2006, p. 28), and renesting after a failed nesting attempt is rare (Gutiérrez 1996, p. 4). The small clutch size, temporal variability in nesting success, and delayed onset of breeding all contribute to the relatively low fecundity of this species (Gutiérrez 1996, p. 4).

Courtship behavior usually begins in February or March, and females typically lay eggs in late March or April. The timing of nesting and fledging varies with latitude and elevation (Forsman et al. 1984, p. 32). After they leave the nest in late May or June, juvenile spotted owls depend on their parents until they are able to fly and hunt on their own. Parental care continues after fledging into September (USDI FWS 1990a; Forsman et al. 1984, p. 38). During the first few weeks after the young leave the nest, the adults often roost with them during the day. By late summer, the adults are rarely found roosting with their young and usually only visit the juveniles to feed them at night (Forsman et al. 1984, p. 38). Telemetry and genetic studies indicate that close inbreeding between siblings or parents and their offspring is rare (Haig et al. 2001, p. 35; Forsman et al. 2002, p. 18). Hybridization of northern spotted owls with California spotted owls and barred owls has been confirmed through genetic research (Hamer et al. 1994, pp. 487-492; Gutiérrez et al. 1995, pp. 2-3; Dark et al. 1998, p. 52; Kelly 2001, pp. 33-35; Funk et al. 2008, pp. 161-171).

1.2.7 Dispersal Biology

Natal dispersal of spotted owls typically occurs in September and October with a few individuals dispersing in November and December (Miller et al. 1997; Forsman et al. 2002, p. 13). Natal dispersal occurs in stages, with juveniles settling in temporary home ranges between bouts of dispersal (Forsman et al. 2002, pp. 13-14; Miller et al. 1997, p. 143). The median natal dispersal distance is about 10 miles for males and 15.5 miles for females (Forsman et al. 2002, p. 16). Dispersing juvenile spotted owls experience high mortality rates, exceeding 70 percent in some studies (USDI FWS 1990a; Miller 1989, pp. 32-41). Known or suspected causes of mortality during dispersal include starvation, predation, and accidents (Miller 1989, pp. 41-44; USDI FWS 1990a; Forsman et al. 2002, pp. 18-19). Parasitic infection may contribute to these causes of mortality, but the relationship between parasite loads and survival is poorly understood (Hoberg et al. 1989, p. 247; Gutiérrez 1989, pp. 616-617; Forsman et al. 2002, pp. 18-19). Successful dispersal of juvenile spotted owls may depend on their ability to locate unoccupied suitable habitat in close proximity to other occupied sites (LaHaye et al. 2001, pp. 697-698).

There is little evidence that small openings in forest habitat influence the dispersal of spotted owls, but large, non-forested valleys such as the Willamette Valley apparently are barriers to both natal and breeding dispersal (Forsman et al. 2002, p. 22). The degree to which water bodies, such as the Columbia River and Puget Sound, function as barriers to dispersal is unclear, although radio telemetry data indicate that spotted owls move around large water bodies rather than cross them (Forsman et al. 2002, p. 22). Analysis of the genetic structure of spotted owl populations suggests that gene flow may have been adequate between the Olympic Mountains and the Washington Cascades, and between the Olympic Mountains and the Oregon Coast Range (Haig et al. 2001, p. 35).

Breeding dispersal occurs among a small proportion of adult spotted owls; these movements were more frequent among females and unmated individuals (Forsman et al. 2002, pp. 20-21). Breeding dispersal distances were shorter than natal dispersal distances and also are apparently random in direction (Forsman et al. 2002, pp. 21-22). In California spotted owls, a similar subspecies, the probability for dispersal was higher in younger owls, single owls, paired owls that lost mates, owls at low quality sites, and owls that failed to reproduce in the preceding year (Blakesley et al. 2006, p.77). Both males and females dispersed at near equal distances (Blakesley et al. 2006, p. 76). In 72 percent of observed cases of dispersal, dispersal resulted in increased habitat quality (Blakesley et al. 2006, p. 77).

Dispersal can also be described as having two phases: transience and colonization (Courtney et al 2004, p. 5-13). Fragmented forest landscapes are more likely to be used by owls in the transience phase as a means to move rapidly between denser forest areas (Courtney et al 2004, p. 5-13; USDI FWS 2012, p. 14086). Movements through mature and old growth forests occur during the colonization phase when birds are looking to become established in an area (Miller et al 1997, p. 144; Courtney et al 2004, p. 5-13). Transient dispersers use a wider variety of forest conditions for movements than colonizing dispersers, who require habitats resembling nesting/roosting/foraging habitats used by breeding birds (USDI FWS 2012, p. 14086). Dispersal success is likely highest in mature and old growth forest stands where there is more likely to be adequate cover and food supply (USDI FWS 2012, p. 14086).

1.2.8 Food Habits

Spotted owls are mostly nocturnal, although they also forage opportunistically during the day (Forsman et al. 1984, p. 51; 2004, pp. 222-223; Sovern et al. 1994, p. 202). The composition of the spotted owl's diet varies geographically and by forest type. Generally, flying squirrels (*Glaucomys sabrinus*) are the most prominent prey for spotted owls in Douglas-fir and western hemlock (*Tsuga heterophylla*) forests (Forsman et al. 1984, pp. 40-41) in Washington and Oregon, while dusky-footed wood rats (*Neotoma fuscipes*) are a major part of the diet in the Oregon Klamath, California Klamath, and California Coastal provinces (Forsman et al. 1984, pp. 40-42; 2004, p. 218; Ward et al. 1998, p. 84; Hamer et al. 2001, p. 224). Depending on location, other important prey include deer mice (*Peromyscus maniculatus*), tree voles (*Arborimus longicaudus, A. pomo*), red-backed voles (*Clethrionomys* spp.), gophers (*Thomomys* spp.), snowshoe hare (*Lepus americanus*), bushy-tailed wood rats (*Neotoma cinerea*), birds, and insects, although these species comprise a small portion of the spotted owl diet (Forsman et al. 1984, pp. 40-43; 2004, p. 218; Ward et al. 1998; p. 84; Hamer et al. 2001, p.224).

Other prey species such as the red tree vole (*Arborimus longicaudus)*, red-backed voles (*Clethrionomys gapperi)*, mice, rabbits and hares, birds, and insects) may be seasonally or locally important (reviewed by Courtney et al. 2004, pp. 4-27). For example, Rosenberg et al. (2003, p. 1720) showed a strong correlation between annual reproductive success of spotted owls (number of young per territory) and abundance of deer mice (*Peromyscus maniculatus*) (r2 = 0.68), despite the fact they only made up 1.6±0.5 percent of the biomass consumed. However, it is unclear if the causative factor behind this correlation was prey abundance or a synergistic response to weather (Rosenberg et al. 2003, p. 1723). Ward (1990, p. 55) also noted that mice were more abundant in areas selected for foraging by owls. Nonetheless, spotted owls deliver larger prey to the nest and eat smaller food items to reduce foraging energy costs; therefore, the importance of smaller prey items, like *Peromyscus*, in the spotted owl diet should not be underestimated (Forsman et al. 2001, p. 148; 2004, pp. 218-219). In the southern portion of their range, where woodrats are a major component of their diet, northern spotted owls are more likely to use a variety of stands, including younger stands, brushy openings in older stands, and edges between forest types in response to higher prey density in some of these areas (Forsman et al. 1984, pp. 24-29).

1.2.9 Population Dynamics

The spotted owl is relatively long-lived, has a long reproductive life span, invests significantly in parental care, and exhibits high adult survivorship relative to other North American owls (Forsman et al. 1984; Gutiérrez et al. 1995, p. 5). The spotted owl's long reproductive life span allows for some eventual recruitment of offspring, even if recruitment does not occur each year (Franklin et al. 2000, p. 576).

Annual variation in population parameters for spotted owls has been linked to environmental influences at various life history stages (Franklin et al. 2000, p. 581). In coniferous forests, mean fledgling production of the California spotted owl (*Strix occidentalis occidentalis*), a closely related subspecies, was higher when minimum spring temperatures were higher (North et al. 2000, p. 805), a relationship that may be a function of increased prey availability. Across their range, spotted owls have previously shown an unexplained pattern of alternating years of high and low reproduction, with highest reproduction occurring during even-numbered years (e.g., Franklin et al. 1999, p. 1). Annual variation in breeding may be related to weather (i.e., temperature and precipitation) (Wagner et al. 1996, p. 74; Zabel et al. 1996, p.81 *In*: Forsman et al. 1996) and fluctuation in prey abundance (Zabel et al. 1996, pp.437-438).

A variety of factors may regulate spotted owl population levels. These factors may be density-dependent (e.g., habitat quality, habitat abundance) or density-independent (e.g., climate). Interactions may occur among factors. For example, as habitat quality decreases, density-independent factors may have more influence on survival and reproduction, which tends to increase variation in the rate of growth (Franklin et al. 2000, pp. 581-582). Specifically, weather could have increased negative effects on spotted owl fitness for those owls occurring in relatively lower quality habitat (Franklin et al. 2000, pp. 581-582). A consequence of this pattern is that at some point, lower habitat quality may cause the population to be unregulated (have negative growth) and decline to extinction (Franklin et al. 2000, p. 583).

Olson et al. (2005, pp. 930-931) used open population modeling of site occupancy that incorporated imperfect and variable detectability of spotted owls and allowed modeling of temporal variation in site occupancy, extinction, and colonization probabilities (at the site scale). The authors found that visit detection probabilities average less than 0.70 and were highly variable among study years and among their three study areas in Oregon. Pair site occupancy probabilities declined greatly on one study area and slightly on the other two areas. However, for all owls, including singles and pairs, site occupancy was mostly stable through time. Barred owl presence had a negative effect on these parameters (see barred owl discussion in the New Threats section below). However, there was enough temporal and spatial variability in detection rates to indicate that more visits would be needed in some years and in some areas, especially if establishing pair occupancy was the primary goal.

1.3 Threats

1.3.1 Reasons for Listing

The spotted owl was listed as threatened throughout its range "due to loss and adverse modification of suitable habitat as a result of timber harvesting and exacerbated by catastrophic events such as fire, volcanic eruption, and wind storms" (USDI FWS 1990a, p. 26114). More specifically, threats to the spotted owl included low populations, declining populations, limited habitat, declining habitat, inadequate distribution of habitat or populations, isolation of provinces, predation and competition, lack of coordinated conservation measures, and vulnerability to natural disturbance (USDI FWS 1992a, pp. 33-41). These threats were characterized for each province as severe, moderate, low, or unknown (USDI FWS 1992a, pp. 33-41). Declining habitat was recognized as a severe or moderate threat to the spotted owl throughout its range, isolation of populations was identified as a severe or moderate threat in 11 provinces, and a decline in population was a severe or moderate threat in 10 provinces. Together, these three factors represented the greatest concerns about range-wide conservation of the spotted owl. Limited habitat was considered a severe or moderate threat in nine provinces, and low populations were a severe or moderate concern in eight provinces, suggesting that these factors were also a concern throughout the majority of the spotted owl's range. Vulnerability to natural disturbances was rated as low in five provinces.

The degree to which predation and competition might pose a threat to the spotted owl was unknown in more provinces than any of the other threats, indicating a need for additional information. Few empirical studies exist to confirm that habitat fragmentation contributes to increased levels of predation on spotted owls (Courtney et al. 2004, pp. 11-8 to 11-9). However, great horned owls (*Bubo virginianus*), an effective predator on spotted owls, are closely associated with fragmented forests, openings, and clearcuts (Johnson 1992, p. 84; Laidig and Dobkin 1995, p. 155). As mature forests are harvested, great horned owls may colonize fragmented forests, thereby increasing spotted owl vulnerability to predation.

1.3.2 New Threats

The Service conducted a 5-year review of the spotted owl in 1994 (USDI FWS 2004), for which the Service prepared a scientific evaluation of the status of the spotted owl (Courtney et al.

2004). An analysis was conducted assessing how the threats described in 1990 might have changed by 2004. Some of the key threats identified in 2004 are:

- "Although we are certain that current harvest effects are reduced, and that past harvest is also probably having a reduced effect now as compared to 1990, we are still unable to fully evaluate the current levels of threat posed by harvest because of the potential for lag effects…In their questionnaire responses…6 of 8 panel member identified past habitat loss due to timber harvest as a current threat, but only 4 viewed current harvest as a present threat" (Courtney and Gutiérrez 2004, pp.11-7).

- "Currently the primary source of habitat loss is catastrophic wildfire, although the total amount of habitat affected by wildfires has been small (a total of 2.3 percent of the range-wide habitat base over a 10-year period)" (Courtney and Gutiérrez 2004, pp.11-8).

- "Although the panel had strong differences of opinion on the conclusiveness of some of the evidence suggesting [barred owl] displacement of [spotted owls], and the mechanisms by which this might be occurring, there was no disagreement that [barred owls] represented an operational threat. In the questionnaire, all 8 panel members identified [barred owls] as a current threat, and also expressed concern about future trends in [barred owl] populations" (Courtney and Gutiérrez 2004, pp. 11-8).

Threats, as identified in the 2011 Revised Recovery Plan for the Northern Spotted Owl, continue to emphasize that habitat loss and barred owls are the main threats to northern spotted owl recovery (USDI FWS 2011b, Appendix B).

1.3.2.1 Barred Owls (*Strix varia*)

With its recent expansion to as far south as Marin County, California (Gutiérrez et al. 2004, pp. 7-12 to 7-13; Steger et al. 2006, p.226), the barred owl's range now completely overlaps that of the northern spotted owl. Barred owls may be competing with spotted owls for prey (Hamer et al. 2001, p.226) or habitat (Hamer et al. 1989, p.55; Dunbar et al. 1991, p. 467; Herter and Hicks 2000, p. 285; Pearson and Livezey 2003, p. 274). In addition, barred owls physically attack spotted owls (Pearson and Livezey 2003, p. 274), and circumstantial evidence strongly indicated that a barred owl killed a spotted owl (Leskiw and Gutiérrez 1998, p. 226). Evidence that barred owls are causing negative effects on spotted owls is largely indirect, based primarily on retrospective examination of long-term data collected on spotted owls (Kelly et al. 2003, p. 46; Pearson and Livezey 2003, p. 267; Olson et al. 2005, p. 921). Recent research has shown that the two species of owls share similar habitats and are likely competing for food resources (Hamer et al. 2001, p. 226). Research on barred owls and their interactions with northern spotted owls is lacking, but necessary to determine the specific effects barred owls may have on northern spotted owls and their habitat. Forsman et al. (2011, pp. 69-70) found that the presence of barred owls led to a decrease in fecundity, apparent survival, and caused a decline in populations in most of the demography study areas included in their large scale modeling effort. However, given that the presence of barred owls has been identified as a negative effect while using methods designed to detect a different species (spotted owls), it seems safe to presume that the effects are stronger than estimated. Because there has been no research to evaluate quantitatively the strength of different types of competitive interactions, such as resource partitioning and competitive interference, the particular mechanism by which the two owl species may be competing is unknown.

Barred owls, though they are generalists, likely compete with northern spotted owls for prey resources (Hamer et al. 2001, p. 226; Gutiérrez et al. 2007, p. 187; Livezey and Fleming 2007, p. 319). The only study comparing northern spotted owl and barred owl food habits in the Pacific Northwest indicated that barred owl diets overlap strongly (76 percent) with northern spotted owl diets (Hamer et al. 2001, pp. 221, 226). Barred owl diets are more diverse than northern spotted owl diets and include species associated with riparian and other moist habitats (e.g. fish, invertebrates, frogs, and crayfish), along with more terrestrial and diurnal species (Smith et al. 1983; Hamer et al. 2001; Gronau 2005). Even though barred owls may be taking northern spotted owls' primary prey only as a generalist, northern spotted owls may be affected by a sufficient reduction in the density of these prey items due to barred owls, leading to a depletion of prey to the extent that the northern spotted owl cannot find an adequate amount of food to sustain maintenance or reproduction (Gutiérrez et al. 2007, p. 187; Livezey and Fleming 2007, p. 319).

Barred owls were initially thought to be more closely associated with early successional forests than spotted owls, based on studies conducted on the west slope of the Cascades in Washington (Hamer et al 1989, p. 34; Iverson 1993, p.39). However, recent studies conducted in the Pacific Northwest show that barred owls frequently use mature and old-growth forests (Pearson and Livezey 2003, p. 270; Gremel 2005, Schmidt 2006, p. 1; Singleton et al. 2010, pp. 290-292). In the fire prone forests of eastern Washington, a telemetry study conducted on barred owls showed that barred owl home ranges were located on lower slopes or valley bottoms, in closed canopy, mature, Douglas-fir forest, while spotted owl sites were located on mid-elevation areas with southern or western exposure, characterized by closed canopy, mature, ponderosa pine or Douglas-fir forest (Singleton et al. 2005, p. 1).

The presence of barred owls has been reported to reduce spotted owl detectability, site occupancy, reproduction, and survival. Olson et al. (2005, p. 924) found that the presence of barred owls had a significant negative effect on the detectability of spotted owls, and that the magnitude of this effect did not vary among years. The occupancy of historical territories by spotted owls in Washington and Oregon was significantly lower ($p < 0.001$) after barred owls were detected within 0.8 kilometer (0.5 miles) of the territory center but was "only marginally lower" ($p = 0.06$) if barred owls were located more than 0.8 kilometer (0.5 miles) from the spotted owl territory center (Kelly et al. 2003, p. 51). Pearson and Livezey (2003, p. 271) found that there were significantly more barred owl site-centers in unoccupied spotted owl circles than occupied spotted owl circles (centered on historical spotted owl site-centers) with radii of 0.8 kilometer (0.5 miles) ($p = 0.001$), 1.6 kilometer (1 mile) ($p = 0.049$), and 2.9 kilometer (1.8 miles) ($p = 0.005$) in Gifford Pinchot National Forest. In Olympic National Park, Gremel (2005, p. 11) found a significant decline ($p = 0.01$) in spotted owl pair occupancy at sites where barred owls had been detected, while pair occupancy remained stable at spotted owl sites without barred owls. Olson et al. (2005, p. 928) found that the annual probability that a spotted owl territory would be occupied by a pair of spotted owls after barred owls were detected at the site declined by 5 percent in the HJ Andrews study area, 12 percent in the Coast Range study area, and 15 percent in the Tyee study area. In contrast, Bailey et al. (2009, p. 2983), when using a two-species occupancy model, showed no evidence that barred owls excluded northern spotted owls from territories in Oregon. Most recently, preliminary results from a barred owl and northern spotted owl radio-telemetry study in Washington reported two northern spotted owls fleeing their territories and traveling six and 15 miles, believed to be as a result of frequent direct encounters with barred owls (Irwin et al. 2010, pp. 3-4). Both northern spotted owls were subsequently found dead (Irwin et al. 2010, p. 4).

Olson et al. (2004, p. 1048) found that the presence of barred owls had a significant negative effect on the reproduction of spotted owls in the central Coast Range of Oregon (in the Roseburg study area). The conclusion that barred owls had no significant effect on the reproduction of spotted owls in one study (Iverson 2004, p. 89) was unfounded because of small sample sizes (Livezey 2005, p. 102). It is likely that all of the above analyses underestimated the effects of barred owls on the reproduction of spotted owls because spotted owls often cannot be relocated after they are displaced by barred owls (E. Forsman, pers. comm., cited in USDI FWS 2011b, p. B-11). Anthony et al. (2006, p. 32) found significant evidence for negative effects of barred owls on apparent survival of spotted owls in two of 14 study areas (Olympic and Wenatchee). They attributed the equivocal results for most of their study areas to the coarse nature of their barred owl covariate. Dugger et al. (2011, pp. 2463-2467) confirmed the synergistic effects of barred owls and territory habitat characteristics on extinction and colonization rates of territories by northern spotted owls. Extinction rates of northern spotted owl territories nearly tripled when barred owls were detected (Dugger et al. 2011, p. 2464).

Monitoring and management of northern spotted owls has become more complicated due to their possible reduced detectability when barred owls are present (Kelly et al. 2003, pp. 51-52; Courtney et al. 2004, p. 7-16 ; Olson et al. 2005, p. 929; Crozier et al. 2006, p.766-767). Evidence that northern spotted owls were responding less frequently during surveys led the Service and its many research partners to update the northern spotted owl survey protocol. The recent changes to the northern spotted owl survey protocol were based on the probability of detecting northern spotted owls when barred owls are present (See USDI FWS Memorandum dated February 7, 2011, "2011 Northern Spotted Owl Survey Protocol" and attached "Protocol for Surveying Proposed Management Activities That May Impact Northern Spotted Owls" for guidance and methodology).

In a recent analysis of more than 9,000 banded spotted owls throughout their range, only 47 hybrids were detected (Kelly and Forsman 2004, p. 807). Consequently, hybridization with the barred owl is considered to be "an interesting biological phenomenon that is probably inconsequential, compared with the real threat—direct competition between the two species for food and space" (Kelly and Forsman 2004, p. 808).

Evidence suggests that barred owls are exacerbating the spotted owl population decline, particularly in Washington, portions of Oregon, and the northern coast of California (Gutiérrez et al. 2004, pp. 739-740; Olson et al. 2005, pp. 930-931). There is no evidence that the increasing trend in barred owls has stabilized in any portion of the spotted owl's range in the western United States, and "there are no grounds for optimistic views suggesting that barred owl impacts on northern spotted owls have been already fully realized" (Gutiérrez et al. 2004, pp. 7-38). In Oregon, Dugger et al. (2011, p. 2466) reported that some northern spotted owl pairs retained their territories and continued to survive and successfully reproduce during their study even when barred owls were present, but that the effects of reduced old growth forest in the core habitat areas were compounded when barred owls were present.

1.3.2.2 Wildfire

Studies indicate that the effects of wildfire on spotted owls and their habitat are variable, depending on fire intensity, severity, and size. Within the fire-adapted forests of the spotted owl's range, spotted owls likely have adapted to withstand fires of variable sizes and severities. However, fire is often considered a primary threat to spotted owls because of its potential to alter habitat rapidly (Bond et al. 2009, p. 1116) and is a major cause of habitat loss on Federal lands (Courtney et al. 2004, executive summary). Bond et al. (2002, p. 1025) examined the demography of the three spotted owl subspecies after wildfires, in which wildfire burned through spotted owl nest and roost sites in varying degrees of severity. Post-fire demography parameters for the three subspecies were similar or better than long-term demographic parameters for each of the three subspecies in those same areas (Bond et al. 2002, p. 1026). In a preliminary study conducted by Anthony and Andrews (2004, p. 8) in the Oregon Klamath Province, their sample of spotted owls appeared to be using a variety of habitats within the area of the Timbered Rock fire, including areas where burning had been moderate.

In 1994, the Hatchery Complex fire burned 17,603 hectares in the Wenatchee National Forest in Washington's eastern Cascades, affecting six spotted owl activity centers (Gaines et al. 1997, p. 125). Spotted owl habitat within a 2.9-kilometer (1.8-mile) radius of the activity centers was reduced by 8 to 45 percent (mean = 31 percent) as a result of the direct effects of the fire and by 10 to 85 percent (mean = 55 percent) as a result of delayed mortality of fire-damaged trees and insects. Direct mortality of spotted owls was assumed to have occurred at one site, and spotted owls were present at only one of the six sites 1 year after the fire (Gaines et al. 1997, p. 126). In 1994, two wildfires burned in the Yakama Indian Reservation in Washington's eastern Cascades, affecting the home ranges of two radio-tagged spotted owls (King et al. 1998, pp. 2-3). Although the amount of home ranges burned was not quantified, spotted owls were observed using areas that burned at low and medium intensities. No direct mortality of spotted owls was observed, even though thick smoke covered several spotted owl site-centers for a week. It appears that, at least in the short term, spotted owls may be resilient to the effects of wildfire—a process with which they have evolved. More research is needed to understand further the relationship between fire and spotted owl habitat use. Overall, we can conclude that fires are a change agent for northern spotted owl habitat, but there are still many unknowns regarding how much fire benefits or adversely affects northern spotted owl habitat (USDI FWS 2011b, p. III-31).

At the time of listing there was recognition that large-scale wildfire posed a threat to the spotted owl and its habitat (USDI FWS 1990a, p. 26183). New information suggests fire may be more of a threat than previously thought. In particular, the rate of habitat loss in the relatively dry East Cascades and Klamath provinces has been greater than expected (see "Habitat Trends" below). Moeur et al. (2005, p. 110) suggested that 12 percent of late-successional forest rangewide would likely be negatively impacted by wildfire during the first 5 decades of the Northwest Forest Plan.

Currently, the overall total amount of habitat affected by wildfires has been relatively small (Lint 2005, p. v). It may be possible to influence through silvicultural management how fire prone forests will burn and the extent of the fire when it occurs. Silvicultural management of forest fuels are currently being implemented throughout the spotted owl's range, in an attempt to reduce the levels of fuels that have accumulated during nearly 100 years of effective fire suppression. However, our ability to protect spotted owl habitat and viable populations of spotted owls from large fires through risk-reduction endeavors is uncertain (Courtney et al. 2004, pp. 12-11). The NWFP recognized wildfire as an inherent part of managing spotted owl habitat in certain portions of the range. The distribution and size of reserve blocks as part of the NWFP design may help mitigate the risks associated with large-scale fire (Lint 2005, p. 77).

1.3.2.4 West Nile Virus

West Nile virus (WNV), caused by a virus in the family Flaviviridae, has killed millions of wild birds in North America since it arrived in 1999 (McLean et al. 2001; Caffrey 2003; Caffrey and Peterson 2003, pp. 7-8; Marra et al. 2004, p. 393). Mosquitoes are the primary carriers (vectors) of the virus that causes encephalitis in humans, horses, and birds. Mammalian prey may also play a role in spreading WNV among predators, like spotted owls. Owls and other predators of mice can contract the disease by eating infected prey (Garmendia et al. 2000, p. 3111; Komar et al. 2001). One captive spotted owl in Ontario, Canada, is known to have contracted WNV and died.

Health officials expect that WNV will eventually spread throughout the range of the spotted owl (Courtney et al. 2004; Blakesley et al. 2004, pp. 8-31), but it is unknown how WNV will ultimately affect spotted owl populations. Susceptibility to infection and the mortality rates of infected individuals vary among bird species (Blakesley et al. 2004, pp. 8-33), but most owls appear to be quite susceptible. For example, breeding Eastern screech owls (*Megascops asio*) in Ohio experienced 100 percent mortality (T. Grubb pers. comm. in Blakesley et al. 2004, pp. 8-33). Barred owls, in contrast, showed lower susceptibility (B. Hunter pers. comm. in Blakesley et al. 2004, pp. 8-34). Some level of innate resistance may occur (Fitzgerald et al. 2003), which could explain observations in several species of markedly lower mortality in the second year of exposure to WNV (Caffrey and Peterson 2003). Wild birds also develop resistance to WNV through immune responses (Deubel et al. 2001). The effects of WNV on bird populations at a regional scale have not been large, even for susceptible species (Caffrey and Peterson 2003), perhaps due to the short-term and patchy distribution of mortality (K. McGowan, pers. comm., cited in Courtney et al. 2004) or annual changes in vector abundance and distribution.

Blakesley et al. (2004, pp. 8-35) offer competing propositions for the likely outcome of spotted owl populations being infected by WNV. One scenario is that spotted owls can tolerate severe, short-term population reductions due to WNV, because spotted owl populations are widely distributed and number in the several hundreds to thousands. An alternative scenario is that WNV will cause unsustainable mortality, due to the frequency and/or magnitude of infection, thereby resulting in long-term population declines and extirpation from parts of the spotted owl's current range. Thus far, no mortality in wild, northern spotted owls has been recorded; however, WNV is a potential threat of uncertain magnitude and effect (Blakesley et al. 2004, pp. 8-34).

1.3.2.5 Sudden Oak Death

Sudden oak death was recently identified as a potential threat to the spotted owl (Courtney et al. 2004). This disease is caused by the fungus-like pathogen, *Phytopthora ramorum* that was recently introduced from Europe and is rapidly spreading. The disease is now known to extend over 650 km from south of Big Sur, California to Curry County, Oregon (Rizzo and Garbelotto 2003, p. 198), and has reached epidemic proportions in oak (Quercus spp.) and tanoak (*Lithocarpus densiflorus*) forests along approximately 300 kilometers of the central and northern California coast (Rizzo et al. 2002, p. 733). At the present time, sudden oak death is found in natural stands from Monterey to Humboldt Counties, California, and has reached epidemic proportions in oak (*Quercus* spp.) and tanoak (*Lithocarpus densiflorus*) forests along approximately 300 km of the central and northern California coast (Rizzo et al. 2002, p. 733). It has also been found near Brookings, Oregon, killing tanoak and causing dieback of closely associated wild rhododendron (*Rhododendron* spp.) and evergreen huckleberry (*Vaccinium ovatum*) (Goheen et al. 2002, p. 441). It has been found in several different forest types and at elevations from sea level to over 800 m. During a study completed between 2001 and 2003 in California, one-third to one-half of the hiker's present in the study area carried infected soil on their shoes (Davidson et al. 2005, p. 587), creating the potential for rapid spread of the disease. Sudden oak death poses a threat of uncertain proportion because of its potential impact on forest dynamics and alteration of key prey and spotted owl habitat components (e.g., hardwood trees - canopy closure and nest tree mortality); especially in the southern portion of the spotted owl's range (Courtney et al. 2004, pp. 11-8).

1.3.2.6 Inbreeding Depression, Genetic Isolation, and Reduced Genetic Diversity

Inbreeding and other genetic problems due to small population sizes were not considered an imminent threat to the spotted owl at the time of listing. Recent studies show no indication of reduced genetic variation and past bottlenecks in Washington, Oregon, or California (Barrowclough et al. 1999, p. 922; Haig et al. 2004, p. 36). Canadian populations may be more adversely affected by issues related to small population size including inbreeding depression, genetic isolation, and reduced genetic diversity (Courtney et al. 2004, pp. 11-9). A 2004 study (Harestad et al. 2004, p. 13) indicates that the Canadian breeding population was estimated to be less than 33 pairs and annual population decline may be as high as 35 percent. In 2007, a recommendation was made by the Spotted Owl Population Enhancement Team to remove northern spotted owls from the wild in British Columbia (USDI FWS 2012, p. 14078). This recommendation resulted in the eventual capture of the remaining 16 wild northern spotted owls in British Columbia for a captive breeding program (USDI FWS 2012, p. 14078). Low and persistently declining populations throughout the northern portion of the species range (see "Population Trends" below) may be at increased risk of losing genetic diversity. Hybridization of northern spotted owls with California spotted owls, Mexican spotted owls, and barred owls has been confirmed through genetic research (Funk et al. 2008, p. 1; Hamer et al. 1994, p. 487; Gutiérrez et al. 1995, p. 3; Dark et al. 1998, p. 50; Kelly 2001, pp. 33-35).

1.3.2.7 Climate Change

Climate change, combined with effects from past management practices is influencing current forest ecosystem processes and dynamics by increasing the frequency and magnitude of wildfires, insect outbreaks, drought, and disease (USFWS 2011b, pp. III-5 - III-11). In the

Pacific Northwest, mean annual temperatures rose 0.8° C (1.5° F) in the 20th century and are expected to continue to warm from 0.1° to 0.6° C (0.2° to 1° F) per decade (Mote and Salathe 2010, p. 29). Climate change models generally predict warmer, wetter winters and hotter, drier summers and increased frequency of extreme weather events in the Pacific Northwest (Salathe et al. 2010, pp. 72-73).

Predicted climate changes in the Pacific Northwest have implications for forest disturbances that affect the quality and distribution of spotted owl habitat. Both the frequency and intensity of wildfires and insect outbreaks are expected to increase over the next century in the Pacific Northwest (Littell et al. 2010, p. 130). One of the largest projected effects on Pacific Northwest forests is likely to come from an increase in fire frequency, duration, and severity. Westerling et al. (2006, pp. 940-941) analyzed wildfires and found that since the mid-1980s, wildfire frequency in western forests has nearly quadrupled compared to the average of the period from 1970-1986. The total area burned is more than 6.5 times the previous level and the average length of the fire season during 1987-2003 was 78 days longer compared to 1978-1986 (Westerling et al. 2006, p. 941). The area burned annually by wildfires in the Pacific Northwest is expected to double or triple by the 2080s (Littell et al. 2010, p. 140). Wildfires are now the primary cause of spotted owl habitat loss on Federal lands, with over 236,000 acres of habitat loss attributed to wildfires from 1994 to 2007 (Davis et al. 2011, p. 123).

Potential changes in temperature and precipitation have important implications for spotted owl reproduction and survival. Wet, cold weather during the winter or nesting season, particularly the early nesting season, has been shown to negatively affect spotted owl reproduction (Olson et al. 2004, p. 1039, Dugger et al. 2005, p. 863), survival (Franklin et al. 2000 pp. 576-577, Olson et al. 2004, p. 1039, Glenn et al. 2011, p. 1279), and recruitment (Glenn et al. 2010, pp.2446-2547). Cold, wet weather may reduce reproduction and/or survival during the breeding season due to declines or decreased activity in small mammal populations so that less food is available during reproduction when metabolic demands are high (Glenn et al. 2011, pp. 1288-1289). Cold, wet nesting seasons may increase the mortality of nestlings due to chilling and reduce the number of young fledged per pair per year (Franklin et al. 2000, p.557, Glenn et al. 2011, p. 1286).

Drought or hot temperatures during the summer have also been linked to reduced spotted owl recruitment (Glenn et al. 2010, p. 2549). Drier, warmer summers and drought conditions during the growing season strongly influence primary production in forests, food availability, and the population sizes of small mammals that spotted owls prey upon (Glenn et al. 2010, p. 2549).

In summary, climate change is likely to exacerbate some existing threats to the spotted owl such as the projected potential for increased habitat loss from drought-related fire, tree mortality, insects and disease, as well as affecting reproduction and survival during years of extreme weather.

1.3.2.8 Disturbance

Northern spotted owls may also respond physiologically to a disturbance without exhibiting a significant behavioral response. In response to environmental stressors, vertebrates secrete stress hormones called corticosteroids (Campbell 1990, p. 925). Although these hormones are essential for survival, extended periods with elevated stress hormone levels may have negative effects on reproductive function, disease resistance, or physical condition (Carsia and Harvey 2000, pp. 517-518; Saplosky et al. 2000, p. 1). In avian species, the secretion of corticosterone is the primary non-specific stress response (Carsia and Harvey 2000, p. 517). The quantity of this hormone in feces can be used as a measure of physiological stress (Wasser et al. 1997, p. 1019). Recent studies of fecal corticosterone levels of northern spotted owls indicate that low intensity noise of short duration and minimal repetition does not elicit a physiological stress response (Tempel and Gutiérrez 2003, p. 698; Tempel and Gutiérrez 2004, p. 538). However, prolonged activities, such as those associated with timber harvest, may increase fecal corticosterone levels depending on their proximity to northern spotted owl core areas (Wasser et al. 1997, p.1021; Tempel and Gutiérrez 2004, p. 544).

The effects of noise on spotted owls are largely unknown, and whether noise is a concern has been a controversial issue. The effect of noise on birds is extremely difficult to determine due to the inability of most studies to quantify one or more of the following variables: 1) timing of the disturbance in relation to nesting chronology; 2) type, frequency, and proximity of human disturbance; 3) clutch size; 4) health of individual birds; 5) food supply; and 6) outcome of previous interactions between birds and humans (Knight and Skagan 1988, pp. 355-358). Additional factors that confound the issue of disturbance include the individual bird's tolerance level, ambient sound levels, physical parameters of sound, and how it reacts with topographic characteristics and vegetation, and differences in how species perceive noise.

Information specific to behavioral responses of spotted owls to disturbance is limited, research indicates that recreational activity can cause Mexican spotted owls (*S. o. lucida*) to vacate otherwise suitable habitat (Swarthout and Steidl 2001, p. 314) and helicopter overflights can reduce prey delivery rates to nests (Delaney et al. 1999, p. 70). Additional effects from disturbance, including altered foraging behavior and decreases in nest attendance and reproductive success, have been reported for other raptors (White and Thurow 1985, p. 14; Andersen et al. 1989, p. 296; McGarigal et al. 1991, p. 5).

Although it has not been conclusively demonstrated, it is anticipated that nesting spotted owls may be disturbed by heat and smoke as a result of burning activities during the breeding season.

1.4 Conservation Needs of the Spotted Owl

Based on the above assessment of threats, the spotted owl has the following habitat-specific and habitat-independent conservation (i.e., survival and recovery) needs:

1.4.1 Habitat-specific Needs

1. Large blocks of habitat capable of supporting clusters or local population centers of spotted owls (e.g., 15 to 20 breeding pairs) throughout the owl's range;

2. Suitable habitat conditions and spacing between local spotted owl populations throughout its range that facilitate survival and movement;

3. Suitable habitat distributed across a variety of ecological conditions within the northern spotted owl's range to reduce risk of local or widespread extirpation;

4. A coordinated, adaptive management effort to reduce the loss of habitat due to catastrophic wildfire throughout the spotted owl's range, and a monitoring program to clarify whether these risk reduction methods are effective and to determine how owls use habitat treated to reduce fuels; and

5. In areas of significant population decline, sustain the full range of survival and recovery options for this species in light of significant uncertainty.

1.4.2 Habitat-independent Needs

1. A coordinated research and adaptive management effort to better understand and manage competitive interactions between spotted and barred owls; and

2. Monitoring to understand better the risk that WNV and sudden oak death pose to spotted owls and, for WNV, research into methods that may reduce the likelihood or severity of outbreaks in spotted owl populations.

1.4.3 Conservation Strategy

Since 1990, various efforts have addressed the conservation needs of the spotted owl and attempted to formulate conservation strategies based upon these needs. These efforts began with the ISC's Conservation Strategy (Thomas et al. 1990); they continued with the designation of critical habitat (USDI FWS 1992a), the Draft Recovery Plan (USDI FWS 1992b), and the Scientific Analysis Team report (Thomas et al. 1993), report of the Forest Ecosystem Management Assessment Team (Thomas and Raphael 1993); and they culminated with the NWFP (USDA FS and USDI BLM 1994a). Each conservation strategy was based upon the reserve design principles first articulated in the ISC's report, which are summarized as follows:

- Species that are well distributed across their range are less prone to extinction than species confined to small portions of their range.

- Large blocks of habitat, containing multiple pairs of the species, are superior to small blocks of habitat with only one to a few pairs.

- Blocks of habitat that are close together are better than blocks far apart.

- Habitat that occurs in contiguous blocks is better than habitat that is more fragmented.

- Habitat between blocks is more effective as dispersal habitat if it resembles suitable habitat.

1.4.4 Federal Contribution to Recovery

Since it was signed on April 13, 1994, the NWFP has guided the management of Federal forest lands within the range of the spotted owl (USDA FS and USDI BLM 1994a, 1994b). The NWFP was designed to protect large blocks of old growth forest and provide habitat for species that depend on those forests including the spotted owl, as well as to produce a predictable and sustainable level of timber sales. The NWFP included land use allocations which would provide for population clusters of northern spotted owls (i.e., demographic support) and maintain connectivity between population clusters. Certain land use allocations in the plan contribute to supporting population clusters: LSRs, Managed Late-successional Areas, and Congressionally Reserved areas. Riparian Reserves, Adaptive Management Areas, and Administratively Withdrawn areas can provide both demographic support and connectivity/dispersal between the larger blocks, but were not necessarily designed for that purpose. Matrix areas were to support timber production while also retaining biological legacy components important to old-growth obligate species (in 100-acre owl cores, 15 percent late-successional provision, etc. (USDA FS and USDI BLM 1994a, USDI FWS 1994b) which would persist into future managed timber stands.

The NWFP with its rangewide system of LSRs was based on work completed by three previous studies (Thomas et. al. 2006): the 1990 Interagency Scientific Committee (ISC) Report (Thomas et. al. 1990), the 1991 report for the Conservation of Late-successional Forests and Aquatic Ecosystems (Johnson et. al. 1991), and the 1993 report of the Scientific Assessment Team (Thomas et. al. 1993). In addition, the 1992 Draft Recovery Plan for the Northern Spotted Owl (USDI FWS 1992b) was based on the ISC report.

The Forest Ecosystem Management Assessment Team predicted, based on expert opinion, the spotted owl population would decline in the Matrix land use allocation over time, while the population would stabilize and eventually increase within LSRs as habitat conditions improved over the next 50 to 100 years (Thomas and Raphael 1993, p. II-31; USDA FS and USDI BLM 1994a, 1994b, p. 3&4-229). Based on the results of the first decade of monitoring, Lint (2005, p. 18) could not determine whether implementation of the NWFP would reverse the spotted owl's declining population trend because not enough time had passed to provide the necessary measure of certainty. However, the results from the first decade of monitoring do not provide any reason to depart from the objective of habitat maintenance and restoration as described in the NWFP (Lint 2005, p. 18; Noon and Blakesley 2006, p. 288). Bigley and Franklin (2004, pp. 6-34) suggested that more fuels treatments are needed in east-side forests to preclude large-scale losses of habitat to stand-replacing wildfires. Other stressors that occur in suitable habitat, such as the range expansion of the barred owl (already in action) and infection with WNV (which may or may not occur) may complicate the conservation of the spotted owl. Recent reports about the status of the spotted owl offer few management recommendations to deal with these emerging threats. The arrangement, distribution, and resilience of the NWFP land use allocation system may prove to be the most appropriate strategy in responding to these unexpected challenges (Bigley and Franklin 2004, p. 6-34). The Revised Recovery Plan builds on the NWFP and recommends continued implementation of the NWFP and its standards and guides (USDI FWS 2011b, p. I-1).

Under the NWFP, the agencies anticipated a decline of spotted owl populations during the first decade of implementation. Recent reports (Courtney et al. 2004; Anthony et al. 2006, pp. 33-34) identified greater than expected spotted owl declines in Washington and northern portions of Oregon, and more stationary populations in southern Oregon and northern California. The reports did not find a direct correlation between habitat conditions and changes in vital rates of spotted owls at the meta-population scale. However, at the territory scale, there is evidence of negative effects to spotted owl fitness due to reduced habitat quantity and quality. Also, there is no evidence to suggest that dispersal habitat is currently limiting (Courtney et al. 2004, p. 9-12; Lint 2005, p. 87). Even with the population decline, Courtney et al (2004, p. 9-15) noted that there is little reason to doubt the effectiveness of the core principles underpinning the NWFP conservation strategy.

The current scientific information, including information showing northern spotted owl population declines, indicates that the spotted owl continues to meet the definition of a threatened species (USDI FWS 2004, p. 54). That is, populations are still relatively numerous over most of its historic range, which suggests that the threat of extinction is not imminent, and that the subspecies is not endangered; even though, in the northern part of its range population trend estimates are showing a decline.

On June 28, 2011 the Service published the Revised Recovery Plan for the Northern Spotted Owl (USDI FWS 2011b). The recovery plan identifies threats from competition with barred owls, ongoing loss of northern spotted owl habitat as a result of timber harvest, loss or modification of northern spotted owl habitat from uncharacteristic wildfire, and loss of amount and distribution of northern spotted owl habitat as a result of past activities and disturbances (USDI FWS 2011b, p. II-2 and Appendix B). To address these threats, the current recovery strategy identifies five main steps: 1) development of a range-wide habitat modeling framework; 2) barred owl management; 3) monitoring and research; 4) adaptive management; and 5) habitat conservation and active forest restoration (USDI FWS 2011b, p. II-2). The recovery plan lists recovery actions that address each of these items, some of which were retained from the 2008 recovery plan. The Managed Owl Conservation Areas and Conservation Support Areas recommended in the 2008 recovery plan are not a part of the recovery strategy outlined in the revised recovery plan. The Service completed a range-wide, multi-step habitat modeling process to help evaluate and inform management decisions and critical habitat development (USDI FWS 2011b, Appendix C).

The final recovery plan (USDI FWS 2011b) recommended implementing a robust monitoring and research program for the spotted owl. The recovery plan encourages these efforts by laying out the following primary elements to evaluate progress toward meeting recovery criteria: monitoring spotted owl population trends, comprehensive barred owl research and monitoring, continued habitat monitoring; inventory of spotted owl distribution, and; explicit consideration for climate change mitigation goals consistent with recovery actions (USDI FWS 2011b, p. II-5). The revised recovery plan also strongly encourages land managers to be aggressive in the implementation of recovery actions. In other words, land managers should not be so conservative that, to avoid risk, they forego actions that are necessary to conserve the forest ecosystems that are necessary to the long-term conservation of the spotted owl. But they should also not be so aggressive that they subject spotted owls and their habitat to treatments where the long-term benefits do not clearly outweigh the short-term risks. Finding the appropriate balance to this dichotomy will remain an ongoing challenge for all who are engaged in spotted owl conservation (USDI FWS 2011b, p. II-12). The revised recovery plan estimates that recovery of the spotted owl could be achieved in approximately 30 years (USDI FWS 2011b, p. II-3).

1.4.5 Conservation Efforts on Non-Federal Lands

In the report from the Interagency Scientific Committee (Thomas et al. 1990, p. 3, p. 272), the draft recovery plan (USDI FWS 1992b), and the report from the Forest Ecosystem Management Assessment Team (Thomas and Raphael 1993, p. IV-189), it was noted that limited Federal ownership in some areas constrained the ability to form a network of old-forest reserves to meet the conservation needs of the spotted owl. In these areas in particular, non-Federal lands would be important to the range-wide goal of achieving conservation and recovery of the spotted owl. The U.S. Fish and Wildlife Service's primary expectations for private lands are for their contributions to demographic support (pair or cluster protection) to Federal lands, or their connectivity with Federal lands. In addition, timber harvest within each state is governed by rules that provide protection of spotted owls or their habitat to varying degrees.

There are 17 current and ongoing conservation plans (CPs) including Habitat Conservation Plans (HCPs) and Safe Harbor Agreements (SHAs) that have incidental take permits issued for northern spotted owls—eight in Washington, three in Oregon, and six in California (USDI FWS 2011b, p. A-15). The CPs range in size from 76 acres to more than 1.8 million acres, although not all acres are included in the mitigation for northern spotted owls. In total, the CPs cover approximately 3 million acres (9.4 percent) of the 32 million acres of non-Federal forest lands in the range of the northern spotted owl. The period of time that the HCPs will be in place ranges from 20 to 100 years. While each CP is unique, there are several general approaches to mitigation of incidental take:

- Reserves of various sizes, some associated with adjacent Federal reserves
- Forest harvest that maintains or develops nesting habitat
- Forest harvest that maintains or develops foraging habitat
- Forest management that maintains or develops dispersal habitat
- Deferral of harvest near specific sites

Washington. In 1996, the State Forest Practices Board adopted rules (Washington Forest Practices Board 1996) that would contribute to conserving the spotted owl and its habitat on non-Federal lands. Adoption of the rules was based in part on recommendations from a Science Advisory Group that identified important non-Federal lands and recommended roles for those lands in spotted owl conservation (Hanson et al. 1993, pp. 11-15; Buchanan et al. 1994, p. ii). The 1996 rule package was developed by a stakeholder policy group and then reviewed and approved by the Forest Practices Board (Buchanan and Swedeen 2005, p. 9). Spotted owl-related HCPs in Washington generally were intended to provide demographic or connectivity support (USDI FWS 1992b, p. 272). There are over 2.1 million acres of land in six HCPs and two SHAs (USDI FWS 2011b, p. A-15). Some of these CPs focus on providing nesting/roosting habitat throughout the area or in strategic locations; while others focus on providing connectivity through foraging habitat and/or dispersal habitat. In addition, there is a long term habitat management agreement covering 13,000 acres in which authorization of take was provided through an incidental take statement (section 7) associated with a Federal land exchange (USDI FWS 2011b, p. A-15).

Oregon. The Oregon Forest Practices Act provides for protection of 70-acre core areas around sites occupied by an adult pair of spotted owls capable of breeding (as determined by recent protocol surveys), but it does not provide for protection of spotted owl habitat beyond these areas (Oregon Department of Forestry 2007, p. 64). In general, no large-scale spotted owl habitat protection strategy or mechanism currently exists for non-Federal lands in Oregon. The three spotted owl-related HCPs currently in effect cover more than 300,000 acres of non-Federal lands. These HCPs are intended to provide some nesting habitat and connectivity over the next few decades (USDI FWS 2011b, p. A-16). On July 27, 2010, the Service completed a programmatic SHA with the Oregon Department of Forestry that will enroll up to 50,000 acres of non-federal lands within the State over 50 years. The primary intent of this programmatic SHA is to increase time between harvests and to lightly to moderately thin younger forest stands that are currently not habitat to increase tree diameter and stand diversity (USDI FWS 2011b, p. A-16).

California. The California State Forest Practice Rules, which govern timber harvest on private lands, require surveys for spotted owls in suitable habitat and to provide protection around activity centers (California Department of Forestry and Fire Protection 2007, pp. 85-87). Under the Forest Practice Rules, no timber harvest plan can be approved if it is likely to result in incidental take of federally listed species, unless the take is authorized by a Federal incidental take permit (California Department of Forestry and Fire Protection 2007, pp. 85-87). The California Department of Fish and Game initially reviewed all timber harvest plans to ensure that take was not likely to occur; the U.S. Fish and Wildlife Service took over that review function in 2000. Several large industrial owners operate under spotted owl management plans that have been reviewed by the U.S. Fish and Wildlife Service and that specify basic measures for spotted owl protection. Four HCPs and two SHAs authorizing take of spotted owls have been approved; these HCPs cover more than 622,000 acres of non-Federal lands. Implementation of these plans is intended to provide for spotted owl demographic and connectivity support to NWFP lands (USDI FWS 2011b, p. A-16).

1.5 Current Condition of the Spotted Owl

The current condition of the species incorporates the effects of all past human activities and natural events that led to the present-day status of the species and its habitat (USDI FWS and USDC NMFS 1998, pp. 4-19).

1.5.1 Range-wide Habitat and Population Trends

1.5.1.1 Range-wide Habitat Baseline

The Service has used information provided by the USFS, BLM, and National Park Service to update the habitat baseline conditions by tracking relative habitat changes over time on Federal lands for northern spotted owls on several occasions, since the northern spotted owl was listed in 1990 (USDA and USDI 1994b, USDI 2001, Lint 2005, Davis et al. 2011). The estimate of 7.4 million acres used for the NWFP in 1994 (USDA and USDI 1994b) was believed to be representative of the general amount of northern spotted owl habitat on NWFP lands at that time. The most recent mapping effort (Davis et al. 2011, Appendix D, Table D) indicates approximately 8.85 million acres of spotted owl nesting/roosting habitat existed on Federal lands and 4.19 million acres existed on non-federal lands at the beginning of the NWFP in 1994/1996. Davis et al. (2011, pp. 28-30) further evaluated changes in spotted owl nesting/roosting habitat using data from California that covered 14 years from 1994 to 2007, and data from Oregon and Washington that covered 10 years from 1996 to 2006. Although the spatial resolution of this new habitat map currently makes it unsuitable for tracking habitat effects at the scale of individual projects, the Service has evaluated the map for use in tracking provincial and range-wide habitat trends and now considers these data as the best available information on the distribution and abundance of extant spotted owl habitat within its range as of 2006 for Oregon and Washington, and 2007 for California, when the base imagery was collected.

Periodic range-wide evaluations of habitat, as compared to the Final Supplemental Environmental Impact Statement (FSEIS; USDA and USDI 1994b), are necessary to determine if the rate of potential change to northern spotted owl habitat is consistent with the change anticipated in the NWFP: a reduction in suitable habitat of approximately 2.5 percent per decade (USDA and USDI 1994a, p. 46). In particular, the Service considers habitat effects that are documented through the section 7 consultation process since 1994. In general, the analytical framework of these consultations focuses on the reserve and connectivity goals established by the NWFP land-use allocations (USDA and USDI 1994a), with effects expressed in terms of changes in suitable northern spotted owl habitat within those land-use allocations.

In 2001, the Service conducted the first assessment of habitat baseline conditions since implementation of the NWFP (USDI 2001). The Service determined that actions and effects were consistent with the expectations for implementation of the NWFP from 1994 to June 2001 (USDI 2001). April 13, 2004, marked the start of the second decade of the NWFP. Decade-specific baselines and summaries of effects by State, physiographic province and land use function from proposed management activities and natural events are not provided here, but are consistent with expected habitat changes under the NWFP.

In February 2013, the Service adopted the 2006/07 satellite imagery data on spotted owl habitat as the new range-wide habitat baseline for Federal lands which effectively resets the timeframe for establishing changes in the distribution and abundance of spotted owl habitat. On that basis, the assessment of local, provincial and range-wide spotted owl habitat status in this and future Opinions as well as Biological Assessments will rely on these 2006/07 habitat data to characterize changes in the status of spotted owl habitat.

1.5.1.2 Service's Consultation Database

To update information considered in 2001 (USDI 2001), the Service designed the Consultation Effects Tracking System database in 2002, which recorded impacts to northern spotted owls and their habitat at different spatial and temporal scales. In 2011, the Service replaced the Consultation Effects Tracking System with the Consulted on Effects Database located in the Service's Environmental Conservation Online System (ECOS). The ECOS Database corrected technical issues with the Consultation Effects Tracking System. Data are currently entered into the ECOS Database under various categories including; land management agency, land-use allocation, physiographic province, and type of habitat affected.

1.5.1.3 Range-wide Consultation Effects: 1994 to October 24, 2013

Between 1994 and October 24, 2013, the Service has consulted on the proposed removal/downgrade of approximately 708,155 acres (Table A1) or eight percent of the 8.854 million acres of northern spotted owl nesting/roosting habitat estimated by Davis et al. (2011) to have occurred on Federal lands (Table A1). These changes in suitable northern spotted owl habitat are consistent with the expectations for implementation of the NWFP, which anticipated a rate of habitat harvested at 2.5 percent per decade (USFS and BLM 1994a).

The Service tracks habitat changes on non-NWFP lands through consultations for long-term Habitat Conservation Plans, Safe Harbor Agreements, or Tribal Forest Management Plans. Service consultations conducted since 1992 have documented the eventual loss of over 507,169 acres habitat on non-NWFP lands. Most of these losses have yet to be realized because they are part of large-scale, long-term Habitat Conservation Plans. However, the NWFP 15 year monitoring report documented habitat losses on non-federal lands associated with timber harvest continues to occur at a rate of approximately 2 percent per year in Oregon and Washington, and at a lesser rate in California (Davis et al. 2011, pp. 123-124).

Table A1. NWFP Timeframe - Consulted on actions by land ownership

Thu Oct 24 14:44:32 MDT 2013

Land Ownership	Consulted On Habitat Changes[2]		Other Habitat Changes[3]	
	Removed/ Downgraded	Maintained/ Improved	Removed/ Downgraded	Maintained/ Improved
NWFP (FS,BLM,NPS)	200,986	542,456	246,112	39,720
Bureau of Indian Affairs / Tribes	111,627	28,372	2,398	0
Habitat Conservation Plans/Safe Harbor Agreements	326,868	27,208	N/A	N/A
Other Federal, State, County, Private Lands	68,674	28,433	2,392	0
Total Changes	**708,155**	**626,469**	**250,902**	**39,720**

Notes:

1. Nesting, roosting, foraging (NRF) habitat. In California, suitable habitat is divided into two components; nesting - roosting (NR) habitat, and foraging (F) habitat. The NR component most closely resembles NRF

habitat in Oregon and Washington. Due to differences in reporting methods, effects to suitable habitat compiled in this, and all subsequent tables include effects for nesting, roosting, and foraging (NRF) for 1994-6/26/2001. After 6/26/2001 suitable habitat includes NRF for Washington and Oregon but only nesting and roosting (NR) for California.

2. Includes both effects reported in USFWS 2001 and subsequent effects reported in the Northern Spotted Owl Consultation Effects Tracking System (web application and database.). Note consulted on effects to NSO habitat (NR and F) for Fruit Growers' HCP is included in these totals, but has not yet been entered into the web application database.
3. Includes effects to suitable NRF habitat (as generally documented through technical assistance, etc.) resulting from wildfires (not from suppression efforts), insect and disease outbreaks, and other natural causes, private timber harvest, and land exchanges not associated with consultation.

1.5.1.4 Range-wide Consultation Effects: 2006/2007 to October 24, 2013

The Service updated the ECOS Database to reflect the 2006/2007 habitat baseline developed for the NWFP 15-year monitoring report (Davis et al. 2011, Appendix D, Table D). This mapping effort accounted for habitat loss due to wildfire, harvest, insects and disease, and indicates approximately 8.555 million acres of spotted owl nesting/roosting habitat existed on Federal lands in 2006/2007. Because the data developed for the NWFP monitoring program is only current through 2006/2007, the Service continues to rely on information compiled in the spotted owl consultation database to summarize current owl habitat trends at provincial and range-wide scales.

Table A2 summarizes the habitat impacts on Federal lands that have occurred since 2006/2007 through October 24, 2013. The effects from 2013 fires were not available for the preparation of this biological opinion. To date, an estimated 100,700 acres of nesting, roosting, and foraging habitat has been lost from Federal lands since 2006/2007 due to land management activities and natural events. When overall habitat loss is evaluated as a proportion of provincial baselines, the Oregon Cascades and the California Klamath provinces have proportional losses greater than the loss of habitat across all provinces. Effects have varied among the individual provinces; most of the impacts are due to management-related actions and are concentrated within the 'Non-Reserves' land-use allocations. When habitat loss is evaluated as a proportion of the affected acres range-wide, the most pronounced losses have occurred from management activities within Oregon (85 percent of total habitat removed range-wide; especially within its Cascades West and Cascades East provinces). Wildland fires have resulted in considerable loss of NRF habitat within the California Klamath Province (about 40 percent of total lost habitat range-wide).).

Table A2. Summary of northern spotted owl suitable habitat (NRF[1]) acres removed or downgraded as documented through Section 7 consultations on all Federal Lands within the Northwest Forest Plan area. Environmental baseline and summary of effects by State, Physiographic Province, and Land Use Function from 2006 to present.

Thu Oct 24 14:54:51 MDT 2013

State	Physiographic Province[2]	Evaluation Baseline (2006/2007)[3]			Habitat Removed/Downgraded[4]							% Provincial Baseline Affected	% Range-wide Effects

Notes:

1. Nesting, roosting, foraging (NRF) habitat. In WA/OR, the values for Nesting/Roosting habitat generally represent the distribution of suitable owl habitat, including foraging habitat. In CA, foraging habitat occurs in a much broader range of forest types than what is represented by nesting/roosting habitat. Baseline information for foraging habitat as a separate category in CA is currently not available at a provincial scale.
2. Defined in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) as Recovery Units as depicted on page A-3.
3. Spotted owl nesting and roosting habitat on all Federal lands (includes USFS, BLM, NPS, DoD, USFWS, etc.) as reported by Davis et al. 2011 for the the Northwest Forest Plan 15-Year Monitoring Report (PNW-GTR-80, Appendix D). NR habitat acres are approximate values based on 2006 (OR/WA) and 2007 (CA) satellite imagery.

4. Estimated NRF habitat removed or downgraded from land management (timber sales) or natural events (wildfires) as documented through section 7 consultation or technical assistance. Effects reported here include all acres removed or downgraded from 2006 to present. Effects in California reported here only include effects to Nesting/Roosting habitat. Foraging habitat removed or downgraded in California is not summarized in this table. 2013 fire effects have not been reported at the date of this biological opinion.
5. Reserve land use allocations under the NWFP intended to provide demographic support for spotted owls include LSR, MLSA, and CRA. Non-reserve allocations under the NWFP intended to provide dispersal connectivity between reserves include AWA, AMA, and MX.

Table A3: Summary of northern spotted owl suitable habitat (NRF)[1] acres removed or downgraded on Federal lands within the Northwest Forest Plan area through timber harvest, natural disturbance, or other management actions as documented through section 7 consultation and technical assistance. Range-wide changes by land-use function from 2006 to present. Fri Oct 25 18:25:20 MDT 2013

Suitable Habitat (NRF) Effects	Reserves (LSR, MLSA, CRA)[3]	Non-reserves (AWA, AMA, Matrix)[3]	Totals
Evaluation Baseline (2006/2007)[2]	5,961,000	2,594,200	8,555,200
Removed/Downgraded (timber harvest only)[4]	8,011	37,214	45,225
Removed/Downgraded (other management activities)[5]	2,257	1,946	4,203
Subtotal	10,268	39,160	49,428
Removed/Downgraded (natural disturbance)[6]	28,598	22,698	51,296
Total Net Change	38,866	61,858	100,724
Baseline Balance	**5,922,134**	**2,532,342**	**8,454,476**
Habitat Maintained[7]	36,955	58,498	95,453

Notes:

1. Nesting, roosting, foraging (NRF) habitat. In WA/OR, the values for Nesting/Roosting habitat generally represent the distribution of suitable owl habitat, including foraging habitat. In CA, foraging habitat occurs in a much broader range of forest types than what is represented by nesting/roosting habitat. Baseline information for foraging habitat as a separate category in CA is currently not available at a provincial scale. Effects to spotted owl habitat in California reported here include effects to Nesting/Roosting habitat only. Foraging habitat removed or downgraded in California is not summarized in this table.
2. Spotted owl nesting and roosting habitat on all Federal lands (includes USFS, BLM, NPS, DoD, USFWS, etc.) as reported by Davis et al. 2011 for the the Northwest Forest Plan 15-Year Monitoring Report (PNW-GTR-80, Appendix D). NR habitat acres are approximate values based on 2006 (OR/WA) and 2007 (CA) imagery.
3. Reserve land use allocations under the NWFP intended to provide demographic support for spotted owls include LSR, MLSA, and CRA. Non-reserve allocations under the NWFP intended to provide dispersal connectivity between reserves include AWA, AMA, and MX.
4. NRF habitat removed or downgraded from timber harvest on Federal lands.
5. NRF habitat removed or downgraded from recreation, roads, minerals, or other non-timber programs.
6. NRF habitat losses resulting from wildfires, insect and disease, windthrow or other natural causes.
7. Habitat maintained means that stands have been modified by management, but the habitat function remains the same.

1.5.1.5 Other Habitat Trend Assessments

In 2005, the Washington Department of Wildlife released the report, "An Assessment of Spotted Owl Habitat on Non-Federal Lands in Washington between 1996 and 2004" (Pierce et al. 2005). This study estimates the amount of spotted owl habitat in 2004 on lands affected by state and private forest practices. The study area is a subset of the total Washington forest practice lands, and statistically-based estimates of existing habitat and habitat loss due to fire and timber harvest are provided. In the 3.2-million acre study area, Pierce et al. (2005) estimated there was 816,000 acres of suitable spotted owl habitat in 2004, or about 25 percent of their study area. Based on their results, Pierce et al. (2005) estimated there were less than 2.8 million acres of spotted owl habitat in Washington on all ownerships in 2004. Most of the suitable owl habitat in 2004 (56%) occurred on Federal lands, and lesser amounts were present on state-local lands (21%), private lands (22%) and tribal lands (1%). Most of the harvested spotted owl habitat was on private (77%) and state-local (15%) lands. A total of 172,000 acres of timber harvest occurred in the 3.2 million-acre study area, including harvest of 56,400 acres of suitable spotted owl habitat. This represented a loss of about 6 percent of the owl habitat in the study area distributed across all ownerships (Pierce et al. 2005). Approximately 77 percent of the harvested habitat occurred on private lands and about 15 percent occurred on State lands. Pierce and others (2005) also evaluated suitable habitat levels in 450 spotted owl management circles (based on the provincial annual median spotted owl home range). Across their study area, they found that owl circles averaged about 26 percent suitable habitat in the circle across all landscapes. Values in the study ranged from an average of 7 percent in southwest Washington to an average of 31 percent in the east Cascades, suggesting that many owl territories in Washington are significantly below the 40 percent suitable habitat threshold used by the State as a viability indicator for spotted owl territories (Pierce et al. 2005).

Moeur et al. 2005 estimated an increase of approximately 1.25 to 1.5 million acres of medium and large older forest (greater than 20 inches dbh, single and multi-storied canopies) on Federal lands in the NWFP area between 1994 and 2003. The increase occurred primarily in the lower end of the diameter range for older forest. In the greater than 30 inch dbh size class, the net area increased by only an estimated 102,000 to 127,000 acres (Moeur et al. 2005). The estimates were based on change-detection layers for losses due to harvest and fire and re-measured inventory plot data for increases due to ingrowth. Transition into and out of medium and large older forest over the 10-year period was extrapolated from inventory plot data on a subpopulation of Forest Service land types and applied to all Federal lands. Because size class and general canopy layer descriptions do not necessarily account for the complex forest structure often associated with northern spotted owl habitat, the significance of these acres to northern spotted owl conservation remains unknown.

In 2011, Davis *et al.* produced the second in a series of monitoring reports on northern spotted owl population and habitat trends on Northwest Forest Plan administered lands. They summarized demographic analyses from Forsman *et al.* (2011) discussed below under trends in numbers, distribution and reproduction, and reported on a new effort using remotely sensed data from 1994 to 2007 to develop "habitat suitability" models, and ultimately suitable habitat maps for the entire range of the northern spotted owl for each of these time periods. They also created change-detection maps and reported on the cause of habitat change during this time period. The authors suggest that because of improvements in remotely sensed vegetation, and change-detection mapping, their habitat maps represent the best available information and should replace the baseline versions used for the first monitoring report. Davis *et al*. (2011) estimated 8.9 million acres of suitable habitat for the 1994 baseline map, as compared to 7.4 million acres estimated by FEMAT in 1994, and 10.3 million acres estimated by Davis and Lint (2005) for the 10-year report.

Davis *et al*. (2011) were not able to report on gains in nesting/roosting habitat suitability due to issues with current technology, and the need for additional time to capture the slow process of forest succession. However, they were able to report on gains in recruitment of younger forests or dispersal habitat. They estimated a gain of about 1.26 million ac of dispersal habitat, with the greatest increases in nonreserves than reserves. The largest increase in dispersal habitat was in the Oregon Coast Range province.

Davis *et al*. (2011) estimated that nesting/roosting habitat declined by 3.4 percent (298,600 ac) rangewide on federal lands since 1994, which is less than the anticipated rate of habitat loss under the NWFP of 5 percent per decade. Most of the loss (79 percent) occurred within reserves and was the result of wildfires. Wildfires also were responsible for about half of the loss in nonreserves. Timber harvest accounted for about 45 percent (37,400 ac) in nonreserves, and 7 percent (16,000 ac) in reserves. The Oregon Klamath province lost the most nesting/roosting habitat (93,730 ac) due to the Biscuit Fire in 2002. They estimated a rangewide loss of about 417,000 ac of dispersal habitat, but like nesting/roosting habitat, most of the loss of dispersal habitat was due to wildfire.

Davis *et al*. (2011) created a wildfire suitability (likelihood) map for large fires throughout the range of the northern spotted owl. Their goal was to identify landscape-scale areas where large wildfires are more probable. They report that the California Klamath province has the most owl habitat in fire-prone landscapes, followed by the Oregon Western Cascades and Oregon Klamath provinces.

1.5.2 Spotted Owl Population Trends and Distribution

There are no estimates of the historical population size and distribution of spotted owls, although they are believed to have inhabited most old-growth forests throughout the Pacific Northwest prior to modern settlement (mid-1800s), including northwestern California (USFWS 1989, pp. 2-17).

The current range of the spotted owl extends from southwest British Columbia through the Cascade Mountains, coastal ranges, and intervening forested lands in Washington, Oregon, and California, as far south as Marin County (USDI FWS 1990a, p. 26114). The range of the spotted owl is partitioned into 12 physiographic provinces (Figure 1) based on recognized landscape subdivisions exhibiting different physical and environmental features (USFWS 1992a, p. 31). The spotted owl has become rare in certain areas, such as British Columbia, southwestern Washington, and the northern coastal ranges of Oregon.

As of July 1, 1994, there were 5,431 known site-centers of spotted owl pairs or resident singles: 851 sites (16 percent) in Washington, 2,893 sites (53 percent) in Oregon, and 1,687 sites (31 percent) in California (USDI FWS 1995, p. 9495). The actual number of currently occupied spotted owl locations across the range is unknown because many areas remain unsurveyed (USFWS 2011b, p. A-2). In addition, many historical sites are no longer occupied because spotted owls have been displaced by barred owls, timber harvest, or severe fires, and it is possible that some new sites have been established due to reduced timber harvest on Federal lands since 1994. The totals above represent the cumulative number of locations recorded in the three states, not population estimates.

Because the existing survey coverage and effort are insufficient to produce reliable range-wide estimates of population size, demographic data are used to evaluate trends in spotted owl populations. Analysis of demographic data can provide an estimate of the finite rate of population change (λ), which provides information on the direction and magnitude of population change. A λ of 1.0 indicates a stationary population, meaning the population is neither increasing nor decreasing. A λ of less than 1.0 indicates a decreasing population, and a λ of greater than 1.0 indicates a growing population. Demographic data, derived from studies initiated as early as 1985, have been analyzed periodically (Anderson and Burnham 1992; Anthony et al. 2006; Burnham et al. 1994; Forsman et al. 2011; Forsman et al. 1996) to estimate trends in the populations of the spotted owl.

In January 2009, two meta-analyses modeled rates of population change for up to 24 years using the re-parameterized Jolly-Seber method (λ_{RJS}). One meta-analysis modeled the 11 long-term study areas (Table 4), while the other modeled the eight study areas that are part of the effectiveness monitoring program of the NWFP (Forsman et al. 2011, pp. 65-67).

Table A4. Summary of spotted owl population trends from in demographic study areas (Forsman et al. 2011, p. 65).

Study Area	Fecundity	Apparent Survival[1]	λ_{RJS}	Population change[2]
Cle Elum	Declining	Declining	0.937	Declining
Rainier	Increasing	Declining	0.929	Declining
Olympic	Stable	Declining	0.957	Declining
Coast Ranges	Increasing	Declining since 1998	0.966	Declining
HJ Andrews	Increasing	Declining since 1997	0.977	Declining
Tyee	Stable	Declining since 2000	0.996	Stationary
Klamath	Declining	Stable	0.990	Stationary
Southern Cascades	Declining	Declining since 2000	0.982	Stationary
NW California	Declining	Declining	0.983	Declining
Hoopa	Stable	Declining since 2004	0.989	Stationary
Green Diamond	Declining	Declining	0.972	Declining

[1]Apparent survival calculations are based on model average.
[2]Population trends are based on estimates of realized population change.

Point estimates of λRJS were all below 1.0 and ranged from 0.929 to 0.996 for the 11 long-term study areas. There was strong evidence that populations declined on 7 of the 11 areas (Forsman et al. 2011, p. 65), these areas included Rainier, Olympic, Cle Elum, Coast Range, HJ Andrews, Northwest California and Green Diamond. On other four areas (Tyee, Klamath, Southern Cascades, and Hoopa), populations were either stable, or the precision of the estimates was not sufficient to detect declines.

The weighted mean λRJS for all of the 11 study areas was 0.971 (standard error [SE] = 0.007, 95 percent confidence interval [CI] = 0.960 to 0.983), which indicated an average population decline of 2.9 percent per year from 1985 to 2006. This is a lower rate of decline than the 3.7 percent reported by Anthony et al. (2006, p. 23), but the rates are not directly comparable because Anthony et al. (2006) examined a different series of years and because two of the study areas in their analysis were discontinued and not included in Forsman et al. (2011, p. 65). Forsman et al. (2011, p. 65) explains that the indication populations were declining was based on the fact that the 95 percent confidence intervals around the estimate of mean lambda did not overlap 1.0 (stable) or barely included 1.0.

The mean λRJS for the eight demographic monitoring areas (Cle Elum, Olympic, Coast Range, HJ Andrews, Tyee, Klamath, Southern Cascades and Northwest California) that are part of the effectiveness monitoring program of the NWFP was 0.972 (SE = 0.006, 95 percent CI = 0.958 to 0.985), which indicated an estimated decline of 2.8 percent per year on Federal lands with the range of the spotted owl (Forsman et al. 2011, p. 67). The weighted mean estimate λRJS for the other three study areas (Rainier, Hoopa and Green Diamond) was 0.969 (SE = 0.016, 95 percent CI = 0.938 to 1.000), yielding an estimated average decline of 3.1 percent per year. These data suggest that demographic rates for spotted owl populations on Federal lands were somewhat better than elsewhere; however, this comparison is confounded by the interspersion of non-Federal land in study areas and the likelihood that spotted owls use habitat on multiple ownerships in some demography study areas.

The number of populations that declined and the rate at which they have declined are noteworthy, particularly the precipitous declines in the Olympic, Cle Elum, and Rainier study areas in Washington and the Coast Range study area in Oregon. Estimates of population declines in these areas ranged from 40 to 60 percent during the study period through 2006 (Forsman et al. 2011, p. 66). Spotted owl populations on the HJ Andrews, Northwest California, and Green Diamond study areas declined by 20-30 percent whereas the Tyee, Klamath, Southern Cascades, and Hoopa study areas showed declines of 5 to 15 percent (Forsman et al. 2011, p. 66).

Decreases in adult apparent survival rates were an important factor contributing to decreasing population trends. Forsman et al. (2011, pp. 65-66) found apparent survival rates were declining on 10 of the study area with the Klamath study area in Oregon being the exception. Estimated declines in adult survival were most precipitous in Washington where apparent survival rates were less than 80 percent in recent years, a rate that may not allow for sustainable populations (Forsman et al. 2011, p. 66). In addition, declines in adult survival for study areas in Oregon have occurred predominately within the last five years and were not observed in the previous analysis by Anthony et al. (2006). Forsman et al. (2011, p. 64) express concern for the decline in adult survival rates across the subspecies range because spotted owl populations are most sensitive to changes in adult survival.

There are few spotted owls remaining in British Columbia. Chutter et al. (2004, p. v) suggested immediate action was required to improve the likelihood of recovering the spotted owl population in British Columbia. In 2007, personnel in British Columbia captured and brought into captivity the remaining 16 known wild spotted owls (USFWS 2011b, p. A-6). Prior to initiating the captive-breeding program, the population of spotted owls in Canada was declining by as much as 10.4 percent per year (Chutter et al. 2004, p. v). The amount of previous interaction between spotted owls in Canada and the United States is unknown.

1.5.3 Spotted Owl Recovery Units

The 2011 Final Revised Recovery Plan for the Northern Spotted Owl determined that the 12 existing physiographic provinces meet the criteria for use as recovery units (USDI FWS 2011b, p. III 1-2). The proposed project is within the Eastern Oregon Cascades Physiographic Province. Recovery criteria, as described in the 2011 Final Revised Recovery Plan (p. 11-3), are measurable and achievable goals that are believed to result through implementation of the recovery actions described in the recovery plan. Achievement of the recovery criteria will take time and are intended to be measured over the life of the plan, not on a short-term basis. The criteria are the same for all 12 identified recovery units. The four recovery criterion are: 1) stable population trend, 2) adequate population distribution, 3) continued maintenance and recruitment of northern spotted owl habitat, and 4) post-delisting monitoring (USDI FWS 2011b, p III-3).

As discussed in the Section 3.5.1, demographic data are used to evaluate trends in northern spotted owl populations. The Southern Oregon Cascades Demographic Study Area, which overlaps a portion of the Eastern Oregon Cascades Physiographic Province, is one of five demographic study areas in Oregon that are part of the Effectiveness Monitoring Program for Spotted Owls in the Northwest Forest Plan. A workshop was conducted to analyze range-wide demographic data of northern spotted owls in January 2004 and fecundity, apparent survival, and population trend were estimated for the Southern Oregon Cascades Study Area during the workshop for a period of 1985 to 2003 (Anthony et al. 2008, pp.23-24). Anthony et al. (2008, p. 24) found that apparent survival estimated from the model that "best fit" the data indicated that there were no sex related differences but that subadult (first and second year combined) survival differed from adult owls. Anthony et al. (2006) also found that the "best fit" model of fecundity incorporated a three-age-class effect, an odd-even year effect, and linear time trend. The model indicated that fecundity for the southern Cascades was possibly decreasing for the period of study. Results from this study also suggest that the population was stationary (neither increasing nor decreasing) during the period of the study. Similarly, Forsman et al. (2011) indicate that fecundity (young produced) within the Southern Oregon Cascades Study Area is declining. At the population scale, Forsman et al. (2011) indicate that the population in the Southern Oregon Cascades Study Area may be stable (Table 4); however, the precision of the estimates (95 percent confidence interval) may not be sufficient to detect declines in this population (Forsman et al. 2011).

APPENDIX B

NORTHERN SPOTTED OWL CRITICAL HABITAT

Conservation Role of Critical Habitat

Critical habitat contains those areas that are essential to the conservation of the species. The expectation of critical habitat is to ameliorate habitat-based threats. The recovery of the northern spotted owl requires habitat conservation in concert with the implementation of recovery actions that address other, non-habitat-based threats to the species, including the barred owl (USFWS 2012, p. 71879). The conservation role of northern spotted owl critical habitat is to "adequately support the life-history needs of the species to the extent that well-distributed and inter-connected northern spotted owl nesting populations are likely to persist within properly functioning ecosystems at the critical habitat unit and range-wide scales" (USDI FWS 2012, p. 71938). The specific conservation role of the subunit included in the action area is described in the Environmental Baseline in the document.

Physical or Biological Features and Primary Constituent Elements

When designating critical habitat, the Service considers "the physical or biological features [PBFs] essential to the conservation of the species and which may require special management considerations or protection" (50 CFR §424.12; USDI FWS 2012, p. 71897). "These include, but are not limited to: (1) space for individual and population growth and for normal behavior; (2) food, water, air, light, minerals, or other nutritional or physiological requirements; (3) cover or shelter; (4) sites for breeding, reproduction, or rearing (or development) of offspring; and (5) habitats that are protected from disturbance or are representative of the historical, geographical, and ecological distributions of a species" (USDI FWS 2012, p. 71897). The final critical habitat rule states that "for the northern spotted owl, the physical or biological features essential to the conservation of the species are forested areas that are used or likely to be used for nesting, roosting, foraging, or dispersing" (USDI FWS 2012, p. 71897). The final critical habitat rule for the northern spotted owl provides an in-depth discussion of the PBFs, which may be referenced for further detail (USDI FWS 2012, pp. 71897-71906).

The primary constituent elements (PCEs) are the specific elements of the PBFs that are considered essential to the conservation of the northern spotted owl and are those elements that make areas suitable as nesting, roosting, foraging, and dispersal habitat (USDI FWS 2012, p. 71904). The PCEs should be arranged spatially such that it is favorable to the persistence of populations, survival, and reproductive success of resident pairs, and survival of dispersing individuals until they are able to recruit into a breeding population (USDI FWS 2012, p. 71904).

Within areas essential for the conservation and recovery of the northern spotted owl, the Service has determined that the PCEs are:

1) Forest types that may be in early-, mid-, or late-seral stages and that support the northern spotted owl across its geographic range;
2) Habitat that provides for nesting and roosting;
3) Habitat that provides for foraging;
4) Habitat to support the transience and colonization phases of dispersal, which in all cases would optimally be composed of nesting, roosting, or foraging habitat (PCEs 2 or 3), but which may also be composed of other forest types that occur between larger blocks of nesting, roosting, or foraging habitat (USDI FWS 2012, pp. 72051-72052).

Some critical habitat subunits may contain all of the above PCEs and support multiple life history requirements of the northern spotted owl, while some subunits may contain only those PCEs necessary to support the species particular use of that habitat. All of the areas designated as critical habitat, however, do contain PCE 1, forest type. Therefore, PCE 1 always occurs in concert with at least one other PCE (PCE 2, 3, or 4; USDI FWS 2012, p. 72051). Northern spotted owl critical habitat does not include meadows, grasslands, oak woodlands, aspen woodlands, or manmade structures and the land upon which they are located (USDI FWS 2012, p. 71918).

PCE 1: Forest Types

The primary forest types that support the northern spotted owl are: Sitka spruce, western hemlock, mixed conifer, mixed evergreen, grand fir, Pacific silver fir, Douglas-fir, white fir, Shasta red fir, redwood/Douglas-fir, and moister ponderosa pine (USDI FWS 2012, p. 72051). Specific to the California Klamath Province, the western portions of this zone support a diverse mix of mesic forest communities interspersed with drier forest types. Forests of mixed conifers and evergreen hardwoods are typical of the zone. Eastern portions of this zone have a Mediterranean climate with increased occurrence of ponderosa pine.

PCE 2: Nesting and Roosting Habitat (California Klamath Emphasis)

Nesting and roosting habitat for northern spotted owl provides structural features for nesting, protection from adverse weather conditions, and cover to reduce predation risk for adults and young. In many cases, the same habitat may also provide for foraging. Nesting and roosting habitats must provide: sufficient habitat for foraging by territorial pairs, moderate to high canopy closure (60 to over 80 percent), multilayered and multispecies canopies with large overstory trees (20 to 30 inches dbh), basal area greater than 240 square feet per acre, high diversity of tree diameters, high incidence of large live trees with various deformities (e.g., large cavities, broken tops, mistletoe infections, and other evidence of decadence), large snags and large accumulations of woody debris on the ground, and sufficient open space beneath the canopy for flight (USDI FWS 2012, p. 72051).

PCE 3: Foraging Habitat (California Klamath Emphasis)

Across the range of the northern spotted owl, nesting and roosting habitats also provide foraging opportunities; however, northern spotted owls may use other habitat types for foraging as well. The components of PCE 3 for northern spotted owl foraging habitat in the East Cascades are: stands of nesting and roosting habitat including stands composed of Douglas-fir and white fir/Douglas-fir, quadratic mean diameter of trees greater than 16.5 inches, higher densities of large trees (greater than 26 inches dbh) and higher basal areas leading to increased foraging habitat quality, large accumulations of fallen trees and other down woody debris, and sufficient open space beneath the canopy for flight (USDI FWS 2012, p. 72051).

PCE 4: Dispersal habitat

Northern spotted owl dispersal habitat is habitat that supports the transience and colonization phases of owl dispersal, and in all cases would optimally be composed of nesting, roosting, or foraging habitat (PCE 2 or 3), but which may also be composed of other forest types that occur between larger blocks of northern spotted owl nesting, roosting, or foraging habitat. In cases where nesting, roosting, or foraging habitats are insufficient to provide for dispersing or nonbreeding owls, the specific dispersal PCEs are: habitat supporting transience phase of dispersal (protection from avian predators, minimal foraging opportunities, younger and less diverse forests that provide some roosting structures and foraging opportunities) and habitat supporting the colonization phase of dispersal (nesting, roosting, and foraging habitat but in smaller amounts than needed to support a nesting pair) (USDI FWS 2012, p. 72052).

Current Condition of Northern Spotted Owl Critical Habitat

The current condition of critical habitat incorporates the effects of all past human activities and natural events that led to the present-day status of the habitat (USDI and USDC 1998, pg. 4-19). With the revision of spotted owl critical habitat, the range-wide condition has been “reset” as of December 4, 2012.

Range-Wide Critical Habitat Baseline

The Service updated the ECOS Database to reflect the 2006/2007 habitat baseline developed for the NWFP 15-year monitoring report (Davis et al. 2011, Appendix D, Table D). This mapping effort indicates that approximately 9.577 million acres of spotted owl critical habitat existed in 2006/2007 (Table 1). As of July 18, 2013 the database reports 10,927acres have been removed or downgraded from critical habitat range-wide. The majority of these impacts originated in the Oregon Coast Range and Oregon Cascades (east and west) Physiographic Provinces, and less than half (3,207 acres) occurred in land use allocations under the NWFP that were intended to emphasize maintenance of spotted owl habitat values (i.e., late-successional reserves).

Notes:

1. Nesting, roosting, foraging (NRF) habitat. In California, suitable habitat is divided into two components; nesting - roosting (NR) habitat, and foraging (F) habitat. The NR component in CA most closely resembles NRF habitat in Oregon and Washington.

2. Defined in the Revised Recovery Plan for the Northern Spotted Owl (USFWS 2011) as Recovery Units as depicted on page A-3.
3. Northern spotted owl critical habitat as designated December 4, 2012 (77 FR 71876). Total designated critical habitat acres listed here (9,577,342 acres) are derived from GIS data, and vary slightly from the total acres (9,577,969 acres) listed in the Federal Register (-627 acres).
4. Calculated from GIS data for spotted owl Nesting/Roosting habitat generated by Davis et al. 2011 for the Northwest Forest Plan 15-year Monitoring Report (PNW-GTR-850). NR habitat acres are approximate values based on 2006 (OR/WA) and 2007 (CA) satellite imagery.
5. Reserve land use allocations under the NWFP intended to provide demographic support for spotted owls include LSR, MLSA, and CRA. Non-reserve allocations under the NWFP intended to provide dispersal connectivity between reserves include AWA, AMA, and MX.

Zones *of Habitat Associations used by Northern Spotted Owls*

Differences in patterns of habitat associations used by the northern spotted owl across its range suggest four different broad zones of habitat use, which we characterize as the (1) West Cascades/Coast Ranges of Oregon and Washington, (2) East Cascades, (3) Klamath and Northern California Interior Coast Ranges, and (4) Redwood Coast (Figure 3.1). We configured these zones based on a qualitative assessment of similarity among ecological conditions and habitat associations within the 11 different regions analyzed during the critical habitat designation process (see USDI FWS 2012). These four zones capture the range in variation of some of the PBFs essential to the conservation of the northern spotted owl. Summarized below are the PBFs for each of these four zones, emphasizing zone-specific features that are distinctive within the context of general patterns that apply across the entire range of the northern spotted owl.

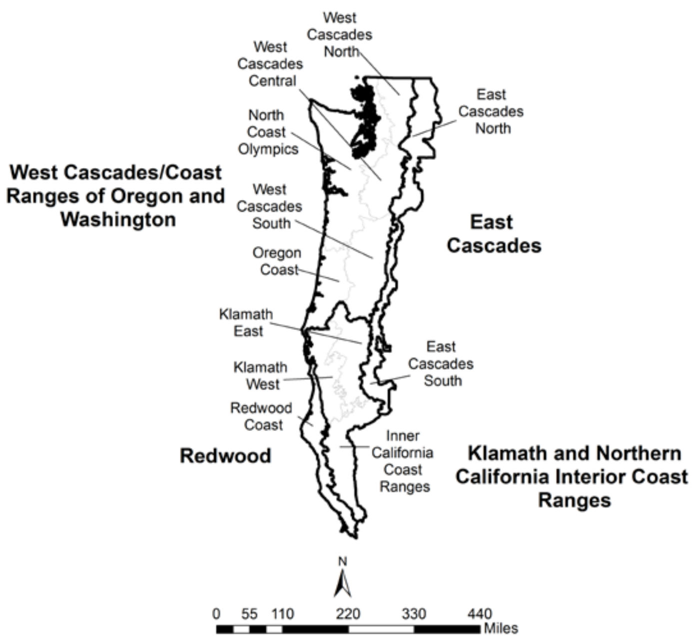

Figure 1. Eleven regions and four zones of habitat associations used by northern spotted owls in Washington, Oregon, and California.

West Cascade/Coast Ranges of Oregon and Washington

This zone includes five regions west of the Cascade crest in Washington and Oregon (Western Cascades North, Central and South; North Coast Ranges and Olympic Peninsula; and Oregon Coast Ranges; USDI FWS 2011, p. C–13). Climate in this zone is characterized by high rainfall and cool to moderate temperatures. Variation in elevation between valley bottoms and ridges is relatively low in the Coast Ranges, creating conditions favorable for development of contiguous forests. In contrast, the Olympic and Cascade ranges have greater topographic variation with many high-elevation areas supporting permanent snowfields and glaciers. Douglas-fir and western hemlock dominate forests used by northern spotted owls in this zone. Root diseases and wind-throw are important natural disturbance mechanisms that form gaps in forested areas. Flying squirrels (*Glaucomys sabrinus*) are the dominant prey, with voles and mice also representing important items in the northern spotted owl's diet.

Our habitat modeling indicates that vegetation structure has a dominant influence on owl population performance, with habitat pattern and topography also contributing. High canopy cover, high density of large trees, high numbers of sub-canopy vegetation layers, and low to moderate slope positions are all important features.

Nesting habitat in this zone is mostly limited to areas with large trees with defects such as mistletoe brooms, cavities, or broken tops. The subset of foraging habitat that is not nesting/roosting habitat generally had slightly lower values than nesting habitat for canopy cover, tree size and density, and canopy layering. Prey species (primarily the northern flying squirrel) in this zone are associated with mature to late-successional forests, resulting in small differences between nesting, roosting, and foraging habitats.

East Cascades

This zone includes the Eastern Cascades North and Eastern Cascades South regions (USDI FWS 2011, p. C–13). This zone is characterized by a continental climate (cold, snowy winters and dry summers) and a high frequency of natural disturbance due to fires and outbreaks of forest insects and pathogens. Flying squirrels are the dominant prey species, but the diet of northern spotted owls in this zone also includes relatively large proportions of bushy-tailed woodrats (*Neotoma cinerea*), snowshoe hare (*Lepus americanus*), pika (*Ochotona princeps*), and mice (*Microtus spp*. (Forsman et al. 2001, pp. 144–145).

Our modeling indicates that habitat associations in this zone do not show a pattern of dominant influence by one or a few variables (USDI FWS 2011, Appendix C). Instead, habitat association models for this zone included a large number of variables, each making a relatively modest contribution (20 percent or less) to the predictive ability of the model. The features that were most useful in predicting northern spotted owl habitat quality were vegetation structure and composition, and topography, especially slope position in the north. Other efforts to model habitat associations in this zone have yielded similar results (e.g., Gaines et al. 2010, pp. 2048–2050; Loehle et al. 2011, pp. 25–28).

Relative to other portions of the northern spotted owls' range, nesting and roosting habitat in this zone includes relatively younger and smaller trees, likely reflecting the common usage of dwarf mistletoe (*Arceuthobium douglasii*) brooms (dense growths) as nesting platforms (especially in the north). Forest composition that includes high proportions of Douglas-fir is also associated with this nesting structure. Additional foraging habitat in this zone generally resembles nesting and roosting habitat, with reduced canopy cover and tree size, and reduced canopy layering. High prey diversity suggests relatively diverse foraging habitats are used. Topographic position was an important variable, particularly in the north, possibly reflecting competition from barred owls (Singleton et al. 2010, pp. 289, 292). Barred owls, which have been present for over 30 years in the northern portions of this zone, preferentially occupy valley-bottom habitats, possibly compelling northern spotted owls to establish territories on less productive, mid-slope locations (Singleton et al. 2010, pp. 289, 292).

Klamath and Northern California Interior Coast Ranges

This zone includes the Klamath West, Klamath East, and Interior California Coast regions (USDI FWS 2011, p. C–13). This region in southwestern Oregon and northwestern California is characterized by very high climatic and vegetative diversity resulting from steep gradients of elevation, dissected topography, and large differences in moisture from west to east. Summer temperatures are high, and northern spotted owls occur at elevations up to 5,800 feet. The western portions of this zone support a diverse mix of mesic forest communities interspersed with drier forest types. Forests of mixed conifers and evergreen hardwoods are typical of the zone. The eastern portions of this zone have a Mediterranean climate with increased occurrence of the ponderosa pine. Douglas-fir/dwarf mistletoe is rarely used for nesting platforms in the western part of the northern spotted owl's range, but is commonly used in the east.

The prey base for northern spotted owls in this zone is correspondingly diverse, but dominated by dusky-footed woodrats, bushy-tailed woodrats, and flying squirrels. Northern spotted owls have been well studied in the western Klamath portion of this zone (Forsman et al. 2004, p. 217), but relatively little is known about northern spotted owl habitat use in the eastern portion and the California Interior Coast Range portion of the zone.

Our habitat association models for this zone suggest that vegetation structure and topographic features are nearly equally important in influencing owl population performance, particularly in the Klamath. High canopy cover, high levels of canopy layering, and the presence of very large dominant trees were all important features of nesting and roosting habitat. Compared to other zones, additional foraging habitat for this zone showed greater divergence from nesting habitat, with much lower canopy cover and tree size. Low to intermediate slope positions were strongly favored. In the eastern Klamath, the presence of Douglas-fir was an important compositional variable in our habitat model (USDI FWS 2011, Appendix C).

Redwood Zone

This zone is confined to the northern California coast, and is represented by the Redwood Coast region (USDI FWS 2011, p. C–13). It is characterized by a maritime climate with moderate temperatures and generally mesic conditions. Near the coast, frequent fog delivers consistent moisture during the summer. Terrain is typically low-lying (0 to 3,000 feet). Forest communities are dominated by redwood, Douglas-fir–tanoak (*Lithocarpus densiflorus*) forest, coast live oak (*Quercus agrifolia*), and tanoak series. Dusky footed woodrats are the dominant prey items for northern spotted owls in this zone.

Habitat association models for this zone diverged strongly from models for other zones. Topographic variables (slope position and curvature) had a dominant influence with vegetation structure having a secondary role. Low position on slopes was strongly favored, along with concave landforms.

Several studies of northern spotted owl habitat relationships suggest that stump-sprouting and rapid growth of redwood trees, combined with high availability of woodrats in patchy, intensively managed forests, enables northern spotted owls to occupy a wide range of vegetation conditions within the redwood zone. Rapid growth rates enable young stands to develop structural characteristics typical of older stands in other regions. Thus, relatively small patches of large remnant trees can also provide nesting habitat structure in this zone.

Climate Change and Range-wide Spotted Owl Critical Habitat

There is growing evidence that recent climate change has impacted a wide range of ecological systems (Stenseth et al. 2002, entire; Walther et al. 2002, entire; Ådahl et al. 2006, entire; Karl et al. 2009, entire; Moritz et al. 2012, entire; Westerling et al. 2011, p. S459; Marlon et al. 2012, p. E541). Climate change, combined with effects from past management practices, is exacerbating changes in forest ecosystem processes and dynamics to a greater degree than originally anticipated under the NWFP. Environmental variation affects all wildlife populations; however, climate change presents new challenges as systems may change beyond historical ranges of variability. In some areas, changes in weather and climate may result in major shifts in vegetation communities that can persist in particular regions.

Climate change will present unique challenges to the future of northern spotted owl populations and their habitats. Northern spotted owl distributions (Carroll 2010, entire) and population dynamics (Franklin et al. 2000, entire; Glenn et al. 2010, entire; Glenn et al. 2011a, entire; Glenn et al. 2011b, entire) may be directly influenced by changes in temperature and precipitation. In addition, changes in forest composition and structure as well as prey species distributions and abundance resulting from climate change may impact availability of habitat across the historical range of the subspecies. The *2011 Northern Spotted Owl Revised Recovery Plan* provides a detailed discussion of the possible environmental impacts to the habitat of the northern spotted owl from the projected effects of climate change (USDI FWS 2011, pp. III-5 to III-11).

Because both northern spotted owl population dynamics and forest conditions are likely to be influenced by large-scale changes in climate in the future, we have attempted to account for these influences in our designation of critical habitat by recognizing that forest composition may change beyond the range of historical variation, and that climate changes may have unpredictable consequences for both Pacific Northwest forests and northern spotted owls. Our critical habitat designation also recognizes that forest management practices that promote ecosystem health under changing climate conditions will be important for northern spotted owl conservation.

Do you need all of them--even the ones that you cited in your original draft? Here are the new ones that I added (one of the three is a webinar, for which I provided a link at the bottom of the draft).

Thanks, Dan.

If you have them, can you send me the papers that are cited here? I don't have them and really don't have time to look them up at this point.

Thanks for all your efforts! See you in June!

Subject: Fire discussion for comment letter

Hi Rob,

Great to see you and Gary today! Here's my very quickly written version of the fire section. Feel free to use all, part, or none of it as you see fit. FYI, for the status review, we will look at quite a bit more information than is discussed here--this is just to get CDFW on the right track.

Have a great vacation!

Dan

Effects of the Hatchery Complex Fires on Northern Spotted Owls in the Eastern Washington Cascades

William L. Gaines, Robert A. Strand, and Susan D. Piper

Abstract. During the summer of 1994 the Hatchery Complex fires burned 17,603 ha in the east Cascades of Washington. These fires affected three habitat reserves and six activity centers for the northern spotted owl (*Strix occidentalis* caurina). The availability of spotted owl habitat within a 2.9 km radius of these activity centers was reduced by the direct effects of the fire, (average habitat loss=31%, range 8%-45%) but was also significantly reduced by delayed tree mortality and insect caused mortality (average habitat loss=55%, range 10%-85%). Fewer spotted owls occuppied and reproduced at these sites than in previous years. Spotted owl habitat located in riparian areas or on a bench was somewhat more likely to remain as fire refugia than habitat located on mid-upper slopes. This was especially true on south aspects. The availability of spotted owl habitat under current and inherent fire regimes was very dynamic across the east Cascades landscape. Appropriate management strategies may include strategically located low density fuel areas created to protect adjacent spotted owl habitat.

Introduction

Fires are a natural event within the eastside Cascades ecosystems (Agee 1994), however, fire suppression and logging have contributed to higher fuel loadings that can lead to higher fire intensity than would have inherently occurred (Agee and Edmunds 1992). The fires of 1994 were a dramatic example of this. Areas in which the inherent disturbance regime would have been low to moderate intensity and high frequency fires, burned as moderate to high intensity stand replacement fires. Several of these fires were part of the Hatchery Complex that included the Rat, Hatchery, Eightmile, Blackjack I and Blackjack II fires. In total these fires burned about 17,603 ha.

These fires burned within three areas that have been identified as Late-Succesional Reserves (USFS 1994 and 1995). These areas have management objectives to provide habitat for late- successional associated species, including the Threatened northern spotted owl (*Strix occidentalis* caurina). Agee and Edmunds (1992) stated that: "There is a very low probability that any (spotted owl habitat reserve) created in the East Cascades subregion will avoid catastrophic wildfire over a significant portion of its landscape over the next century." Thus the management dilema, while fire suppression may have increased the amount of suitable spotted owl habitat across the lanscape, it has also resulted in a greater risk of habitat loss due to catastrophic fires (Agee and Edmunds 1992, Buchanan et al. 1995). Management of these landscapes must consider the short-term habitat needs of the spotted owl and the risk associated with stand replacement fires.

Important in the management of these landscapes is understanding how fire affects spotted owls and their habitat. Our objectives were to quantify, as much as possible, the effects of the Hatchery Complex fires on spotted owl habitat, occupancy rates, and reproduction. In addition, the future risk to additional owl sites and possible management strategies will be presented.

Study Area

This study was conducted on the Leavenworth Ranger District, Wenatchee National Forest, located on the east side of the Cascades of Washington state (Figure 1). Elevations range from 650 meters to 1300 meters. The study area is composed of ponderosa pine (*Pinus ponderosa*) plant associations at lower elevations, and Douglas-fir (*Pseudotsuga menziesii*) and grand fir (*Abies grandis*) plant associations at the mid-elevations.

Disturbances, such as fire, have been shown to have a significant influence on the vegetation patterns and processes of east Cascade landscapes (Gast et al. 1991, Agee 1994, Johnson et al. 1994, Harrod et al. 1996). Prior to fire suppression, fire occurred at relatively frequent intervals within east Cascade forests (Agee and Edmunds 1992). For example, within the ponderosa pine and dry Douglas fir plant series fire occurred at intervals of 10 to 25 years resulting in a forest structure largely composed of open park-like ponderosa pine forests (Agee 1991 and 1994). Fires in these forests were usually of low to moderate intensity.

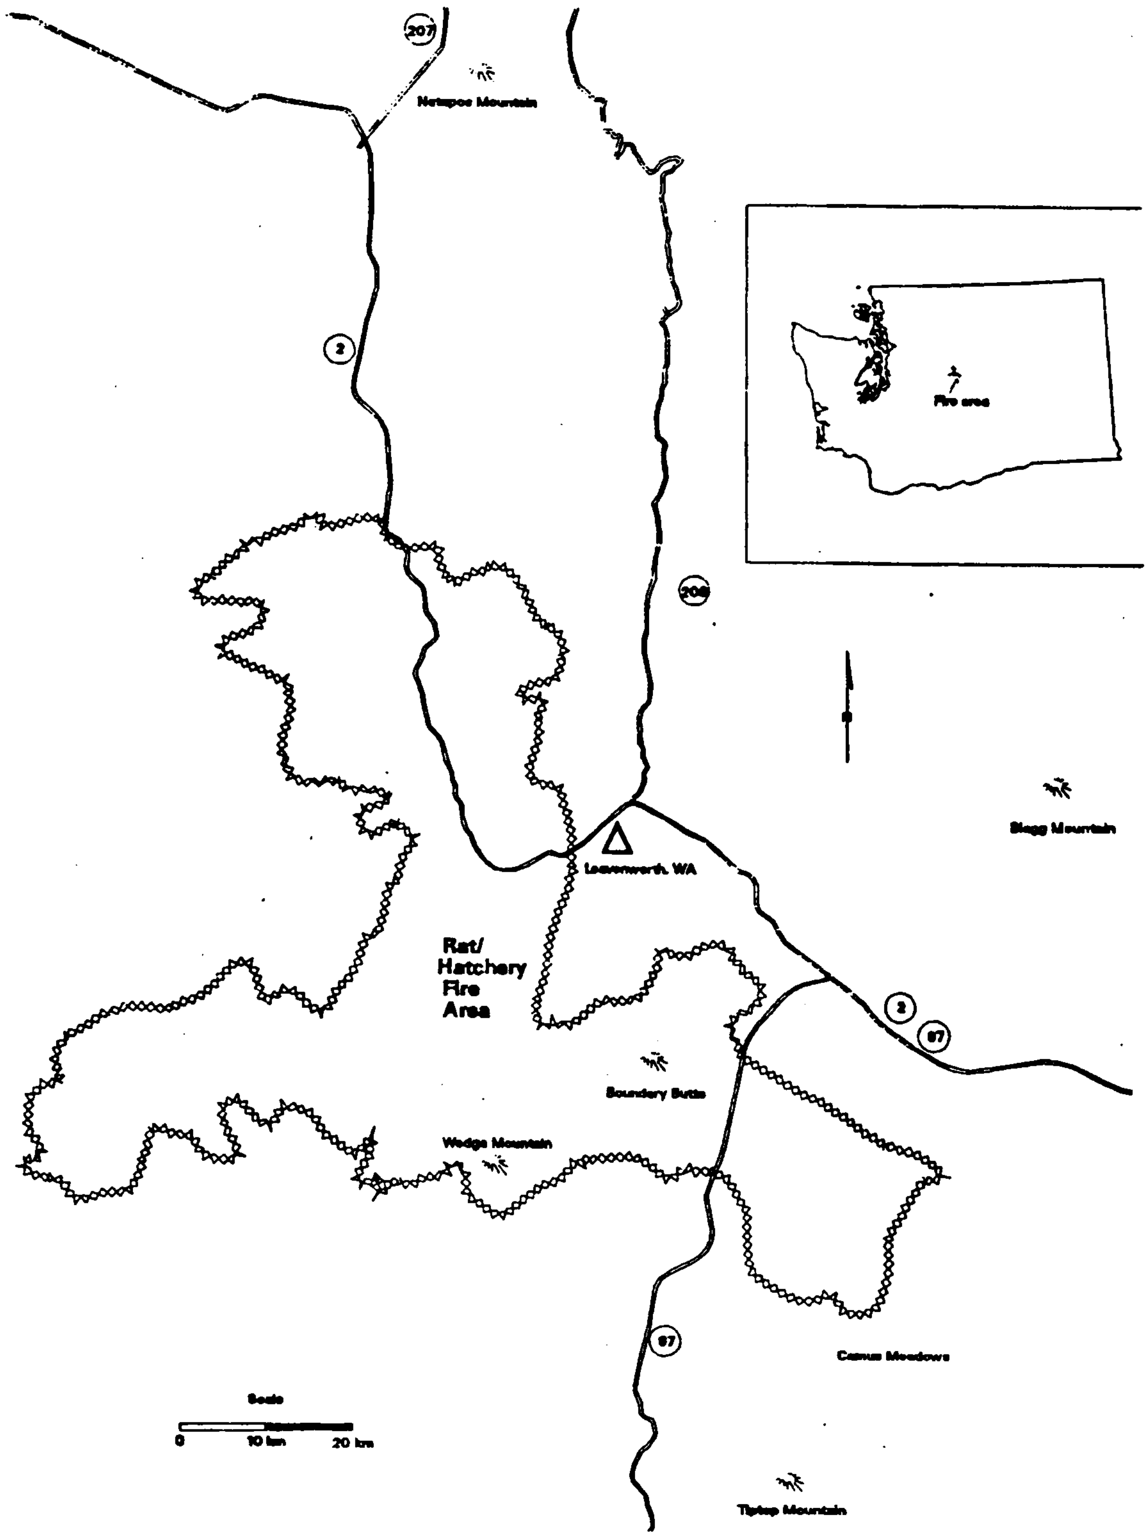

Figure 1. Vicinity map of the Rat and Hatchery Fires.

Fire suppression and logging have signficantly altered these forests. With the advent of effective fire supression technologies, fire frequency within these forests was significantly reduced (Agee and Edmunds 1992). In addition, logging practices until about 1950 often focused on removing the most fire tolerant species, the large ponderosa pine (Wellner 1984). The end result is that eastside forests are now composed of more shade tolerant tree species, are less fire tolerant, are at higher densities, and are more prone to large scale high intensity fires (Agee and Edmunds 1992, Camp 1995).

Methods

Habitat Inventory

Inventories of spotted owl habitat were completed from aerial photo-interpretation followed by field verification. These data were then loaded into MOSS geographic information system for habitat analyses. Habitat inventories were completed prior to the fire, immediately post-fire, and one year after the fires occurred in order to measure habitat changes over time. Suitable habitat was defined as having at least a 60% canopy closure presence of numerous snags and several down logs, and two or more canopy layers. The habitat mapping resolution was 0.8 ha.

Once habitat maps were developed an additional analysis was conducted to describe landscape features for habitat that was within the fire perimeter but remained suitable following the fire. This analysis was completed for all habitat within a 2.9 km radius around three of the six fire affected activity centers. A spotted owl activity center is the location in which there was a resident single, pair or nest site (USFS 1991). These three spotted owl activity centers were selected because they were distributed across the burned landscape, they were the most extensively affected, and there was no overlap in habitat within the 2.9 km radius. This information was developed to determine if habitat at particular landscape locations burned at proportions equal to, greater than or less than was available within the three activity centers. Habitat was classified into one of the following categories: north aspect (>270 to 89 degrees), south aspect (>90 to 270 degrees), riparian, valley (>300m wide), bench (<10% slope and >6 ha), and mid-upper slope.

Spotted Owl Inventories

The Region 6 spotted owl survey protocol was followed (USFS 1991). During 1995, spotted owl activity centers were surveyed regardless of how extensive the habitat was changed as a result of the fires. Sites were monitored to determine if spotted owls were present, and if so, their status: single, pair, or reproductive pair. If spotted owls were determined to be reproductive, additional monitoring was conducted to determine the number of young. Surveys and site monitoring were accomplished through a cooperative effort between the U.S. Forest Service, National Council on Air and Stream Improvement, and Natapoc Resources.

Data Analysis

A linear correlation analysis (Zar 1984) was completed to determine if there was a relationship between site status and the degree to which habitat was affected by the fires within a 0.8 km and 2.9 km radius. A Chi-Square Goodness of Fit test (Zar 1984) was used to determine if there was a significant difference between habitat burned vs habitat available at several locations on the burned landscape.

Persistence of Spotted Owl Nest Sites

Camp (1995) presents a probability model for the development of late-successional fire refugia under an inherent disturbance regime for the eastern Cascade mountains. Because spotted owl nesting habitat has been shown to be associated with these late- successional conditions (Buchanan et al. 1993, Buchanan et al. 1995) this model was used to show the potential for a fire under an inherent disturbance regime, at the 28 known nest sites on the Leavenworth Ranger District.

Results and Discussion

Habitat Availability

The availability of suitable spotted owl habitat within a 2.9 km radius of the six affected activity centers prior to the fire, immediately following the fire and one year post-fire are shown in Table 1. The average amount of habitat loss that occurred within a 2.9 km radius was 31% and ranged from 8% to 45%. The average amount of habitat lost within a 2.9 km radius as of one year after the fire was 55% and ranged from 10% to 85%.

These data show that a considerable reduction in habitat occurred as a result of the direct effects of the fire, however, additional habitat reductions occurred well after the fires were out. This occurred because trees damaged but not directly killed by the fires eventually died.

Table 1. Habitat availability pre-fire, post-fire, and one year post-fire within a 2.9 km radius of spotted owl activity centers (n=6), Hatchery Complex Fires.

Site No.	Pre-fire (ha)	Post-fire (ha)	1 Yr Post-fire (ha)
1	691	463	342
2	493	454	446
3	512	399	114
4	604	344	92
5	618	420	324
6	377	208	171

In addition, some trees that survived the fires have been killed by increased insect activity. It is expected that this trend will continue as insect populations increase, however the extent is not yet known.

The results of the analysis to determine if suitable habitat at various locations on the landscape burned in proportion to its availability are shown in Figures 2 and 3. Habitat located on north aspects and within riparian areas burned less than available, though not statistically different ($p>0.05$). Habitat on north slopes located on a bench burned at proportions equal to it's availability. Habitat on north slopes on the mid-upper part of the slope burned at levels slightly greater than available, but not statistically different than expected ($p>0.05$). On south slopes habitat located on a bench burned at levels that were significantly less than expected ($p<0.05$). Habitat located on south slopes and on the mid-upper portion of the slope burned at proportions greater than available, but not at levels significantly different than expected ($p>0.05$).

Site Status

The results of the spotted owl surveys at the six fire affected activity centers are shown in Table 2. Four of the six sites were not occupied during 1995. At one of these sites the fire overtook the activity center very rapidly and at extremely high intensity. It is likely that these owls did not survive the fire, and their activity center is likely no longer capable of supporting an owl pair. Habitat at an additional site was reduced to levels that make it unlikely that it could support spotted owls. This site was not occupied in 1995. Fewer of these activity centers were occupied in 1995 than at any time during the previous four years. In addition, only one site was reproductive, also the lowest level compared to the previous four years.

Site Status and Habitat Availability

There was no correlation between the habitat available within a 2.9 km radius one year post-fire and the site status ($\alpha=0.05$, $p>0.05$). There was, however, a cor-

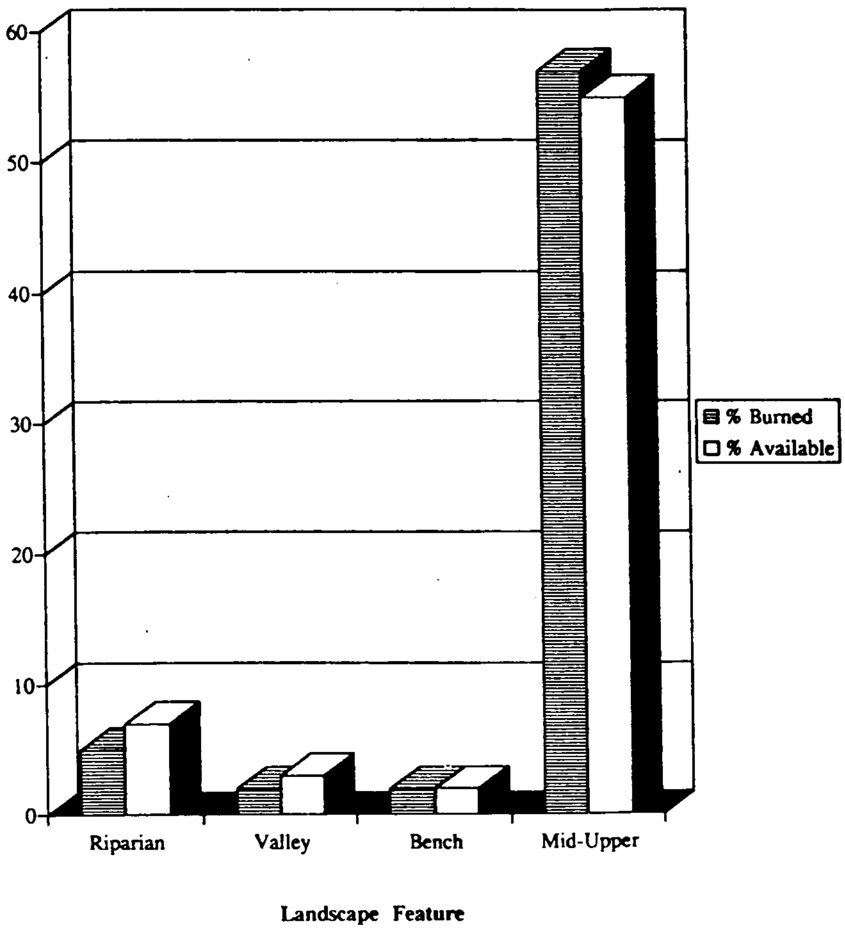

Figure 2. Proportion of spotted owl habitat that burned vs that available at various locations on north aspects, Hatchery Complex fires.

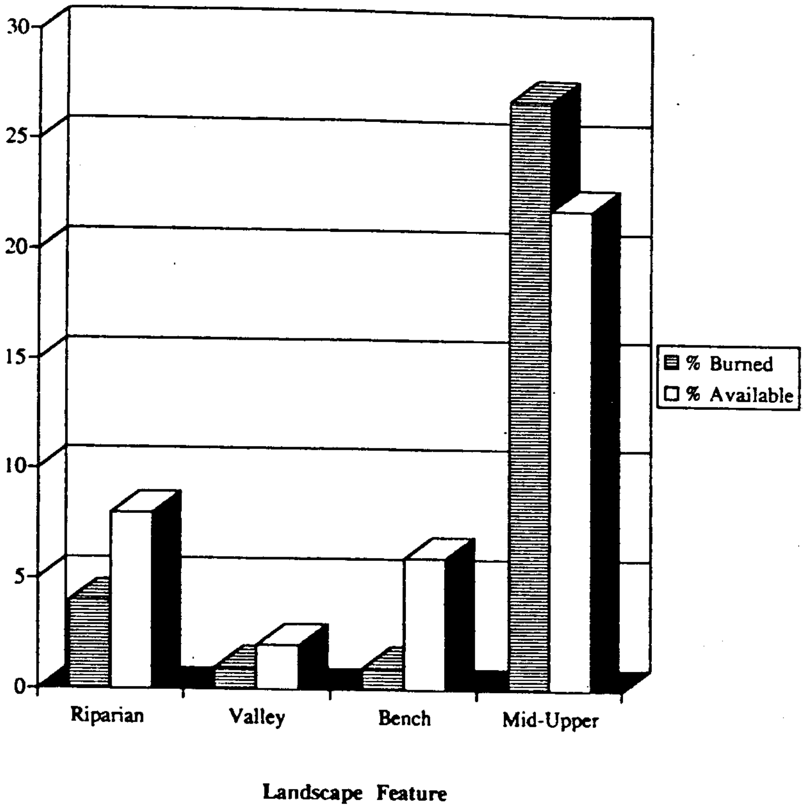

Figure 3. Proportion of spotted owl habitat that burned vs that available at various locations on south aspects, Hatchery Complex fires.

Table 2. Status of spotted owl activity centers for four years prior to the Hatchery Complex fires and one year following.

Status	1991	1992	1993	1994	1995
No Present	50%	25%	20%	17%	66%
Single		25%		33%	
Pair			20%	17%	17%
Reproductive	50%	50%	60%	33%	17%
No. sites	4	4	5	6	6

relation between site status and the amount of habitat remaining after the fire within a 0.8 mile radius (alpha=0.05, $p<0.05$). As the availability of habitat increased so did the site status (no presence being low status and reproductive pair being the highest status).

Reproduction

Data from all owl sites on the Leavenworth Ranger District were used to compare reproduction at burned vs unburned sites. These data are shown in Table 3. The 1995 season (one year post burn) was lower than any of the previous four years at the sites affected by the fires. However, reproduction during 1994 was also quite low, and as shown in Table 3, 1995 was overall a low year for reproduction. Reproduction, at least one year post-fire was not reduced much below previously reported low years.

Spotted Owl Nest Sites and Inherent Fire Regime

A total of 28 nest sites on the Leavenworth Ranger District were evaluated using the fire refugia model developed by Camp (1995). The results of this evaluation are shown in Figure 4. Two (7%) of the nest sites were in

Table 3. Comparison of # young/site at spotted owl activity centers affacted and not by the Hatchery Complex fires.

Site Data	1991	1992	1993	1994	1995
Affected by fires (# young/site)	0.6	1	0.8	0.3	0.2
No. sites	5	5	6	6	6
Not affected fy fires (# young/site)	0.9	1.3	.03	1.8	0.3
No. sites	13	15	15	14	17

locations where there was only a 2% probability of them remaining as fire refugia under an inherent fire regime. Fourteen (50%) of the sites occurred at a position on the landscape in which there was a 10% probability of them remaining as fire refugia under an inherent disturbance regime. Eleven (39%) of the nest sites occurred at locations in which there was a 19% probability, and 1 (4%) was at a location in which there was a 51% probability of them remaining as fire refugia. This assessment examplifies the dynamic nature of spotted owl habitat across a landscape in which fire played its inherent role. This is especially true on forests on the east side of the Cascades where relatively dry conditions resulted in frequent fires (Agee 1994).

Conclusions

Because data from only one season has been collected up to this point, conclusions must be mae very cautiously. Additional monitoring of these sites will occur in succeeding years and data may support the findings made in this initial evaluation or it may provide new insights. However, at this point the following observations about the effects of the Hatchery Complex fires on spotted owls and their habitat have been made.

The fires reduced the availability of spotted owl habitat around six activity centers. The initial direct reduction caused by the fire was not an accurate reflection of the total affects on habitat availability. Fire damaged trees continued to die, and increased insect activity contributed to the total reduction in spotted owl habitat within the burned landscape.

Habitat located within riparian areas and on a bench is somewhat more likely to remain as suitable following a fire vs habitat located on the mid-upper slopes, especially on south slopes. This information should be useful in the development of management plans for habitat reserves.

In the six fire affected activity centers there was a decrease in the number of reproductive pairs and an increase in the number of sites not occupied. Direct mortality likely occurred at one of the sites as a result of rapid and intense fire.

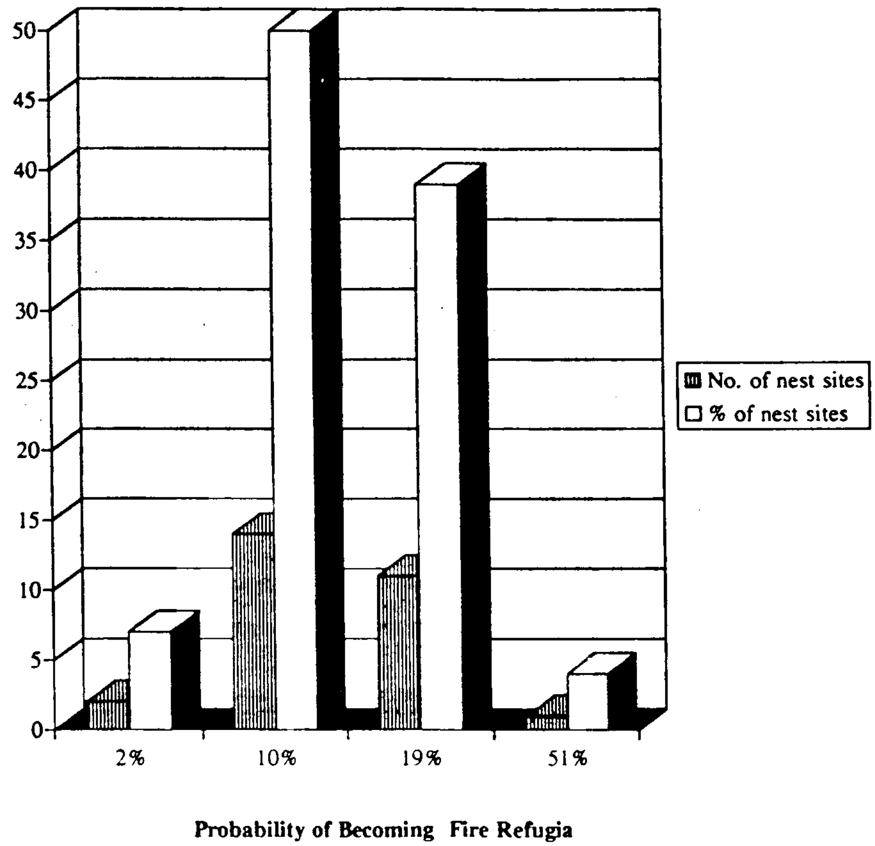

Figure 4. Persistence of spotted owl nest sites (n=28) using the Fire Refugia model (Camp 1995), Hatchery Complex fires.

The availability of spotted owl habitat across the eastern Cascades landscape appears to have been very dynamic under inherent disturbances (Camp 1995). This is an important consideration when developing management strategies for habitat reserves. The fire refugia model developed by Camp (1995) and information from this study should be useful in developing strategies that result in the highest probability of sustaining spotted owl habitat.

Management of fuel loading and tree density within habitat reserves may be neccessary to protect activity centers (Agee and Edmunds 1992). Strategically located low fuel density areas could accomplish dual objectives: protection of adjacent spotted owl habitat and restoration of fire climax ponderosa pine.

Introduction

Knowledge regarding the effects of fuels and vegetation management on California spotted owls (***Strix occidentalis occidentalis;*** CSOs) and their habitat is a primary information need for addressing conservation and management objectives in Sierra Nevada forests. The specific research objectives of the California spotted owl module as identified and described in the Plumas-Lassen Study (PLS) Plan are:

1) What are the associations among landscape fuels treatments and CSO density, distribution, population trends and habitat suitability at the landscape-scale?

2) What are the associations among landscape fuels treatments and CSO reproduction, survival, and habitat fitness potential at the core area/home range scales?

3) What are the associations among landscape fuels treatments and CSO habitat use and home range configuration at the core area/home range scale?

4) What is the population trend of CSO in the northern Sierra Nevada and which factors account for variation in population trend?

5) Are barred owls increasing in the northern Sierra Nevada, what factors are associated with their distribution and abundance, and are they associated with reduced CSO territory occupancy?

6) Does West Nile Virus affect the survival, distribution and abundance of California spotted owls in the study area?

7) What are the effects of wildfire on California spotted owls and their habitat?

Our focus in 2010 was to conduct landscape inventories of CSO distribution and abundance, and continue banding to provide the required data and baseline information to meet the objectives of Research Questions 1-4 identified above. Current information on the distribution and density of CSOs across the HFQLG study area is required to provide the data necessary to build predictive habitat models and provide baseline population information against which we will assess post-treatment changes in CSO populations and habitat. Continued monitoring on the Lassen Demographic Study Area is critical for estimating CSO population trends and status. Complete landscape inventory surveys were conducted across 9 of the 11 original project survey areas in 2010 (Figure 1). Surveys were not conducted in 2 survey areas in 2006-2010 (SA-5, SA-7, Figure 1); sufficient data for determining the number and distribution of CSO sites for initial habitat modeling efforts was collected in these areas from 2004-2005. In 2010, we conducted a second year of surveys in two proposed project areas on the Lassen NF (Scotts John) and Plumas NF (Empire). We added these two new survey areas to the project in 2009 to bring our sample size of survey areas slated for treatment to four (Meadow Valley, Creeks, Scotts John, Empire).

Details on survey methods are described in the study plan. Efforts were made to monitor the pair and reproductive status of each owl, and to capture, uniquely color-mark, and collect blood samples from each individual owl across the study area. Capture and color-marking is necessary to estimate survival and population trend, and to assess exposure to West Nile Virus (WNV) (Research Question #5). We also recorded all barred and hybrid barred-spotted owls encountered in the study area and synthesized all existing barred owl records for the northern Sierra Nevada to address Research Question #6. Additionally, we completed a radio-telemetry study on CSOs within SA-4 in the Meadow Valley project area to document home range size and configuration, and to assess habitat associations relative to the recently implemented treatments. In response to a need for information on the association between CSOs and wildfire we conducted a second year of surveys to assess CSO distribution, abundance and habitat associations in the Cub Onion Complex fire area (COCFA) on the Lassen NF. The information from the COCFA complements our data from the Moonlight-Antelope Complex fire area (MACFA) collected in 2008-2009. The MACFA fires burned in 2007 and we conducted surveys in 2008 and 2009 to assess the immediate post-fire response of CSOs. The COCFA burned in 2008 and we conducted surveys in 2009 and 2010. For both study areas, we surveyed for CSOs in the first and second years immediately post-fire. Finally, we completed an analysis of the demographic data from the Lassen Demographic Study area collected through 2010 to provide the most current information on the status, demography and population trend of CSOs in the northern Sierra Nevada.

Results

CSO Numbers, Reproductive Success, Density and Population Trends:

A total of 71 territorial CSO sites were documented across the core PLS study area in 2010 (Figure 2). This total consisted of 58 confirmed pairs, 3 unconfirmed pairs (i.e., one member of pair confirmed as territorial single plus single detection of opposite sex bird), and 10 territorial single CSOs (single owl detected multiple times with no pair-mate detected). Thirty-one pairs successfully reproduced in 2010 (50.8% of confirmed/unconfirmed pairs). Of these 31 pairs, 18 were located on the Lassen Study Core Area and 13 were located on the Plumas NF. A total of 54 fledged young were documented in 2010 (1.74 young per successful nest) (Table 1). Across the last seven years of the study, CSO reproduction has been highest in 2004, 2007, 2009 and 2010 in terms of the percent of CSO pairs that successfully reproduced, and in terms of the number of young fledged per successful nest. Approximately 50% of CSO pairs successfully reproduced in 2004, 2007, 2009 and 2010 whereas the proportion of pairs successfully reproducing ranged between 14%-18% in 2005, 2006 and 2008. The number of young produced per successful nest was more similar across years, ranging between 1.47 -1.81. Our second year of surveys conducted in 2010 within two project areas yielded 4 pairs (2 pairs present in 2009) of CSOs in the Empire project area and 2 pairs (3 pairs present in 2009) in the Scotts John project area. Two pairs in the Empire project area reproduced in 2010 producing 3 fledglings, whereas neither pair reproduced in the Scotts John project area.

CSO reproduction is known to vary with spring weather: precipitation patterns were more similar in 2004 and 2007, with total precipitation relatively low during March-April of 2004 and 2007 as compared to 2005 and 2006 (Figure 3). From 2004 through 2007, CSO reproduction was high in years of low spring precipitation and low in years with high spring precipitation. However, this pattern between spring precipitation and reproduction varied during 2008-2010. In 2008 spring precipitation was low in March-April, yet CSO reproduction was also low. In contrast, during 2009 spring precipitation was high in February-March, low in April, and CSO reproduction was high on the Lassen portion of the study area and low on the Plumas portion of the study area. In 2010, precipitation was moderate and consistent over the February-May period and CSO reproduction was high. These patterns indicate that additional factors influence CSO energetics and are associated with annual variation in CSO reproduction. Potential factors include elevational variation in cold and hot temperatures, precipitation, duration of spring/summer and snowpack, in addition to annual variation in prey populations.

The Lassen Demographic Study Area (SA-1A, SA-11, SA-12, SA-13, SA-14, SA-15) and Plumas NF Survey Areas (SA-2, SA-3, SA-4, SA-5, SA-7) were fully integrated in 2005 to define the overall Plumas-Lassen Study project area and provide consistent CSO survey effort across the project area (Figures 1 & 2). We estimated the crude density of CSOs based on the number of territorial owls detected across 9 survey areas during 2010 at the Survey Area spatial scales (Tables 2 and 3). The estimated crude density across the overall study area in 2010 was 0.070 territorial owls/km^2. Overall study area crude densities are not directly comparable across years because different total areas were surveyed in each year. However, crude density estimates within individual Survey Areas indicate similar densities and number of territorial sites (pair sites plus territorial single sites) between 2004-2010 for the survey areas on the Plumas NF (SA-2, SA-3, SA-4). while numbers have declined somewhat on the Lassen survey areas (SA-1A, SA-11, SA-12, SA-13, SA-14, SA-15) between 2005-2007 and then stabilized or slightly increased between 2008-2010 (Tables 2 and 3).

We conducted a 5-year update and re-analyzed the demographic data through 2010 following the methods described in Blakesley et al. (2010). These data continue to provide the best estimates of CSO population trends. The Lassen Demographic Study Area is contained within the overall PLS study area and consists of survey areas SA-1A, SA-11, SA-12, SA-13, SA-14 and SA-15 in Figure 1. The estimated mean lambda for the Lassen Demographic Study between 1990-2010 was 0.979 (SE = 0.0097), with 95% confidence limits ranging from 0.959-0.999 (Scherer et al 2010). There was no evidence of linear, quadratic or pseudo-threshold trends in lambda, rather the means model was strongly supported by the data. These results suggest a decline in the CSO population within the Lassen study area over the 20-year study period. Annual lambda estimates from the best model ranged between 0.87-1.13. Estimates of realized population change based on the time series of lambda estimates generated from our modeling suggests that there have been declines in the number of territory holding CSOs within the study area (Scherer et al. 2010). These updated results are similar to the findings reported for the the 1990-2005 period reported in Blakesley et al. (2010).

Habitat Assessment – Nest/Roost Plot Scale

We documented a total of 103 CSO territorial sites between 2004-2006. We overlayed the primary nest/roost locations for each of the 103 CSO sites with the CWHR vegetation classes available within the VESTRA photo-interpreted vegetation map for the PLS to examine nest/roost-site habitat association patterns. Approximately 53% of the nest sites were located within CWHR 5M, 5D and 6 size classes (Table 4, Figure 4). An additional 37% of the sites were located within CWHR size class 4M and 4D polygons. CWHR size class 4 is defined as stands with average tree sizes of 12-24 inch diameter-at-breast-height (dbh) trees. Of the 38 sites located in size class 4 polygons, 25 (66%) were in size class 4 polygons with a large tree component (i.e., presence of >24 inch dbh trees). Overall, about 90% of the sites were located within CWHR 4M, 4D, 5M, 5D, and 6 size classes. The remaining 10 sites were located in more open, smaller-tree size polygons, with nests or roosts located within remnant, scattered larger trees (Table 4, Figure 4).

While the distribution of nest site locations relative to broad vegetation classes provides insight into patterns of nest-site habitat, we also conducted vegetation sampling at nest or primary roost sites to describe vegetation structure and composition. Vegetation plot sampling was conducted at 80 CSO territories across 2005-2007. Vegetation plots were centered on CSO nest trees, or on a primary roost tree for sites where no nest has been documented, and were measured using the national Forest and Inventory Assessment (FIA) protocol. The FIA protocol is used nationally by the USDA Forest Service for inventorying and monitoring vegetation. FIA sampling consists of measuring vegetation structural and compositional variables within a 1-ha plot centered on a CSO nest or roost tree. Only one plot was collected from each CSO territory, with the most frequently used nest tree serving as the plot center location, or the most recent nest tree used at sites where no nest tree was used more frequently than another. CSO nest sites were characterized by mean total basal areas of 260.8 ft^2/acre, 7.4 snags (>15 inch dbh)/acre, and 10.7 trees (>30 inch dbh)/acre (Table 5). Under the FIA protocol, canopy cover is modeled based on the tree inventory list. The modeled canopy cover for these plots averaged 64.1%. Shrub cover averaged 7.7%. Fuel loads averaged 0.75 tons/acre for 1-hr fuels, 4.0 tons/acre for 10-hr fuels and 4.44 tons/acre for 100-hr fuels (Table 5). Use of the FIA sampling protocol will facilitate monitoring of vegetation and development of CSO habitat models that can be used as adaptive management planning tools. Habitat models are currently being evaluated that can be used to assess projected changes in CSO nesting habitat suitability under varying fuels and vegetation treatment scenarios.

Habitat Assessment – Core Area/Home Range Scale

Core area habitat associations around 102 CSO nest and roost sites was assessed by using a Geographic Information System (GIS) and the VESTRA photo-interpreted vegetation map to determine the vegetation patterns within a 500 acre (201 ha) circle centered on each of the CSO territory sites. To compare the CSO sites with the general availability of habitat across the study area we also assessed the same vegetation patterns around 130 points determined by placing a systematic grid across the study area. For this summary we assessed vegetation using the USDA Forest Service Region 5 classification system. Overall, CSO core areas averaged 75.7% suitable habitat (classes 3N, 3G, 4N, 4G) whereas the grid points averaged 61.9% (Table 6, Figure 5). Approximately 32% of CSO core areas was composed of large tree polygons (>24inch dbh, >=40% canopy cover) compared to 19.6% of the grid points (Table 6, Figure 6).

Meadow Valley Project Area Case Study

The Meadow Valley Project Area (MVPA) is the first area within the PLS where the full implementation of HFQLG treatments has occurred. Treatments were implemented on the ground within this project area during 2001-2008, with primarily light-thinning and underburning occurring in 2001-2005, and Defensible Fuel Profile Zones and Group Selections implemented during 2005-2008. The MVPA corresponds closely with the boundaries of SA-4 of the PLS (Figure 7).

We began monitoring CSOs SA-4 in 2003 and have annually monitored the distribution, abundance and reproduction of CSOs within SA-4. Additionally, we have color-banded all individuals within this area, with the exception of one male who could not be captured. Full survey methods are described in detail in our study plan (available from field project leaders) and are consistent with USDA Forest Service R5 survey methods. Briefly, we conduct 3 nocturnal broadcast surveys during the breeding period (April-August) across a network of survey points to detect CSOs. When a CSO is detected we then conduct dusk status surveys to pinpoint roost and nest locations for each bird. Status surveys are used to determine the social status of each bird (pair or single), nesting and reproductive status (breeding, non-breeding, unknown), and to identify color-banded individual birds.

In general, in years of higher CSO reproduction, such as occurred in 2004 and 2007, it is easier to establish pair and reproductive status and to identify individual birds as they are more vocal and exhibit stronger ties to their core areas. In years of lower reproduction, such as occurred in 2005, 2006, 2008, and 2009 (reproduction was low on the Plumas NF, while high on the Lassen NF portion of the study area in 2009) it is more difficult to determine the status of birds as they tend to range more widely and are not as vocal and territorial, particularly the females. Based on our cumulative survey results, we then use accepted, standardized methods for estimating the overall number of territorial sites (confirmed pairs, unconfirmed pairs and territorial singles) for each year. Confirmed pairs consist of a reproductive pair of CSOs or, at non-reproductive sites, the detection of a male and female on more than one occasion within 1/2-mile of each other across the breeding period. Unconfirmed pairs consist of at least two sightings of one sex but only one detection of the opposite sex within 1/2-mile of each other across the breeding period. Territorial singles are considered to be individuals that are detected on at least 2 occasions within a 1/2-mile distance across the breeding period without a detection of the opposite sex. Birds detected on only a single occasion across the breeding period are not considered to be territorial.

Figure 7 illustrates treatment project areas and the cumulative number and distribution of CSO territorial sites across the seven years between 2003-2010. The number of territorial sites across SA-4 varied annually between 6-9 (Table 7, Fig. 8a&b). Overall, the numbers of territorial sites was fairly similar with 7 sites documented between 2004-2006, an increase to 9 territorial sites during the high reproductive year that occurred in 2007, decreasing to 6 territorial sites in both 2008 and 2009, with 7 sites documented in 2010.

Whereas we have not detected much change in the number of CSO territorial sites across SA-4, we have documented changes in occupancy status and spatial movements of individual sites that may be associated with treatments. The Maple Flat site, located in the NW corner of SA-4 was occupied from 2004-2007, not occupied in 2008 following treatments in autumn 2007, and was colonized by an unconfirmed pair of new CSOs who were present in the area during 2009 and 2010. Whether or not the treatments caused the site to be unoccupied in 2008 is uncertain as the male also died during the winter of 2007-2008 (determined by radio-telemetry). The female from 2007 visited the site in early 2008 then moved and summered 14.5 km (9 miles) from Maple Flat near Seneca in early June 2008. She remained in this area through October 2008 when she was recaptured and the radio-transmitter was removed. No new CSOs were detected or colonized the Maple Flat site in 2008.

We also observed movement of a site in the SW corner of SA-4 that corresponded to the timing of treatments in the nest core. This site (Miller Fork) was occupied by CSO pairs in 2003-2005, a single male in 2006 following treatments in 2005-2006, and then was not occupied between 2007-2009. However, a new CSO pair established a site (Big Creek) in 2007 about 2km to the NW of this site. This new site has been occupied by a pair from 2007-2010.

Changes in occupancy status were recorded at a third site that coincided with the timing of treatments. A pair of CSOs occupied Whitlock Ravine from 2003-2008. Treatments were implemented near the core area during 2008. The female CSO was found with a broken wing alongside a road in November 2008. In 2009, the historic male occupied the site as a single male. No CSOs occupied the site in 2010; the male was located 8.1 km (5 mi) southwest of Whitlock Ravine.

CSO pairs were present at Deer Creek from 2003-2007 and fledged triplets in 2007. The female died during the winter 2007-2008 and the site was not occupied from 2008-2010. Treatments had been conducted to the south of the core area of this pair in 2006 and the female was observed to forage in this area in 2007.

We also documented changes in occupancy at 1 site in the eastern portion of SA-4 that were outside the area of treatments. Slate Creek was occupied by a male in 2003 and a pair in 2004, yet has not been occupied since. The female from 2004 was detected on the Lassen NF, and then she was back on the Plumas in subsequent years. This female was not detected in 2009 but was again observed in 2010.

We documented the colonization of a new site (Pineleaf Creek) during and following treatments in the north portion of SA-4. A single territorial male was present in this area in 2006, with a pair of CSOs then present from 2007-2010. This pair successfully reproduced in 2009.

To date, we have not observed dramatic changes in the numbers of territorial CSO sites within SA-4 as an immediate acute response to treatments. These initial findings should be tempered by the need to assess possible chronic, or longer-term, responses by CSOs. Of importance, 2008 and 2009 were low reproductive years on the Plumas NF, with only 2 nests in 2008 and 7 nests in 2009 documented across all of the Plumas NF sites. The conditions leading to the low reproductive activity in 2008 and 2009 may have resulted in a low probability of recruitment and occupancy of sites in both years. For example, a higher number of territorial sites (9) were documented within SA-4 in the higher breeding year of 2007 as compared to the 7 territorial sites documented in the low reproductive years of 2005-2006. Also, higher CSO reproduction in 2007 may result in increased number of recruits available to colonize sites in 2009-2010. In 2010, we again documented 7 territorial sites. Thus far in our study, this landscape has supported 6-7 CSO territorial sites in each year, except for the high reproductive year in 2007 when 9 territorial sites were documented. We recommend that monitoring be continued to assess: (1) long-term occupancy, abundance and distribution of CSOs across the project area to document longer-term responses to address concerns that site fidelity in such a long-lived species may obscure possible negative effects of habitat change over the short term; and (2) to continue to monitor color-banded birds to assess longer-term associations between CSO survival, reproduction, and recruitment related to changes in habitat. Each of the pieces of above information is necessary to fully assess the potential acute and chronic responses of CSOs to landscape treatments.

Whereas we have not observed dramatic short-term changes in CSO numbers across the broader MVPA in response to treatments, we have documented some changes in the distribution and occupancy of CSO territories where treatments have occurred within SA-4 that may be associated with treatments. Accurate spatial post-treatment maps for the MVPA have been recently completed (March 1, 2010) documenting: (1) the specific locations where treatments were actually implemented on the ground; (2) the specific site-specific treatments that were implemented on a piece of ground; and (3) when the treatments were implemented on the ground (which year at minimum). Unfortunately, significant errors in the classification of canopy cover within base vegetation maps were discovered in 2010 while conducting habitat analyses and modeling exercises designed to explore the association between CSOs, their habitat, and treatments. This resulted in the need to recreate an updated landscape vegetation map for the project area. This updated vegetation map for MVPA is scheduled to be completed by March 2011. Understanding the what, where, when, and effects of treatments is the foundation on which subsequent adaptive management assessments will be constructed. This information has been difficult to obtain and is required to be able to explore the associations between treatments and CSO responses at the landscape and home range spatial scales, in addition to relating within home range habitat use through our telemetry studies.

Radio-Telemetry – Meadow Valley Project Area

Our landscape-scale research in the MVPA provides insight into CSO response at population and territory spatial scales. Within home ranges, CSOs may also respond to treatments in terms of selection of foraging habitat. To evaluate spotted owl foraging and home range characteristics in a landscape recently modified by fuels-reduction treatments, we radio-marked and tracked 9 CSOs in the MVPA area from April 2007-October 2008. Prior to this study, spotted owl foraging patterns in post-treatment landscapes had not been well-described. This telemetry study was designed to explore initial behavioral responses of California spotted owls to fuels treatments by characterizing home range configuration and foraging site selection immediately following treatment installation.

We gathered 446 owl foraging locations across 2 breeding seasons, and categorized fuels treatments into 4 types: Defensible Fuel Profile Zones (DFPZs), understory thin (removal of trees <10-inches diameter); group selection (removal of all trees <30-inches diameter in <0.8-ha patches); and understory thin followed by underburn. We estimated owl home ranges from 30-60 owl locations per home range, using a fixed kernel density estimator; only owl locations with an error ellipse <1.5 ha were used in analyses. We evaluated spotted owl home range size and composition using repeated measures analysis of variance (ANOVA) and resource selection functions. To analyze owl foraging patterns within home ranges, we evaluated a priori hypotheses using an information-theoretic approach and Akaike's Information Criterion corrected for small sample sizes.

During the 2007 season, we gathered 236 nocturnal use locations across all individuals, with 4 locations occurring within fuels treatments. In 2008, we gathered 210 nocturnal use locations, and 32 of these locations occurred within fuels treatments. Spotted owls used all treatment types for nocturnal activities on at least one occasion; 51% of within-treatment locations were accounted for by one spotted owl foraging repeatedly in underburn.

At the landscape scale, owl home ranges contained fuels treatments in proportion to their availability on the landscape. Owl home ranges contained 7-35% fuels treatments ($\bar{x}$= 16%), with home range size positively correlated with the total amount of fuels treatment within the home range (p=0.049). Spotted owls selected against DFPZs (p=0.006), but not other fuels treatments, for nocturnal activities; we hypothesize that the habitat character of DFPZs may be unfavorable for common spotted owl prey species (Figure 9). One owl strongly selected underburn treatments over untreated forest for foraging; limited availability of underburn within the study area prevents further extrapolation of this result. Spotted owls foraged much closer to their site center than expected by chance; because fuels treatments are not permitted within PACs (located at most owl site centers), the required travel distance between the site center and fuels treatments complicates result interpretation. Conclusions from this study are exploratory and are intended to provide a baseline for further research (Gallagher 2010).

Our next action, scheduled for completion in 2011, is to use a detailed landscape-scale habitat map to incorporate habitat metrics into home range and foraging analyses. The plot-scale vegetation structure and composition will also be analyzed at a subsample of CSO radio-telemetry locations. Eighty-seven vegetation plots were measured to the standard FIA protocol between August-November 2008, and forty-five additional vegetation plots were measured to the same protocol in September-October 2009.

We recommend further exploration of spotted owl use of fuels treatments, particularly underburn, across multiple time periods and at patch, home range, and landscape spatial scales. Additionally, considerations should be given to the design and implementation of rigorous experimental studies to address the effects of fuels treatments on spotted owl nesting and foraging habitat. A repeat of this study in 4-5 years, coupled with a study of spotted owl population dynamics, would provide a comprehensive assessment of owl response in the MVPA area. Evaluation of long-term effects is critical for long-lived species such as the spotted owl (Blakesley et al. 2010); effects of fuels treatments on the owl may manifest after short and long time periods, each with ramifications for ecological understanding in the Sierra Nevada.

Wildfire –California Spotted Owl Case Studies

A primary source of uncertainty regarding the effects of fuels treatments is an assessment of risk to CSOs and their habitat from treatments versus the risk from wildfire that occurs across untreated landscapes. Prior to 2008 our PLS work had focused on assessing CSO distribution, abundance and habitat associations across the untreated overall project area landscape and being in position to monitor effects as treatments are implemented within specific project areas, as illustrated by the MVPA case study described above. Beginning in 2008 we were fortunate to have the opportunity and funding support from the Plumas and Lassen National Forests to extend our work to inventory CSO distribution, abundance, and status across the Moonlight and Antelope Complex fire area (MACFA) that burned on the Plumas National Forest in 2007. In 2009 we conducted a second year of surveys in the MACFA and also conducted the first year of similar surveys in the Cub-Onion Complex fire area (COCFA) that burned on the Lassen National Forest in 2008. As described below, the MACFA was largely a high severity wildfire while the COCFA burned primarily at low-moderate severity. In 2010 we conducted a second year of surveys in the COCFA. Incorporating these two study areas which differ in wildfire severity allow us to directly assess response of CSOs to landscapes that burned with different severities.

The MACFA consists of two fires burned adjacent to each other in 2007 and both were primarily high severity fires (Fig. 10). The MACFA covers approximately 88,000 acres. The COCFA consist of two low-moderate severity fires that burned adjacent to each other during June 2008 over approximately 21,000 acres (Fig. 10). About 52% of the MACFA burned at high severity whereas only 11% of the COCFA burned at high severity (Fig. 11).

In both wildfire study areas we conducted CSO surveys during the breeding period across the entire landscape and within a 1.6 km (1 mile) unburned buffer surrounding the fire perimeter. We used our standardized survey protocol and conducted 3 nocturnal surveys across the landscape with follow-up visits to attempt to located nest/roost locations for birds detected on nocturnal surveys. These methods are described in the section above and fully in protocol described in the study plan.

The high-severity fires that burned in the MACFA resulted in significant changes to the vegetation (Fig. 12 & 13). The amount of suitable CSO habitat (CWHR classes 4M, 4D, 5M, 5D) within the 88,000 acre MACFA decreased from 70.1% of the pre-fire landscape to 5.8% of the landscape following the fires. The largest increase in the post-fire landscape occurred in the CWHR classes <= 2D which increased from 8.2% to 64.9%. The remaining forested areas across the post-fire landscape were predominantly classified as either 4P (18.5%) or 4S (7.9%).

We are still in the process of synthesizing all of the pre-fire CSO survey information for the MACFA as there is not a solid baseline of consistently collected survey information prior to the fire such as exists for our core PLS project area. Nevertheless, this synthesis may provide us with a reasonable estimate of the pre-fire distribution and abundance of

CSO sites across the MACFA. All or parts of at least 23 PACs were located within the pre-fire MACFA. Given the lack of continuous annual CSO survey effort we are uncertain what proportion of those PACs were occupied in 2007 prior to the fires.

During our 2008 surveys we documented a single confirmed pair of CSOs (non-breeding) within the MACFA, with the female from this pair being the only female we detected within the fire area (Fig. 14). We had 10 single detections of male CSOs across the burned area. In each of these ten cases we were not able to locate the birds at nests or roosts on follow-up status surveys. Each of these ten locations occurred primarily in the middle of the night when birds are out foraging and none of the detections occurred within 1/2-mile of each other as required to classify these individuals as territorial birds under currently accepted protocols. Within the unburned 1-mile buffer area surrounding the burned area we documented 5 confirmed pairs, 1 unconfirmed pair, 1 territorial male single, and 6 single detections (4 males, 2 sex unknown). Thus, in the immediate unburned buffer area we observed territorial sites whereas we only were able to document the single confirmed territorial pair within the burned area.

During our 2009 surveys within the MACFA we documented a single confirmed pair of CSOs in the same location as the pair documented in 2008 (Fig. 14). Within the 1-mile buffer area we documented 7 confirmed pairs, 0 unconfirmed pairs, 2 territorial single males, and 3 single detections. In contrast to 2008, in 2009 we did not record single detections of apparently non-territorial single birds within the fire perimeter across the MACFA landscape. Rather, we only recorded 3 detections of CSOs near the perimeter of the fire in the vicinity of confirmed pairs located within the buffer around the fire.

In our two years of work we were able to document significant changes to the vegetation and amounts and distribution of CSO habitat within the MACFA as a result of the high-severity wildfires. Our CSO survey work suggests that the immediate post-fire landscape may not support territorial CSO sites as evidenced by the single confirmed pair of owls that we documented in 2008 in 2009. In 2009 we did not document single male CSOs across the burned landscape, suggesting that the apparently non-territorial single males observed in 2008 may have been present because of previous site fidelity or were perhaps opportunistically utilizing a flush of prey in the first year following the fire. In both years, territorial CSOs were present in similar numbers and distributed at expected spacing within the buffer area surrounding the fire. Thus, our results from our 2 years of work suggest that the primarily high-severity MACFA does not support CSOs other than a single pair that is using the landscape. Further, territorial CSO sites are well-distributed within the buffer area outside of the fire perimeter. Our 3 detections of individual CSOs just within the perimeter of the burned areas suggest that some CSOs are able to exploit the edge between the burned and unburned areas for foraging.

In our first year of surveys during 2009 in the COCFA we documented 3 confirmed territorial pairs, 1 unconfirmed territorial pair, and 2 territorial single male CSOs, for a total of 6 territorial CSOs sites within the fire perimeter (Fig. 15). Additionally, we had 6 single detections (3 male, 3 unknown sex) of individual CSOs within the fire perimeter. Within the buffer area we documented 3 confirmed pairs and 3 single detections (2 male, 1 female). These results and distribution patterns suggest that CSOs were able to persist in the post-fire COCFA landscape with similar abundance and spacing as has been observed in unburned forests outside the burned areas.

In 2010 we attempted to repeat the complete landscape survey coverage of the COCFA. However, we were precluded from accessing the entire landscape area by law enforcement restrictions due to safety concerns for field crews. Extensive, illegal marijuana growing operations were distributed widely across the COCFA landscape. Due to this limitation we instead conducted focused surveys within approximately 1-2 miles surrounding each of the sites that were occupied by CSOs in 2009. Although we may have missed new sites colonized in 2010 outside our focused survey areas, our efforts allowed us to determine if the 2009 sites were still occupied in 2010. In 2010 we documented 2 confirmed territorial pairs and 1 unconfirmed territorial pair of CSOs within the fire perimeter, and 2 confirmed territorial pairs and 1 unconfirmed territorial pair within the 1-mile buffer. Overall, in 2009 there were 7 pairs (6 confirmed and 1 unconfirmed) within the fire plus the 1-mile buffer. In 2010, there were 6 pairs (4 confirmed and 2 unconfirmed) in this same area. These results suggest that CSOs are able to persist within landscapes that experience predominantly low-moderate severity wildfire.

It is important to determine both the acute and chronic responses of CSOs and their habitat to wildfire as it is unknown if CSOs can persist over both the short-term and long-term in these areas. Whether a post-fire landscape can support CSOs likely depends on the pre-fire habitat suitability and variable fire severity patterns both within individual fires and across different fires. Largely low-moderate severity fires may have positive or neutral effects on CSOs and their habitat while high severity fires may result in greater negative effects. Our results into the acute, short-term response of CSOs to wildfire from the primarily high-severity MACFA and primarily low-moderate severity COCFA support this hypothesis. Additionally, information on the pre- and post-fire vegetation, location of salvage logging, and habitat conditions are needed to fully assess the response of CSOs and their habitat to wildfire in the MACFA and COCFA wildfire landscapes.

Banding, Blood Sampling, West Nile Virus Monitoring

Sixty-three owls were captured and banded in 2010. Blood samples were collected from 11 individuals that will be screened at the University of California, Davis for West Nile Virus (WNV) antibodies. None of the 141 individual blood samples collected from the northern Sierra Nevada from 2004-2008 have tested positive for WNV antibodies (Hull et al. 2010). The 2009 and 2010 samples have not been analyzed to date.

Barred and Sparred (Spotted x Barred hybrid) Distributional Records

We detected 7 barred owl and 3 sparred owls during 2010 surveys within our PLS study area. This result represents the highest number of barred and sparred owls that we have detected in any year during our study from 2004-2010. Our synthesis and update of barred-sparred owl records through 2010 based on Forest Service and California Department of Fish and Game databases indicates that there are a minimum of 44 individual site records across the broader HFQLG Project Area and a minimum total of 57 across the Sierra Nevada (Figure 16). This includes a minimum total of 24 records that have been documented within our intensively surveyed PLS study area. The first barred owl in the region was reported in 1989. The first documented breeding in the PLS survey area was in 2007 and consisted of a sparred owl paired with a CSO. In 2010, we documented the first barred-barred owl nest record for the northern Sierra Nevada to the best of our knowledge. Despite several surveys, the outcome of this barred-barred owl nesting attempt is uncertain, as the pair was non-responsive during the fledgling period. The pattern of records suggests that barred/sparred owls have been increasing in the northern Sierra Nevada from 1989-2010 and are now present in low, stable numbers over the past 4-5 years on our study area. This pattern is consistent with that observed in other areas as barred owls have expanded their range in western North America. Initially barred owls colonize an area and persist at low population numbers, during this period they may hybridize with spotted owls. At some threshold population size or when ecological conditions allow they are then poised for, and capable of, exhibiting exponential population growth. Notably, we detected an increase in barred numbers in 2010. This situation requires further monitoring and we recommend that an inventory of barred owls be conducted using barred owl-specific survey methods to document the distribution and status of barred owls in the northern Sierra Nevada.

California Spotted Owl Diet

A single diet survey plot was established at a CSO nest or roost location at each CSO territory on the Plumas National Forest during 2003-2007. Systematic searches for pellets and prey remains were conducted in each plot during each year. A total of approximately 3398 pellets have been collected during 2003-2007 (2003 = 606; 2004 = 807; 2005 = 838; 2006 = 516; 2007 = 552). We completed sorting of all pellets and identification of all prey remains in January 2010. All prey items are identified to species, or taxonomic group when species identification could not be ascertained. A total of 8,595 prey items have been recorded from the pellets. Mammals are the dominant taxonomic group and comprise of 96.5% of the total biomass identified in the diet. Across years the highest biomass contributions were from the dusky-footed woodrat (contributed 45% of the estimated total biomass) and northern flying squirrel (10.8%). Our objective has been to sample over several years to assess temporal variation in diets and possible relationships to variation in CSO reproduction, and to sample widely over space in order to investigate potential variation in CSO diets associated with elevation and vegetation conditions. We will now be able to address these questions given completion of the sorting and prey identification from the pellet samples.

Summary 2003-2010

Our efforts from 2003-2010 have focused on monitoring CSO distribution, abundance and demographics to address our primary research objectives and provide the baseline data for assessing the effects of HFQLG implementation. In conjunction with the now fully integrated Lassen Demographic Study we have collected landscape-scale information on the distribution and abundance of CSOs across approximately 650,000 acres of land. Determining the accurate number and distribution of CSO sites requires multiple years of survey and marking of individual CSOs to delineate separate territories and identify individual birds that move among multiple sites within and across years. These baseline data are fundamental for developing empirically-based habitat models for understanding CSO habitat associations and developing adaptive management tools and models. The completion of the Meadow Valley area projects in 2007-2008 marked the first landscape series of HFQLG treatments to be implemented within the study area, providing the first opportunity to address treatment effects within a case study framework. Our baseline information on CSO distribution and habitat associations, coupled with our 2007-2008 radio-telemetry work, will allow us to assess associations between CSOs and vegetation changes. In 2009-2010 we were now able to monitor post-treatment CSO distribution and abundance in the Meadow Valley project area, providing the first empirical data from a treated landscape. Our short-term results to date suggest that CSOs are able to persist in this treated landscape, although we have observed territory-specific responses in both areas that have experienced treatments and sites where no treatments have occurred. In 2010, we also completed the analysis of the radio-telemetry work which has provided insight into how individual owls respond to treatments within the first 1-2 years following implementation.

Additionally we were able to expand our work to address the effects of wildfire and CSOs and their habitat through our 2008-2010 survey work in the Moonlight-Antelope Complex and Cub-Onion Complex fire areas. In summary, we are working towards being able to broadly address CSO management questions across a gradient of landscape conditions ranging across untreated landscapes, landscapes treated to meet desired fuels/vegetation conditions, and landscapes that have experienced wildfire in order to address primary management issues.

Dedicated monitoring of CSOs on the Lassen Demographic study continues to provide critically valuable demographic and population trend information for determining the status of CSOs. Our analyses of the demographic data through 2010 continue to suggest that the CSO population on study area declined over the 20-year study period, similar to the results through 2005 reported in Blakesley et al. (2010). These results warrant close continued monitoring of the status of CSOs within the study area, along with continued management focus on providing high-quality CSO habitat during the planning and implementation of HFQLG treatments. We lack similar long-term demographic data for the Plumas NF study areas, but our baseline information on CSO distribution and abundance suggests that numbers of territorial CSOs and sites have been fairly consistent from 2004-2010.

Our focused diet analyses have broadened and deepened our understanding of CSO diets and sources of variation in CSO diets among pairs and across environmental gradients. Monitoring of WNV exposure coupled with demographic monitoring has provided an opportunity to assess if WNV may ultimately be a factor influencing CSO viability. We have provided the first information investigating evidence for CSO exposure to West Nile Virus in the Sierra Nevada (Hull et al. 2010). To date we have not had a positive detection for WNV within CSOs. Through our research into historical and current occurrence records, in conjunction with our field surveys, we have been able to document the colonization of the northern Sierra Nevada by barred owls. Our results indicate that barred owls are increasing in the northern Sierra Nevada and may become an increasing risk factor to CSOs.

Current Research: 2011

In 2011 we will continue monitoring owl distribution, abundance, demography, and population trend across the core PLS study area, including post-treatment monitoring in the Meadow Valley Project area. Additionally, we will continue monitoring within the Creeks Project Area on the Lassen NF, as this area is projected to receive forest and fuels treatments in the near future. In 2011 we will also initiate surveys in suitable CSO habitat within the Storrie Fire footprint to collect information on CSO response to this wildfire following 10-11 years of post-fire vegetation change. These data will also be used to inform restoration efforts within the Storrie Fire landscape. Together this work will contribute to our efforts to build a more comprehensive base of knowledge regarding CSO habitat associations and the effects of treatments and wildfires.

In addition to continuing field surveys designed to address our seven research questions, we have broadened our emphasis on the development of predictive habitat relationship models as described in the module study plan. We have continued to work closely with biologists on the Plumas and Lassen National Forests, and the R5 Regional Office, to identify and define the types of analyses and tools that would best address management needs. Baseline information collected during this study forms the foundation for this phase of the research. The combination of broad-scale landscape CSO distribution data, in conjunction with detailed demographic information available from the Lassen Demographic Study, will facilitate exploration and development of predictive habitat models for use in an adaptive management framework and to directly monitor implementation of the HFQLG project. The greatest challenge and obstacle to this research has been the lack of accurate pre- and post-treatment vegetation information and accurate spatial locations of treatments. Significant progress has been made in these 2 areas over the past year. Efforts to address vegetation and treatment mapping information needs for habitat modeling are underway and accurate vegetation maps are projected to be completed in 2011. Completion of the needed vegetation maps will facilitate completion of the primary research objectives for this project.

Table 4. Distribution of California spotted owl nest/primary roost sites (n = 103) across CWHR tree size classes within the Plumas-Lassen Study on the Plumas and Lassen National Forests, 2004-2006.

CWHR Size Class*	CWHR Size Class Description	Number of Nests	Percent
Barren	Open, sparse tree coverage	1	1.0
3S	6-12 inch dbh, ,20% CC	1	1.0
3M-LT	6-12 inch dbh, 40-60% CC, large trees recorded	1	1.0
3D	6-12 inch dbh, >60% CC	4	3.9
4P	12-24 inch dbh, 20-40% CC	3	2.9
4M	12-24 inch dbh, 40-60% CC	3	2.9
4M-LT	12-24 inch dbh, 40-60% CC, large trees recorded	12	11.7
4D	12-24 inch dbh, >60% CC	10	9.7
4D-LT	12-24 inch dbh, >60% CC, large trees recorded	13	12.6
5M	>24 inch dbh, 40-60% CC	25	24.3
5D	>24 inch dbh, >60% CC	9	8.7
6	>24 inch dbh, >60% CC, multi-layer canopy	21	20.1

*defined by average tree size (dbh = diameter at breast-height) and average percent canopy cover (CC).

Table 5. Nest-site (1 ha (2.47 acres)) habitat characteristics collected using the Forest Inventory and Analysis sampling protocol at California spotted owl nest sites (n = 80) on the Plumas and Lassen National Forests, California, 2005-2006.

Variable	Mean	SE
Total Basal Area (ft^2/acre)	260.8	6.47
# Trees >= 30 inch dbh (#/acre)	10.7	0.58
Basal Area Trees >= 30 inch dbh (ft^2/acre)	96.0	5.70
# Trees >= 24 inch dbh (#/acre)	19.9	0.90
Basal Area Trees >= 24 inch dbh (ft^2/acre)	131.7	6.29
# Trees <12 inch dbh (#/acre)	383.5	26.36
Basal Area Trees , <12 inch dbh (ft^2/acre)	50.1	2.71
# Snags >=15 inch dbh (#/acre)	7.4	0.80
Mean Duff Depth (inches)	3.0	0.16
Duff (tons/acre)	67.4	3.64
Mean Litter Depth (inches)	2.3	0.18
Litter (tons/acre)	23.7	1.81
1 Hour Fuels (tons/acre)	0.75	0.03
10 Hour Fuels (tons/acre)	4.0	0.21
100 Hour Fuels (tons/acre)	4.4	0.28
Shrub Cover (%)	7.7	1.16
Canopy Cover (%)*	64.1	1.24

* estimated through Forest Vegetation Simulator modeling of plot-based tree lists.

Table 6. Distribution of USDA Region 5 vegetation classes (Mean (SE)) within 500 acre (201 ha) circles centered on California spotted owl (CSO) territories (n = 102) and systematic grid (Grid) points (n = 130) within the Plumas-Lassen Study on the Plumas and Lassen National Forests, 2004-2006.

R5 Size Class*	**R5 Size Class Description**	**CSO**	**Grid**
Non-forest	Sum of non-forest land types	4.4 (1.0)	8.4 (1.2)
Total Size 1	Sum of 1G,1N, 1P, 1S: <6 inch dbh, all %CC classes	1.7 (0.3)	1.6 (0.3)
2P & 2S	6-12 inch dbh, 10-39% CC	3.4 (0.4)	4.1 (0.5)
2N	6-12 inch dbh, 40-69% CC	3.8 (0.6)	4.4 (0.9)
2G	6-12-24 inch dbh, >=70% CC	1.6 (0.5)	0.5 (0.1)
3P&3S	12-24 inch dbh, >10-39% CC	9.2 (0.8)	16.1 (1.3)
3N	12-24 inch dbh, 40-69% CC	37.2 (2.4)	38.5 (1.8)
3G	12-24 inch dbh, >=70% CC	6.2 (1.0)	3.8 (0.7)
4P&4S	>24 inch dbh, >10-39% CC	1.0 (0.3)	2.1 (0.4)
4N	>24 inch dbh, 40-69% CC	25.8 (2.0)	17.3 (1.6)
4G	>24 inch dbh, >=70% CC	6.5 (0.1)	2.4 (0.8)
Total 4N & 4G	Sum of 4N & 4G: >24 inch dbh, >= 40% CC	32.4 (2.3)	19.6 (1.8)
Total Suitable habitat	Sum of classes 3N, 3G, 4N, 4G = >12 inch dbh, >40% CC	75.7 (2.19)	61.9 (1.75)

*defined by average tree size (dbh = diameter at breast-height) and average percent canopy cover (CC).

Table 7. Annual number of California spotted owls documented during the breeding period (April-August) in SA-4 (Meadow Valley Project Area), Plumas National Forest, California, 2003-2010.

Year	Confirmed Pairs	Unconfirmed Pairs	Territorial Singles	Total Territorial Sites
2003	7	0	1	8
2004	7	0	0	7
2005	4	1	2	7
2006	3	1	3	7
2007	8	0	1	9
2008	5	0	1	6
2009	5	0	1	6
2010	5	0	2	7
