

STREAM INVENTORY REPORT

Two Log Creek

INTRODUCTION

A stream inventory was conducted during the summer of 1997 on Two Log Creek, beginning at the confluence with a right bank tributary near Jackson State Forest boundary. The inventory was conducted in two parts: habitat inventory and biological inventory. The objective of the habitat inventory was to document the habitat available to anadromous salmonids in Two Log Creek. The objective of the biological inventory was to document the presence and distribution of juvenile salmonid species.

The objective of this report is to document the current habitat conditions, and recommend options for the potential enhancement of habitat for coho salmon and steelhead trout. Recommendations for habitat improvement activities are based upon target habitat values suitable for salmonids in California's north coast streams.

WATERSHED OVERVIEW

Two Log Creek is tributary to the Big River, tributary to the Pacific Ocean, located in Mendocino County, California (Map 1). Two Log Creek's legal description at the confluence with Big River is T17N R16W S23. Its location is 39°19'12" north latitude and 123°36'47" west longitude. Two Log Creek is a second order stream and has approximately 3.9 miles of blue line stream according to the USGS Comptche 7.5 minute quadrangle. Two Log Creek drains a watershed of approximately 4.9 square miles. Elevations range from about 100 feet at the mouth of the creek to 900 feet in the headwater areas. Mixed conifer forest dominates the watershed. The watershed is primarily owned by private timber companies and is managed for timber production. This survey was conducted entirely within state forest ownership. Vehicle access exists via State Route 20.

METHODS

The habitat inventory conducted in Two Log Creek follows the methodology presented in the *California Salmonid Stream Habitat Restoration Manual* (Flosi and Reynolds, 1991 rev. 1994). The California Conservation Corps (CCC) Technical Advisors and Watershed Stewards Project/AmeriCorps (WSP/AmeriCorps) Members that conducted the inventory were trained in standardized habitat inventory methods by the California Department of Fish and Game (DFG). This inventory was conducted by a two-person team.

SAMPLING STRATEGY

The inventory uses a method that samples approximately 10% of the habitat units within the survey reach (Hopelain, 1994). All habitat units included in the survey are classified according

Two Log Creek

to habitat type and their lengths are measured. All pool units are measured for maximum depth, depth of pool tail crest, dominant substrate composing the pool tail crest, and embeddedness. Habitat unit types encountered for the first time are further measured for all the parameters and characteristics on the field form. Additionally, from the ten habitat units on each field form page, one is randomly selected for complete measurement.

HABITAT INVENTORY COMPONENTS

A standardized habitat inventory form has been developed for use in California stream surveys and can be found in the *California Salmonid Stream Habitat Restoration Manual*. This form was used in Two Log Creek to record measurements and observations. There are nine components to the inventory form.

1. Flow:

Flow is measured in cubic feet per second (cfs) at the bottom of the stream survey reach using standard flow measuring equipment, if available. In some cases flows are estimated.

2. Channel Type:

Channel typing is conducted according to the classification system developed and revised by David Rosgen (1985 rev. 1994). This methodology is described in the *California Salmonid Stream Habitat Restoration Manual*. Channel typing is conducted simultaneously with habitat typing and follows a standard form to record measurements and observations. There are five measured parameters used to determine channel type: 1) water slope gradient, 2) entrenchment, 3) width/depth ratio, 4) substrate composition, and 5) sinuosity.

3. Temperatures:

Both water and air temperatures are measured and recorded at every tenth habitat unit. The time of the measurement is also recorded. Both temperatures are taken in degrees Fahrenheit at the middle of the habitat unit and within one foot of the water surface.

4. Habitat Type:

Habitat typing uses the 24 habitat classification types defined by McCain and others (1988). Habitat units are numbered sequentially and assigned a type identification number selected from a standard list of 24 habitat types. Dewatered units are labeled "dry". Two Log Creek habitat typing used standard basin level measurement criteria. These parameters require that the minimum length of a described habitat unit must be equal to or greater than the stream's mean wetted width. Channel dimensions were measured using hip chains, range finders, tape measures, and stadia rods. All units were measured for mean length; additionally, the first occurrence of each unit type and a randomly selected 10% subset of all units were sampled for all features on the sampling form (Hopelain, 1995). Pool tail crest depth at each pool unit was measured in the thalweg. All measurements were in feet to the nearest tenth.

Two Log Creek

5. Embeddedness:

The depth of embeddedness of the cobbles in pool tail-out reaches is measured by the percent of the cobble that is surrounded or buried by fine sediment. In Two Log Creek, embeddedness was ocularly estimated. The values were recorded using the following ranges: 0 - 25% (value 1), 26 - 50% (value 2), 51 - 75% (value 3) and 76 - 100% (value 4). Additionally, a value of 5 was assigned to tail-outs deemed unsuited for spawning due to inappropriate substrate particle size, having a bedrock tail-out, or other considerations.

6. Shelter Rating:

Instream shelter is composed of those elements within a stream channel that provide salmonids protection from predation, reduce water velocities so fish can rest and conserve energy, and allow separation of territorial units to reduce density related competition. The shelter rating is calculated for each fully-described habitat unit by multiplying shelter value and percent cover. Using an overhead view, a quantitative estimate of the percentage of the habitat unit covered is made. All cover is then classified according to a list of nine cover types. In Two Log Creek, a standard qualitative shelter value of 0 (none), 1 (low), 2 (medium), or 3 (high) was assigned according to the complexity of the cover. Thus, shelter ratings can range from 0-300 and are expressed as mean values by habitat types within a stream.

7. Substrate Composition:

Substrate composition ranges from silt/clay sized particles to boulders and bedrock elements. In all fully-described habitat units, dominant and sub-dominant substrate elements were ocularly estimated using a list of seven size classes and recorded as a one and two respectively. In addition the dominant substrate composing the pool tail outs is recorded for each pool.

8. Canopy:

Stream canopy density was estimated using modified handheld spherical densimeters as described in the *California Salmonid Stream Habitat Restoration Manual*. Canopy density relates to the amount of stream shaded from the sun. In Two Log Creek, an estimate of the percentage of the habitat unit covered by canopy was made from the center of approximately every third unit in addition to every fully-described unit, giving an approximate 30% sub-sample. In addition, the area of canopy was estimated ocularly into percentages of coniferous or deciduous trees.

9. Bank Composition and Vegetation:

Bank composition elements range from bedrock to bare soil. However, the stream banks are usually covered with grass, brush, or trees. These factors influence the ability of stream banks to withstand winter flows. In Two Log Creek, the dominant composition type and the dominant vegetation type of both the right and left banks for each fully-described unit were selected from the habitat inventory form. Additionally, the percent of each bank covered by vegetation was estimated and recorded.

Two Log Creek

BIOLOGICAL INVENTORY

Biological sampling during stream inventory is used to determine fish species and their distribution in the stream. In Two Log Creek fish presence was observed from the stream banks, and three sites were electrofished using a Smith-Root Model 12 electrofisher. These sampling techniques are discussed in the *California Salmonid Stream Habitat Restoration Manual*.

DATA ANALYSIS

Data from the habitat inventory form are entered into Habitat, a dBASE 4.2 data entry program developed by Tim Curtis, Inland Fisheries Division, California Department of Fish and Game. This program processes and summarizes the data, and produces the following six tables:

- Riffle, flatwater, and pool habitat types
- Habitat types and measured parameters
- Pool types
- Maximum pool depths by habitat types
- Dominant substrates by habitat types
- Mean percent shelter by habitat types

Graphics are produced from the tables using Quattro Pro. Graphics developed for Two Log Creek include:

- Riffle, flatwater, pool habitats by percent occurrence
- Riffle, flatwater, pool habitats by total length
- Total habitat types by percent occurrence
- Pool types by percent occurrence
- Total pools by maximum depths
- Embeddedness
- Pool cover by cover type
- Dominant substrate in the pool tail-outs
- Percent canopy
- Bank composition by composition type
- Bank vegetation by vegetation type

HABITAT INVENTORY RESULTS

The habitat inventory of August 19 through 22, 1997, was conducted by Tara Cooper and Craig Mesman (CCC). The total length of the stream surveyed was 1,417 feet.

Flow was estimated to be less than 0.05 cubic feet per second (cfs) during the survey period.

Two Log Creek is an B4 channel type for the entire 1,417 feet of stream reach surveyed. B4 channels are moderately entrenched, moderate gradient, riffle dominated channels, with infrequently spaced pools; very stable plan and profile; stable banks; gravel channel.

Two Log Creek

Water temperatures taken during the survey period ranged from 56 to 59 degrees Fahrenheit. Air temperatures ranged from 50 to 69 degrees Fahrenheit.

Table 1 summarizes the Level II riffle, flatwater, and pool habitat types. Based on frequency of **occurrence** there were 10% riffle units, 18% flatwater units, 35% pool units, and 35% dry units (Graph 1). Based on total **length** of Level II habitat types there were 7% riffle units, 24% flatwater units, 13% pool units, and 51% dry units (Graph 2).

Seven Level IV habitat types were identified (Table 2). The most frequent habitat types by percent **occurrence** were dry units, 35%; mid-channel pools, 20%; and step runs, 15% (Graph 3). Based on percent total **length**, dry units made up 51%, step runs, 23%, and mid-channel pools made up 8% of the total length.

A total of 14 pools were identified (Table 3). Main channel pools were most frequently encountered at 64% and comprised 69% of the total length of all pools (Graph 4).

Table 4 is a summary of maximum pool depths by pool habitat types. Pool quality for salmonids increases with depth. One of the 14 pools (7%) had a depth of two feet or greater (Graph 5).

The depth of cobble embeddedness was estimated at pool tail-outs. Of the 14 pool tail-outs measured, 1 had a value of 1 (7.1%); 2 had a value of 2 (21.4%); 3 had a value of 3 (21.4%); 1 had a value of 4 (7.1%) and 6 had a value of 5 (42.9%) (Graph 6). On this scale, a value of 1 indicates the highest quality of spawning substrate and a value of 5 indicates the tail-out is not suitable for spawning. In Two Log Creek, 3 of the 6 pool tail-outs which were valued at 5 had silt/clay/sand or gravel too small to be suitable for spawning as the substrate. The other tail-outs were unsuitable for spawning due to the tail-outs being comprised of large cobble

A shelter rating was calculated for each habitat unit and expressed as a mean value for each habitat type within the survey using a scale of 0-300. Riffle habitat types had a mean shelter rating of 8, flatwater habitat types had a mean shelter rating of 42, and pool habitats had a mean shelter rating of 17 (Table 1). Of the pool types, the scour pools had the highest mean shelter rating at 23. Main channel pools had a mean shelter rating of 8 (Table 3).

Table 5 summarizes mean percent cover by habitat type. Boulders and small woody debris are the dominant cover types in Two Log Creek. Large woody debris are lacking in nearly all habitat types. Graph 7 describes the pool cover in Two Log Creek.

Table 6 summarizes the dominant substrate by habitat type. Of the two low gradient riffles measured both had gravel as the dominant substrate. Gravel was the dominant substrate observed in 7 of the 14 pool tail-outs measured (50%). Silt/clay and large cobble were the next most frequently observed dominant substrate types and occurred equally in 21.4% of the pool tail-outs (Graph 8).

The mean percent canopy density for the stream reach surveyed was 94%. The canopy consisted of entirely coniferous trees. Graph 9 describes the canopy in Two Log Creek.

Two Log Creek

For the stream reach surveyed, the mean percent right bank vegetated was 96%. The mean percent left bank vegetated was 83.5%. The dominant elements composing the structure of the stream banks consisted of 0% bedrock, 0% boulder, 55% cobble/gravel, and 45% sand/silt/clay (Graph 10). Grass was the dominant vegetation type observed in 42.11% of the units surveyed. Additionally, 30% had coniferous trees as the dominant vegetation, including down trees, logs, and root wads (Graph 11).

BIOLOGICAL INVENTORY RESULTS

Three sites were electrofished on August 26, 1997, in Two Log Creek. The sites were sampled by Craig Mesman and Tara Cooper (CCC).

The first site sampled was habitat unit 28, a plunge pool approximately 736 feet from the beginning of the survey. The site yielded 1 coho.

The second site sampled was above the end of survey, approximately 2,970 feet from the survey beginning. The site yielded no fish.

The third site, also above the end of survey, included several isolated pools located approximately 3,570 feet above the start of the survey. The site yielded no fish.

DISCUSSION

Two Log Creek is a B4 channel type for the entire 1,417 feet of stream surveyed. The suitability of B4 channel types for fish habitat improvement structures is as follows: excellent for plunge weirs, boulder clusters, bank placed boulders, single and opposing wing deflectors, and log cover.

The water temperatures recorded on the survey days August 19 through 22, 1997, ranged from 56 to 59 degrees Fahrenheit. Air temperatures ranged from 50 to 69 degrees Fahrenheit. This is a good water temperature range for salmonids. To make any further conclusions, temperatures would need to be monitored throughout the warm summer months, and more extensive biological sampling would need to be conducted.

Flatwater habitat types comprised 24% of the total **length** of this survey, riffles 7%, pools 13%, and dry 51%. The pools are relatively shallow, with only 1 of the 14 (7%) pools having a maximum depth greater than 2 feet. In general, pool enhancement projects are considered when primary pools comprise less than 40% of the length of total stream habitat. In first and second order streams, a primary pool is defined to have a maximum depth of at least two feet, occupy at least half the width of the low flow channel, and be as long as the low flow channel width. Installing structures that will increase or deepen pool habitat is recommended.

One of the 14 pool tail-outs measured had an embeddedness rating of 1. Four of the pool tail-outs had embeddedness ratings of 3 or 4. Six of the pool tail-outs had a rating of 5 or were considered unsuitable for spawning. Three of the six were unsuitable for spawning due to the

Two Log Creek

dominant substrate being silt/sand/clay or gravel being too small to be suitable. Cobble embeddedness measured to be 25% or less, a rating of 1, is considered to indicate good quality spawning substrate for salmon and steelhead. In Two Log Creek, sediment sources should be mapped and rated according to their potential sediment yields, and control measures should be taken.

The mean shelter rating for pools was low with a rating of 17. The shelter rating in the flatwater habitats was slightly better at 42. A pool shelter rating of approximately 100 is desirable. The relatively small amount of cover that now exists is being provided primarily by small woody debris and boulders in all habitat types. Log and root wad cover structures in the pool and flatwater habitats are needed to improve both summer and winter salmonid habitat. Log cover structure provides rearing fry with protection from predation, rest from water velocity, and also divides territorial units to reduce density related competition.

Seven of the 14 (50%) pool tail-outs measured had gravel as the dominant substrate. This is generally considered good for spawning salmonids.

The mean percent canopy density for the stream was 94%. This is a relatively high percentage of canopy. In general, revegetation projects are considered when canopy density is less than 80%.

The percentage of right and left bank covered with vegetation was high at 96% and 83.5%, respectively. In areas of stream bank erosion or where bank vegetation is not at acceptable levels, planting endemic species of coniferous and deciduous trees, in conjunction with bank stabilization, is recommended.

RECOMMENDATIONS

- 1) Two Log Creek should be managed as an anadromous, natural production stream.
- 2) The limited water temperature data available suggest that maximum temperatures are within the acceptable range for juvenile salmonids. To establish more complete and meaningful temperature regime information, 24-hour monitoring during the July and August temperature extreme period should be performed for 3 to 5 years.
- 3) Where feasible, design and engineer pool enhancement structures to increase the number of pools. This must be done where the banks are stable or in conjunction with stream bank armor to prevent erosion.
- 4) Increase woody cover in the pools and flatwater habitat units. Most of the existing cover is from boulders. Adding high quality complexity with woody cover is desirable.
- 5) Active and potential sediment sources related to the road system need to be identified, mapped, and treated according to their potential for sediment yield to the stream and its tributaries.

Two Log Creek

COMMENTS AND LANDMARKS

The following landmarks and possible problem sites were noted. All distances are approximate and taken from the beginning of the survey reach.

Position

(ft): Comments:

0' Begin survey at confluence with right bank tributary near Jackson Demonstration State Forest boundary (next to eastern boundary of section 12) . Channel type is a B4.

Approximately 50' up the right bank tributary is the out-fall of the culvert (under Highway 20). There is a 4' high jump into a 5' diameter corrugated metal pipe (CMP). The tributary could support fish above the culvert. The surveyors walked 250 feet of the right bank tributary above the culvert and observed one steelhead. Most of the flow of the stream flow is coming from the right bank tributary.

738' First electrofishing site.

1,082' Channel completely overgrown with bulrush, ferns, and woody debris.

1,417' End of survey. The channel is completely overgrown. Creek meets up with the forest floor.

2,970' Second electrofishing site.

3,570' Third electrofishing site.
