Report Revised April 14, 2006 Report Completed 2000 Assessment Completed 1999 CALIFORNIA DEPARTMENT OF FISH AND GAME STREAM INVENTORY REPORT

Little Sulphur Creek

INTRODUCTION

A stream inventory was conducted during the summer of 1999 on Little Sulphur Creek. The inventory was conducted in two parts: habitat inventory and biological inventory. The objective of the habitat inventory was to document the amount and condition of available habitat to fish and other aquatic species with an emphasis on anadromous salmonids. The objective of the biological inventory was to document the presence and distribution of salmonids and other aquatic species.

The objective of this report is to document the current habitat conditions and recommend options for the potential enhancement of habitat for Chinook salmon, coho salmon and steelhead trout. Recommendations for habitat improvement activities are based upon target habitat values suitable for salmonids in California's north coast streams.

WATERSHED OVERVIEW

Little Sulphur Creek, located in Sonoma County, is a tributary of Big Sulphur Creek, which in turn flows into the Russian River (see Little Sulphur Creek map, page 2). The legal description at the confluence with Big Sulphur Creek is T11N, R10W, S12. Its location is 38°48'35" N. latitude and 122°55'32" W. longitude. Year round vehicle access exists from Geysers Road via River Road via Hwy 101 at Cloverdale.

Little Sulphur Creek and its tributaries drain a basin of approximately 43.9 square miles. Little Sulphur Creek is a third order stream and has approximately 16.6 miles of blue line stream, according to the USGS Asti, The Geysers, Jimtown and Mt. St. Helena 7.5 minute quadrangles. Major tributaries include Lover's Gulch and Anna Belcher, which are included in this report, and North Branch Little Sulphur, which is described in a separate stream report. Summer flow in Little Sulphur Creek was measured as approximately 1.89 cfs. Elevations range from about 640 feet at the mouth of the creek to 2.438 feet in the headwaters. Oak woodland dominates the watershed, but there are zones of mixed conifer forest in the upper watershed. The predominant upland vegetation throughout the watershed consists of annual grasses, buckeye, oak, California laurel, madrone, and fir, while the riparian corridor is dominated by alder and willow. The watershed is entirely privately owned and is managed for grazing and vineyard production, with scattered rural development. Sensitive species listed from the CNPS Inventory and DFG's Natural Diversity Database within Little Sulphur watershed includes the foothill yellow-legged frog (Rana boylii) and the Socrates mine jewel-flower (Streptanthus brachiatus ssp brachiatus), both federally listed Species of Concern. Also present in this watershed is the Steelhead (Onchorynchus mykiss), federally listed as threatened.

METHODS

The habitat inventory conducted in Little Sulphur Creek follows the methodology presented in the <u>California Salmonid Stream Habitat Restoration Manual</u> (Flosi et al. 1998). The Americorps Volunteers that conducted the inventory were trained in standardized habitat inventory methods by the California Department of Fish and Game (DFG). This inventory was conducted by a two-person team and was supervised by Bob Coey, Russian River Basin Planner (DFG).

HABITAT INVENTORY COMPONENTS

A standardized habitat inventory form has been developed for use in California stream surveys and can be found in the <u>California Salmonid Stream Habitat Restoration Manual</u> (1998). This form was used in Little Sulphur Creek to record measurements and observations. There are nine components to the inventory form: flow, channel type, temperatures, habitat type, embeddedness, shelter rating, substrate composition, canopy, and bank composition.

1. Flow:

Flow is measured in cubic feet per second (cfs) at the bottom of the stream survey reach using standard flow measuring equipment, if available. In some cases flows are estimated. Flows are also measured or estimated at major tributary confluences.

2. Channel Type:

Channel typing is conducted according to the classification system developed and revised by David Rosgen (1985 rev. 1994). This methodology is described in the <u>California Salmonid Stream</u> <u>Habitat Restoration Manual</u> (1998). Channel typing is conducted simultaneously with habitat typing and follows a standard form to record measurements and observations. There are five measured parameters used to determine channel type: 1) Water Slope Gradient, 2) Entrenchment, 3) Width/Depth Ratio, 4) Substrate Composition, and 5) Sinuosity.

3. Temperatures:

Water and air temperatures, and time, are measured by crew members with hand-held thermometers and recorded at each tenth unit typed. Temperatures are measured in Fahrenheit at the middle of the habitat unit and within one foot of the water surface. Temperatures are also recorded using remote Temperature recorders which log temperature every two hours, 24 hours/day.

4. Habitat Type:

Habitat typing uses the 24 habitat classification types defined by McCain and others (1988). Habitat units are numbered sequentially and assigned a type identification number selected from a standard list of 24 habitat types. Dewatered units are labeled "DRY". Little Sulphur Creek habitat typing used standard basin level measurement criteria. These parameters require that the minimum length of a described habitat unit must be equal to or greater than the stream's mean wetted width. All unit lengths were measured. The first occurrence of each unit type and a randomly selected 10% subset of all units were completely sampled (Length, Mean Width, Mean Depth, Maximum Depth and Pool Tail Crest Depth). All measurements are in feet to the nearest tenth.

5. Embeddedness:

The depth of embeddedness of the cobbles in pool tail-out reaches is measured by the percent of the cobble that is surrounded or buried by fine sediment. In Little Sulphur Creek, embeddedness was visually estimated. The values were recorded using the following ranges: 0 - 25% (value 1), 26 - 50% (value 2), 51 - 75% (value 3), 76 - 100% (value 4). "Not suitable" (value 5) is assigned to tail-outs deemed unsuited for spawning due to inappropriate substrate particle size, absence of particulate substrate (e.g. bedrock), or other considerations.

6. Shelter Rating:

Instream shelter is composed of those elements within a stream channel that provide salmonids protection from predation, reduce water velocities so fish can rest and conserve energy, and allow separation of territorial units to reduce density related competition. Using an overhead view, a quantitative estimate of the percentage of the habitat unit covered is made. All shelter is then classified according to a list of nine shelter types. In Little Sulphur Creek, a standard qualitative shelter value of 0 (none), 1 (low), 2 (medium), or 3 (high) was assigned according to the complexity of the shelter. The shelter rating is calculated for each habitat unit by multiplying shelter value and percent covered. Thus, shelter ratings can range from 0-300, and are expressed as mean values by habitat types within a stream.

7. Substrate Composition:

In all fully measured habitat units, dominant and sub-dominant substrate elements are visually estimated using a list of seven size classes: Silt/Clay, Sand, Gravel, Small Cobble, Large Cobble, Boulder, and Bedrock.

8. Canopy:

Stream canopy density is estimated using modified handheld spherical densiometers as described in the <u>California Salmonid Stream Habitat Restoration Manual</u> (1998). Canopy density relates to the amount of stream shaded from the sun. In Little Sulphur Creek, an estimate of the percentage of the habitat unit covered by canopy was made from the center of approximately every third unit in addition to every fully-described unit, giving an approximate 30% sub-sample. Finally, the total canopy over each habitat unit is visually divided into evergreen and deciduous, and the estimated percentages are recorded. 9. Bank Composition and Vegetation:

Banks may be composed primarily of (1) Bedrock, (2) Boulders, (3) Cobble/Gravel, or (4) Silt/Clay/Sand, and may be covered predominantly with (5) Grass, (6) Brush, (7) Deciduous Trees, (8) Coniferous Trees, or (9) No Vegetation at all. These factors influence the ability of stream banks to withstand winter flows. For each fully measured habitat unit in Little Sulphur Creek, the dominant Bank Composition Type and Vegetation Type of both the right and left banks were chosen from the options above. Additionally, the percentage of vegetal coverage was estimated and recorded for each bank.

BIOLOGICAL INVENTORY

Biological sampling during the stream inventory is used to determine fish species present and their distribution in the stream. Biological inventory is conducted using one or more of three basic methods: 1) stream bank observation, 2) underwater observation, and 3) electro-fishing. These sampling techniques are discussed in the <u>California Salmonid Stream Habitat Restoration Manual</u> (1998).

DATA ANALYSIS

Data from the habitat inventory form are entered into <u>Habitat</u>, a dBASE IV data entry program developed by CDFG. This program processes and summarizes the data, and produces the following tables and appendices:

- Riffle, flatwater, and pool habitat types
- Habitat types and measured parameters
- Pool types
- Maximum pool depths by habitat types
- Shelter by habitat types
- Dominant substrates by habitat types
- Vegetative cover and dominant bank composition
- Fish habitat elements by stream reach

Graphics are produced from the tables using Lotus 1,2,3. Graphics developed for Little Sulphur Creek include:

- Level II Habitat Types by % Occurrence and % Total Length
- Level IV Habitat Types by % Occurrence
- Pool Habitat Types by % Occurrence
- Maximum Depth in Pools
- Pool Shelter Types by % Area
- Substrate Composition in Low Gradient Riffles
- Percent Cobble Embeddedness by Reach

- Mean Percent Canopy
- Mean Percent Canopy by Reach
- Percent Bank Composition and Bank Vegetation

HISTORICAL STREAM SURVEYS:

The Department of Fish and Game conducted surveys of Little Sulphur Creek in August 1965, August 1968, September 1973 and September 1974.

In 1965, surveyors recorded a flow of 1.5-2 cfs, and a velocity was noted as rapid; more than .5 foot/second. The substrate was composed primarily of gravel and rubble. There was a good pool to riffle ratio; 50% pool and 50% riffle. Shelter was composed of overhanging branches, undercut banks, boulders and logs. It was rated as good shelter. There was good spawning habitat throughout the stream and only a few areas that were not spawnable due to heavy concentrations of clay. The stream temperature was 70_F. Partial barriers were noted in the survey.

In 1968, DFG conducted a partial survey from the confluence of Big Sulphur to Pine Flat Road, for a total of 15 miles. The gradient was about 5 feet per 100 feet of stream, or 5% gradient. The average depth of the riffles was about 6 inches, and average maximum depth of pools was 3 feet. The following flows were recorded: 2.5 cfs near the confluence with Big Sulphur Creek; 1.8 cfs upstream from the confluence to the north branch; 1.7 cfs at the auger hole on the Pocket Ranch; and 0.5 cfs upstream from the Healdsburg Geyser Rd.

The substrate was composed primarily of gravel and rubble, followed by sand and silt. Approximately 5% of the stream gravel appeared to be suitable for spawning and less than 5% for chinook salmon spawning. There was excellent pool development in the upper portion surveyed. The pools found above Pocket Ranch Rd. were generally large and deep. Pools downstream from this road were generally long, narrow and shallow. Most of the stream had good shelter, provided primarily by undercut rocks and banks.

Two barriers in the form of waterfalls were observed 2 miles downstream from Healdsburg Geysers Rd. They were located within 100 feet of each other and appear to have been complete barriers to fish. A small temporary earthen dam located about 1 mile downstream from the Pine Flat on the Cinnabar Ranch was washed out.

Air temperatures were recorded as follows: 60° F to 90° F throughout the day. Corresponding water temperatures were recorded as between 57° F to 76° F.

In September 1973, Little Sulphur was surveyed from the confluence to the upper fisheries limit, which was 14 miles. The flow was recorded from 0.5 cfs in the upper section to 1.0 cfs at the confluence with Big Sulphur.

The streambed in the lower 5 miles was mainly composed of bedrock outcroppings covered with 60% boulder, 20% rubble, 10% gravel, 10% sand and silt. The streambed in the remainder of the creek consisted of 30% boulder, 10% bedrock, 30% gravel, 20% rubble, 10% silt and organic debris. Approximately .75 of the stream consisted of pools, which were larger and deeper in the lower stretches. The average pool was 10 feet in diameter and 4 feet deep. Much of the shelter was provided by undercut banks and rocks. About 1/10 of the streambed was suitable for spawning. An exception to this was a 2 mile section, 4 miles above the confluence with Big Sulphur, in which .75 of the streambed was suitable for spawning.

Several roads had recently been constructed across the creek one mile downstream from the Healdsburg Geysers Road Bridge. This road building created many intermittent, murky pools. There was one diversion noted.

In September 1974, the entire creek was surveyed, for a total of 15.6 miles. The flow ranged from 2 cfs at the confluence with Big Sulphur and 1 cfs in the upper stream section. The average flow for Little Sulphur Creek was 2 cfs.

The streambed in the upper section of Little Sulphur was composed of 30% boulder, 30% rubble, 30% gravel, 5% sand, 4% silt and 1% detritus. In the lower section, the substrate was composed of 5% bedrock, 5% boulder, 40% rubble, 40% gravel, 5% sand and 5% silt. Pools were frequent along the stream with a pool to riffle ration of 2.5 to1. The average pool length was 30 feet and the average width was 12 feet, with an average depth of 3 feet. Shelter consisted of undercut banks and boulders with a few fallen trees.

Suitable spawning areas for steelhead and rainbow trout occurred throughout the stream. Total stream usable for spawning was estimated at 8%, while an estimated 80% was suitable as nursery habitat.

An 8 foot high rock falls barrier was found and one water diversion was observed, which consisted of a 2" water pipe leading to a house. The average water temperature was 62° F, and the average air temperature was 85° F.

Pollution consisted of feces from cattle in and around the stream. There were also 3 car bodies and automobile parts in one section of the stream.

HABITAT INVENTORY RESULTS FOR LITTLE SULPHUR CREEK

* ALL TABLES AND GRAPHS ARE LOCATED AT THE END OF THE REPORT *

The habitat inventory of August 16 through October 12, 1999, was conducted by Morgan Knechtle, Gary Neargardner, Stephanie Carey, Bryan Freele, Sarah Nossaman and Aaron Fairbrook (CDFG). The survey began at the confluence with Big Sulphur Creek and extended up Little Sulphur Creek

to the end of surface flows. The total length of the stream surveyed was 84,475 feet, with an additional 3,614 feet of side channel.

A flow of 1.9 cfs was measured on August 17, 1999 at habitat unit #68, 6,245 feet above survey start, with a Marsh-McBirney Model 2000 flowmeter.

This section of Little Sulphur Creek has 14 channel types: from the mouth to 8,954 feet an F3; next 5,707 feet a C3; next 1,514 feet a B2; next 4,615 feet a G1; next 2,635 feet an F4; next 2,550 feet a B4; next 1,499 feet a B1; next 4,885 feet a B2; next 3,108 feet an F4; next 16,595 feet a B2; next 2,761 feet an A2; next 10,475 feet a B2; next 16,863 feet an F3 and the upper 2,314 feet an F4.

F channel types are entrenched meandering riffle/pool channels on low gradients (<2%) with a high width/depth ratio. F3 channels have a predominantly cobble substrate and F4 channels have a predominantly gravel substrate.

C3 channel types are low gradient (<2%), meandering, point-bar, riffle/pool, alluvial channels with a broad, well defined floodplain and a predominantly cobble substrate.

B channel types are moderately entrenched, moderate gradient (2-4%), riffle dominated channels, with infrequently spaced pools, a very stable plan and profile, stable banks and. B2 channels have a predominantly boulder substrate, B4 channels have a predominantly gravel substrate, and B1 channels have a predominantly bedrock substrate.

G1 channel types are characterized as well entrenched "gully" step-pool channels with a low width/depth ratio, a moderate gradient (2-4%) and a predominantly bedrock substrate.

A2 channel types are steep (4-10%), narrow, cascading, step-pool streams with a high energy/debris transport associated with depositional soils and a predominantly boulder substrate.

Water temperatures on the survey dates ranged from 46°F to 80°F. Air temperatures ranged from 50°F to 92°F. Summer temperatures were also measured using remote temperature recorders placed in pools (see Temperature Summary graphs at end of report). A recorder in lower Little Sulphur Creek, beneath Pocket Ranch Road bridge, logged temperatures every 2 hours from June 30 through September 28, 1999. The highest temperature recorded was 76°F in July, and the lowest was 60°F in September. The mean of the daily highs was 71°F for the month of July, 69°F for August, and 65°F for September. Another recorder in upper Little Sulphur Creek, beneath Geysers Road bridge, logged temperatures from July 1 through September 27, 1999. The highest temperature recorded was 51°F in September. The mean of the lowest was 51°F in September.

Table 1 summarizes the Level II riffle, flatwater, and pool habitat types. Based on frequency of **occurrence** there were 39% pool units, 37% flatwater units, 23% riffle units, and 1% dry streambed units. Based on total **length** there were 52% flatwater units, 28% pool units, 18% riffle units, and 1% dry streambed units.

One thousand and forty-five habitat units were measured and 21% were completely sampled. Twenty-three Level IV habitat types were identified. The data is summarized in Table 2. The most frequent habitat types by percent **occurrence** were step runs at 16%, low gradient riffles at 15%, runs at 13% and mid-channel pools at 12%. By percent total **length**, step runs made up 32%, low gradient riffles 14%, runs 11%, and mid-channel pools 10%.

Four hundred and five pools were identified (Table 3). Scour pools were most often encountered at 54%, and comprised 55% of the total length of pools.

Table 4 is a summary of maximum pool depths by pool habitat types. Pool quality for salmonids increases with depth. Two hundred and eighty of the 405 pools (69%) had a depth of three feet or greater. These deeper pools comprised 22% of the total length of stream habitat.

A shelter rating was calculated for each habitat unit and expressed as a mean value for each habitat type within the survey using a scale of 0-300. Pool types had the highest shelter rating at 25. Riffle had the lowest rating with 9 and flatwater rated 13 (Table 1). Of the pool types, the backwater pools had the highest mean shelter rating at 29, main channel pools rated 26, and scour pools rated 24 (Table 3).

Table 5 summarizes fish shelter by habitat type. By percent area, the dominant pool shelter types were boulders at 45%, bedrock ledges at 18%, root masses at 9%, and small woody debris at 7%.

Table 6 summarizes the dominant substrate by habitat type. Gravel was the dominant substrate observed in 10 of the 31 low gradient riffles measured. Small cobble was dominant in 6 of the low gradient riffles.

No mechanical gravel sampling was conducted in 1999 surveys due to inadequate staffing levels.

The depth of cobble embeddedness was estimated at pool tail-outs. Of the 384 pool tail-outs measured, 45 had a value of 1 (12%), 146 had a value of 2 (38%), 91 had a value of 3 (24%), and 16 had a value of 4 (4%). Eighty-six (22%) riffles rated a 5 (unsuitable substrate type for spawning). On this scale, a value of one is best for fisheries.

The mean percent canopy density for the stream reach surveyed was 54%. The mean percentages of deciduous and evergreen trees were 60% and 39%, respectively.

For the entire stream reach surveyed, the mean percent right bank vegetated was 38% and the mean percent left bank vegetated was 34%. For the habitat units measured, the dominant vegetation types for the stream banks were: 54% deciduous trees, 22% evergreen trees, 12% grass, 8% bare soil and 4% brush. The dominant substrate for the stream banks were: 37% bedrock, 29% cobble/gravel, 25% boulder and 9% silt/clay/sand.

HABITAT INVENTORY RESULTS FOR LOVER'S GULCH

The habitat inventory of October 6, 1999, was conducted by Morgan Knechtle and Sarah Nossaman (CDFG). The survey began at the confluence with Little Sulphur Creek and extended up Lover's Gulch to the end of the survey. The total length of the stream surveyed was 4,168 feet, with an additional 9 feet of side channel.

A flow of .031 cfs was measured on October 12, 1999 134 feet downstream of Bastian's road crossing, with a Marsh-McBirney Model 2000 flowmeter.

Lover's Gulch has 1 channel type; an F3. F3 channel types are entrenched meandering riffle/pool channels on low gradients (<2%) with a high width/depth ratio and a predominantly cobble substrate.

Water temperatures on the survey date ranged from 54 °F to 59 °F. Air temperatures ranged from 56 °F to 64 °F.

Table 1 summarizes the Level II riffle, flatwater, and pool habitat types. Based on frequency of **occurrence** there were 38% riffle units, 31% flatwater units, and 31% pool units, with no dry streambed. Based on total **length** there were 51% flatwater units, 40% riffle units, and 9% pool units.

Eighty habitat units were measured and 35% were completely sampled. Nine Level IV habitat types were identified. The data is summarized in Table 2. The most frequent habitat types by percent **occurrence** were step runs at 31%, followed by low gradient riffles at 25%, mid-channel pools at 18%, and cascades at 8%. By percent total **length**, step runs made up 51%, low gradient riffles 36%, mid-channel pools 5%, and high gradient riffles 4%..

Twenty-five pools were identified (Table 3). Main Channel pools were most often encountered at 64%, and comprised 78% of the total length of pools.

Table 4 is a summary of maximum pool depths by pool habitat types. Pool quality for salmonids increases with depth. Seven of the 25 pools (28%) had a depth of two feet or greater. These deeper pools comprised 3% of the total length of stream habitat.

A shelter rating was calculated for each habitat unit and expressed as a mean value for each habitat type within the survey using a scale of 0-300. Pool types had the highest shelter rating at 27. Riffles had the lowest rating with 2 and flatwater rated 12 (Table 1). Of the pool types, the scour pools had the highest mean shelter rating at 37, main channel pools rated 24, and backwater pools rated 10 (Table 3).

Table 5 summarizes fish shelter by habitat type. By percent area, the dominant pool shelter types were boulders at 61%, followed by root masses at 13%, aquatic vegetation at 9%, and bedrock ledges at 5%.

Table 6 summarizes the dominant substrate by habitat type. Gravel was the dominant substrate observed in 1 of the 6 low gradient riffles measured. Small cobble was dominant in 2 of the low gradient riffles.

The depth of cobble embeddedness was estimated at pool tail-outs. Of the 23 pool tail-outs measured, 1 had a value of 1 (4%), 6 had a value of 2 (26%), 9 had a value of 3 (39%), and 3 had a value of 4 (13%). Four (17%) riffles rated a 5 (unsuitable substrate type for spawning). On this scale, a value of one is best for fisheries.

The mean percent canopy density for the stream reach surveyed was 65%. The mean percentages of deciduous and evergreen trees were 64% and 36%, respectively.

For the entire stream reach surveyed, the mean percent right bank vegetated was 55% and the mean percent left bank vegetated was 51%. For the habitat units measured, the dominant vegetation types for the stream banks were: 47% deciduous trees, 28% evergreen trees, 22% grass, and 3% brush. The dominant substrate for the stream banks were: 45% boulder, 34% cobble/gravel, 12% bedrock and 9% silt/clay/sand.

HABITAT INVENTORY RESULTS FOR ANNA BELCHER CREEK

The habitat inventory of July 27, 1999, was conducted by Morgan Knechtle and Gary Neargardner (CDFG). The survey began at the confluence with Little Sulphur Creek and extended up Anna Belcher Creek to the end of anadromous fish passage at a 15' vertical cascade. The total length of the stream surveyed was 3,306 feet.

Flows were not measured on Anna Belcher Creek, as surface flow was intermittent.

This section of Anna Belcher Creek has 1 channel type; a B4. B4 channel types are moderately entrenched, moderate gradient (2-4%), riffle dominated channels, with infrequently spaced pools, a very stable plan and profile, stable banks and a predominantly gravel substrate.

Water temperatures on the survey dates ranged from 62 °F to 71 °F. Air temperatures ranged from 72 °F to 75 °F.

Table 1 summarizes the Level II riffle, flatwater, and pool habitat types. Based on frequency of occurrence there were 33% dry streambed units, 29% flatwater units, 29% pool units, and 7% riffle units. Based on total **length** there were 60% dry streambed units, 27% flatwater units, 10% pool units, and 2% riffle units.

Forty-five habitat units were measured and 11% were completely sampled. Nine Level IV habitat types were identified. The data is summarized in Table 2. The most frequent habitat types by percent **occurrence** were dry streambed at 33%, followed by runs at 22%, bedrock scour pools at 16% and low gradient riffles at 7%. By percent total **length**, dry streambed made up 60%, runs 24%, bedrock scour pools 4%, and glides 3%.

Thirteen pools were identified (Table 3). Scour pools were most often encountered at 85%, and comprised 79% of the total length of pools.

Table 4 is a summary of maximum pool depths by pool habitat types. Pool quality for salmonids increases with depth. Three of the 13 pools (23%) had a depth of two feet or greater. These deeper pools comprised 3% of the total length of stream habitat.

A shelter rating was calculated for each habitat unit and expressed as a mean value for each habitat type within the survey using a scale of 0-300. Flatwater types had the highest shelter rating at 39. Riffles had the lowest rating with 0 and pools rated 11 (Table 1). Of the pool types, the scour pools had the highest mean shelter rating at 12, and main channel pools rated 5.

Table 5 summarizes fish shelter by habitat type. By percent area, the dominant pool shelter types were root masses at 56%, followed by aquatic vegetation at 21%, undercut banks at 13%, and bedrock ledges at 6%.

Table 6 summarizes the dominant substrate by habitat type. Gravel was the dominant substrate observed in the one low gradient riffle measured.

The depth of cobble embeddedness was estimated at pool tail-outs. Of the 9 pool tail-outs measured, 0 had a value of 1 (0%), 6 had a value of 2 (67%), 3 had a value of 3 (33%), and 0 had a value of 4 (0%). No riffles rated a 5 (unsuitable substrate type for spawning). On this scale, a value of one is best for fisheries.

The mean percent canopy density for the stream reach surveyed was 30%. The mean percentages of deciduous and evergreen trees were 26% and 74%, respectively.

For the entire stream reach surveyed, the mean percent right bank vegetated was 85% and the mean percent left bank vegetated was 83%. For the habitat units measured, the dominant vegetation types for the stream banks were: 73% grass, 14% deciduous trees, 9% brush, and 5% evergreen trees. The dominant substrate for the stream banks were: 64% silt/clay/sand, 27% cobble/gravel, and 9% bedrock.

BIOLOGICAL INVENTORY

JUVENILE SURVEYS OF LITTLE SULPHUR CREEK:

Biological surveys were conducted by CDFG in 1954, 1958, 1963, 1965, 1968, 1973, 1974, and 1999, to document the fish species composition and distribution at several locations in Little Sulphur Creek.

Notes dated August 1954 indicate that Little Sulphur Creek was chemically treated, but not sampled, in 1952. No sampling or treatment was performed in 1953. In 1954 Little Sulphur Creek

was electro-fished. The notes indicate that the observers believed a barrier in Big Sulphur Creek impeded passage of the majority of migrating adult steelhead during the 1953-1954 winter season.

During the 1954 sampling, a total of 115 fish (Sacramento sucker and rainbow trout/steelhead) were identified. Of this total, 85 were rainbow trout/steelhead varying in size from 2.0 inches to 6.5 inches with 70 individuals less than 3 inches and 15 individuals over 3 inches in length.

In August 1965, DFG noted large quantities of fish: trout, California roach, and Sacramento pike minnow. These fish were noted as occurring at the following densities: trout, 100/100' section in upper area, 75/100' in middle area and 50/100' in lower area; roach, 10/100' section in upper area; and Sacramento pike minnow, 5/100' in upper area and 50/100' in lower area.

Numbers of fish were estimated by Braille seining and eye count. Estimated total number of trout for the entire stream length: 112 to 860.

In August 1968, fish species noted as present in Little Sulphur Creek included steelhead, rainbow trout, green sunfish, suckers and roach. Juvenile steelhead and/or rainbow trout ranging from 2 to 10 inches were found in the entire length of the stream; about 100/100 feet of stream. Numbers of salmonids were slightly less downstream from Pocket Ranch Road. Green sunfish ranging from 1 to 7 inches were found upstream from the Cinnabar Ranch. Numbers were approximately 50 /100 feet of stream. California roach averaging about 2 inches dominated the stream downstream from the Pocket Ranch. Numbers of roach were estimated at more than 250/100 feet of stream. Suckers averaging 8" long were found downstream from Pocket Ranch Road in numbers of about 150/ 100 feet of stream. Green sunfish, suckers and roach were not found upstream of Pocket Ranch Road.

On October 13, 1999, a biological inventory was conducted on four sites in Little Sulphur Creek to document the fish species composition and distribution. Each site was single pass electrofished using one Smith Root Model 12 electrofisher. Fish from each site were counted by species, and returned to the stream. A random sample of fish were selected from each site and tissues were taken for genetic analysis. The air temperature ranged from 61° to 84°F and the water temperature ranged from 52° to 62°F. The observers were Sarah Nossaman, Bryan Freele, and Morgan Knechtle of CDFG.

The inventory of Site 1 started at habitat unit #755 and ended approximately 397 feet upstream. In riffle, step-run and pool habitat types, 48 steelhead (ranging from 50-170mm) were observed along with 3 yellow-legged frogs, one Pacific Giant salamander and one Pacific lamprey.

The inventory of Site 2 started at habitat unit #808 and ended approximately 364 feet upstream. In riffle, step-run and pool habitat types, 46 steelhead (ranging from 45-165mm) were observed along with 3 Pacific lamprey.

The inventory of Site 3 started at habitat unit #471 and ended approximately 114 feet upstream. In riffle, run and pool habitat types, 36 steelhead (ranging from 45-175mm) were observed along

with approximately 80 California roach, approximately 80 sculpin, 5 signal crayfish, 2 Pacific lamprey and one yellow-legged frog.

The inventory of Site 4 started at habitat unit #549 and ended approximately 228 feet upstream. In riffle, run and pool habitat types, 30 steelhead (ranging from 60-110mm) were observed along with approximately 107 California roach, approximately 123 sculpin, and 7 signal crayfish. It was noted that this reach is impacted by cattle.

During the habitat inventory, no salmonids were observed upstream of unit #984, 7,150 feet above the confluence with Big Sulphur Creek.

JUVENILE SURVEYS OF LOVER'S GULCH:

No historical biological surveys were conducted by CDFG on Lover's Gulch.

On October 11, 1999, a biological inventory was conducted on one site in Lover's Gulch to document the fish species composition and distribution. The site was single pass electrofished using one Smith Root Model 12 electrofisher. Fish were counted by species, and returned to the stream. A random sample of fish were selected from each reach and tissues were taken for genetic analysis. The air temperature was 67°F and the water temperature was 54°F. The observers were Bryan Freele and Morgan Knechtle of CDFG.

The inventory of Site 1 started at habitat unit #26 and ended approximately 463 feet upstream at habitat unit #34. In run, riffle, and pool habitat types, 18 steelhead (ranging from 30-125mm) were observed, along with 12 foothill yellow-legged frogs, 5 pacific giant salamanders and one rough-skinned newt. It was noted that bovine feces was found in the creek bed.

ADULT SURVEYS:

No carcass/spawning surveys were conducted on Little Sulphur Creek in 1999 due to inadequate staffing levels.

DISCUSSION FOR LITTLE SULPHUR CREEK

Little Sulphur Creek has 14 channel types: F3 (8,954 ft.), C3 (5,707 ft.), B2 (1,514 ft.), G1 (4,615 ft.), F4 (2,635 ft.), B4 (2,550 ft.), B1 (1,499 ft.), B2 (4,885 ft.), F4 (3,108 ft.), B2 (16,595 ft.), A2 (2,761 ft.), B2 (10,475 ft.), F3 (16,863 ft.) and F4 (2,314 ft.).

According to the DFG <u>Salmonid Stream Habitat Restoration Manual</u>, F3 channel types are good for bank-placed boulders as well as single and opposing wing-deflectors. They are fair for low-stage weirs, boulder clusters, channel constrictors and log cover. F4 channel types are good for bank-placed boulders and fair for low-stage weirs, single and opposing wing-deflectors, channel constrictors and log cover. Many site specific projects can be designed within F channel types, especially to increase pool frequency, volume and shelter. Any work considered for F channel types will require careful design, placement, and construction that includes protection for unstable banks.

C3 channel types are excellent for bank-placed boulders and good for low-stage weirs, boulder clusters, single and opposing wing deflectors and log cover. They are fair for medium-stage weirs.

B2 channel types are excellent for low and medium-stage plunge weirs, single and opposing wing deflectors and bank cover. B4 channel types are excellent for low-stage plunge weirs, boulder

clusters, bank placed boulders, single and opposing wing-deflectors and log cover. They are also good for medium-stage plunge weirs. B1 channel types are excellent for bank-placed boulders and bank cover and good for log cover. All B channel types have banks of suitable gradient and stability for the installation of instream structures designed to increase pool habitat, trap spawning gravels, and provide protective shelter for fish. Many site specific projects can be designed within B channel types, especially to increase pool frequency, volume and shelter.

G1 channel types are fair for log cover.

A2 channel types have stable stream banks and poor gravel retention capabilities and are generally not suitable for instream enhancement structures.

The water temperatures recorded on the survey days ranged from $46^{\circ}F$ to $80^{\circ}F$. Air temperatures ranged from $50^{\circ}F$ to $92^{\circ}F$. The warmer water temperatures were recorded in Reach 2. These temperatures, if sustained, are above the threshold stress level ($65^{\circ}F$) for salmonids.

The Temperature Summary graphs shows summer temperatures measured using remote temperature recorders placed in pools. For much of the summer (June through September) the lower watershed exhibited temperatures above the optimal for salmonids, and the upper watershed exhibited temperatures near or slightly above optimal.

Pools comprised 28% of the total **length** of this survey. In third and fourth order streams a primary pool is defined to have a maximum depth of at least three feet, occupy at least half the width of the low flow channel, and be as long as the low flow channel width. In Little Sulphur Creek, only 69% of pools have a maximum depth of at least 3 feet. These pools comprised 22% of the total length of stream habitat. In coastal coho and steelhead streams, it is generally considered desirable to have primary pools comprise approximately 50% of total habitat length.

The mean shelter rating for pools was 25. A pool shelter rating of approximately 80 is desirable. The relatively small amount of pool shelter that now exists is being provided primarily by boulders (45%) and bedrock ledges (18%), with the remainder provided by root masses (9%) and small woody debris (7%). Log and root wad cover in the pool and flatwater habitats would improve both summer and winter salmonid habitat. Log cover provides rearing fry with protection from predation, respite from high flow water velocity, and also divides territorial units to reduce density-related competition.

Sixteen of the 31 low gradient riffles measured (52%) had either gravel or small cobble as the dominant substrate. This is generally considered fair for spawning salmonids.

Cobble embeddedness measured to be 25% or less, a rating of 1, is considered best for the needs of salmon and steelhead. Twenty-eight of the pool tail-outs measured had embeddedness ratings of either 3 or 4. Only 12% had a rating of 1. In a reach comparison, Reach 7 had the best ratings and Reach 4 had the poorest ratings.

The mean percent canopy for the survey was 54%. This is a low percentage of canopy, since 80% is generally considered desirable. Cooler water temperatures are desirable in Little Sulphur Creek. Elevated water temperatures could be reduced by increasing stream canopy. The large trees required for adequate stream canopy would also eventually provide a long term source of large woody debris needed for instream shelter and bank stability.

Furthermore, the riparian buffer is thin or nearly absent in areas with livestock grazing. Riparian removal and intensive grazing within the riparian corridor have lead to less stream canopy and channel incision causing bank erosion and higher water temperatures.

DISCUSSION FOR LOVERS GULCH

Lovers Gulch has one channel types: F3.

There are 4168 feet of F3 channel type in Reach 1. According to the DFG <u>Salmonid Stream</u> <u>Habitat Restoration Manual</u>, F3 channel types are good for bank-placed boulders as well as single and opposing wing-deflectors. They are fair for low-stage weirs, boulder clusters, channel constrictors and log cover. Many site specific projects can be designed within this channel type, especially to increase pool frequency, volume and shelter. Any work considered will require careful design, placement, and construction that must include protection for any unstable banks.

The water temperatures recorded on the survey days 10/06/99 to 10/06/99 ranged from 54 °F to 59 °F. Air temperatures ranged from 56 °F to 64 °F. This temperature regime is favorable to salmonids.

It is unknown if this thermal regime is typical. To make any further conclusions, temperatures need to be monitored for a longer period of time through the critical summer months, and\or more extensive biological sampling conducted.

Pools comprised 9% of the total **length** of this survey. In first and second order streams a primary pool is defined to have a maximum depth of at least two feet, occupy at least half the width of the low flow channel, and be as long as the low flow channel width. In LOVERS GULCH, the pools are relatively shallow/deep with 28% having a maximum depth of at least 2 feet. These pools comprised 3% of the total length of stream habitat. However, in coastal coho and steelhead streams, it is generally desirable to have primary pools comprise approximately 50% of total habitat length.

The mean shelter rating for pools was 27. However, a pool shelter rating of approximately 80 is desirable. The relatively small/moderate/large amount of pool shelter that now exists is being provided primarily by boulders (61%), root masses (13%), aquatic vegetation (9%), and bedrock ledges (5%).Log and root wad cover in the pool and flatwater habitats would improve both summer and winter salmonid habitat. Log cover provides rearing fry with protection from predation, rest from water velocity, and also divides territorial units to reduce density related

competition.

Three of the six low gradient riffles measured (50%) had either gravel or small cobble as the dominant substrate. This is generally considered good/poor/fair for spawning salmonids.

Fifty-two of the pool tail-outs measured had embeddedness ratings of either 3 or 4. Only 4% had a rating of 1. Cobble embeddedness measured to be 25% or less, a rating of 1, is considered best for the needs of salmon and steelhead.

The mean percent canopy for the survey was 65%. This is a low percentage of canopy, since 80 percent is generally considered desirable. Cooler water temperatures are desirable in LOVERS GULCH. Elevated water temperatures could be reduced by increasing stream canopy. The large trees required for adequate stream canopy would also eventually provide a long term source of large woody debris needed for instream shelter and bank stability.

DISCUSSION FOR ANNA BELCHER

Anna Belcher Creek has one channel type: B4.

There are 3306 feet of B4 channel type in Reach 1. According to the DFG <u>Salmonid Stream</u> <u>Habitat Restoration Manual</u>, B4 channel types are excellent for low-stage plunge weirs, boulder clusters, bank placed boulders, single and opposing wing-deflectors and log cover. They are also good for medium-stage plunge weirs. Many site specific projects can be designed within this channel type, especially to increase pool frequency, volume and shelter. These channel types have suitable gradients and the stable stream banks that are necessary for the installation of instream structures designed to increase pool habitat, trap spawning gravels, and provide protective shelter for fish.

The water temperatures recorded on the survey days 07/27/99 to 07/27/99 ranged from 62 °F to 71 °F. Air temperatures ranged from 72 °F to 75 °F. The warmer water temperatures were recorded in Reach 1.

It is unknown if this thermal regime is typical. To make any further conclusions, temperatures need to be monitored for a longer period of time through the critical summer months, and\or more extensive biological sampling conducted.

Pools comprised 10% of the total **length** of this survey. In first and second order streams a primary pool is defined to have a maximum depth of at least two feet, occupy at least half the width of the low flow channel, and be as long as the low flow channel width. In Anna Belcher Creek, the pools are relatively shallow with 23% having a maximum depth of at least 2 feet. These pools comprised 3% of the total length of stream habitat. In coastal coho and steelhead streams, it is generally desirable to have primary pools comprise approximately 50% of total habitat length.

The mean shelter rating for pools was 11. However, a pool shelter rating of approximately 80 is desirable. The relatively small amount of pool shelter that now exists is being provided primarily by root masses (56%), and aquatic vegetation (21%). Log and root wad cover in the pool and flatwater habitats would improve both summer and winter salmonid habitat. Log cover provides rearing fry with protection from predation, rest from water velocity, and also divides territorial units to reduce density related competition.

One low gradient riffles measured (100%) had either gravel or small cobble as the dominant substrate. This is generally considered poor for spawning salmonids.

Thirty three of the pool tail-outs measured had embeddedness ratings of either 3 or 4. None had a rating of 1. Cobble embeddedness measured to be 25% or less, a rating of 1, is considered best for the needs of salmon and steelhead.

The mean percent canopy for the survey was 30%. This is a very low percentage of canopy, since 80 percent is generally considered desirable. Cooler water temperatures are desirable in Anna Belcher Creek. Elevated water temperatures could be reduced by increasing stream canopy. The large trees required for adequate stream canopy would also eventually provide a long term source of large woody debris needed for instream shelter and bank stability.

GENERAL MANAGEMENT RECOMMENDATIONS

Little Sulphur Creek should be managed as an anadromous, natural production stream.

Woody debris, if left undisturbed, will provide fish shelter and rearing habitat, and offset channel incision. Landowners should be sensitive about the natural and positive role woody debris plays in the system, and encouraged <u>not to remove woody debris</u> from the stream, except under extreme buildup and only under guidance by a fishery professional.

PRIORITY FISHERY ENHANCEMENT OPPORTUNITIES

- 1) There are several sections (Reaches 1, 2, 5-10 and Reach 13) where the stream is being impacted from livestock in the riparian zone. Livestock in streams generally inhibit the growth of new trees, exasperate erosion, and reduce summertime survival of juvenile fish due to defecation in the water. Alternatives to limit cattle access, control erosion and increase canopy, should be explored with landowners, and developed if possible.
- 2) Increase the canopy on Little Sulphur Creek by planting willow, alder, redwood, and Douglas fir along the stream where shade canopy is not at acceptable levels (portions of all reaches, excluding Reach 13). In many cases, planting will need to be coordinated to follow bank stabilization or upslope erosion control projects.
- 3) Map sources of upslope and in-channel erosion, and prioritize them according to present

and potential sediment yield. Identified sites should then be treated to reduce the amount of fine sediments entering the stream. Near-stream riparian planting along any portion of the stream should be encouraged to provide bank stability and a buffering against agricultural, grazing and urban runoff.

- 4) Reaches throughout the stream (excluding Reach 11 and Reach 14) would benefit from the utilization of bio-technical vegetative techniques to re-establish floodplain benches and a defined low flow channel. This would discourage lateral migration of the base flow channel and decrease bank erosion.
- 5) Where feasible, increase woody cover in the pool and flatwater habitat units along the entire stream. Most of the existing shelter is from boulders and bedrock ledges. Adding high quality complexity with larger woody cover is desirable. Combination cover/scour structures constructed with boulders and woody debris would be effective in many flatwater and pool locations throughout the stream. This must be done where the banks are stable (Reaches 3, 6, 7, 8, 10 and Reach 12) or in conjunction with stream bank armor to prevent erosion. In some areas the material is at hand.
- 6) Where feasible, design and engineer pool enhancement structures to increase the number and depth of pools throughout the stream. This must be done where the banks are stable (Reaches 3, 6, 7, 8, 10 and Reach 12) or in conjunction with stream bank armor to prevent erosion. In some areas the material is at hand.
- 7) If riparian areas are not improved throughout Little Sulphur Creek, temperatures in the lower sections of the stream should be monitored to determine if they are having a deleterious effect upon juvenile salmonids. To achieve this, biological sampling is also required.

PROBLEM SITES AND LANDMARKS --LITTLE SULPHUR CREEK SURVEY COMMENTS

The following landmarks and possible problem sites were noted. All distances are approximate and taken from the beginning of the survey reach. The survey started at the confluence with Big Sulphur Creek.

824.00	67055	0+ SHD
825.00	67084	brown color to water
830.00	67355	wet trib left bank
832.00	67464	leaves in the water, water still brown.
833.00	67526	PGS Juv, slump left bank, benefit from tree planting.
834.00	67734	alders dead along both banks, dry trib and road LB.
835.00	68029	yoy SHD, dry trib right bank, road access via mark remmel.
838.00	68159	wet trib left bank
839.00	68194	water still brown
845.00	68560	dripping left bank trib
847.00	68652	water still brown
848.00	68740	wet trib left bank, house right bank, evidence of grazing
849.00	68800	evidence of grazing
850.00	68945	dripping left bank, evidence of grazing.
851.00	68990	18" culvert left bank from road, evidence of grazing
852.00	69108	20% covered by alder leaves
853.00	69157	old bridge abuttment
854.00	69262	Gevsers Road bridge, hobo temp
855.00	69423	wet trib left bank, 24" culvert RB from Gruyers Rd.
857.00	69679	saturated left bank, slump left bank, dripping trib on left bank

858.00	69753	fishing line in tree, water still brown, dry trib right bank
859.00	70005	Juv PGS
860.00	70090	road along right bank, dripping spring LB.
861.00	70152	riprap boulders on right bank
862.00	70251	leaves cover 30% of pool, wet spring LB, rip rap RB.
866.00	70465	leaves cover 20% of pool, dark pool, 2' visibility.
868.00	70761	leaves cover 15% of pool
871.00	70932	dry trib left bank
872.00	70978	water still very dark
875.00	72229	covered 10% by leaves
876.00	72312	spring left bank 56 degrees, still dark water.
877.00	72347	30% covered by leaves
878.00	72369	possible channel change
881.00	72482	left third of channel debris jam not a current problem
885.00	72776	rough skin newt, dry trib RB - major source of boulders,
		2' vis. very dark, back to "F3".
889.00	73022	water dark brown, high amount of leaf litter in stream (alder leaves)
893.00	73328	nice well established alders lining channel throughout reach.
897.00	74592	water still brownish with improved visibility.
898.00	74775	fish present
000.00		dry side channel RB, wet trib LB 51 deg. Comes in appearing like
899.00	75785	secondary channel.
000.00	75000	
900.00	75900	PG sals
901.00	76111	drv trib right bank, wet tribLB 51 deg.
903.00	76262	fish present - species? (poor vis.)
904.00	76358	RS newt
907.10	76495	dry trib right bank (comes in at 907.3)
907.30	76561	unit nearly dry in spots
908.00	76656	Unit nearly dry in spots
913.00	77063	dry side channel left bank, small dry trib LB
914.00	77108	right bank is vert. silt bank +/- 5'.
915.00	77209	voy, water clarity improving
917.00	77330	2+SHD
