# Marine Life Protection Act Initiative

Spatial Bioeconomic Model Evaluations of Round 1 External Proposed MPA Arrays for the MLPA North Coast Study Region

Presentation to the North Coast Regional Stakeholder Group
March 24, 2010 • Crescent City, CA

Dr. Eric Bjorkstedt, Member • MLPA Master Plan Science Advisory Team

What Bioeconomic Models Do

INPUT

Biology
Oceanography
Habitat
Fishery Management
Marine Protected Areas (MPAs)
(Fleet Response)
(Weather)

OUTPUT

Adult Biomass
Larval Supply
Fishery Yield
(Connectivity)

Why Models?

- MPA size and spacing guidelines are presented as ranges of values that are minimum or maximum thresholds
- Spatially explicit models augment the MPA size and spacing guidelines by:
  - counting benefits of MPAs that are larger or closer to each other than size and spacing guidelines
  - evaluating contribution of MPAs that do not meet size and spacing guidelines
  - simultaneously assessing conservation and economic consequences of MPAs
  - accounting for context (e.g., fleet dynamics, fishery management, location of habitat within MPAs)

Model Inputs

- **Geographic**
  - Habitat maps
  - Ocean circulation
  - Proposed MPA boundaries and regulations
- **Species-specific**
  - Life history (growth, natural mortality, fecundity)
  - Adult movement (home range diameter)
  - Larval dispersal (pelagic larval duration, spawning season)
  - Egg-recruit or settler-recruit relationship
- **Fleet response**
  - Spatial abundance of fish
 - Distance from port

Model Outputs

- All outputs are based on long-term steady states—*What will the system look like 30 to 50 or more years from now?*
- Each output is calculated for a range of assumptions about future fishery management outside MPAs:
  - Conservative management
  - Maximum sustainable yield (MSY)-type management
  - Unsuccessful management

# Model Results: Rankings in Context
- Conservation and economic values vary together; plotting them together puts proposals in context
- Choice of location along the conservation-economics curve is a matter of policy priorities
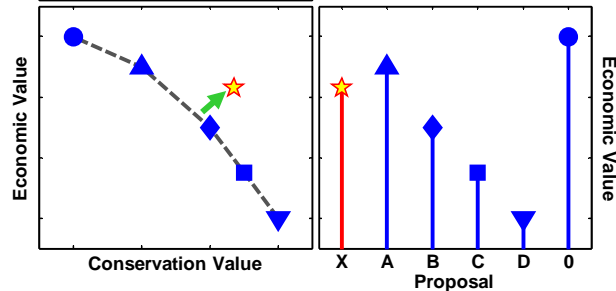

Conservation Value

Proposal: 0, D, C, B, A

Economic Value vs **Conservation Value**

Economic Value vs **Proposal**: A, B, C, D, 0

Hypothetical example under MSY-type fishery management

Model Results: Rankings in Context

- Models can reveal whether a proposal is superior to others with respect to balance between conservation and economic values

Hypothetical example under MSY-type fishery management

Model Description

- For Round 1, two models were used:
  - University of California, Davis (UCD)
  - University of California, Santa Barbara (UCSB)
- For Round 1, four species were modeled:
  - Black rockfish
  - Cabezon
  - Redtail surfperch
  - Red sea urchin

Consideration of Tribal Uses

- In Round 1, SAT evaluated all MPAs that proposed allowing tribal uses only (including some SMCAs in ExC) as no-take SMRs because SAT currently does not have sufficient information to consider tribal uses in evaluations

- In subsequent rounds, SAT will evaluate no-take areas as SMRs; MPAs that allow any type of consumptive uses will be evaluated according to level of protection afforded by the suite of proposed uses

Consideration of Mobile MPAs

- External MPA Array A (ExA) proposed mobile MPAs that are intended to shift each year within a specified zone
- For Round 1, mobile MPAs considered static for the purpose of modeling evaluation
- In External MPA Array A, affected MPAs are:
    - Crescent City Mobile SMCA
    - Trinidad Mobile SMCA
    - Eureka Mobile SMCA
    - Shelter Cove Mobile SMCA
    - Noyo Mobile SMCA
    - Albion Mobile SMCA
   - Point Arena Mobile SMCA

Updates for Round 2

- Additional fine-scale habitat data will be included
- UCSB and UCD models will be integrated
- Three (3) more species will be modeled:
  - Red abalone
  - Brown rockfish
  - Dungeness crab
- External MPA arrays will be re-run with updated data and model before Round 2

Oceanographic Dispersal Matrix

Matrix for black rockfish (2000-2006 average)

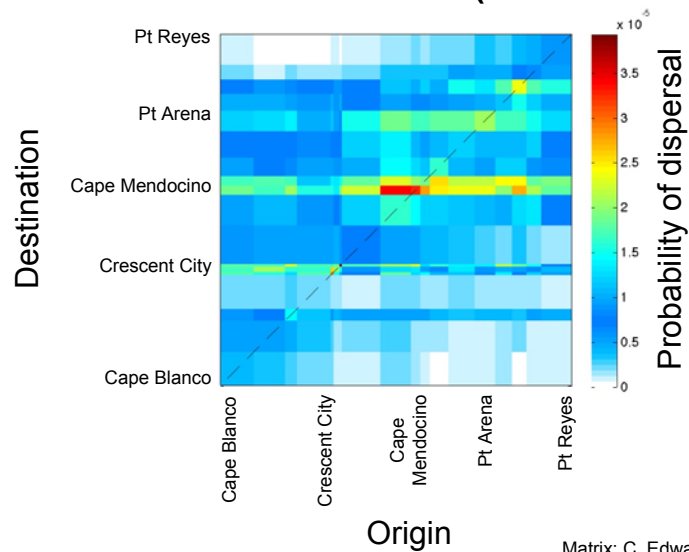

Matrix: C. Edwards & P. Drake, UCSC

Model Outputs

- **Conservation**
  - Maps of larval settlement and biomass
  - Total settlement and biomass (summed over study region, weighted sum across species)

- **Economic**
  - Maps of fishery yield
  - Total fishery yield (summed over study region, weighted sum across species)

- **Other Model Outputs**
  - Maps of fishing effort
 - Connectivity patterns that integrate larval production, dispersal, and settlement

---

Model Results: Black Rockfish Biomass

- Map represents predicted spatial distribution of biomass

- Outputs available for each:
  - Model species
  - Proposal
  - Management scenario

- Maps are posted online for:
  - Biomass
  - Fishery yield
  - Fishing effort
 - Larval production
  - Biomass for each MPA (deletion analysis)

Conclusions

- Assumptions about **fishery management** outside MPAs influenced the outcomes more than differences between proposed External MPA Arrays

- **ExA, ExD, ExE** and **ExC** consistently had highest* conservation value; rank order varied among models and management assumptions

- **Ex0, ExB, ExF, ExG** and **ExH** had highest* economic value for all models under MSY-type or conservative management

- **ExA** and **ExE** (UCSB model) or **ExD** and **ExE** (UCD model) had the highest* economic value under unsuccessful management

- All model outputs from Round 1 evaluations posted to MLPA website (www.dfg.ca.gov/mlpa)

Outputs focus on 4 species: Black rockfish, cabezon, redtail surfperch, and red sea urchin.
